A SOURCE OF DAMAGE TO LINEN, ETC., MARKED WITH INK CONTAINING SILVER.

BY B. H. PAUL.

When linen etc., has been marked with any of the ordinary varieties of marking ink containing silver, it sometimes happens that the fabric becomes so weak at the part where the letters are traced that the least exercise of force suffices to produce a rent; and if the material marked is of delicate texture it is especially liable to injury in this way.

A similar effect was sometimes produced when marking ink was used which required the application of heat to the linen after the mark had been written, and it was then ascribed to the overheating of the iron under which the marked linen was pressed. That this was, in some cases, the real cause of the injury is very probable, but no such explanation of the effect above mentioned is admissible as regards marking ink that does not require the application of a hot iron to bring out the mark.

Quite recently I had occasion to examine a quantity of linen which had been affected in the way described. It was a new supply of house linen to a public establishment, and each article had been marked with a well-known kind of marking ink by means of a box-wood stamp. The mark consisted of a monogram surrounded by a garter forming a circle about two inches in diameter. This was printed upon the linen in the centre of each article, and after the linen had been for some little time in use the fibres gave way exactly at the places where the ink marks were situated, so that eventually a piece came away altogether, leaving a hole corresponding in size to the device marked on the articles. This happened in so many instances and so soon after the linen had been taken into use that it became a very serious question who was responsible for the damage.

Several conjectures were started to account for the results observed, and among the first to be put forward was the idea that the marking ink, being a chemical preparation, must have contained something of an acid or corrosive nature which had burnt the linen. Others assumed that the fibre of the linen had been cut by the pressure exerted upon it when the marking was done with the box-wood stamp, or at least so much weakened in this way that it subsequently tore more readily than the adjoining portions upon which no pressure of the raised parts of the stamp had been exercised. Both of these suggestions were consistent with the appearance of the damaged linen, for on examination it was easily recognizable that the injury was very sharply limited to those parts of the fabric which bore the marks of the device, and that the parts immediately adjoining still retained their natural strength and capability of resisting strain. But though the injury which the fabric had undergone was thus obviously connected with the presence of the marking ink upon the linen, it was not difficult to arrive at the conclusion that however plausible the above mentioned attempts at explanation might appear at first sight they would not bear the test of minute examination. The marking ink on examination proved to be free from uncombined acid; it was in fact strongly alkaline, and like the majority of such preparations it was a silver salt that had been rendered ammoniacal, and there was nothing to support the idea that it could produce any corrosive effect. Still less probability attached to the idea that the fibres of the linen had been damaged by the mechanical pressure of the stamp used in marking the linen, for the force required for that purpose would be quite inadequate to cut the fibre.

In addition to the absence of any acid from the marking ink that had been used in this case, it was further observed that the linen which had not been washed at all was free from any injury: and since those articles would retain the whole of the ink printed upon them and be more fully exposed to the influence of any corrosive ingredient than the articles which had been washed, it became quite evident that the damage presented by the linen was not referable either to the presence of corrosive ingredients in the marking ink or to the weakening of the fibre by the direct action of the ink. At the same time there was an evident connection between the occurrence of the damage and the washing of the linen. Those articles which had been washed once or twice showed no sign of injury, or at least very slight injury, while in the case of others which had been washed a dozen times there were holes corresponding to the place where the mark had been, or the marked parts of the linen were so weakened that they tore asunder with the least strain.

However, it was ascertained that mere washing was not in itself sufficient to cause the damage which the linen had undergone, for two of the marked articles subjected to this operation with ordinary soap and water about a score times and in a rougher manner than usual, failed to show any signs of injury such as that complained of. Even after boiling one of these articles subsequently for an entire day in a strong solution of soda it remained quite sound at the parts marked as well as elsewhere. It appeared, therefore, clear that the injury was not the result of any influence necessarily appertaining to the washing operation, and further, that there was a probability of its being due to something abnormal in the way that operation had been carried out in this case.

The evident connection between the extent of injury and the number of times the linen had been washed showed that the action was gradually progressive, and the local connection of the injury in the linen with the marks of the ink likewise indicated that the substance of which those marks consisted had something to do with the action which resulted in damage to the linen. The inquiry was therefore narrowed to these limits, and as the ink mark probably consists of silver oxide, the question was, what combination of other conditions besides the presence of that substance would result in corrosion of the linen? Remembering the statement that bleaching powder is sometimes used to expedite the whitening of linen, and the fact that oxide of silver is converted into chloride of silver when brought into contact with a solution of a hypochlorite, it struck me that the conditions under which this reaction takes place were such as to be worth examining with the view of ascertaining whether they might not furnish an explanation of the damage done to the linen. The reaction which takes place is represented by the following equation, taking calcium hypochlorite as being represented by a solution of ordinary bleaching powder.

$$Ag_2O + CaCl_2O_2 = 2\,AgCl + CaO + 2\,O.$$

Parallel with the formation of chloride of silver and lime which takes place in this reaction, there is a liberation of oxygen, and the conditions under which the reaction takes place are precisely those which are favourable to the production of that allotropic form of oxygen known as ozone. The reaction takes place without the aid of heat by the mere contact of the silver oxide with the hypochlorite solution; it is not a sudden reaction, because the particles of silver oxide becoming coated with chloride are protected from further change until this coating is removed, and consequently the action is progressive and gradual. The other product of this reaction being ozone, the well-known characters of this form of oxygen would fully account for damage of the kind described being produced when hypochlorite solution is used by laundresses in washing linen marked with silver oxide, for in addition to the bleaching action of ozone it corrodes most organic substances, and by its action upon the fibre of linen would produce effects such as those above described. The progressive character of the damage and the connection between its extent and the number of times the linen has been washed, are also circumstances which favoured the conclusion that the damage was caused by the use of bleaching powder in washing the linen.

In order to test this conclusion some of the articles were dipped into a solution of bleaching powder, and it was found that when a sufficiently strong solution was used the linen presented the appearance of having had pieces corresponding to the ink marks cut out with a sharp steel punch. With a weak solution the results were not so marked, but when the action was continued long enough the fibre of the linen was rendered so weak at the marked places that with a very slight strain the articles treated in this way presented all the characters of damage shown by the linen after it had passed several times through the hands of the laundress.

Analytical Laboratory, 106, *Fenchurch Street, E.C.*

NOTE ON SO-CALLED WOOD OIL.

BY PROFESSOR F. A. FLÜCKIGER.

In a note communicated to the *Archiv der Pharmacie*, for May, the author states that he has found that the ethereal oil of Dipterocarpus balsam, known as Gurgun balsam or wood oil, when dissolved in about 20 parts carbon bisulphide, and a drop of a cooled mixture of equal parts of sulphuric and nitric acids added, takes a splendid violet colour. A single drop of the ethereal oil is sufficient to produce the reaction, and the colour lasts several hours. It is not prevented by the presence of resin or by copaiva balsam, so that the reaction takes place with the crude Gurgun balsam, or even when that is mixed with eight times its volume of copaiva balsam. The reaction can therefore be used to detect the presence of Gurgun balsam in copaiva balsam. Under the same conditions fish liver and oil of valerian are also coloured a beautiful violet, but only transiently so. In order to exclude fish oil from the test it is recommended to distil off the ethereal oil, although on account of its high boiling point (250° to 260° C.) this is not an agreeable task. Only a few drops are required, however, for the test.

Should a wood oil not correspond to this reaction the author thinks it might probably be due to the fact that some Dipterocarpus trees yield a varying balsam. The balsam is obtained in large quantities from the following species:—*Dipterocarpus turbinatus*, Gaertn. (syn. D. lævis, *Ham.*, D. indicus, *Bedd.*), *D. incanus*, Roxb., *D. zeylanicus*, Thw., *D. trinervis* Blume, *D. littoralis*, Bl., *D. alatus*, Roxb., *D. hispidus* Thw., *D. gracilis*, Bl., *D. retusus*, Bl. All these species occur in India and in the Archipelago, and the last even in the Philippines. Their resinous juice is used very generally as varnish, hence the name "wood oil." It is hardly probable that they all yield a resin chemically and physically identical. The author has found that the oil distilled by him from undoubtedly true dipterocarpus balsam is dextrogyre, whilst Werner, who first examined Gurgun balsam, in 1862, speaks of it as lævogyre. In all the specimens examined by the author to the present time, however, he has found the colour reaction constant.

Another possible ground for failure in obtaining the reaction is its confusion with other liquids used for similar purposes. The balsam obtained from *Hardwickia pinnata*, Roxb., a leguminaceous plant, is used in Southern India in the same medical cases as copaiva balsam; but an authentic specimen in the author's possession is not fluorescent like Dipterocarpus balsam, and dissolved in carbon bisulphide gives only a yellow colour with the acid mixture. The author does not know, however, that it is ever there called "wood oil."

A fat oil, used in enormous quantities in Eastern Asia for paint and varnish, and also as a drastic medicine, and very generally called "wood oil," is obtained from the seeds of *Aleurites cordata*, Muller (syn. Dryandra cordata, *Thunb.*, Elaeococca Vernicia, *Sprgl.*, E. verrucosa, *A. Juss.*), a euphorbiaceous tree. The tree is common in China and Japan, of very characteristic appearance, and is known in China as the "tung tree." The oils from the seeds of *Ricinus* and *Croton Tiglium* differ in chemical properties and physiological action from most known oils; how far such peculiarities occur principally in the Euphorbiaceæ is a question that yet requires answering. That the "wood oil" from the Tung tree is a fat worthy of notice is shown by the experiments of Cloez. This chemist obtained from the seeds of *Aleurites cordata*, by means of carbon bisulphide, 41 per cent. of a fixed oil, forming a solid crystalline mass below 32° C. When on the contrary the seeds were treated with ether an oil was obtained that did not solidify even at − 18° C. But what is most surprising is that when prepared either by pressure or by one of the solvents mentioned, and heated in the air to 200° C., it changes suddenly into a solid transparent jelly, which is no longer soluble in ether or carbon bisulphide.* This change takes place also after a few days, when excluded from the air, under the influence of light alone. The oil dries more rapidly than linseed oil. The principal acid in it was obtained in crystals that melted at 44°, but very rapidly resinified, and therefore did not consist of linoleic acid.

In many respects this Chinese wood oil recalls the singular "axin" or "age" of Mexico, examined by Hoppe-Seyler, in 1860.† The Nin fat of Yucatan, described by Dondé,‡ might also be mentioned here. All these oils appear to correspond in yielding a peculiar body, which Mulder described as linoxyn.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from Vol. VI., page* 1003.)

EMBELIA RIBES.—*Local name*, WAIWARUNG,

Common in the neighbourhood of Bombay, has a nearly globular red fruit, rather smaller than a peppercorn, which grows in large bunches. The drug has the five partite calyx and stalk often attached; the outer shell is striated from the base to the apex, where there is a small beak; its colour is reddish-brown, marked with dark spots. Inside the outer shell is the seed, enveloped in a delicate membrane, on removing which a cup-like hollow is seen opposite the insertion of the stalk. The seed is horny, of a reddish colour, and its external surface appears to be covered with spots of white mildew; this appearance, however, with the aid of a lens, is seen to be due to a delicate crystalline efflorescence. If kept for any time the outer shell of the fruit becomes nearly black, hence the statements that two kinds are met with in the shops. From the rapidity with which this change takes place I should suppose the quality of the drug to be not affected by it. Waiwarung is held in high repute as an anthelmintic among the country people, especially in cases of tape-worm, a disorder not uncommon among the native Christians of the western coast. The dose is a teaspoonful of the powder twice a day for a child, and a dessert spoonful for an adult; it is not purgative; the taste is rather pleasant, slightly astringent, and not unlike that of tea leaves. The worm is expelled dead. A purgative should be given to prepare the patient for the drug.

ADANSONIA DIGITATA.—*Local name*, GOWIK CHENTZ, *or* CHUREE CHENTZ.

This remarkable tree is not uncommon upon this part of the western coast. The fruit varies much, both in shape and size; some specimens correspond to the description given by Adanson and others to that of Guibourt (confer. Guibourt, vol. iii., p. 644). The shell is hard, woody and light, clothed with a dull green, felt-like down, composed of simple hairs; it is made up of regularly arranged wood cells, intersected here and there by vascular bundles. The fruit is full of a subacid pulp, which is divided by fibrous bands into a number of compartments. The pulp dries up into a starch-like powder, which adheres together in polyhedral masses, a seed forming the centre of each. The seeds are enclosed in a horny shell, with a rusty red rough exterior; they are kidney shaped, and half an inch in length. The structure of the bark is very confused: it consists of a mixture of pitted and wood cells, without any regular arrangement; the epidermis is scabrous, and appears to consist of the desquamating cells of the bark. When fresh the bark is about five-eighths of an inch in thickness; a section shows a mottled yellowish green and reddish brown surface; internally it is intimately united with the woody fibre of the trunk; it does not taste bitter, but is said by Duchassaing to be a useful substitute for cinchona. The pulp is very mucilaginous, and has a pleasant cool subacid taste, which it retains when dry. It may probably be a useful demulcent acid refrigerant. No part of the tree appears to be used medicinally in Bombay. The fruit makes floats for fishing nets and bottles for holding water.

SALMALIA MALABARICA.—*Local name*, SAUR.

The astringent exudation Muchurrus, or Supari che phool. A red fungus like mass, changing to a dark mahogany colour when old; it is brittle and flaky. The larger tears are hollow in the centre, and the cavity is of a cinnamon colour, and has a cellular appearance. Muchurrus is not a simple juice but the product of a diseased action, being a proliferation of the cells of the suberous tissue of the bark. Upon making a section of the diseased part a number of small cavities are seen which contain a semitransparent jelly-like substance, consisting of oblong cells with botryoidal nuclei. At the margin of the cavity the columns of healthy cells are seen breaking up and the cells separating to join the jelly-like mass; this gradually increases in size, and finds its way to the surface to be extruded as muchurrus. Upon its first appearance it is of an opaque yellowish white colour, firm externally, but semi-fluid internally, and there is no central cavity. The dry exudation when soaked in water swells up and communicates a red colour and slight astringency to it; a section can then be made to show its cellular structure. I have not been able to satisfy myself as to the cause of the disease in the bark which produces this substance, but traces of insects are always to be seen at the site of exudation. Incisions in the healthy bark yield nothing. Muchurrus has a purely astringent taste like tannin, for which it probably is an efficient substitute. I have only met with one kind in the market.

ODINA WODIER.—*Local name*, SHIMPTEE, *or* MOOI.

The gum, Shimptee, or Mooi cha goud. This gum is partly in tears of a yellowish tinge, and partly in colourless angular fragments, which are full of fissures like gum arabic; it has a disagreeable taste, and is not astringent; about one half of it is com-

* *Comptes Rendus*, Sept. 1875, p. 469, and 1876, p. 501.
† Gmelin, vol. vii., p. 1471.
‡ *Pharm. Journ.* [3], iv., 836.

pletely soluble in water, the remaining portion forms a slimy mucilage, but is not gelatinous. The soluble portion, which is feebly acid, is precipitated by alcohol, and in a less degree by oxalate of ammonium—not at all by perchloride of iron or borax. Odina gum is mentioned in the Pharmacopœia of India, but is probably of no medicinal value; it might be of use in calico printing.

ZANTHOXYLON Sp.?

The bark, Tejbul. A soft, light, reddish bark about five-eighths of an inch thick, in pieces about as large as the palm of the hand, trimmed, the epidermis being removed and the inner surface scraped; sometimes it is deeply fissured. The structure is like that of cork, only much coarser, which gives it a glistening appearance. The cells are about six times the size of cork cells. This bark is slightly aromatic, and is in repute as a stimulant.

Bombay, May 29, 1876.

(*To be continued.*)

ERGOTINE.

The researches of Professor Salkowski and other German chemists on the active principle in the preparation of ergotine were recently referred to. Professor Buchheim now writes to the *Klinische Wochenschrift* confessing that he also has not succeeded in isolating completely that principle, though he worked on it for several months; and he states his reasons why he thinks that such isolation might be impossible, and that for practical medical purposes the infusion of ergot, or the freshly prepared extract, will alone remain available. The organization of the ergot fungus seems to him so low that its mycelium cannot build up organic matter, so as to constitute an alkaloid or glucoside substance from water, carbonic acid and ammonia, but feeds, so to speak, more directly on the vegetable material of the mother plant. He believes that less elementary compouds are taken up by it from the rye grain, and thinks the gluten the most likely material from which to form the gelatine-like substance which he isolated partly from ergotine. On this modified albuminous constituent of the rye, at a certain stage of its metamorphosis, he infers, depends the peculiar action of the fresh infusion or extract. Any further complex chemical processes and reactions for the isolation of the active substance must necessarily have changed it so much in its natural course of decomposition that it has lost its efficacy, in the same manner, for instance, as the decomposing albuminous substances of putrid blood lose their poisonous effects when decomposition has reached to a certain point.

The freshly prepared ergotine seems therefore to give alone a guarantee of success. For subcutaneous application it ought to be carefully neutralized by carbonate of soda, as it contains much acid, especially lactic acid, as Buchheim found, besides quantities of leucine.

MATÉ, OR PARAGUAYAN TEA.

Some interesting paragraphs respecting this substance are quoted in the *Revista Farmacéutica*, the organ of the Argentine Pharmaceutical Society, from an unpublished work by Dr. Bialet, entitled 'Compendio de Anatomia, Fiscologia é Higiene humana.' Of these the following is an abstract:—

The Maté or Paraguay Tea tree (*Ilex mate paraguayensis*), is a small tree belonging to the family of the Celastrineæ,* which reaches at the most a height of seven metres; ordinarily it does not exceed four or five. Its trunk is about twenty centimetres in circumference, and is covered by a whitish bark. The leaves are oblong, cuneiform, obtuse and finely dentate. It has axillary multipartite peduncles; calyx tetrasepalous; the corolla with four petals in the form of a crown; stile none; stigma 4-fid; fruit a 4-seeded berry. The plant grows very abundantly in Paraguay, North Corrientes, Chaco, and South Brazil, where it forms woods called "*yerbales*."

* Not to the Iliciea, as stated by some authors.

According to Dr. Mantegazza, maté is prepared in Paraguay in the following way:—The entire trees are cut down, and the small branches and shoots are taken with the leaves and placed in the tatacúa, a plot of earth about six feet square surrounded by a fire, where the plant undergoes its first roasting. From thence it is taken to the *barbacúa*, which is a grating supported by a strong arch, underneath which burns a large fire; here it is submitted to a particular torrefaction, determined by experience, which develops the aromatic principle. Then it is reduced to a coarse powder in mortars formed of pits dug in the earth and well rammed. It is next put into fresh bullock skins, well pressed and placed in the sun to dry. The packages (*tercois*) thus obtained, which weigh 90 to 100 kilograms, are very compact; and have an average value in commerce of one to two dollars the kilo, according to quality, those of Paraguay and Missiones being the better, or least hurtful, those of Oran and Paranaguá being much more prejudicial to health.

Of all the analyses of maté that have appeared in books, Dr. Bialet considers not one, up to the present time, deserves much credit. Senor Arata, however, who has devoted much time and skill to the subject has placed the following data at his service:—

Maté contains in 100 parts:

Organic combustible substances	91·685
Ash	8·315

The ash contains—

Calcium Oxide	12·344
Magnesium Oxide	11·395
Sodium Oxide	7·281
Potassium Oxide	2·984
Manganese Oxide	2·500
Ferric Oxide	3·410
Sulphuric Acid	0·926
Hydrochloric Acid	0·716
Phosphoric Acid	5·540
Carbonic Acid	8·150
Sand, Silica, Carbon, and Loss	44·754

It will be understood that the enormous relative quantities of sand found in the analysis is a result of the mode of preparation, in excavations made in the soil.

The plant contains—

Principles soluble in Ether	9·820
" " Alcohol	8·482
" " Water	26·208
" " Water Acidulated with Hydrochloric Acid	7·260
In Solution of Caustic Soda	16·830
Cellulose	13·280
Water	9·000
Sand	9·120
	100·000

Among the soluble principles is an average of 1·300 of caffeine. The quantity, however, was found to be very variable in different plants analysed; the Paraguay and Missiones plants contained the most and the Paranaguá and Argentine the least. Senor Arata has made a careful search for caffeic acid and the caffeates that some say they have found in maté, but hitherto always with negative results; the same remark applies to the examination for a volatile acid.

The tannin of maté is peculiar; it does not tan hides, and requires a special method for its estimation; the average amount obtained by the ordinary method is not more than 12 per cent.; but the whole quantity present amounts to about 16 per cent.

Maté contains also a large quantity of a peculiar fatty matter, not entirely saponifiable by potash, besides pectic matters.

Comparing maté with the other caffeic substances it ranks between coffee and tea for the proportion of caffeine it contains, and has the largest proportion of mineral salts.

The action of maté, like that of all other caffeic substances, is upon the nervous system; but though it contains a large quantity of caffeine it does not exalt the peripheric nerves like tea, nor the cerebric like coffee; but rather contributes in a high degree to the indolence and drowsiness of the ordinary drinkers of maté, whose mental faculties become at length disarranged and impoverished to a lamentable degree. It accelerates the cardiac contractions, producing many more affections of the heart than tea or coffee. Upon the digestive organs it acts variously; no other beverage disturbs them so much, though there are persons who can tolerate its use. It accelerates the peristaltic movements and produces an irritation of the organs generally. These effects are produced in whatever way the maté may be taken, but the most injurious effects are produced upon the mucous membrane when the maté is taken hot and is sucked through a "bombilla," as it then passes into the stomach uncooled by previous contact with the mouth.

When the use of maté is prolonged it becomes an imperious necessity, such a gloominess following abstention from it, that habitual drinkers would rather go without food than without maté. The moderate use of two or three doses a day during the summer heats or great fatigue is convenient, but it should be taken from a cup. It adds to the disadvantage of the "bombilla" that by indiscriminate use of the same bombilla by different persons it may become the vehicle of contagion for the most repulsive complaints.

A HITHERTO NEGLECTED SOURCE OF IODINE. IODINE AND BROMINE IN FRESH-WATER PLANTS.*

BY H. ZENGER, OF MUNICH.

As early as 1862, Mr. Retter† examined the ashes of *Cladophora glomerata* for iodine, and on heating in a closed tube the palladic iodide, which he had obtained by precipitating the solution of the ashes of the plant with palladious nitrate, he detected the violet vapour of the liberated iodine. Although only a very small quantity of the plant could be obtained, from a reservoir in the garden of Professor Dr. G. C. Wittstein, he was, nevertheless, quite able to complete a qualitative analysis of the ashes and to prove the presence of iodine.

My own efforts were chiefly directed, first, towards the quantitative determination of the bromine, whose presence, though not yet detected in fresh-water plants, was suspected by me as a companion of the iodine; secondly, to try some methods of precipitation for the iodine other than the palladium solution; and thirdly, to examine various fresh-water plants, not yet investigated, and to obtain the iodine and bromine from them in a pure state, even if in very small quantities.

The extensive peat-bogs, as well as the canals for irrigation and drainage of the estate "Zengermoos," placed me in a position to collect great quantities of fresh-water plants with which to begin my investigations.

As in the quantitative analysis of Mr. Jessler‡ to which I shall hereafter call attention, I had a sure basis for my operations, [illegible] an my work with *Cladophora glomerata.*

* Translated [illegible] the *American Chemist.*

† Vierteljahresschrift für pract. Pharm. von Wittstein, xi, 545.

‡ Vierteljahresschrift für pract. Pharm., xii, 279, 1863.

The plants, after being collected, were most thoroughly freed from all animal life, mud, and foreign organic and inorganic substances, and dried in an airy place (granary) on grain-sifters of split tubing. In cleansing the plants, innumerable water and swamp-animals were found, among which I will mention the following; Large numbers of four species of fresh-water Polyps (Hydra), chiefly *H. vulgaris* and *H. fusca*, *H. grisea* and *H. viridis* being less abundant. Also an innumerable quantity of water-snails (Limophila), often replaced by several species of *Limnæa*, such as *L. vulgaris*, *palustris*, *ovata*, *stagnalis*, *peregra*, *truncatula*, *auricularia*, and numbers of *Planorbis* (Ger. "Tellerschnecken"); e. g., *P. hispidis*, *vortex*, *spirorbis*, *marginatus*, *charteus*, *leucostoma*, *contortus*, *complanatus*, and *nitidus*.

Among the most prominent insects present, both in the larva and perfect state, were the large water beetle—*Dytiscus latissimus;* also, *Gyrinus natator*, *Nepa cinerea*, and *Notonecta glauca*; two specimens of Nepa and Notonecta making themselves felt by their penetrating stings. The larvæ of the *Sialidæ* were rarely to be found; those of the *Ephemerinæ* more frequently.

When we consider that the above named animals were present, not singly but in masses, and some of them in different varieties, we can get an idea of the population of these water plants, and understand why the water-fowl are so fond of them.

I will only add that, to cleanse a quantity of *C. glomerata*, which only weighed 18⅜ pounds, I was obliged to work five days, with but slight intermission, and my hands were covered with blisters, and remained swollen for a fortnight, from the attacks of the inhabitants.

In spite of all my pains, the tiny skeletons of *Limnæa* and *Planorbis*, which before had been invisible, could be discerned in the ashes.

In a botanical point of view, I will briefly remark that *Cladophora glomerata* was called in the older classifications of the fresh-water Algæ *Conferva glomerata*, L., also *Chautrausia glomerata*, Dec. In the newer classifications, "Conferva" (English), "Crow Silk"—French, "la conferve") forms a species of the family of the *Confervaceæ*. It consists of long, fine, dark-green threads, and, with its kindred, assists in the formation of peat. The green colour is due to chlorophyll, which is contained in the cells.

Examination of Cladophora glomerata.

To determine the amount of water contained in it 2000* of the air-dried plants were heated in an air-bath at 110° C., and lost thereby 8·950 per cent. For analysis, and for the various iodine and bromine reactions, 100·0 of the plant were carefully reduced to ashes in a porcelain dish, over a charcoal fire, with frequent stirring with an iron spatula. This required considerable time, owing to the large amount of lime that was present. These 100·0 gave 52·850 ash; *i.e.*, over half the weight of the dried plants. 2·0 of these ashes were treated with distilled water for an half an hour in a porcelain dish, at ordinary temperature, filtered; the residue washed, and dried in an air-bath at 110° C., and weighed; the weight being 1·899. The loss in weight is the amount of soluble salts found in the ashes:—

2·003
1·899

0·101—or in 100 parts = 5·050.

The further investigations were conducted exactly in accordance with the directions of the approved method of Dr. G. C. Wittstein, for the analysis of the ashes of plants or of organic substances in general, and gave the following result, calculated for 100 parts. I place the analysis of Jessler alongside of my own for the purpose of comparison:—

* All these weights are expressed in grammes and fractions of the same.

	Zenger.	Jessler.
Potash	1·729	0·256
Soda	3·837	4·028
Lime	48·937	43·655
Magnesia	1·047	1·365
Alumina	0·029	0·225
Ferric Oxide	1·148	0·388
Mangano-manganic Oxide	0·342	——
Chlorine	1·564	0·770
Iodine	0·043	——
Bromine	0·017	——
Carbonic Acid	31·450	25·229
Sulphuric Acid	2·555	10·832
Silicic Acid	5·555	7·822
Phosphoric Acid	7·711	3·054
Sodium		0·504
	100·00	99·124

The 0·504 sodium was combined, according to Jessler, with 0·770 chlorine to form 1·274 NaCl. Iodine having already been discovered, I began my investigation with the qualitative determination of bromine, whose presence I suspected along with the chlorine and iodine. For this purpose I chose the following way, which is, without doubt, the easiest: 10·0 ash were treated with cold water and filtered. As the filtrate gave a very slight alkaline reaction, in order to avoid the escape of iodine and bromine, I added a little sodic carbonate and concentrated the solution. In this way most of the salts separated out in crystals and could be removed by filtration, excepting the salts of the alkalies. The filtrate was then saturated with hydrochloric acid and chlorine water added, whereupon the iodine present was set free; though, nevertheless, converted into iodic acid by the excess of chlorine. At the same time the bromine was liberated, and on being caught by agitation with chloroform showed not only its characteristic colour, but also its reaction with organic substances, imparting an intense orange-yellow colour to starch. *The presence of bromine was thus clearly proved.* Before I speak of my method of determining the bromine quantitatively, or of my method of separating the chloride, iodide, and bromide of silver, I will mention one or two of the means I have used to precipitate the iodine. The basis of these is the precipitation of the iodine in a slightly acid solution, in the presence of chlorine and bromine, as *cuprous iodide.* It would, I admit, be possible to employ this method of precipitation quantitatively by using cupric sulphate alone; the result obtained would have to be doubled, however, as only half of the iodine would be precipitated as cuprous iodide, and the other half set free. By a simultaneous or previous addition of some reducing agent, such as SO_2 or $FeSO_4$, the whole of the iodine may be thrown down as Cu_2I_2. The precipitated Cu_2I_2 contains when dried at 40° C., 4 per cent. water, and is, therefore, Cu_2I_2Aq or Cu_2O,HI. On this account I dissolved in a porcelain dish, with the necessary amount of water, five parts by weight of cupric sulphate, and eight parts of ferrous sulphate, and, as a little ferric oxide had been deposited, I added hydrochloric acid until it disappeared. With this solution the precipitation of all the iodine was effected exactly as if I had treated a very dilute solution of potassium iodide with an equal volume of the above-mentioned solution of cupric and ferrous sulphate. Nevertheless with this reagent, I was, in one experiment, unable to obtain a precipitate in a solution from the ash, although through the use of another reagent, I had been convinced that iodine was present in minute quantity. I shall return to this fact again after I have mentioned another method of determining iodine suggested by Dr. F. Mohr.* Dr. Mohr proposes the following way: In 200 c. c. of a clear solution consisting of cuprous chloride, sal ammoniac, and water, the first drop of a potassium iodide solution, which contained 1 per cent. iodine (1·308 potassium iodide) to the litre, caused immediately a large precipitate. Thirty-two drops from the pipette used made 1 c. c., therefore each drop contained $\frac{0·01}{32} = 0·0002$ iodine, which reckoned for 200 c. c. $= \frac{3}{2,000,000}$ iodine, which were detected by this reagent. Therefore, for a complete precipitation of iodine from its soluble salts, we do not need either palladium or thallium. The palladious oxide test is less delicate than with cuprous chloride.

A very dilute solution of potassium iodide was still further diluted with water, and poured into two glasses, side by side. To one of them was added cuprous chloride which had been clarified by ammonic chloride; to the other palladium solution. After some time the former showed a milky cloudiness, but the palladium solution none at all. These are the facts presented by Mohr. I might with certainty consider that Mohr had not regarded the difficult solubility of cuprous chloride *per se* in water, and that owing to a too small addition of NH_4Cl the Cu_2Cl_2 came down and caused the cloudiness which he concluded was cuprous iodide.

Let us consider these points more closely. The basis and starting point of Mohr's method of proceeding is, strictly speaking, identical with that by means of cuprous oxide; for in both cases we have to do with the lower state of oxidation of the copper, whether suboxide or subchloride is immaterial, as the secondary reactions taking place at the same time are only important so far as they may act to dissolve or decompose the Cu_2I_2 after it is formed. That this is really the case, my own observations have shown. The resulting salts of the ferrous oxide dissolve the cuprous iodine in no small quantity, a fact which Dr. Fleischer* has also noticed. The latter proposes stannous chloride as a reducing agent. The precipitation, he says, is complete and the stannous chloride does not act in the least on the cuprous iodide to dissolve it. Both facts I have found to be entirely true.

From all these experiments, it follows, that the precipitation of iodine as Cu_2I_2, in the presence of chlorine and bromine, could be conducted on a large scale with success, where a comparatively small loss of iodine is of no great moment, and that this method more than answers the requirements of exactness, which chemical industry on a large scale demands. But for a quantitative determination of iodine in very dilute solutions, such as we meet with in the analysis of ashes and many mineral waters, none of these methods give perfectly satisfactory results, and we are always forced back to the palladious oxide method. Dr. Mohr declares that with cuprous chloride a milky cloudiness will occur even after the palladium solution shows no more reaction. As already remarked, in a very dilute solution I obtained no precipitate of cuprous iodide, even after long standing, while the addition of palladium solution caused an immediate precipitate. That this precipitate was really palladic iodide was shown by drying and heating it in a tube closed at one end, whereby the violet iodine vapours were distinctly to be seen. Hence: *In delicacy none of the hitherto discovered methods of precipitation can replace the palladious nitrate.*

In the investigation of other water-plants, in which I am at present engaged, I shall have opportunity to note more exactly the degree of dilution in which the palladium solution will still show a reaction.

The quantitative determination of the iodine and bromine I accomplished in the following way: The difference of the behaviour of the chloride, iodide, and bromide of silver to different degrees of concentration of ammonia, served as a basis for my work. For precipita-

* Mohr, Zeitschrift von Fresenius. XII. Jahrgang, 4 heft.

* Titrirmethode als selbstständige quan. analyse, § 33, Kupfer und Iodbestimmung, p. 73.

tion, a concentrated solution of argentic nitrate (1 : 4) was employed. The washed precipitate was treated with 5 per cent. ammonia water; it dissolved the argentic chloride; on the filter remained the argentic iodide and bromide. The argentic chloride was precipitated with nitric acid, and the iodide and bromide having been washed were treated with strong (15 per cent.) ammonia. Only the argentic bromide was dissolved, which having been filtered off was likewise re-precipitated by nitric acid.

In all the operations, such as digesting, precipitating, filtering, and washing, the light was excluded as much as possible. The endeavour to prepare a little iodine from the ashes of *C. glomerata* did not succeed, owing to the circumstance that I employed a too thin and soft glass tube, which melted on being heated, before the palladic iodide contained in it was decomposed. However, I removed the palladic iodide from the tube and heated it in a platinum crucible, whereupon the iodine escaped in a thick cloud. In this manner it could not be caught. I have therefore commenced work upon a still larger quantity of ash to obtain the iodine.

Palladic iodide certainly requires quite a high temperature to decompose it into its constituents.

Mr. Carl Petter remarks that in his experiments the loss in weight of *C. glomerata* dried at 110° C. was 8 per cent. Mr. Jessler calculated that 18¾ lb. of the dried algæ gave 0·23431 grm. iodine: *i.e.*, 23·431 grms. per cwt. According to my analysis, the amount of ash in the plant was 52·850 per cent., and in 1 cwt. of ash there were 21·50 grms. iodine, and 8·50 grms. bromine. This large amount of ash consisted chiefly of lime, and had its origin in the extremely "hard" waters of Zengermoos.

Without reference to an analysis by Prof. Kaisen, this fact would be proved alone by the tufa and the broad belt of that peculiar, white, calcareous earth, known as "alm," which stretches eastward towards Erding. Without doubt both the tufa and alm owe their origin to the Isar, which contained the calcic carbonate in solution and deposited it in Erdingermoos. A piece of sound wood which has lain for a short time in the Golbach, a stream which flows around Zengermoos, loses the power to float, owing to the impregnation with lime. The bed of this brook is formed, for the most part, of alm and tufa; from this fact comes the large percentage of lime in the soil and in the plants, as well as the semi-alpine flora of the district. The yellow, sweet smelling *Primula auricula*, with its flesh-coloured leaves and powdered stalk, flourishes here, as well as many varieties of Gentian, *e.g.*, *Gentiana lutea, purpurea, pannonica, acaulis, punctata*. It is readily to be seen that the lime in Cladophora glomerata existed previously as carbonate from the fact that the plants effervesce strongly with acid, which was long ago noticed.

How varying the composition of one and the same plant may be, according to its location, can be seen from the analysis of Mr. Jessler and my own. He obtained the plants out of pure spring water; I, out of very hard water. It would be impossible to detect iodine in this water, no matter how concentrated, *but the plants have the property of absorbing the iodine and bromine, and thus concentrating and storing them up.*

I think that after my experience with Cladophora and other water plants, I am justified in believing that iodine and bromine occur in water plants to an extent as yet hardly dreamed of, and that also in land plants these bodies can be recognized with certainty.

Karl Sprengel, whose worth has been wrongly undervalued, to whom with better right than to Liebig we should ascribe the foundation of the new scientific agriculture (for Liebig only built upon the foundation laid by Sprengel, and more than ignored him whose too great modesty and lack of self-conceit—faults no one ever accused Liebig of—were his only mistakes), says: "Very probably iodine is contained in all earths which are rich in sodic chloride. I have found it in small quantities in the subsoil of the marshes on the coast of the North Sea. *Whether or not the iodine belongs to the nourishing materials absorbed by the plant, which is probable, it is at any rate present,* and we will therefore, etc."*

That the manganese was present as manganous oxide in the ashes is proved by the evolution of chlorine on treating the ash with hydrochloric acid.

Alumina, almost completely ignored by Liebig, I found in every analysis of the ash. The same result has been very often obtained in Wittstein's laboratory, and by scientists such as Sprengel, Boussingault, and others, who have done so much for agriculture. All these have found alumina constantly present and often in comparatively large quantities in the ashes of plants, and hence we are obliged to set it down among the prominent constituents of plants.

On account of the great number of fresh-water plants existing everywhere, it is quite possible that the manufacture of iodine from them may grow to be a branch of chemical industry. I shall direct my attention to the examination for bromine and iodine, of as many land and water plants as possible. At present I am engaged upon another water plant, *Lemna minor*. This plant surpasses *Cladophora glomerata* in the large amount of salts soluble in water it contains. Iodine, in considerable quantity, and bromine are present. The exact quantitative results will be given later. Nevertheless we can already say with certainty that iodine and bromine occur much more extensively in the vegetable kingdom than has hitherto been supposed.

A METHOD OF ESTIMATING BISMUTH VOLUMETRICALLY.†

BY M. M. PATTINSON MUIR, F.R.S.E.,

Assistant Lecturer on Chemistry, The Owens College, Manchester.

Löwe (*J. prakt. Chemie*, lxvii., 288 and 463), has described two salts produced by the action of potassium chromate and potassium dichromate respectively upon warm, nearly neutral solutions of bismuth nitrate. To the first of these salts he assigns the formula $3Bi_2O_3.2CrO_3$, and to the second the formula $Bi_2O_3.2CrO_3$. The same author has described a process for estimating bismuth gravimetrically, based upon the formation of these salts (*ibid.*, 464). Pearson has described a process for the estimation of bismuth, nearly identical with that of Löwe, and in addition a process based upon the same reaction, for the volumetric examination of the same metal (*Phil. Mag.* [4], xi, 204). In Pearson's volumetric process potassium dichromate solution is run into the solution of bismuth until the whole of that metal is precipitated, the termination of the reaction being determined by noting the point at which the supernatant liquid acquires a permanent yellow tint.

The process described by the author of the present paper depends upon the facts concerning the formation of chromate of bismuth made known by Löwe and referred to above. Potassium chromate or potassium dichromate solution is run into a nearly neutral solution of bismuth nitrate until the whole of the metal is precipitated in the form of chromate. The final point of the reaction is determined by bringing a drop of the supernatant yellow liquid into contact with a drop of the silver nitrate solution upon a white slab, when red silver chromate is produced.

On account of the uncertainty which still exists in reference to the exact composition of the chromates of bismuth, and also on account of the fact that a slight excess of either of the potassium chromates appears

---

† From a paper read before the Chemical Society (*Journ. Chem. Soc.*, April, 1876.)

necessary in order to cause the complete precipitation of the bismuth salts, no attempt was made to calculate the exact quantity of chromate needed to precipitate a known weight of bismuth, and upon such a calculation to base the composition of a standard liquid; but the plan was adopted of titrating a dilute chromate solution against a standard bismuth solution, and from these results calculating the strength of the chromate in terms of bismuth precipitated.

The author first describes the results of the experiments made with a solution of potassium chromate. The chromate was purified by recrystallization from aqueous solution. About 10 grams were dissolved in 1000 c.c. of water. A solution of bismuth nitrate was prepared by dissolving a known weight of pure bismuthic trioxide (Bi_2O_3) in dilute nitric acid, and making up the liquid to one litre. The chromate solution was run into a measured quantity of the bismuth-containing liquid (made nearly neutral with ammonia and maintained at the boiling point) until a faint reddish colour was produced on bringing a drop of the supernatant liquid in contact with a drop of an aqueous solution of silver nitrate spotted upon a glass plate, which rested upon a sheet of white paper.

Partial neutralization of the acid liquid containing bismuth was effected by dropping in ammonia until a very faint precipitate was formed, then boiling the liquid, and continuing to add ammonia very carefully until the solution was but slightly acid. Before this point was reached a precipitate invariably formed, but it was found that this did not interfere with the results. If an excess of ammonia were inadvertently added it was found better to add nitric acid in quantity sufficient to dissolve the precipitate, and again to nearly neutralize with ammonia, rather than to add merely such a quantity of nitric acid as should cause but a faint acid reaction in the liquid. The chromate was run in from a burette graduated in tenths of a cubic centimeter and furnished with a glass stop-cock. After the addition of a few drops of chromate solution, the liquid was boiled for some minutes, and the precipitate was then allowed to settle, which it did very rapidly and completely. In order to bring a drop of silver nitrate solution on to the glass plate, and at the same time to prevent the continued exposure of this solution to the air of the laboratory—an exposure which always resulted sooner or later in the production of silver sulphide in the solution—a special apparatus was made use of, by which the formation of silver sulphide was reduced to a minimum. The formation of silver chromate only became apparent after a few moments, and when an excess of silver nitrate was used relatively to the quantity of potassium chromate in the drop of liquid. The following results were obtained:—

A. *Standardizing Chromate Solution.*

Bismuth taken.	c.c. of chromate used.
0·1623 gram.	27·6
„ „	27·2
„ „	27·2
Mean	= 27·33

1 c.c. = 0·005945 gram bismuth.

B. *Estimation of Bismuth by means of the Standard Chromate.*

Bismuth taken.	c.c. of chromate used.	Bismuth found.	Difference.
0·3246 gram.	55·0	0·3269 gram.	+ ·0023

A_1. *Standardizing Second Chromate Solution.*

Bismuth taken.	c.c. of chromate used.
0·3246 gram.	40·0
„ „	40·0
„ „	40·0
Mean	= 40·0

1 c.c. = 0·008115 gram bismuth.

B_1. *Estimation of Bismuth by means of Standard Chromate.*

Bismuth taken.	c.c. of chromate used.	Bismuth found.	Difference.
0·3246 gram.	40·8	0·3311 gram.	+ ·0065
0·3246 „	39·8	0·3229 „	− ·0017
0·6492 „	79·5	0·6452 „	+ ·0040
0·2494 „	30·5	0·2475 „	− ·0019

These results may be stated in another way. From the quantity of chromate used in each experiment the value of 1 c.c. of the liquid in terms of bismuth may be deduced. Thus, taking the second series of experiments, the following values are obtained:—

1. 1 c.c. of chromate liquid = 0·008115 gram bismuth.
2. 1 c.c. „ „ = 0·008115 „ „
3. 1 c.c. „ „ = 0·008115 „ „
4. 1 c.c. „ „ = 0·007956 „ „
5. 1 c.c. „ „ = 0·008156 „ „
6. 1 c.c. „ „ = 0·008166 „ „
7. 1 c.c. „ „ = 0·008177 „ „

The following results were obtained when working with a solution of potassium dichromate. The process was carried out in a manner similar to that already described. The dichromate was purified by recrystallization from aqueous solution:—

C. *Standardizing Dichromate Solution.*

Bismuth taken.	c.c. of dichromate used.
6·1623 gram	17·0
„ „	17·0
„ „	17·5
Mean	17·16

1 c.c. = 0·009458 gram bismuth.

D. *Estimation of Bismuth by means of Standard Dichromate.*

Bismuth taken.	c.c. of chromate used.	Bismuth found.	Difference.
0·1247 gram	13·0	0·1229 gram	—·0018
0·1247 „	13·0	0·1229 „	—·0018
0·2494 „	26·2	0·2478 „	—·0016
0·1247 „	13·1	0·1239 „	—·0008

If these results be stated so as to show the value of 1 c.c. of the dichromate liquid in terms of bismuth, as deduced from each experiment, the following numbers are obtained:—

1. 1 c.c. of chromate liquid = 0·009429 gram bismuth.
2. 1 c.c. „ „ = 0·009429 „ „
3. 1 c.c. „ „ = 0·009274 „ „
4. 1 c.c. „ „ = 0·009592 „ „
5. 1 c.c. „ „ = 0·009592 „ „
6. 1 c.c. „ „ = 0·009519 „ „
7. 1 c.c. „ „ = 0·009519 „ „

The dichromate method is, the author thinks, rather to be preferred to the chromate method. It is easy to crystallize potassium dichromate, and therefore easy to obtain a pure solution of this salt. The reaction with silver nitrate is more marked than in the case of the chromate, but a slight excess of silver nitrate should here also be added, and a little time should be allowed to elapse before a conclusion is drawn as to the completion of the process. The difference between the quantities of bismuth taken and the quantities found are smaller in the results obtained by the dichromate than in those obtained by the chromate method.

It is necessary to neutralize the greater part of the free nitric acid before running in the dichromate liquid.

The presence of a considerable quantity of chlorides also interferes with the estimation of bismuth by this method. The precipitate formed being totally unlike the chromate of bismuth usually obtained: it was white or light yellow, heavy, and granular, and probably consisted in large part of bismuth oxychloride.

Attempts were made to estimate bismuth by this method in the presence of nearly equal quantities of copper (as nitrate), of arsenic (as arsenious oxide), and of calcium as nitrate, but in no case were satisfactory results obtained. The metals which may exist in solution along with bismuth should therefore be removed before the estimation of the latter by means of potassium dichromate. Some experiments that were made showed that bismuth may be separated from other metals by the ordinary methods, and then estimated by the dichromate method.

The Pharmaceutical Journal.

SATURDAY, JULY 1, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

MILK OF SULPHUR.

THE discussion on the question "What is Milk of Sulphur," by the Society of Public Analysts has been useful not only in furnishing some members of that body with an opportunity of correcting their notions on this subject, but also as a means of eliciting an expression of opinion respecting it from two of the medical journals. It was indeed literally somewhat out of order that, on the occasion referred to, this question should have been raised by Dr. ALFRED HILL after he had so positively disposed of it at Birmingham but a few days before, and had succeeded in leading the magistrates to declare that the preparation known and in use, for more than a century and a half, by the familiar name of "milk of sulphur" cannot be lawfully sold now unless with a distinctive label stating that "it contains sulphate of lime."

But notwithstanding this inconsistency, suggestive of the old practice of hanging a man first and trying him afterwards, we trust some good may result from the discussion, especially since the President of the Society of Public Analysts took the trouble to expose the numerous fallacies into which the Public Analyst for Birmingham had fallen. The letter which appears in this number of the Journal from Mr. GROVES will also contribute to the same result. It is further satisfactory to find that the *Lancet*, in speaking of this subject and distinctly expressing objection to the sale of uncertain mixtures with titles capable of misconception, unreservedly admits that the title "milk of sulphur" can hardly be said to mean necessarily pure sulphur. Unfortunately, the misuse of this title by some persons as a designation of the precipitated sulphur of the Pharmacopœia has led to some confusion and difficulty. Whenever the term is used with that meaning the Pharmacopœia preparation should be supplied. But we are disposed to believe that in the majority of instances the title "milk of sulphur" is meant to indicate the old-fashioned preparation and that being so, as the *Lancet* observes, "there seems no reason why it should not be sold exclusively under that name."

The *Medical Times and Gazette* also admits that pharmacists have good reason to be dissatisfied with the decision of the Birmingham magistrates. Recognizing the fact that the old-fashioned preparation of sulphur, made—by authority of the old Pharmacopœia—in such a way as to contain a large proportion of sulphate of lime, has long been a popular remedy though it is no longer a Pharmacopœia article, it doubts the propriety of the demand that a druggist should be compelled to supply precipitated sulphur when asked by a customer for "milk of sulphur." Yet this is the position which Dr. HILL, of Birmingham, and certain other public analysts seek to maintain, and as it appears to us it was solely upon the assumption of this view as the correct one, that the decision of the Birmingham magistrates was based. That decision really begs the whole question and, instead of settling the matter, it adds to the necessity of bringing the case before a superior court.

METHYLATED SPIRIT, ETC.

JUDGING from some inquiries and communications that have reached us there seems to be still much uncertainty prevailing as to what is legal and what is not legal as regards the sale and use of methylated spirit and "finish." We doubt whether the permission of the Inland Revenue Commissioners to use methylated spirit would justify the application of it even for making Pharmacopœia preparations that are not intended for internal use, such as liniment of aconite or liniment of belladona. We are still more disposed to question the legality of selling these preparations when made with methylated spirit, inasmuch as the Pharmacopœia orders rectified spirit to be used and deviation from those directions would involve liability under the Sale of Food and Drugs Act, and under the 15th section of the Pharmacy Act, 1868.

Of course every one retailing methylated spirit requires to have a license, and in obtaining that license, as well as in renewing it from year to year, he is brought into communication with the Inland Revenue authorities in such a manner, that he can always obtain information as to the conditions that he must observe as a retailer of the spirit. The danger consists in failing to take out and renew the license.

As regards "finish" it is now five years since we pointed out to our readers the necessity of taking every possibly precaution to make sure that the "finish" they purchased was really prepared according to the requirements of the Inland Revenue authorities. By mixing a little of the "finish" with three times its volume of water, it should become milky, and after a short time a curdy precipitate should be deposited. If the mixture only becomes turbid there is reason to suspect that it does not contain the proper proportion of gum resin, and then a further test should be applied by evaporating a known quantity to complete dryness, and weighing the residue of gum so as to ascertain the exact amount contained in the "finish." These operations are sufficiently simple to be carried out with no great difficulty and the practice of testing every supply as received would furnish the dealer with some satisfactory assurance of the character of the article.

"LEADERS IN MEDICINE AND SURGERY."

MESSRS. BARRAUD and JERRARD, the photographers, who have published several very successful group pictures, have recently issued one which cannot fail to be of interest to many readers of this Journal, representing "Leaders in Medicine and Surgery." The picture comprises 183 portraits of leading physicians or surgeons who have sat for the purpose. The likenesses are exceedingly good, and the grouping affords a very satisfactory representation of individual characteristics.

At the late Conversazione of the Obstetrical Society, held in the rooms of the Royal College of Physicians, this picture was throughout the evening the centre of an admiring throng of spectators, and elicited warm commendation.

COUNTERFEIT COINS.

IN his Sixth Annual Report, just issued, the Deputy Master of the Mint refers to the subject of counterfeit coinage. It is satisfactory to note that, so far as the statistics given can be accepted as evidence, there appears to have been a decrease in the crime of counterfeit coining. The number of prosecutions during the year 1875 was only 180, against 256 in 1870, which was also a decrease on previous years. One of the greatest difficulties these offenders have to contend with is the imitation of the milling or lettering on the edges; another is the necessity for confederacy, shown by the fact that the average of prisoners is nearly two to each prosecution.

It is noted that half sovereigns among gold coins and florins and shillings among silver are the coins most frequently counterfeited, probably, it is thought, because coins of these denominations are found to attract the least attention from the public.

The only counterfeits that can be considered really successful imitations are coins of gilded platinum containing a small percentage of copper and sometimes provided with a rim of pure gold. These have a good ring and are of good weight, and may pass freely without being detected until the gold is worn off, disclosing the platinum beneath. One form of counterfeit, principally met with in America, consists of the shell of a genuine coin from which the interior has been removed and replaced by base metal. Counterfeiters of silver coin usually employ a fusible alloy of lead and tin, which is cast in a mould.

The Deputy Master of the Mint condemns the so-called "detector," used for bending coin, and points out that it affords no proof that a piece is not genuine, and moreover that its use is rendered illegal by the Act passed in 1853 to prevent the defacing of the current coin of the realm. Neither is "ringing" a coin more conclusive, as genuine coins may easily be rendered "dumb." As a rule, he considers the best test to be the weighing of the suspected coin against a piece of the same denomination that is evidently genuine.

THE CULTIVATION OF JABORANDI AND EUCALYPTUS.

AMONG the prizes instituted by the Société d'Acclimatation this year is one of 500 francs for the cultivation of Jaborandi (*Pilocarpus pinnatus*) in France or in Algeria. The prize is to remain open until the 1st of December, 1885, and the conditions of its award are that the plant shall have been successfully cultivated upwards of five years, and that at least during the latter years the cultivation shall have extended over a demi-hectare. The cultivation must also be a commercial success.

Another prize of 500 francs, to remain open until the same date, is offered for a "Practical and Theoretical Guide to the Culture of the Eucalyptus." The authors are especially to make an investigation, based on comparative experiments, as to the species of Eucalyptus that can be best cultivated under various climates, to indicate the nature of the soil that is most suitable and the special cares demanded in the cultivation of each species, the degree of cold which it can resist, and its relative value.

APPRENTICESHIP IN THE SOUTH OF FRANCE.

AN application for information respecting the conditions of pharmaceutical apprenticeship which ordinarily obtain in the city of Bordeaux, addressed to the Editor of the Bulletin of the Pharmaceutical Society of that city, has elicited a reply, which reveals a great diversity of practice, with no better result than that, "everybody complains, everybody accuses everybody else, and nobody thinks of doing anything but beat the breast." This unsatisfactory state of things is attributed to the imperfect training of the apprentices, and the following remedy is suggested. "Instead of complaining let us seek to do better; do not forget that it is upon the discipline of the first years that the worth of the pupil, and subsequently of the pharmacien depends. Require then, from your apprentice—not harshly, but with firmness—that he works without cessation, does not go out much, smokes as little as possible, rises early, studies the preparations made during the day, and that he does not recoil from a greasy bottle, a dirty pan, or a turn with the broom. If he does not submit with good grace to these exigencies, which are not yours, but those of the profession, show him the door, and if he should then go to a confrère who treats him in the same fashion, he will quit the calling or become a good pupil and a good pharmacien. Amen!"

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening, July 6th, at eight o'clock, when a paper on "Polarization of Light" will be read by Mr. CHARLES H. HUTCHINSON.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A lecture was delivered in the rooms of the above Association, Halford Street, on Tuesday evening, June 20, 1876, by Mr. W. B. Baron, President, subject "The Microscope." Mr. J. Garrett, Vice-President, presided.

The lecturer commenced his task by stating that his aim was to give his audience a scientific knowledge of that marvellous instrument the microscope, in place of the empirical knowledge that had perhaps heretofore been their sole possession. With this object in view he intended, as far as his ability would permit, to lay before them the laws of optics bearing more or less upon the construction and working of the microscope. After these and other preparatory remarks the lecturer commented on the linear propagation of the ethereal undulations. Next the reflection of light was touched upon, the law governing the course pursued by the incident and by the reflected rays being carefully explained and illustrated. The refraction of the luminous ray on passing from one optical medium to another was then adverted to at some length; the course of the ray before, during, and after refraction by bodies bounded by plane surfaces and by those whose surfaces are curves, together with the constant ratio existing between the sine of the angle of incidence and that of the angle of reflection, and also the varying refractive power possessed by different bodies, being minutely detailed. A lens was next defined as "a piece of glass or other transparent substance, having its surfaces so formed that rays of light passing through them have their direction changed and are made to converge or diverge from their original parallelism, or to become parallel after converging or diverging." The diversified kinds of lenses, both converging and diverging, were then alluded to, and their action upon the luminous rays particularly explained by means of diagrams, etc. The structure of the crystalline lens of the eye, the manner in which it brings light rays to a focus upon the retina, its inability to properly focus strongly divergent rays, and the necessity consequently existing for the use of convex lenses were all touched upon. Spherical aberration next claimed attention, its cause being explained; likewise its remedy—

1. By the use of lenses whose surfaces are portions of an ellipse or an hyperbola. An effective if it were not impracticable expedient.
2. The tolerably effective though undesirable method of cutting off the circumferential rays by means of a diaphragm or stop.
3. The usual method employed, viz., by continuing lenses in such manner that the aberration of one shall counteract that of the other, and magnifying power be gained at the same time.

The cause and cure of chromatic aberration was treated of in a similar manner. Finally, the application of the foregoing laws in the construction of the microscope, together with its mechanical details were explained. The section on the polarization of light was necessarily postponed owing to lack of time. The speaker concluded by expressing his opinion upon those persons who affected a contempt for the microscope simply because by it were viewed only what they were pleased to call little things, and by quoting Young's well known lines—

"Think nought a trifle though it small appears,
Small sands the mountain, moments make the years,
And trifles life."

The lecture, which was listened to attentively throughout, lasted one hour and fifteen minutes.

Mr. Raynor then very heartily proposed a vote of thanks to the lecturer, which was unanimously carried and appropriately replied to, after which the proceedings terminated.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Prize Competition.

At the recent examinations in connection with the Botany and Tutorial Classes, held under the auspices of this society, the following prizes were awarded:—

BOTANY CLASS.

First prize, Mr. Peter Foa.
Second prize, Mr. John McNicol.

TUTORIAL CLASS.

First prize, Mr. C. McKirdy.
Second prize, Mr. James Rait.

Professor Kiddie and Mr. Fyfe, the teachers, report very favourably regarding the progress made by the various students, and the visiting committee of the Council also report as being highly gratified with the classes generally.

ROYAL INSTITUTION OF GREAT BRITAIN.*

The Mechanical Action of Light.

BY W. CROOKES, F.R.S.

To generate motion has been found a characteristic common, with one exception, to all the phases of physical force. We hold the bulb of a thermometer in our hands, and the mercury expands in bulk, and, rising along the scale, indicates the increase of heat it has received. We heat water, and it is converted into steam, and moves our machinery, our carriages, and our ironclads. We bring a loadstone near a number of iron filings, and they move towards it, arranging themselves in peculiar and intricate lines; or we bring a piece of iron near a magnetic needle, and we find it turned away from its ordinary position. We rub a piece of glass with silk, thus throwing it into a state of electrical excitement, and we find that bits of paper or thread fly towards it, and are, in a few moments, repelled again. If we remove the supports from a mass of matter it falls, the influence of gravitation being here most plainly expressed in motion, as shown in clocks and water-mills. If we fix pieces of paper upon a stretched string, and then sound a musical note near it, we find certain of the papers projected from their places. Latterly, the so-called "sensitive flames," which are violently agitated by certain musical notes, have become well known as instances of the conversion of sound into motion. How readily chemical force undergoes the same transformation is manifested in such catastrophes as those of Bremerhaven, in the recent deplorable coal-mine explosions, and indeed in every discharge of a gun.

But light, in some respects the highest of the powers of nature, has not been hitherto found capable of direct conversion into motion, and such an exception cannot but be regarded as a singular anomaly.

This anomaly the researches which I am about to bring before you have now removed; and, like the other forms of force, light is found to be capable of direct conversion into motion, and of being—like heat, electricity, magnetism, sound, gravitation, and chemical action—most delicately and accurately measured by the amount of motion thus produced.

My research arose from the study of an anomaly.

It is well known to scientific men that bodies appear to weigh less when they are hot than when they are cold; the explanation given being, that the ascending currents of hot air buoy up the body, so to speak. Wishing to get rid of this and other interfering actions of the air

* Lecture delivered on Friday, February 11, 1876.

during a research on the atomic weight of thallium, I had a balance constructed in which I could weigh in a vacuum. I still, indeed, found my apparatus less heavy when hot than when cold. The obvious explanations were evidently not the true ones: *obvious* explanations seldom are true ones, for simplicity is not a characteristic of nature.

An unknown disturbing cause was interfering, and the endeavour to find the clue to the apparent anomaly has led to the discovery of the mechanical action of light.

I was long troubled by the apparent lawlessness of the actions I obtained. By gradually increasing the delicacy of my apparatus I could easily get certain results of motion when hot bodies were brought near them, but sometimes it was one of attraction, at others of repulsion, whilst occasionally no movement whatever was produced.

I will try to reproduce these phenomena in this apparatus. Here are two glass bulbs, each containing a bar of pith about three inches long and half an inch thick, suspended horizontally by a long fibre of cocoon silk. I bring a hot glass rod, or a candle, towards one of them, and you see that the pith is gradually attracted, following the candle as I move it round the bulb. That seems a very definite fact; but look at the action in the other bulb. I bring the candle, or a hot glass rod, near the other bar of pith, and it is strongly *repelled* by it—much more strongly than it was attracted in the first instance.

Here, again, is a third fact. I bring a piece of ice near the pith bar which has just been repelled by the hot rod, and it is attracted, and follows the rod round as a magnetic needle follows a piece of iron.

The repulsion by radiation is the key-note of these researches. The movement of a small bar of pith is not very distinct, except to those near, and I wish to make this repulsion evident to all. I have therefore arranged a piece of apparatus by which it can be seen by all present. I will, by means of the electric light, project an image of a pendulum suspended *in vacuo* on the screen. You see that the approach of a candle gives the bob a veritable push, and by alternately obscuring and uncovering the light, I can make the pendulum beat time to my movements.

What then is the cause of the contradictory action in these two bulbs—attraction in one, and repulsion in the other? It can be explained in a few words. Attraction takes place when air is present, and repulsion when air is absent.

Neutrality, or no movement, is produced when the vacuum is insufficient. A minute trace of air in the apparatus interferes most materially with the repulsion, and for a long time I was unaware of the powerful action produced by radiation in a "perfect" vacuum.

It is not at first sight obvious how ice or a cold body can produce the opposite effect to heat. The law of exchanges, however, explains this perfectly. The pith bar and the whole of the surrounding bodies are incessantly exchanging heat-rays; and under ordinary circumstances the income and expenditure of heat are in equilibrium. Let me draw your attention to the diagram illustrating what takes place when I bring a piece of ice near the apparatus. The centre circle represents my piece of pith; the arrows show the influx and efflux of heat. A piece of ice brought near cuts off the influx of heat from one side, and therefore allows an excess of heat to fall on the pith from the opposite side. Attraction by a cold body is therefore seen to be only repulsion by radiation from the opposite side of the room.

The later developments of this research have demanded the utmost refinement of apparatus. Everything has to be conducted in glass vessels, and these must be blown together till they make one piece, for none but fused joints are admissible. In an investigation depending for its successful prosecution on manipulative dexterity, I have been fortunate in having the assistance of my friend Mr. Charles Gillingham. All the apparatus you see before you are the fruits of his skilful manipulation, and I now want to draw your attention to what I think is a masterpiece of glass-working—the pump which enables me so readily to produce a vacuum unattainable by ordinary means.

The pump here at work is a modification of the Sprengel pump, but it contains two or three valuable improvements. I cannot attempt to describe the whole of the arrangements, but I will rapidly run over them as illuminated by the electric light. It has a triple fall tube in which the mercury is carried down, thus exhausting with threefold rapidity; it has Dr. McLeod's beautiful arrangement for measuring the residual gas; it has gauges in all directions, and a small radiometer attached to it to tell the amount of exhaustion that I get in my experiments; it has a contrivance for admitting oil of vitriol into the tubes without interfering with the progress of the exhaustion, and it is provided with a whole series of most ingenious vacuum taps devised by Mr. Gillingham. The exhaustion produced in this pump is such that a current of electricity from an induction coil will not pass across the vacuum. This pump is now exhausting a torsion balance, which will be described presently. Another pump, of a similar kind but less complicated, is exhausting an apparatus which has enabled me to pass from the mere exhibition of the phenomena to the obtaining of quantitative measurements.

A certain amount of force is exerted when a ray of light or heat falls on the suspended pith, and I wish to ascertain—

First. What were the actual rays—invisible heat, luminous, or ultra-violet—which caused this action?

Secondly. What influence had the colour of the surface on the action?

Thirdly. Was the amount of action in direct proportion to the amount of radiation?

Fourthly. What was the amount of force exerted by radiation?

I required an apparatus which would be easily moved by the impact of light on it, but which would readily return to zero, so that measurements might be obtained of the force exerted when different amounts of light acted on it. At first I made an apparatus on the Zöllner's horizontal pendulum. For a reason that will be explained presently, I am unable to show you the apparatus at work; but the principle of it is shown in the diagram. The pendulum represented by this horizontal line has a weight at the end. It is supported on two fibres of glass, one stretched upwards and the other stretched downwards, both firmly fastened at the ends, and also attached to the horizontal rod at points near together, but not quite opposite to one another.

It is evident that if there is a certain amount of pull upon each of these fibres, and that the pull can be so adjusted as to counteract the weight at the end and keep it horizontal, the nearer the beam approaches the horizontal line the slower its rate of oscillation. If I relax the tension, by throwing the horizontal beam downwards, I get a more rapid oscillation sideways. If I turn the levelling screw so as to raise the beam and weight, the nearer it approaches the horizontal position the slower the oscillation becomes, and the more delicate is the instrument. Here is the actual apparatus that I tried to work with. The weight at the end is a piece of pith; in the centre is a glass mirror, on which to throw a ray of light, so as to enable me to see the movements by a luminous index. The instrument, enclosed in glass and exhausted of air, was mounted on a stand with levelling screws, and with it I tried the action of a ray of light falling on the pith. I found that I could get any amount of sensitiveness that I liked; but it was not only sensitive to the impact of a ray of light, it was immeasurably more so to a change of horizontality. It was, in fact, too delicate for me to work with. The slightest elevation of one end of the instrument altered the sensitiveness, or the position of the zero-point, to such a degree that it was impossible to try any experiments with it in such a place as London. A person stepping from one room to another altered the position of the centre of gravity of the house. If I walked from one side of my own laboratory to the other, I tilted the house over sufficiently to upset the equilibrium of the apparatus. Children playing in the streets disturbed it. Professor Rood, who has worked with an apparatus of this kind in America, finds that an elevation of its side equal to $\frac{1}{360000000}$ part of an inch is sufficient to be shown on the instrument. It was therefore out of the question to use an instrument of this construction, so I tried another form in which a fine glass beam, having discs of pith at each end, is suspended horizontally by a fine glass fibre, the whole being sealed up in glass and perfectly exhausted. To the centre of oscillation a glass mirror is attached.

Now a glass fibre has the property of always coming back to zero when it is twisted out of its position. It is almost, if not quite, a perfectly elastic body. I will show this by a simple experiment. This is a long glass fibre hanging vertically, and having a horizontal bar suspended on it. I hold the bar, and turn it half round; it swings backwards and forwards for a few times, but it quickly comes back to its original position. However much twist, however much torsion, may be put on this, it always returns ultimately to the same position. I have twisted glass fibres round, and kept them in a permanent state of twist more than a hundred complete revolutions, and they always came back accurately to zero. The principle of an instrument that I shall describe farther on depends entirely on this property of glass.

Instead of using silk to suspend the torsion beam with, I employ a fibre of glass, drawn out very fine before the blow-pipe. A thread of glass of less than the thousandth of an inch in thickness is wonderfully strong, of great stiffness, and of perfect elasticity, so that however much it is twisted round short of the breaking point, it untwists itself perfectly when liberated. The advantage of using glass fibres for suspending my beam is, therefore, that it always returns accurately to zero, after having tried an experiment, whilst I can get any desired amount of sensitiveness by drawing out the glass fibre sufficiently fine.

Here, then, is the torsion apparatus sealed on to a Sprengel pump. It consists of a horizontal beam suspended by a glass fibre, and having discs of pith at each end coated with lampblack. The whole is enclosed in a glass case, made of tubes blown together, and by means of the pump the air is entirely removed. In the centre of the horizontal beam is a silvered mirror, and a ray from the electric light is reflected from it on to a scale in front, where it is visible as a small circular spot of light. It is evident that an angular movement of the torsion beam will cause the spot of light to move to the right or to the left along the scale. I will first show you the wonderful sensitiveness of the apparatus. I simply place my finger near the pith disc at one end, and the warmth is quite sufficient to drive the spot of light several inches along the scale. It has now returned to zero, and I place a candle near it. The spot of light flies off the scale. I now bring the candle near it alternately from one side to the other, and you see how perfectly it obeys the force of the candle. I think the movement is almost better seen without the screen than with it. The fog, which has been so great a detriment to every one else, is rather in my favour, for it shows the luminous index like a solid bar of light swaying to and fro across the room. The warmth of my finger or the radiation from a candle is therefore seen to drive the pith disc away. Here is a lump of ice, and on bringing it near one of the discs the luminous index promptly shows a movement of apparent attraction.

With this apparatus I have tried many experiments, and amongst others I have endeavoured to answer the question, "Is it light, or is it heat, that produces the movement?" for that is a question that is asked me by almost every one; and a good many appear to think that if the motion can be explained by an action of heat, all the novelty and the importance of the discovery vanishes. Now this question of light or heat is one I cannot answer, and I think that when I have explained the reason you will agree with me that it is unanswerable. There is no physical difference between light and heat. The spectrum, as scientific men understand it, extends from an indefinite distance beyond the red to an indefinite distance beyond the violet. We do not know how far it would extend one way or the other if no absorbing media were present; but, by what we may call a physiological accident, the human eye is sensitive to a portion of the spectrum situated between the line A in the red to about the line H in the violet. But this is not a physical difference between the luminous and non-luminous parts of the spectrum; it is only a physiological difference. Now, the part at the red end of the spectrum possesses, in the greatest degree, the property of causing the sensation of warmth, and of dilating the mercury in a thermometer, and of doing other things which are conveniently classed among the effects of *heat*; the centre part affects the eye, and is therefore called *light*; whilst the part at the other end of the spectrum has the greatest energy in producing *chemical action*. But it must not be forgotten that any ray of the spectrum, from whatever part it is selected, will produce all these physical actions in more or less degree. A ray here, at the letter C, for instance, in the orange, if concentrated on the bulb of a thermometer, will cause the mercury to dilate, and thus show the presence of *heat*; if concentrated on my hand I feel *warmth*; if I throw it on the face of a thermo-pile it will produce a current of *electricity*; if I throw it upon a sensitive photographic plate it will produce *chemical action*; and if I throw it upon the instrument I have just described, it will produce *motion*. What, then, am I to call that ray? Is it light, heat, electricity, chemical action, or motion? It is neither. All these actions are inseparable attributes of the ray of that particular wave-length, and are not evidences of separate identities. I can no more split that ray up into five or six different rays, each having different properties, than I can split up the element iron, for instance, into other elements, one possessing the specific gravity of iron, another its magnetic properties, a third its chemical properties, a fourth its conducting power for heat, and so on. A ray of light of a definite refrangibility is one and indivisible, just as an element is, and these different properties of the ray are mere functions of that refrangibility, and inseparable from it. Therefore when I tell you that a ray in the ultra-red pushes the instrument with a force of 100, and a ray in the most luminous part has a dynamic value of about half that, it must be understood that the latter action is not due to heat-rays, which accompany the luminous rays, but that the action is one purely due to the wave-length and the refrangibility of the ray employed. You now understand why it is that I cannot give a definite answer to the question, "Is it heat or is it light that produces these movements?" There is no physical difference between heat and light; so, to avoid confusion, I call the total bundle of rays which come from a candle or the sun, *radiation*.

I found, by throwing the pure rays of the spectrum one after the other upon this apparatus, that I could obtain a very definite answer to my first question, "What are the actual rays which cause this action?"

The apparatus was fitted up in a room specially devoted to it, and was protected on all sides, except where the rays of light had to pass, with cotton-wool and large bottles of water. A heliostat reflected a beam of sunlight in a constant direction, and it was received on an appropriate arrangement of slit, lenses, prisms, etc., for projecting a pure spectrum. Results were obtained in the months of July, August, and September; and they are represented graphically as a curve, the maximum being in the ultra-red and the minimum in the ultra-violet. Taking the maximum at 100, the following are the mechanical values of the different colours of the spectrum:—

Ultra-red	100
Extreme red	85
Red	73
Orange	66
Yellow	57
Green	41
Blue	22
Indigo	8½
Violet	6
Ultra-violet	5

A comparison of these figures is a sufficient proof that the mechanical action of radiation is as much a function of the luminous rays as it is of the dark heat-rays.

The second question, namely, "What influence has the colour of the surface on the action?" has also been solved by this apparatus.

In order to obtain comparative results between discs of pith coated with lampblack and with other substances, another torsion apparatus was constructed, in which six discs *in vacuo* could be exposed one after the other to a standard light. One disc always being lampblacked pith, the other discs could be changed so as to get comparisons of action. Calling the action of radiation from a candle on the lampblacked disc 100, the following are the proportions obtained:—

Lampblacked pith	100
Iodide of palladium	87·3
Precipitated silver	56
Amorphous phosphorus	40
Sulphate of baryta	37
Milk of sulphur	31
Red oxide of iron	28
Scarlet iodide of mercury and copper	22
Lampblacked silver	18
White pith	18
Carbonate of lead	13
Rock-salt	6·5
Glass	6.5

This table gives important information on many points; one more especially—the action of radiation on lampblacked pith is five and a half times what it is on plain pith. A bar like those used in my first experiment, having one half black and one half white, exposed to a broad beam of radiation, will be pushed with five and a half times more strength on the black than on the white half, and if freely suspended will set at an angle greater or less according to the intensity of the radiation falling on it.

This suggests the employment of such a bar as a photometer, and I have accordingly made an instrument on this principle. It consists of a flat bar of pith, half black and half white, suspended horizontally in a bulb by means of a long silk fibre. A reflecting mirror and small magnet are fastened to the pith, and a controlling magnet is fastened outside, so that it can slip up and down the tube, and thus increase or diminish sensitiveness. The whole is completely exhausted and then enclosed in a box lined with black velvet, with apertures for the rays of light to pass in and out. A ray of light from a lamp reflected from the mirror to a graduated scale shows the movements of the pith bar.

The instrument fitted up for a photometric experiment is in front of me on the table. A beam from the electric light falls on the little mirror, and is thence reflected back to the screen, where it forms a spot of light, the displacement of which to the right or the left shows the movement of the pith bar. One end of the bar is blacked on each side, the other end being left plain. I have two candles, each twelve inches off the pith bar, one on each side of it. When I remove the screens the candle on one side will give the pith a push in one direction, and the candle on the other side will give the pith a push in the opposite direction, and as they are the same distance off they will neutralize each other, and the spot of light will not move. I now take the two screens away; each candle is pushing the pith equally in opposite directions, and the luminous index remains at zero. When, however, I cut one candle off, the candle on the opposite side exerts its full influence, and the index flies to one end of the scale. I cut the other one off and obscure the first, and the spot of light flies to the other side. I obscure them both, and the index comes quickly to zero. I remove the screens simultaneously, and the index does not move.

I will retain one candle 12 inches off, and put two candles on the other side 17 inches off. On removing the screens you see the index does not move from zero. Now the square of 12 is 144, and the square of 17 is 289. Twice 144 is 288. The light of these candles, therefore, is as 288 to 289. They therefore balance each other as nearly as possible. Similarly I can balance a gas-light against a candle. I have a small gas-burner here, which I place 28 inches off on one side, and you see it balances the candle 12 inches off. These experiments show how conveniently and accurately this instrument can be used as a photometer. By balancing a standard candle on one side against any source of light on the other, the value of the latter in terms of a candle is readily shown; thus in the last experiment the standard candle 12 inches off is balanced by a gas-flame 28 inches off. The lights are therefore in the proportion of 12_2 to 28_2, or as 1 to 5·4. The gas-burner is therefore equal to about 5½ candles.

In practical work on photometry it is often required to ascertain the value of gas. Gas is spoken of commercially as of so many candle-power. There is a certain "standard" candle which is supposed to be made invariable by Act of Parliament. I have worked a great deal with these standard candles, and I find them to be among the most variable things in the world. They never burn with the same luminosity from one hour to the other, and no two candles are alike. I can now, however, easily get over this difficulty. I place a "standard" candle at such a distance from the apparatus that it gives a deflection of 100 degrees on the scale. If it is poorer than the standard I bring it nearer; if better, I put it farther off. Indeed, any candle may be taken; and if it be placed at such a distance from the apparatus that it will give a uniform deflection, say of 100 divisions, the standard can be reproduced at any subsequent time; and the burning of the candle may be tested during the photometric experiments by taking the deflection it causes from time to time, and altering its distance, if needed, to keep the deflection at 100 divisions. The gas-light to be tested is placed at such a distance on the opposite side of the pith bar that it exactly balances the candle. Then, by squaring the distances, I get the exact proportion between the gas and the candle.

Before this instrument can be used as a photometer or light measurer, means must be taken to cut off from it all those rays coming from the candle or gas which are not actually luminous. A reference to the spectrum diagram will show that at each end of the coloured rays there is a large space inactive, as far as the eye is concerned, but active in respect to the production of motion—strongly so at the red end, less strong at the violet end. Before the instrument can be used to measure luminosity, these rays must be cut off. We buy gas for the light that it gives, not for the heat it evolves on burning, and it would therefore never do to measure the heat and pay for it as light.

It has been found that a clear plate of alum, whilst letting all the light through, is almost, if not quite, opaque to the heating rays below the red. A solution of alum in water is almost as effective as a crystal of alum; if, therefore, I place in front of the instrument glass cells containing an aqueous solution of alum, the dark heat-rays are filtered off.

But the ultra-violet rays still pass through, and to cut these off I dissolve in the alum solution a quantity of sulphate of quinine. This body has the property of cutting off the ultra-violet rays from a point between the lines G and H. A combination of alum and sulphate of quinine, therefore, limits the action to those rays which affect the human eye, and the instrument, such as you see it before you, becomes a true photometer.

This instrument, when its sensitiveness is not deadened by the powerful control magnet I am obliged to keep near it for these experiments, is wonderfully sensible to light. In my own laboratory a candle 36 feet off produces a decided movement, and the motion of the index increases inversely with the square of the distance, thus answering the third question, "Is the amount of action in direct proportion to the amount of radiation?"

The experimental observations and the numbers which are required by the theoretical diminution of light with the square of the distance are sufficiently close, as the following figures show:

Candle	6 feet off	gives a	deflection of	218·0°
"	12	"	"	54·0°
"	18	"	"	24·0°
"	24	"	"	13·0°
"	10	"	"	77·0°
"	20	"	"	19·0°
"	30	"	"	8·5°

The effect of two candles side by side is practically double, and of three candles three times that of one candle.

In the instrument just described the candle acts on a pith bar, one end of which is blacked on each side. But suppose I black the bar on alternate halves and place a light near it sufficiently strong to drive the bar half round. The light will now have presented to it another black surface in the same position as the first, and the bar will be again driven in the same direction half round. This action will be again repeated, the differential action of the light on the black and white surfaces keeps the bar moving, and the result will be rotation.

Here is such a pith bar, blacked on alternate sides, and suspended in an exhausted glass bulb. I project its image on the screen, and the strong light which shines on it sets it rotating with considerable velocity. Now it is slackening speed, and now it has stopped altogether. The bar is supported on a fibre of silk, which has twisted round till the rotation is stopped by the accumulated torsion. I put a water screen between the bar and the electric light to cut off some of the active rays, and the silk untwists, turning the bar in the opposite direction. I now remove the water, and the bar revolves rapidly as at first.

From suspending the pith on a silk fibre to balancing it on a point the transition is slight; the interfering action of torsion is thereby removed, and the instrument rotates continuously under the influence of radiation. Many of these little pieces of apparatus, to which I have given the name of radiometers, are on the table, revolving with more or less speed. The construction is very simple. They are formed of four arms of very fine glass, supported in the centre by a needle-point, and having at the extremities thin discs of pith lamp-blacked on one side, the black surfaces all facing the same way. The needle stands in a glass cup, and the arms and discs are delicately balanced so as to revolve with the slighest impetus.

Here are some rotating by the light of a candle. This one now is rather an historical instrument, being the first one in which I saw rotation. It goes very slowly in comparison with the others, but it is not so bad for the first instrument of the sort that was ever made.

I will now, by means of a vertical lantern, throw on the screen the projection of one of these instruments, so as to show the movement rather better than you could see it on the table. The electric light falling vertically downwards on it, and much of the power being cut of by water and alum screens, the rotation is slow. I bring a candle near and the speed increases. I now lift the radiometer up, and place it full in the electric light, projecting its image direct on the screen, and it goes so rapidly that if I had not cut out the four pieces of pith of different shapes you would have been unable to follow the movement.

(To be continued.)

Parliamentary and Law Proceedings.

IMPORTANT TO DRUG GRINDERS. CONVICTION UNDER THE SALE OF FOOD AND DRUGS ACT.

A special petty session was held at Dunster on Friday, June 23rd, for the purpose of hearing an adjourned case, in which Mr. William Burnell, general shopkeeper, of Wootton Courtney, was summoned by Mr. Durham, inspector of weights and measures, for selling one ounce of adulterated pepper on the 25th of April. Mr. Cooper, wholesale druggist and chemist, of Exeter, by whom the article was supplied to the defendant, was in attendance and conducted the case for the defence.

Mr. Durham stated that on the 25th of April he purchased an ounce of pepper at the defendant's shop and took it, with other samples of various articles, to Mr. Stoddart, the county analyst, at Bristol, on the following day. He had received a certificate from Mr. Stoddart stating that the pepper was adulterated with ten per cent. of starch.

Mr. W. W. Stoddart said he analysed the pepper in question and found that it contained at least ten per cent. of starch from the flour of beans or peas. He produced in a glass the starch which he had extracted from thirty grains of the pepper. He had since received a sample of pepper direct from the defendant for analysis, and had found that it also contained the same proportion of starch. In answer to Mr. Cooper the witness said the glass produced also contained some pure pepper starch. If some beans had been ground in a mill and pepper corns had afterwards been ground with the same stones, particular care not having been taken to cleanse the stones, it was quite probable that some of the bean flour would become mixed with the pepper accidentally. It might not affect the whole of the bulk of the pepper in the same proportion, but the first portion would be most affected. He thought it would pay a manufacturer to adulterate pepper with ten per cent. of starch. He had known Mr. Cooper for a great number of years, and did not think him capable of practising adulteration.

For the defence Mr. Burnell stated that he added nothing whatever to the pepper and that he sent a sample of it, by Mr. Cooper's request, to Professor Attfield of London.

Walter Frost, assistant to Mr. Cooper, of Exeter, proved sending seven pounds of pepper to the defendant about the last week in February. He received it in a ground state from Mr. Tapscott, a wholesale grocer. He had been with Mr. Cooper for sixteen years, and had not during that time known of any article being adulterated by Mr. Cooper or by his instructions. Nothing could be adulterated in his master's place without his (witness's) knowledge.

James Keen, assistant to Mr. Tapscott, wholesale grocer, of Exeter, produced a receiving book which was used for checking goods inwards and outwards, and in it was an entry in the handwriting of a commercial traveller of Mr. Tapscott, implying that two bags of whole white pepper were sent to the Round Tree Mill, Exeter, to be ground, on February 25th. He (witness) received the pepper after it had been ground on March 4th, and one of the bags he sent to Mr. Cooper about two hours afterwards. Nothing was added to it, to his knowledge, while it was in his possession, and nothing could have been added without his being aware of it. He had not known Mr. Tapscott adulterate anything during the time he had been in his employ.

John Middlewick, miller, of Exeter, proved receiving two sacks of pepper corns from the previous witness. He ground them himself. There were no peas or beans with them. He did not add anything whatever to the pepper, but replaced it in the bags. The stones were kept for other uses. Before the pepper the last things ground were beans. A small quantity of the bean flour might have remained in the stones and so contaminated a slight portion of the pepper.

Dr. J. Attfield, professor of practical chemistry to the Pharmaceutical Society, stated that on the 30th of May last he received a sample of pepper by post from the defendant. He analysed it and found no pea meal, pea starch, or bean starch in it. He was well acquainted with the operation of drug grinding, and the previous witness's statement that some bean meal might get mixed with the pepper was correct. From the description which had been given by the miller of the process which he adopted in grinding, he was of opinion that a small portion of the ground pepper would contain bean meal. He explained the finding of starch by Mr. Stoddart and not by himself by the suggestion that the portion sold to the inspector was the portion containing the bean meal. The complete admixture of a little bean meal with the whole bulk of pepper ground would be extremely unlikely.

The Chairman remarked that this theory would no doubt account for the presence of the starch.

Professor Attfield said it was the custom of millers to use the residue of previous grindings for cleansing the stones, and in that way, if beans were used, a small portion of the flour would very likely be mixed with a portion of the pepper ground.

Mr. Cooper drew the attention of the Bench to the fifth section of the Adulteration Act, 1875, by which it was provided that no person should be liable to be convicted if he proved absence of knowledge of the article being adulterated.

The Clerk pointed out that the information was laid under the sixth section, and that this provisal could not apply. There was, however, a clause of the sixth section that a conviction should not take place when it should be proved that any article of food or drug was mixed with extraneous matter in the process of preparation or collection.

The Bench expressed an opinion that this clause could not shield the defendant, as they thought that although the pepper had not been wilfully adulterated, the presence of the starch could have been avoided. The fine would be a nominal one, 6*d*, and costs, and they wished to say that that the case had been conducted very straightforwardly, and that they believed that Mr. Cooper had not wilfully adulterated the pepper.

Mr. Cooper paid the fine and the costs £4 0*s*. 5*d*.—*West Somerset Free Press.*

Alleged Adulterated Arrowroot.

At the Wandsworth Police Court on Wednesday the 21st ult., John Bain, of the Balham Co-operative Stores, Cavendish Road, Clapham Park, was summoned for selling to the prejudice of the purchaser arrowroot which was adulterated with tapioca. A certificate was produced from Dr. Muter, the analyst of the local board of works, stating that the sample was adulterated with 50 per cent. of tapioca.

The Inspector appointed under the Act said that tapioca was sold at 4*d*. per pound. He paid 1*s*. for half a pound of arrowroot.

Mr. Ingham remarked that the defendant made 6*d*. profit upon every half pound of arrowroot.

An application was here made by the secretary of the society which sold the arrowroot to the Co-operative Stores for an adjournment, as he doubted the correctness of Dr. Muter's analysis. The arrowroot was sold in the same state as it was imported from St. Vincent, and there was not a case known of adulterated arrowroot having been sent.

The summons was then adjourned for the sample of arrowroot to be analysed at the laboratory in Somerset House, as directed by the act.—*Standard.*

The Sale of "Ginger Ale."

On Wednesday, at the Bradford Borough Police Court, Mr. Albert Hodgson, hair-dresser, Kirkgate, Bradford, was summoned on a charge of selling an article called ginger ale which was not of the quality demanded by the purchaser. The Town Clerk appeared in support of the summons and Mr. Berry for the defence. The defendant is the local agent for Messrs. Cantrell and Cochrane, Dublin and Belfast, manufacturers of ginger ale, potash water, etc.

The Town Clerk said that the complaint was that the defendant sold what he called "superior ginger ale," but which the prosecution said was not ale at all, and which was, therefore, a fraud upon the public. The analysis of Mr. Rimmington, the borough analyst, who had examined a sample of the "ale," was as follows:—"I am of opinion that the sample contained the parts as under:—12·2 parts of sugar in 100 parts of the liquid, 0·21 parts of tartaric acid, 87·59 parts of water, including very small quantity of capsicum and lemon flavour. This article is sold as ginger ale, but there is a total absence of everything constituting ale, save the water; neither has it undergone any fermentation. The capsicum renders it very irritating." Now ale and beer were described in McCulloch's 'Commercial Dictionary' to be fermented liquors, the principle of which is extracted from several sorts of grain, commonly from barley after it has undergone the process termed malting; and in this case there was neither ginger nor ale.

Mr. Booker, inspector of nuisances, stated that he purchased the ale at the defendant's shop on the 21st of April last. He asked for and obtained three bottles of the ale, and then told Mr. Hodgson that he was the inspector, and that he intended to have the ale analysed. He complied with the formalities of the act by offering to give Mr. Hodgson a sample of the article, but Mr. Hodgson would not take it. He then took the ale to the analyst, and it was divided in his presence, in accordance with the requirements of the act. The certificate which had been put in referred to the ale just purchased. He had made the purchase in consequence of a communication he received about a son of Mr. Manoah Rhodes becoming ill by drinking some of the ale. In cross-examination by Mr. Berry, Mr. Booker said he never had any intimation about ginger ale until this matter came up. It was in consequence of seeing Mr. Rimmington analysing some of the ale which had been sent to him by Mr. Rhodes that he was led to take this action.

Mr. Rimmington was cross-examined by Mr. Berry. He said he ascertained the presence of capsicum by the taste, and he also separated it. He did not detect the taste of ginger. He was prepared to say that there was no ginger perceptible in it. He had no idea of the quantity of capsicum in it. The quantity was small, but it was sufficient to produce the effect he had mentioned on the certificate. He had tested it in two or three ways—with ether and chloroform. He could venture to say that the entire pungency of the ale was to be ascribed to capsicum and not to ginger. Ginger would have made it muddy, and could not be introduced except in a very small quantity indeed. He did not think that the label, "Superior ginger ale, aromatic," properly described the contents of the bottles, because there was no ale in them.

For the defence, Mr. Berry said that a license was required in order to enable a person to sell fermented ale or beer, and on going into Mr. Hodgson's shop Mr. Booker knew that he had not a license, and that he did not sell fermented liquor. He contended that this was the only article known by the name of ginger ale, and that therefore no fraud was attempted by selling it under that name. He further argued that the name ginger ale was as correct as applied to this article as ginger beer was when applied to the article sold under that name. It was not sold to the prejudice of the purchaser, being of the substance, nature, and quality demanded by him, and there was nothing injurious to health in it.

Henry Cochrane, managing partner of the firm of Cantrell and Cochrane, said his firm had manufactured the ginger ale for the last twenty-five years along with other aërated waters, and it was sold very extensively. It was made from ginger, essence of lemon, capsicum, and other ingredients.

Mr. Hodgson, the defendant, said that the bottles sold by him to Mr. Booker were taken from his general stock. He had had other bottles analysed.

Dr. Terry, Bradford, gave evidence as to the wholesomeness of the ginger ale which he kept in his house. He sometimes used it medicinally, the capsicum having a good effect in neutralizing the results of ale drinking.

Mr. Thos. Fairley, public analyst, of Leeds, said he had analysed a sample of the ginger ale, and found nothing injurious to health in it. He found a trace of capsicum and ginger in it.

Dr. C. A. Burghardt, lecturer in mineralogy, and mineralogical chemistry at Owens College, Manchester, corroborated.

The Bench, after a short consultation, dismissed the case.—*Bradford Chronicle.*

DEATH FROM CHLORAL HYDRATE.

Dr. Hardwicke, coroner for Central Middlesex, held an inquiry on the 13th ult. at the Queen's Arms, Haverstock Hill, concerning the death of Adrian Byron Ashford, aged 45, a gentleman of independent means. The evidence of the widow, showed that deceased had suffered from liver complaint for some years. He had been in the habit of taking almost every evening a night-draught, which was supplied by a local chemist from a special prescription, in order to procure sleep. Mr. John West, residing in the same house, said he was called to deceased's bedroom at three o'clock on Friday morning where he found deceased lying on the floor, snoring very loudly. He soon after died. Mr. William Kerr, M.R.C.S., said chloral hydrate would greatly increase the narcotic effects of the stimulants deceased had been accustomed to take on retiring to bed. The cause of death was syncope, or failure of the heart's action whilst under the influence of an overdose of chloral hydrate. The jury unanimously agreed to a verdict of death from misadventure.—*Echo.*

ALLEGED ADULTERATION OF SOLUBLE COCOA LABELLED AS AN "ADMIXTURE."

The following important correspondence has taken place with reference to summonses which were heard before the Southampton County Bench of magistrates on the 26th May last:—

The National Chamber of Trade, 446, Strand, W.C.
8th June, 1876.

SIR,—I am requested by the Committee of the National Chamber of Trade to most respectfully direct your attention to the following extract from the *Grocer* of the 3rd inst., which appears to them to be of an extraordinary character, as the report states "that the cocoa was labelled as a compound."

"Mr. Samuel Read, of Millbrook, and Mr. David Herley, of West End, grocers, were summoned before the magistrates, on Friday, the 26th ult., for selling cocoa containing cocoa-butter, cane-sugar, and sago-starch. The fact was proved that the cocoa was labelled as a compound. The Bench, notwithstanding, decided that the defendants had made themselves liable for not stating this to the purchaser when the sale was effected. Fined 10*s.* 6*d.* each, and costs.

"Mr. Read said he thought they must give up selling cocoa should the conviction be confirmed. The magistrates intimated that it was a matter for the defendants to fight out with Messrs. Taylor Brothers, the manufacturers. The cocoa was one of the cheapest kind."

They have been favoured by the manufacturers with a copy of the label which is used upon the article for which the defendants in the above cases were convicted, a sample of which is appended.

SOLUBLE
COCOA.
Manufactured by
TAYLOR BROTHERS,
LONDON.

This admixture contains no injurious ingredient.
38 & 39 Vic., c. 63.

I am also desired to add that the Committee will much esteem your consideration if you will acquaint them, for the information of the trade, whether the above label is a sufficient notice to the purchaser that the article is a compound, and upon what grounds a penalty was inflicted by the bench of magistrates before whom the cases in question were heard.

I have, etc.,
FRED. MORRISON, Secretary.

To the Right Hon. George Sclater-Booth, M.P.,
President of the Local Government Board, &c.

(COPY OF REPLY FROM THE GOVERNMENT.)

No. 380236.
1876.

Local Government Board, Whitehall, S.W.
19th June, 1876.

SIR,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 8th instant, in which, at the request of the National Chamber of Trade, you call the Board's attention to a decision recently given by a bench of magistrates under the Sale of Food and Drugs Act, 1875.

The Board desire me to state that they have no authority to review the decision of the magistrates to which you refer, nor can any opinion of theirs settle the law in the case. This can only be done by a decision of the High Court of Justice.

The Board has no information as to the grounds on which the decision of the magistrates was based, but they think that the label, of which you have forwarded a copy, might be framed in more distinct terms.

The Statute 38 and 39 Vic. cap. 63, sec. 8, requires that the vendor of any compound article of food shall supply to the person receiving it a notice "by a label distinctly and legibly written or printed on, or with the article, to the effect that the same is mixed.

In this particular case, for example, such words as the following might be used on the label: "This is an admixture, but contains no ingredient injurious to health."

I am, Sir,
Your obedient servant,
(Signed) DANBY C. FRY,
Assistant Secretary.

To F. Morrison, Esq., Secretary of the National Chamber of Trade, 446, Strand, W.C.

Notes and Queries.

QUININE FOR HYPODERMIC USE. — Mr. Wood states (*Amer. Journ. Pharm.*, April, p. 187) that a solution of arabinate of quinine, three minims containing one grain of the salt, has been used for hypodermic injection, giving satisfactory results in its action, and without unpleasant local effects.

[513]. MOTH DESTROYER.—Can any one tell me how to get rid of moths in walls? They are in the walls of a coach house. The place has been stoved with sulphur, lime-washed with lime and carbolic acid, and nothing seems to kill them.—M.P.S.

Obituary.

Notice has been received of the death of the following:—

On the 24th of June, 1876, rather suddenly, Mr. John Elsey, Pharmaceutical Chemist, of Horncastle. Mr. Elsey was 59 years of age, and had been in business 32 years in Horncastle, where his removal by death will be regretted not only by a large circle of friends, but by the town generally. He became a Member of the Pharmaceutical Society in 1845 and for several years had acted as Local Secretary.

On the 22nd of June, 1876, of disease of the brain, Mr. Henry Ellis, Pharmaceutical Chemist, of Mildmay Grove, Islington. Aged 23 years. Mr. Ellis was a student in the School of Pharmacy, Bloomsbury Square, during last session, and was awarded the Silver Medal for Botany and Materia Medica and the first certificate of Honour for Chemistry and Pharmacy; also the Bronze Medal for the first course of Chemistry and Pharmacy.

On the 1st of June, 1876, Mr. George Fawcett, Chemist and Druggist, of Dewsbury. Aged 41 years.

On the 18th of June, 1876, Mr. Andrew McLean, Chemist and Druggist, of Leyton, Essex. Aged 43 years.

Correspondence.

THE GREAT MILK OF SULPHUR CASE.

Sir,—Every one ought I am sure to rejoice at the prospect of a final settlement by the Court of Queen's Bench of a question which as much by its littleness as by its frequency has long harassed the drug dealers of this country.

If I might be allowed to occupy your columns with so trite a subject I should like to point out why in my opinion the main line of defence should be the present *popular* use of the term milk of sulphur, and the *bonâ fide* nature of the demand for it.

The contention that the new name sulphur præcipitatum was invented to designate a new and improved preparation is not borne out by the facts, as I will endeavour to show.

The Pharmacopœia of 1724, a copy of which I have before me, gives the following directions for preparing "Lac Sulphuris."—℞ Sulphuris partem unam; Calcis vivæ *vel* Salis Tartari, partes tres. Coque in Aquæ Fontanæ q.s. ad solutionem Sulphuris. Filtra calide; præcipita cum Spiritu Vitrioli; edulcora et sicca.

The fact that the alternative use of either lime or salt of tartar influenced materially the result of the operation, in the one case yielding pure sulphur, in the other sulphur plus twice its weight or thereabouts of sulphate of lime, seems to have been entirely lost sight of, leaving one to infer that to the minds of the then Royal College of Physicians the term lac sulphuris was as applicable to one preparation as to the other.

In the Pharmacopœia of 1746 the alternative use of salt of tartar is not mentioned, the formula remaining in other respects the same. The name of the product has however undergone a notable alteration, it is now "Sulphur Præcipitatum," notwithstanding that it contains the unavoidable addition of sulphate of lime.

In the one pharmacopœia therefore we have the term lac sulphuris applied to pure precipitated sulphur; in the other the term sulphur præcipitatum applied to the mixture of precipitated sulphur with twice its weight of sulphate of lime. From this I conclude that the change of appellation was simply the substitution of what was intended for a scientific name for one that was trivial or popular.

Pemberton's English translation of the 'Dispensatory of the Royal College of Physicians, London, 1748' (second edition), is preceded by a most valuable and interesting chapter entitled "A Narrative of the Proceedings of the Committee appointed by the College of Physicians to review their Pharmacopœia." From page 2 *et seq.* I extract the following:—"It is needless to repeat that the first care of the committee was to expunge the medicines no longer made use of in general practice and to insert such as have come into esteem since the last revisal of the Pharmacopœia; but the principal part of their labour has been to examine the articles they have retained or given admission to, both in regard to their pharmaceutic composition, and upon the genuine principles of medicine."

The result of the examination of the preparation formerly called lac sulphuris was the exclusion of the alternative use of salt of tartar and the conferring the name sulphur præcipitatum on the mixed substance resulting from the precipitation of a sulphur-lime solution with dilute vitriolic acid. So much for the then current ideas on "pharmaceutic composition," and "the genuine principles of medicine."

Farther on (page 58), in a paragraph where changes of name are discoursed of we find the following:—"Here lac sulphuris, which is a powder, is now more properly called sulphur præcipitatum." The triviality of the name was, therefore, not its main offence, but the absurdity involved in applying to a solid a term appropriate only to a fluid.

In the 'New Dispensatory,' etc. (third ed.), printed for J. Nourse, etc., 1780, but without the editor's name, it is stated with reference to this "that the name lac sulphuris or milk of sulphur, applied among us to the precipitate, is by the French writers confined to the white liquor before the precipitate has fallen from it." In comparing the two preparations the editor says that "quick lime gives the preparation a more saleable whiteness." "The medicine is nearly the same in both cases." The Pharmacopœia of 1788, directs the use of sulphurated kali and diluted vitriolic acid. The editor of the translation appends to the formula the following remark, "This preparation is not so white as that of the last Dispensatory, which was made with quick lime; but it is more purgative."

It seems, then, that throwing aside the discordant opinions of pharmaceutic authorities of various degrees of dignity, we must, in order to establish a valid distinction between the terms "milk of sulphur" and "precipitated sulphur," fall back upon *popular usage*, which will probably vary in different localities. Here no such distinction is, as far as my experience goes, recognized. I supply the pure article to all customers and get no complaints of either price or quality. It might be, and possibly is, otherwise elsewhere; that, however, will have to be proved. A *bonâ fide* demand for an article not possessing injurious qualities, and it is idle to question the wholesomeness the old milk of sulphur, that off and on ever since the time of the alchemists has been in use in almost every household, ought surely to be attended to, and to apply the penal clauses of an Act of Parliament to such supply is not only cruel to the tradesman but contrary to the liberty of the subject.

That sulphate of lime in the dose usually taken is not injurious is a proved fact; that the quantity of sulphur taken with it is amply sufficient has also been established by centuries of experience. Considering the complete insolubility of sulphur in water, its alterative, viewed as distinct from its purgative, quality would doubtless be as fully marked if milk of sulphur contained not 33 but 5 per cent. only of the element—probably 99 per cent. of what is swallowed passes through the system unchanged.

In common with the great bulk of pharmacists, I can look forward to the contemplated decision with equanimity, desiring only a settlement of the "quæstio vexata."

THOS. B. GROVES.

THE EXAMINATIONS.

Sir,—I take this opportunity to express my entire satisfaction with the recent decision of the Council of the Pharmaceutical Society in reference to the manner in which the result of the examinations is announced, as being more strictly in accordance with the Act of Parliament in which the powers committed to them are set forth. The examinations are not to be considered as competitive in their character, but rather as proofs and guarantees of certain qualifications on the part of those who pass them, deemed necessary for the proper discharge of duties connected with our business. I trust great numbers of our young men will not rest satisfied with the lower position but will go in for the higher grade and thus prove themselves worthy not only of the honour attaching to it, but also prepare themselves to take part in carrying forward the great educational work which the founders and members of the Society, supported by the Legislature, deem so highly important.

I quite approve of competitive examinations at the proper time, and have had great pleasure on several occasions in being present at Bloomsbury Square when prizes were distributed to those students who had attained the highest positions in the examinations conducted by the Professors at the close of each session. If, in addition, arrangements on a satisfactory basis could be made for a written examination, and prizes awarded, open to country students generally whose names are on the register, I think it would prove a most excellent stimulus to study.

W. V. RADLEY.

Sheffield, June 21, 1876.

METHYLATED FINISH.

Sir,—The recent excise prosecutions render it very necessary that the druggist should satisfy himself that the "Finish" he sells contains the quantity of resin required by law. If on examining the finish newly received into stock he discovers it deficient in this respect, he will probably find the missing resin as an undissolved but slowly dissolving mass at the bottom of the cask. For it appears that some makers do not keep finish, as finish, in stock at all. When, therefore, an order is received for the latter, they fill a cask with methylated spirit, add thereto the proper quantity of resin in the solid state and straightway dispatch to their customer. Now we can very well understand that if the cask be not well shaken in transit, or on arrival, or if the resin added be a somewhat difficultly soluble one, the first portions will be deficient in resin and the last portion overcharged therewith. I will now refer to two cases which have come under my own observation. A hogshead of finish was found on arrival from the makers to contain only 370 grains of resin to the gallon. After eighteen hours, during which time it had been twice shaken, it contained 414 grains to the gallon. It was again shaken and tested and this was continued until at last, on the nineteenth day after being taken into stock all the resin in the cask was found to have dissolved, and the finish to have reached the excise standard. Just afterwards I had the opportunity afforded me of examining the contents of a nearly empty cask of finish, and was now not very surprised to find the latter containing 5¾ oz. of resin to the gallon. The first portions of finish drawn out of this cask must have contained very little resin indeed, and would, if they had come within the ken of the excise, have brought down on the luckless druggist I know not what pains and penalties.

The foregoing observations may perhaps throw some light on the cause of that deficiency of resin in methylated finish which has of late brought so many druggists into the police courts.

ALFRED N. PALMER.

Manchester.

Sir,—I had the misfortune to be fined, on Monday last, the sum of £12 10*s*. for selling half a pint of finish that did not contain the proper quantity of gum. The wholesale house from whom I purchased it say that it did contain the proper quantity. The analytical chemist connected with the Inland Revenue Department, at Somerset House, stated that it contained 497 grs. instead of 1312. Will you kindly inform me in your next issue of the Journal, whether in the event of the chemist's report being proved correct I can legally recover the amount of the penalty from the firm who supplied me with the finish?

I should perhaps say that the summons was for selling methylated spirit, but I presume the excise authorities consider all finish that is not properly prepared to be methylated spirit.

GEO. K. GOSSOP.

88, *Church Street, Grimsby,*
June 21, 1876.

[*** This is so purely a legal question that we are unable to answer it; but it is evident that the best way for our correspondent to have protected himself would have been to have examined the finish and satisfied himself that it contained the proper quantity of gum before selling any.—ED. PH. J.]

THE SPECTROSCOPICAL EXAMINATION OF FIXED OILS.

Sir,—Will you kindly allow me to gratify Mr. Gilmour's wish to know how far he and I have carried on our investigation "in precisely the same manner" by stating that I believe we have worked on the same lines so far as Mr. Gilmour has gone at present, but that my work has apparently been more extensive than his and therefore, probably, had a different ending. The microspectroscope was used throughout the investigation, but each observation of many hundreds was confirmed by, or at least compared with, the readings of two, and sometimes three, other instruments of different dispersive power, including a stand single prism instrument of considerable power. The only reason why I practically set aside the stand spectroscope was that, in common with all other absorption spectroscopists (or nearly all), I found very early in my work that the direct vision instrument of moderate power was so vastly superior to the other that it was practically the only one fit for the work. There were, and always are, certain cases in which the stand spectroscope was better fitted for the work, and one such case is referred to in the *English Mechanic*, I think a week later, when I took occasion to point out that an unusually pure specimen of linseed oil gave a spectrum differing materially from that figured by me the previous week.

Mr. Gilmour will find when the new work I have done sees the light that the spectroscopical investigation of oils is a much more difficult matter than at present he has any idea of.

So far as the question of priority is concerned I have nothing to say; I have not thought for a moment other than that Mr. Gilmour sincerely believed he had lighted on a new field of research and that he was entirely in ignorance of what had previously been done. We are neither of us the first to examine oils spectroscopically, for I have found only very recently—this week in fact—that Dr. Thudichum worked at them prior to 1867, as witness the following in the tenth report of the Medical Officer of the Privy Council, page 211, appendix:—"Some solutions prolong the red part of the spectrum in the direction of the heat spectrum. This peculiarity belongs to a particular variety of pure yellow olive oil . . . These fluids also exhibit a black absorption band in red; in less pure and very impure olive oil two more feeble absorption bands in green appear. All these absorptions are probably due to the admixture of xanthophylline. Animal fats including human have never yet been found to possess absorptive qualites although they are frequently very powerfully phosphorescent." It is, in fact, extremely difficult to students in absorption spectroscopy to find out what has been and what has not been done in the subject. Many persons have taken it up, made a few observations, published them in the handiest journal, and then let it drop, the result bring that isolated papers are scattered over nearly the whole of our scientific literature.

HENRY POCKLINGTON.

Leeds, June 24, 1876.

THE SALE OF PATENT MEDICINES.

Sir,—For some time past I have been under the impression that the sale of patent medicines by grocers, cobblers, barbers, etc., was caused to a great extent by men who are sent about the country to ornament or disfigure, whichever it may be called, our windows and glass doors. I have lately a case in point: a man called on me a short time since and asked if he should affix to my window and door gold letters referring to the preparations of —— and ——. I made the remark to the man that I supposed he did not introduce these things to other trades; to which he replied, "Oh, no." But, behold, the next day I discovered that Mr. Shaver had the letters "———Pills sold here" on the most prominent part of the window, and to day I have received an enclosure for the same person consisting of books and counter bills for ———'s medicines. I am very much surprised that proprietors of respectable patent medicines should allow themselves to be mixed up with such a lot. If they want to advertise them why don't they send a man purposely, and not join with a mixed medley lot to the injury of their brother chemists. I would recommend all chemists to refuse to have anything whatever to do with the men sent round. If the chemist knows nothing about the particular quack medicine his customer asks for, except that he keeps it, then it will soon be seen how long the sale will stand, however much it is advertised.

MIDLAND.

NOTE ON COCA.

Sir,—The therapeutic value of this drug, and its position in our Materia Medica, are still vexed questions amongst physiologists. From an experience extending over some years in a country subject to the extremes of both frigid and torrid zones, I am inclined to think coca has numerous virtues attributed to it it does not possess, and that travellers when speaking so glowingly of its wonderful sustaining powers are more apt to rely upon information supplied by natives than by direct experiments upon themselves. I have never found any benefit from chewing the leaves during long and tedious tramps over a rough country, the desire of food was just as great, and the muscular system incapable of more prolonged exertion. As a substitute for cinchona, in the form of wine and fluid extract, it has signally disappointed its introducers, both as a "builder up" after long illness and as a restorative to combat the enervating effects of a tropical summer. Dr. Ashburton Thompson, who has made a series of experiments with coca, informed me that the most notable result of a day's chewing of the leaves was a sore tongue and mouth.

THOMAS H. BATEMAN.

June 23, 1876.

THE COLLECTION OF HENBANE.

Sir,—As the time is drawing near for the collection of henbane, I am anxious of educing an opinion from the trade whether in collecting *Fol. Hyoscyami* for the preparation of the tincture the flowering heads should be collected along with the leaves and mixed up with them. The last lot that I had nearly one-half of it was flowering tops.

The instructions in the B.P. are, "that the leaves should be separated from the branches." Squire's 'Companion' says, that "the leaves only" should be collected.

CAPSAICIN, THE ACTIVE PRINCIPLE OF CAPSICUM FRUITS.

BY J. C. THRESH, F.C.S.

As stated in a note added to my paper on the supposed alkaloid "Capsicine,"* I have succeeded in isolating an unmixed organic principle possessing in the highest degree the acrid pungent property so characteristic of cayenne. After the conclusion of my investigation as to the existence of an alkaloid in this fruit possessing the above mentioned properties, I attempted to verify the statement of Buchheim, viz., that the source of the active property is an oily fluid which he called "capsicol." This is obtained by exhausting the powdered fruit with ether, removing the ether by distillation, dissolving the residual extract in boiling caustic alcoholic ley, diluting with water, and precipitating with barium chloride. This precipitate is washed, dried, and treated with ether, and upon evaporation an oily fluid is obtained which is the impure "capsicol." It is purified by a repetition of this same process.

I felt convinced that this red fluid was not the active principle, but as much a mixture as the fat from which it was obtained. I therefore attempted by other means to isolate the substance of which I was in search. Reflecting on the behaviour of the capsicine fat with alcohol,† I thought it probable that as castor oil renders some other oils to a certain extent soluble in alcohol, so this fat might be a mixture of two substances, the presence of the one increasing the solubility of the other. I therefore dissolved a portion of the red oil in twice its volume of almond oil, and agitated the mixture with three successive portions of proof spirit. By these means the whole of the active principle was removed by the alcohol, leaving the oil of a deep red colour, but quite devoid of pungency. The alcoholic solution when evaporated left a red brown fatty residue of the consistency of resin ointment, and of course intensely pungent in taste. This substance dissolved in dilute solution of potash forming a clear solution, but when treated with dilute ammonia a very imperfect soapy solution resulted. This was put aside for some time, and upon again examining it I found the liquid full of well defined pearly white crystals, Fig. 2, which I separated by filtration, washed, and dried.

(Fig. 1)  (Fig. 2)

This substance was most powerfully pungent, a most minute portion volatilized caused severe fits of coughing. It dissolved slightly in cold water, more readily in boiling water, a portion at that temperature being volatilized and causing long continued fits of sneezing. The excess of what is taken up by the water, melted and floated on the surface of the fluid as a colourless oil. The hot solution precipitated on addition of a strong acid, and after a few days the solution was found to have deposited crystals, Fig. 1.

The curious behaviour of this substance at first led me to suppose that it was a fatty acid, forming a soluble salt or soap with potash, and an insoluble one with ammonia. This supposition, however, is not confirmed by further experiments with the perfectly pure capsaicin, obtained by dissolving the first crop of crystals in solution of potash, and adding solution of ammonium chloride in excess. The milky fluid thus formed in a few hours deposits crystals of the pure principle. These (fig. 1), when thoroughly well washed, give no trace of ammonia. When dissolved in absolute alcohol and boiled with sodium carbonate, the filtered solution upon evaporation leaves an oily residue, which does not contain a trace of sodium, and which only begins to crystallize after many days. This residue appears to be totally insoluble in water, consequently the slight solubility of the capsaicin first obtained must be due to a trace of alkali existing in it as an impurity; and the crystals obtained by addition of acid would of course result from the neutralization of the alkali. The pure capsaicin dissolves readily in proof spirit, and the solution, when not too dilute, gives white precipitates with barium and calcium chlorides, both soluble in ether. Silver nitrate gives a precipitate which dissolves in dilute ammonia, and the solution when boiled darkens in colour and deposits a curdy brown-black precipitate. Neutral ferric chloride does not affect it in the cold, but when the solution is boiled a reddish precipitate falls. Boiled with dilute sulphuric acid and bichromate the pungent taste is almost instantly destroyed; dilute nitric acid and potassium permanganate also oxidize it. These reagents, therefore, similarly affect any preparation of cayenne, and this reaction might probably be utilized for determining in certain cases the presence of this substance.

With care capsaicin can be volatilized without decomposition, the sublimate being in the form of fatty globules. It volatilizes slowly at 212° F., and if mixed with water and distilled the distillate has a distinctly pungent taste.

I find this capsaicin can be isolated also by dissolving the capsicum oil in dilute potash, adding a sufficient quantity of solution of ammonium chloride, collecting the coloured precipitate, redissolving in potash solution, and at a temperature of 120° F. adding ammonium chloride in excess. In a few days an abundant crop of crystals will have formed which can be further purified if necessary by a repetition of the process by which they are obtained. I have also obtained it by dialysis, as follows:—A few ounces of strong tincture were placed in a parchment dialyser, and floated in proof spirit. The spirit rapidly acquired a pungent taste, and upon evaporation deposited after a time crystals identical in appearance with Fig. 1. The dialysed solution had a distinctly acid reaction.

I am now preparing a larger quantity of this substance, so as to admit of its elementary analysis (which Professor Flückiger has kindly offered to undertake) and further research as to its chemical and powerful physiological properties. The results I hope to have ready for communication at the ensuing Conference.

Buxton.

THE SPECTROSCOPE APPLIED TO THE DETECTION OF ADULTERATIONS, ETC., OF FIXED OILS.

BY W. GILMOUR.

Olive Oils.

A few weeks ago (June 10th), a communication appeared in the pages of the *Pharmaceutical Journal* in which I suggested in general terms the value of the spectroscope in detecting adulterations in fixed oils. The paper referred to was not intended to do more than call attention to the subject, and indicate the probable value as a detecting agent of the spectroscope. Whether it will become an agent in detecting adulterations under every circumstance, remains yet to be seen, and will probably only be determined after a long and exhaustive series of experiments. That it is an invaluable agent in detecting some (band giving oils, for example, such as rape in non-band-giving such as sperm), I have in many cases already proved, and hold beyond dispute.

Its utility in this respect taken in conjunction with the distinctive character of the spectrum of each oil, and the delicacy of the action of the spectroscope in detecting the slightest variation in the spectra of the same oils, are all features which cause us to hope that it may yet prove of great value in determining their quality, whilst they also demand for it I think the fullest investigation.

I have, therefore, in continuation of my previous experiments made some further and much more minute investigations this time, principally into the spectra of olive oils, which I venture to hope may not be without interest, and probably may be of some little use in the present state of our knowledge regarding them. All the experiments were performed under the same conditions so that I think the results may be taken at least as relatively correct. As far as the samples were concerned they were all marked "Sublime," "Extra Sublime," or "Super Extra," but of their further history I am entirely ignorant. By their taste, smell, colour, etc., I take it they would have all been esteemed commercially good samples, with the exceptions probably, of samples 2, 7, 16, which were rather marked, both in their smell and taste. The appearance of the various samples as

shortly stated in the first column of the accompanying table is therefore not in any way intended to indicate the quality of the oil, but rather simply to give an approximate idea of the relation betwixt the colour of the oil and the nature of the corresponding spectrum. To understand the table itself it is necessary that I should explain that my investigations have mainly been directed to determining the variations (and the amount) that exist in the spectra of different samples of olive oil, and for this purpose I have laid hold of every feature existing in the individual spectrum on which I possibly could, such as the amount of absorption at the extremes of the spectrum, the amount of shading previous to the absorption, the breadth of the several dark bands, and so on. The relative position of these several characteristics, as well as their breadth, or space which they occupy, will at once be understood by referring to the diagram accompanying the table, in which the degrees of the spectroscope are made to coincide with the dark bands of the solar spectrum, Fig I. This is a method of mapping spectra probably not the best, although correct enough for our present purpose, and much more simple and therefore much more readily understood than any other. Fig 2 represents literally the spectrum of sample No. 3, and from it the appearance of the spectrum of the other samples can readily be imagined by referring to the positions and breadths of the bands and shadings contained in the table.

At first sight it may be thought that the variations brought out in the above table are sufficiently unsatisfactory and discouraging. In some respects they would be, did they not at the same time so thoroughly establish the delicacy of the reaction of the spectroscope in thus detecting and disclosing them, however fine or insignificant. In several cases it was quite impossible to detect by any ordinary means the difference existing betwixt some of the foregoing samples; and yet, no sooner were they placed in the spectroscope than the most marked characteristics frequently were brought out. This being the case it is surely not too much to expect that having the delicate appliance at command for detecting the smallest variation in the character of a given oil, the ultimate cause of these variations may also be discovered without any great effort. The principal difficulty to me seems to lie in the almost impossibility of obtaining an oil on which sufficient reliance can be placed, to act not only as a standard oil, but one also on which experiments might be performed for the purpose of discovering how much these variations are dependent on causes inherent in the oil itself, and how much from extraneous sources. Age, exposure, and other similar causes may doubtless exert a modifying influence on the spectrum of an oil, as they do on its character generally; but the discovery of these would not be unimportant in themselves, whilst they would more than probably assist us very materially in the discovery of other and worse agencies, which it is to be feared too often find their way into this and other oils.

NOTE ON CASSAVA STARCH IN ARROWROOT.

BY H. WILLIAMS JONES.

A considerable quantity of arrowroot adulterated with cassava starch, amylum mandiocæ or Brazilian arrowroot, from which tapioca is made, is in the market at the present time; and during the past few months I have seen several samples selected from the bulk offered to wholesale buyers, so adulterated.

Pereira does not appear to have met with it as an adulterant in this country; but on the authority of Guibourt, he mentions its being imported into France and sold there for arrowroot.* Hanbury and Flückiger in their 'Pharmacographia' make no mention of it, though they state that "other starches than that of *Maranta* are occasionally sold."

The cassava granules found in the samples alluded to, agreed perfectly, as to form and size, with an authentic specimen kindly furnished me by Mr. J. R. Jackson, A.L.S., of the Museum, Royal Botanic Gardens, Kew.

17, *Bull Street, Birmingham.*

CRYSTALLIZED HYDROBROMATE OF CONIA.†

BY M. MOURRUT.

In a paper recently read before the Société de Thérapeutique the author described some attempts to obtain crystalline salts of conia. His first experiments were made with various acids upon the ordinary brown conia, from which crystals were obtained, but they were contaminated by a brown matter that could not be removed without great loss. The German conia, which is nearly white, was therefore substituted and this readily gave crystals. The salt obtained most easily was the hydrobromate, by simply treating the alkaloid with the acid. When brown conia was operated on, there was a rise of temperature, an evolution of white vapours and the characteristic odour of conia became manifest; the mixture then became green and finally black with a reddish tinge. After a short time crystals commenced to form; they were contaminated by the brown black substances that coloured the liquid, but by repeated crystallizations they were obtained colourless. There was, however, much loss with the impure alkaloid.

In operating upon the white conia the author places it in a crystallizing vessel with a fragment of blue litmus paper, and dilute hydrobromic acid is added drop by drop, until the litmus paper commenced to turn red, the liquid which was at first yellow has then a rose tint. The crystallization quickly commences, and the evaporation may be expedited by a gentle heat; there will no longer be any smell of conia.

The hydrobromate of conia crystallizes in colourless prismatic needles that are very soluble in water and alcohol, but less so in ether and chloroform. The crystals are not deliquescent; they are odourless and have only a slight taste; but when crushed between the fingers they give off a strong odour of conia. When exposed to the air the salt is coloured red, like many other hydrobromates, but does not decompose, in the dark it remains white. It supports a tolerably high temperature, melts at about 100° C., and above that point volatilizes, giving off an odour of conia. It contains about one-third its weight of bromine, but the author has not yet made an exact analysis.

The salt is reported to have been administered in hourly doses of 2 milligrams to infants one year old suffering from whooping cough, with good results, and in 5 milligram doses to a child three years old. Dr. Regnault has also injected equal to 5 milligrams in the case of an adult suffering from sciatic pains, repeating the dose at an interval of three days, after which the pains ceased.

DRAGENDORFF'S ALKALOID PROCESSES.*

THE STRYCHNINE AND BRUCINE PROCESS.

The substance to be analysed should be first cut into small pieces and treated with water and a little sulphuric acid, enough to give a decidedly acid reaction to the mixture. To about 100 c.c. of the mixture of finely cut substance and water, add 10 c.c. of diluted sulphuric acid (1·5). Digest at 50° C. for several hours and then filter. Treat the undissolved material again with 100 c.c. of water and 10 c.c. of the dilute sulphuric acid, in the same manner, and filter.

Put both filtrates together and add sufficient calcined magnesia to neutralize most of the free acid, but the solution must still retain a decidedly acid reaction. Evaporate on the water-bath to the consistency of thin syrup, but not to dryness.

Mix this concentrated solution with three or four times its volume of alcohol, of from ninety to ninety-five per cent., add a few drops of dilute sulphuric acid, digest at from 30° to 40° for twenty-four hours, and then filter off the insoluble matters. Evaporate the filtrate until all the alcohol has passed off, dilute the remaining solution to 50 c.c. in a flask, and shake it thoroughly with from 20 to 30 c.c. of pure benzol. Remove this benzol and shake again with a fresh portion.

After the second portion of benzol has been removed, the watery solution is to be made decidedly alkaline with ammonia, warmed to 40° or 50°, when the alkaloid set free is taken up by shaking again thoroughly, with from 20 to 30 c.c. of benzol. This is then removed and the shaking is repeated with another portion of benzol.

The benzol solutions obtained in this way are generally colourless, and contain the alkaloids so nearly pure that, after shaking with distilled water and clearing by immersion in warm water, filtering and evaporating, a residue is obtained in which the alkaloids may be proved directly. But it is better, after the washing with distilled water, to take up the alkaloids again, by shaking with water acidulated by sulphuric acid; treating twice with 20 or 30 c.c. of the acidulated water and removing the benzol, then saturate the watery solution obtained in this way with ammonia, and make a new solution of the alkaloids in benzol. Wash with pure water, filter and evaporate, and if all the watery solution has been removed from the benzol, the alkaloids remain, in most cases, so pure and colourless that the identifying reactions may be obtained directly. It is best to divide the benzol solution among several watch-glasses, and evaporate at about 40° C.

THE COMPLETE ALKALOID PROCESS.

I. The substance is digested as above, with water containing sulphuric acid, at a temperature between 40° and 50°, two or three times, and the filtrates are put together after all the liquid has been pressed out of the solid matter. Most of the alkaloids are not injured by this treatment, even when too much acid has been used. Solanine, colchicine, and digitalin, are the only ones that might be injured by a large excess of acid. If there is abundance of time, the macerations may be made at common temperatures.

Berberine is less soluble in acidulated water than in pure water, but it is completely dissolved by the large quantity of liquid used. Piperine also dissolves with difficulty in acidulated water, and part of this alkaloid may remain in the undissolved residuum, where it should be sought for afterwards.

II. Evaporate the filtrates, after the free acid has been partially neutralized with magnesia, until the liquid reaches the consistency of syrup; mix this with three or four times its volume of alcohol and a little dilute sulphuric acid, allow it to digest for twenty-four hours at about 30°, let it become quite cold, and filter from the solid matters that have been separated by the alcohol. Wash the solid residue with spirits of wine, of about seventy per cent. The remarks made at I concerning solanine, colchicine and digitalin, apply equally to this digestion.

III. The alcohol must be separated from the filtrate by distillation (evaporation), and the watery residue, after the addition of a little more water, if necessary, is filtered into a flask, and in its acid condition is treated with freshly rectified petroleum naphtha (see note at the end of this translation), by continued and repeated shaking together, at a temperature of about 40°. After the liquids have separated, the naphtha, sometimes containing colouring matter and such impurities as may be removed by this treatment, is drawn off from the aqueous solution. The naphtha may also take up piperine, and if a considerable quantity has been used, and there is not too much impurity present, the alkaloid will be left upon evaporating the naphtha, in well defined crystals belonging to the rhombic system. Concentrated sulphuric acid dissolves it gradually, with the production of a handsome brown colour.

IV. Shake the aqueous solution with benzol, in the same way, at from 40° to 50°, and evaporate the benzol after removing it. If there are traces of any alkaloid in the residue from this evaporation, it indicates caffeine. In this case, neutralize the greater part of the acid in the aqueous solution with magnesia or ammonia, but still leave it decidedly acid, and treat it again with fresh portions of benzol, until the latter leaves no residue upon evaporation. Wash the benzol solution by shaking it with distilled water, separate from the water, and filter it. Distill off the greater part of the benzol from this filtrate, and evaporate the remainder upon several watch-glasses. Care must be exercised, that in case a drop of the aqueous fluid passes through the filter, it is not evaporated with the benzol.

The residue from this evaporation may contain caffeine, delphine, colchicine, cubebine, digitalin, and traces of veratrine, physostigmine, and berberine. Caffeine forms definite crystals, as colourless, glossy needles; it is known by its reaction with chlorine water and ammonia. Sulphuric acid does not colour it. Cubebine also forms small crystals, which may be known by their behaviour with sulphuric acid, and the same may be said of colocynthe, elaterine, and syringine. A yellow-colored residue indicates colchicine and berberine. Sulphuric acid dissolves and colours colchicine an intense and durable dark yellow; berberine, olive green, becoming clear afterwards. Berberine may be distinguished from colchicine, by the behaviour of its alcoholic solution with tincture of iodine. Delphine, digitalin, veratrine, and physostigmine are left as amorphous, nearly colourless residues. Delphine is coloured light brown by sulphuric acid; digitalin yields with it, in less than fifteen hours, a number of colours changing from amber, through red and brown, to dark cherry-red, and its presence may be confirmed by the sulphuric acid and bromine reaction. Veratrine, with pure sulphuric acid, becomes yellow-orange, and in less than half an hour beautiful orange-red, and this test may be confirmed by boiling with fuming hydrochloric acid. Physostigmine is not coloured by sulphuric acid. It may be known by its action on the eyes of cats.

V. The acid watery liquid is shaken with amylic alcohol, in the same way as in III. and IV. if the presence of theobromine is suspected.

There are also taken up by the amylic alcohol, some of the above-named alkaloids remaining from III. and IV.—namely, veratrine, and berberine, and traces of narcotine, aconitine and atropine, and they are left in crystals after the evaporation of the solution.

Theobromine is recognized by its reaction with chlorine water and ammonia, and also as it dissolves without colour in concentrated sulphuric acid.

Narcotine is not readily soluble in acetic acid, and may be recognized by its reaction when warmed with concentrated sulphuric acid.

* Translated in the *American Chemist*, April, 1876.

VI. The acid watery liquid is shaken with chloroform, only when the presence of the alkaloids of opium is suspected.

Chloroform takes up papaverine, thebaine (slowly) together with small quantities of narceine, brucine, physostigmine, berberine, and, when the treatment given at V. is omitted, veratrine and narcotine.

Crystals of papaverine and brucine are left after the evaporation of the chloroform solution. Papaverine may be readily distinguished by testing with sulphuric acid (beautiful blue violet colour), and brucine by the red colour imparted to it by Erdmann's reagent. Most of the narcotine, thebaine, narceine, veratrine, physostigmine, and berberine, are left as amorphous substances.

Narcotine may be separated from the other alkaloids by dilute acetic acid, in which it is not readily soluble, and it may be proved as in V. Thebaine is characterized by its behaviour with cold sulphuric acid. Veratrine and physostigmine as above.

VII. The watery liquid, at about 40°, is then covered with a layer of petroleum naphtha, made distinctly alkaline with ammonia, and immediately well shaken. After the first naphtha solution has been drawn off, other extractions should be made at the same temperature with fresh portions of petroleum naphtha. The warm naphtha solutions should be washed with distilled water, and afterwards filtered and evaporated. If the solution is too highly coloured by foreign matter, it may be purified by taking up the alkaloids in acidulated water, adding ammonia and shaking with pure naphtha again.

The petroleum naphtha takes up strychnine, brucine, quinine, emetine, veratrine, conine, nicotine, and papaverine.

A. Of these, conine and nicotine are fluids, and have characteristic odours. They may be brought into solution in distilled water, and nicotine is precipitated in minute crystals by potash-cadmium-iodide from the diluted solution after neutralizing with sulphuric acid, while conine is precipitated in amorphous form.

B. Upon cooling the warm naphtha solution, quinine separates, and traces of strychnine and papaverine also crystallize out.

C. After evaporation, the remainder of the quinine, strychnine, and papaverine are left in crystals, and brucine, emetine, and veratrine, in amorphous form.

The dry alkaloids are treated with anhydrous ether, which dissolves quinine, emetine, papaverine, and veratrine, and also conine and nicotine, if they have not been removed by water.

Strychnine and brucine may be separated by absolute alcohol, in which strychnine is nearly insoluble. Brucine is recognized, after the evaporation of its solution, by its behaviour with Erdmann's reagent. Strychnine may be determined by means of sulphuric acid and bichromate of potash.

After evaporating the ether solution, quinine, emetine, veratrine, and papaverine are dissolved in the smallest possible quantity of very dilute sulphuric acid, and the cold solution, which should not contain less than one per cent. of the alkaloids, is treated with carbonate of soda, when quinine, emetine, and papaverine are precipitated.

Quinine may be determined by its behaviour with chlorine-water and ammonia. Emetine by producing an emetic effect, and by the absence of the veratrine reaction with hydrochloric acid. Papaverine by its behaviour with sulphuric acid. Veratrine, after its watery filtrate has been treated with chloroform and the latter evaporated by boiling with hydrochloric acid.

VIII. The alkaline watery liquid is shaken with benzol, at 40° or 50°, purifying as in VII. This removes quinidine, cinchonine, atropine, hyoscyamine, aconitine, physostigmine, and codeine.

Crystals of cinchonine, sometimes accompanied by a little atropine and quinidine, separate from the solution on cooling.

After evaporating the solution, there remain with those just named, crystallized codeine (very distinct), aconitia, hyoscyamine and physostigmine (mostly amorphous).

A. The residue left by evaporation is treated with ether, which dissolves all the above-named alkaloids, excepting cinchonine.

B. The residue from the evaporation of this ether solution must be dissolved in the smallest possible quantity of water containing sulphuric acid, and treated with ammonia slightly in excess, which separates quinidine and aconitine, leaving atropine, hyoscyamine, and codeine in solution.

The precipitate, which may contain quinidine and aconitine, is collected on a very small filter and dissolved in the least quantity of hydrochloric acid. Upon the addition of chloride of platinum the whole of the quinidine is precipitated.

The solution of aconitine is freed from platinum by a current of sulphuretted hydrogen, then it is made alkaline and shaken with chloroform. In the residue left by evaporating this chloroform solution the aconitine may be recognized by means of sulphuric or phosphoric acid.

C. Atropine dissolves with difficulty in cold benzol, and codeine dissolves readily. The former is not coloured by concentrated sulphuric acid, the latter is gradually coloured blue. Atropine, when warmed with concentrated sulphuric acid, gives the characteristic odour previously described; codeine does not. Atropine (and hyoscyamine) distend the pupil of the eye; codeine does not. For physostigmine, see IV.

IX. The watery liquid is now acidulated with sulphuric acid, and heated to 50° or 60°, covered with amylic alcohol, and, after it has been made alkaline again with ammonia, it is shaken with the amylic alcohol, purifying as in VII. and VIII. By shaking with amylic alcohol at the temperature just given, the morphine, solanine, and part of the narceine are obtained. The latter should be dissolved in lukewarm water, and put with the watery liquid at X.

The solution of solanine in amylic alcohol gelatinizes upon cooling, that of morphine forms the best of alkaloid crystals. Morphine is proved by Fröhde's reaction (with molybdate of soda), and by Hersemann's test (concentrated sulphuric acid solution and nitric acid).

Solanine is characterized by its decomposition in hydrochloric acid, and the retention of the products of this decomposition by ether; and also by its behaviour with iodine water and sulphuric acid.

X. The watery liquid may still contain curarine and traces of berberine, narceine (and digitalin).

Evaporate it to dryness with powdered glass; digest the pulverized residue for a day in alcohol, filter, and evaporate the filtrate. If the residue is very impure, it may be repeatedly recrystallized from water and alcohol.

Berberine remains as a yellow-coloured residue, and is known by the behaviour of its alcoholic solution with iodine water.

Narceine is left in colourless crystals. It is recognized by its reaction with sulphuric acid, or by the behaviour of its aqueous solution with iodine water.

Curarine is left mostly amorphous and is distinguished by its reaction with sulphuric acid alone, and with sulphuric acid and chromate of potash.

NOTE.—Petroleum naphtha has a boiling point between 30° and 80°. It should be purified by shaking with an ammoniacal solution of acetate of lead and distilling. That which is sold in Russia as an illuminating fluid under the name of "Chandorine" may be rectified for use in this way.

Petroleum naphtha does not dissolve asphalt, which is soluble in benzol. Benzol boils at 80° or 81°. Petroleum naphtha begins to boil at a much lower temperature.

SANTONIN.*

MM. Cannizzaro and Sestini, having been engaged in an investigation of santonin, have observed that in combining with the elements of water, it yields numerous bodies; one unstable and decomposing in the presence of acids, the other presenting acid characters and decomposing carbonates. To obtain the latter compound, satonin is boiled for twelve hours in a saturated solution of baryta; a salt of baryta is formed, the acid of which has been named by M. Cannizzaro, santonic acid. This can be isolated by treating the baryta salt with hydrochloric acid and shaking with ether which dissolves the santonic acid.

Santonic acid ($C_{15}H_{20}O_4$) forms orthorhombic prisms, which are not, like santonin ($C_{15}H_{18}O_3$), coloured violet by caustic potash, or yellow by the action of light. It melts at 161° to 163° C., and is very soluble in boiling water, alcohol, ether and chloroform. It forms with soda and baryta two salts, $C_{15}H_{19}O_4Na$ and $(C_{15}H_{19}O_4)_2Ba$, which are very soluble and difficult to crystallize.

The authors have attempted to discover the relations of this acid with other compounds containing C_{15}, such as the essential oils of cubebs and of patchouli. They have obtained with santonic acid and hydriodic acid an iodide, $C_{15}H_{25}I$, and a hydrocarbide, $C_{15}H_{25}$, having the same composition as the hydrocarbide prepared with the camphor of patchouli. They have not been able to effect the conversion of santonic acid into santonin, but they have obtained an isomer of santonin, metasantonin, by submitting santonic acid to a prolonged boiling with hydriodic acid and phosphorus. This new body forms white crystals, does not give santonic acid with baryta water, and distils without alteration in a vacuum.

If bromine be added to a solution of santonin in acetic acid, there is formed after a contact of some hours, a new compound, $C_{15}H_{18}O_3Br_2$, which crystallizes in red needles and appears to be a product of addition.

According to M. Hesse a solution of santonate of soda treated with an acid in excess, gives a deposit of santonin, that could only be a product of decomposition of santonic acid.

A HYDRATED DERIVATIVE OF CELLULOSE.†

BY A. GIRARD.

Between the normal cellulose as it is separated from the organs of growth and the modified gelatinous form of the same mentioned by Béchamp in 1856, another peculiar condition has been observed, which has not yet been exactly described; its formation, however, frequently takes place in industrial operations. The cellulose in this condition loses its firmness and becomes friable. The author has undertaken a closer study of this substance, and found that it represents the first modification that cellulose undergoes under the action of acids. In preparing it the conditions requisite for its production must be closely maintained; and the strength of the acid, the time it is allowed to act upon the cellulose, and the temperature very carefully regulated. According to the author the best method of preparing this modification is first to moisten cellulose with, and then dip it into, cold sulphuric acid, sp. gr. 1·42, and allow the duration of the action to be dependent upon the permeability of the cellulose. With pure carded cotton wool it should last twelve hours. At the end of that time the cellulose appears to be unaltered, and under the microscope it only seems to be somewhat puffed and stretched, and to have acquired very adhesive properties; but if pressed between two glass plates it breaks up at once into a multitude of small irregular pieces. Notwithstanding its friability the substance can be well washed and dried at a low temperature without losing its shape. But in the dried condition upon the slightest rubbing between the fingers it crumbles immediately to a fine snow-like powder. An elementary analysis gave results answering to the formula $C_{12}H_{11}O_{11}$, which corresponds to the formula of cellulose plus one molecule of water. This molecule of water is not driven off by drying. The author has given to the substance the name of hydrocellulose.

Hydrocellulose possesses definite characteristic properties. It oxidizes with extraordinary readiness. Heated for several days to 50° C. it gradually turns yellow; its proportion of carbon diminishes, and that of hydrogen increases. If now it be washed with water, it gives up a yellow substance that reduces cupric solution and silver nitrate; but the residue is unaltered hydrocellulose, answering to the formula $C_{12}H_{11}O_{11}$. When heated with a weak (1 per cent.) solution of potash the hydrocellulose is oxidized and dissolves gradually with the formation of a strongly coloured reducing liquid.

Another method of preparation mentioned by the author is that used by Payen to limit the action of acid in the conversion of starch into dextrin; it consists in moistening the substance with a very weakly acid solution, and then exposing it to a temperature of 100° C. Under these conditions the cellulose passes rapidly into hydrocellulose, but is completely carbonized by a longer action of the acid. The production of the friable hydrocellulose through the hydration of cellulose, and the conversion of this into sugar, permits, the author believes, a better explanation of certain manufacturing accidents than has hitherto been given. For instance, the production of paper parchment may be counteracted by the superficial conversion of the paper fibre into hydrocellulose. Also, when a paper is imperfectly freed from the bleaching agent, its pliability and tissue may be destroyed through the formation of hydrocellulose; the bleaching lime being decomposed by carbonic acid in the air and yielding hypochlorous and hydrochloric acids, which then act upon the cellulose.

RESOURCES OF THE PROVINCE OF SHANTUNG.

The following interesting details are quoted in the *Journal of the Society of Arts*, from a report on the geography and natural history of the province of Shantung that has recently been published in Hong-Kong:—

"The province, in the plains and valleys, is very fertile: the hills are cultivated to the extreme limit of available soil, but they are generally barren, with the exception of a dwarf kind of pine, very seldom reaching more than 10 feet in height. Some of the mountains bear names indicating that at a certain period there must have been some trees upon them. For instance, in the high range of the Saw Teetto Mountains on the road from Chefoo to Lay Yung, there is a summit called the Elm Peak, upon which, however, no such tree as an Elm exists; a few dwarf oaks, the leaves of which are eaten by silkworms, is apparently the only vegetation there. In the ravines or stony valleys there is a larger kind of pine, flat-headed and resembling the Italian pine when the Chinese allow it to grow to its full size. Large trees in the plains are not very common, but on the high road to Chi-nan Fu, and near Lay Yung, are some poplars remarkable for their large size, silver-white bark, and contorted branches. There are two kinds, one with large, and the other with small leaves; both furnish a light and excellent timber for carving and junk building.

"A kind of Catalpa, bearing the name of the great naturalist Bunge, is very common in Shantung, and decorates the gardens of Chefoo; its wood is used for making musical instruments, chess-men, chess-tables, and weighing-rods. The ailanthus, or Chinese varnish-tree, is not only useful for feeding silkworms, but its roots furnish an exceedingly useful drug, for use in dysentery; this remedy, long known to the Chinese,

* *L'Union Pharmaceutique*, xvii, 136.

† *Schweizerische Wochenschrift für Pharmacie*, June 2, p. 180

has been experimented with successfully on Europeans during the last two years, and has proved to be one of the most powerful astringents known. The *Cedrela odorata*, a tree closely allied to the mahogany, also grows in Shantung; the wood is of a reddish colour; the fruit is astringent, and is used in cases of ophthalmia. The young shoots are described as having an onion-like taste, and they are boiled and eaten by the Chinese.

"The huai shu (*Sophora japonica*) is a very common tree, and is often found of great size and age, when they take the fantastical shapes the Chinese love so much. The veneration they have for old trees is a great incitement to preserving them from destruction. They support the long branches with poles or pillars, carefully patching the holes of the trunk with bricks and mortar, and often building a little chapel or niche at the foot of the tree, generally dedicated to the Tu-lao-ye, or god of agriculture, when not dedicated to the tree itself, which they call lao-ye. The flowers of this tree are used in China as a yellow dye, for dyeing the silk of which the garments of the mandarins are made. Very large quantities of these flowers are thus consumed, and the tree is largely cultivated for the purpose, not only in Shantung, but also in Tokien and Honan, from whence they are sent in sacks to other parts of China. Small quantities occasionally reach this country, but they have never yet become an established article of commerce.

"The Chinese persimmon (*Diospyros Kaki*) is very common in Shantung. The fruit is sometimes known as the Chinese date-plum; it is of a bright red colour, about the size of an ordinary apple, and the pulp, which somewhat resembles that of a plum, is yellowish transparent. These fruits are sometimes dried and candied; but both in their fresh and preserved states they are very delicious. Considering the ease with which they might be sent, preserved in tins or earthenware jars, it is surprising we do not often see them in the European markets. It seems, however, they are largely exported to Chili. The only uses to which the fruits of the elegant Gingko, or maidenhair tree (*Salisburia adiantifolia*) are put, are for making soups and as an astringent medicine. A large article of export, known as red and black dates, are the fruits of two very common shrubs, one of which is *Rhamnus utilis*, and the other probably *R. chlorophorus*. The former grows extensively on the mountains, and furnishes the well-known dye known as Chinese green indigo, and by the Chinese as lu-ko. It is prepared by chopping the twigs in small pieces and boiling them in water, to which a certain quantity of alum is added for fixing the colour. This dye has been imported in considerable quantities into France, chiefly to the silk weaving districts about Lyons, for dyeing some of the more beautiful shades of green. The fruit-bearing trees of Shantung are somewhat limited. The vines are plentiful and give two or three kinds of grapes, which are not so sweet as the cultivated grapes of Europe. Good wine is nevertheless made from them in Pekin by the French missionaries. A celebrated fruit of the province is the Shantung pear, which is largely exported.

"From the seeds of the millet (*Setaria* species) the Chinese make a fermented beverage in the following manner:—The seeds are boiled till they burst; they are then spread out on a table and mixed with a small quantity of leaves from wheat; the whole is then put into a large leather jar, where it is left to ferment from one to four weeks. It is then placed in linen and pressed with stones, and the liquid so extracted forms huang chin, or yellow wine. Besides this, a kind of brandy or spirit is prepared from viro, sweet potatoes, persimmon fruits, etc. The bean cheese or bean curd, so common in many parts of China, is made from white and yellow beans (*Soia hispida*) steeped in cold water till they are soft, when they are deprived of their skin by pressing them between the fingers, after which they are reduced to pulp by pounding them in a mortar or pressing them under a millstone; the pulp is passed through a sieve and then some *lu-shui*—the residuum of sea salt or nitre, or a gypsum solution is added, which coagulates the albumen; the water is taken off by pressure in a linen cloth loaded with stones; this liquid is carefully thrown away, being said to be poisonous. The cake so obtained is salted, and sold fresh in the streets, or dried to the consistency of a hard cheese. Flour for food is also made from these beans, as well as a sauce or soy. This sauce, now extensively used in this country and in America, is prepared by steeping the beans in water for one hour; they are then half-dried in the sun and mixed with wheat flour and allowed to ferment, being placed for that purpose in a hot damp place. The mould which develops itself in abundance on the beans is scraped off, the beans are then dried and put in salted water, which has been properly boiled and cooled (to expel the air). The brown and black colour of the sauce so obtained is supposed to be produced by a microscopic fungus resembling the ergot of rye, whose properties the soy is said to possess. These kinds of beans are very extensively used in the manufacture of the now famous bean cake. The Customs returns give but a small idea of the enormous export of these cakes; for, if thousands are sent to the southern ports in foreign bottoms, the many millions which have found their way in junks it is impossible even to guess at. The beans being thoroughly crushed under heavy stone wheels turned by mules, are heated under water and the cakes compressed between iron hoops. The pressure is slowly and gradually increased by driving the wedges with an enormous stone suspended as a pendulum and acting as a ram. The oil, which runs from them into a kind of well, is black and very dense; it has a disagreeable smell, and is used for illuminating purposes, and for caulking boats, and being mixed with lime it makes a kind of putty. A foreign firm in Nenchavang, some time ago, tried to extract oil from the beans by the more powerful and expeditious means of a hydraulic press, but the resistance to a sudden pressure was so great that hardly any oil could be obtained.

"The other oil-producing plants of Shantung are *Sesamum orientale*, *Arachis hypogæa*, *Cannabis sativa*, *Ricinus communis*. Some of these oils are exported to Canton to be purified and clarified there, and come back to Chefoo under the pompous but false name of tea-oil. The castor-oil plant is often cultivated in the form of hedges, being considered an effective barrier against the intrusion of animals.

"The Shantung province is also very rich in medicinal plants. A kind of native ginseng found in sandy plains, and accordingly called sha-sen, is exported in quantities. The roots of the *Libanotis* and the fruit of the *Aristolochia* are famous drugs, while the leaves of the *Artemisia* are used as Moxa.

"The products here mentioned are only a few of those constituting the natural resources of the province of Shantung."

THE CULTURE OF TOBACCO IN OHIO.*

BY BENJAMIN T. CREIGHTON PH.G.

The eastern and south-eastern part of the State affords the best soil for tobacco growing, and in these districts this product has become a staple article, affording the main crop of the farmer, and, as a rule, rarely failing pecuniarily, for even in seasons when the yield is small, the price of the article is proportionately large.

In growing this much-used vegetable, the first step is the preparing of the ground for sowing the seed, by burning logs of wood or brush on the section of land chosen for tobacco beds. This is done to warm the soil, as well as to supply the ashes needed in nourishing the young plants. The burning takes place either in the fall or spring previous to sowing. If in the fall, the ground is slightly reburnt in the following spring. The time re-

* *American Journal of Pharmacy* for June.

quired for burning the beds, if logs of wood are used, is generally from two to three days. If brush be used, a much less time. The earth is then dug up and raked to a proper consistency. After the seeds have been deposited, the bed is thoroughly tramped or walked over, in order that it may retain sufficient moisture. In about three weeks the young plant makes it appearance, but it remains quite small for a considerable length of time, and, in fact, the growth is scarcely noticeable from the time of its appearance above ground (about the first of April,) until shortly before transplanting, which is generally about the latter part of June. It then grows with astonishing rapidity, as, when transplanted, it may have been but from 1 to 2 inches in height; when ready to collect (latter part of August) it generally measures from 3 to 6 feet and not unfrequently 10 feet in height. The transplanting of tobacco is not unfrequently attended with much difficulty, dry weather being very detrimental to the plant, and too much moisture equally as injurious. In the former case, the young plants wither and die, and in the latter instance, the earth becomes hardened and baked around the roots of the vegetable, thus killing it. The ground is considered to be of the proper consistency for transplanting after it has been thoroughly moistened by rain.

Tobacco is collected from the last of August until the last of October, until frost, and, if planted late, this unwelcome visitor often finds a large crop not matured, which is consequently worthless after the first touch of its icy breath. In collecting tobacco the first leaves gathered are called "bottom leaves," being from five to seven of the lower leaves of the plant, after which the plant is *topped*, thus producing larger leaves, and causing maturity in a much quicker time. This topping process strengthens the plant materially, as, after its performance, new shoots or branches will almost always spring from the axils of the leaves nearest to where the tops were broken off, and often afford leaves large enough to be gathered. The next in order are the middle leaves, which are collected in about two weeks after taking the bottom leaves; they consist of from ten to twelve leaves from the central part of the plant, and are the largest as well as the most valuable ones of the plant. Finally, the top leaves are collected, in from three to four weeks after taking the middle ones, providing there is no frost to injure them. These are smaller than the middle leaves, and resemble very much those taken from the bottom part of the plant, but are much cleaner than these latter, which often become very much soiled from their close proximity to the soil.

Among other points in cultivating tobacco, we mention the worming process, which, to most persons, is an exceedingly unpleasant task. The worm which is found on the plant is not very attractive in appearance, nor agreeable to handle. It is of a green colour, and, when full size, measures about an inch in circumference and from two to three inches in length. They are very destructive, a single worm often consuming an entire plant in a few days, if unmolested. They are also found to be quite numerous, inasmuch as the tobacco has to be thoroughly cleaned of them several times during a season. To kill them, the worms are grasped with the thumb and finger by the head, and thrown, with considerable force, on the ground, which has the effect of mashing them; when agitated, while taking them from the plant, they will often eject a greenish liquid from the mouth, which is very offensive to the sight, and reminds one somewhat of the tobacco chewers of a higher order.

After collecting the tobacco, it is taken to the tobacco house, and strung upon sticks (by means of a large needle and twine), called "tobacco sticks." Women are employed for this work, who string from one hundred to one hundred and twenty-five sticks per day. It is then placed on the tobacco scaffold, in the open air, until wilted, when it is placed in the "tobacco house," where a gradual heat is applied until it assumes a yellow colour. A higher degree of heat is then immediately applied, for twenty-four hours, to "kill it," as the farmer terms it, meaning the expulsion of all moisture from the leaves. The doors of the house are then thrown open, and the floor often sprinkled with water, in order that the leaves may again become sufficiently moistened to permit manipulation. It is now rolled in bundles ready for market.

The main object sought for by tobacco growers is the colour, which is influenced by various causes, among the leading ones are the modes of drying and the soil upon which it was raised, as the first crop of tobacco on any soil is invariably the finest. The "yellow spangle" is considered the finest colour, and, consequently, brings the highest price. The "light red" also stands high in the list, and is deemed a valuable colour. There are several other colours beside the two named which go to make up the tobacco seen in commerce.

Ashes.—After careful experiments with an extra fine quality of tobacco, furnished by an Ohio grower, the following results have been obtained, being the relative per cent. yielded by bottom, middle, and top leaves:—

Bottom leaves 18·4, middle leaves 14·2, top leaves 14·8 per cent.

In obtaining these results, the tobacco was dried by means of heat until it ceased to lose weight, one thousand grains were then weighed out and subjected to smothered combustion, until charred, after which they were completely incinerated, and the product again weighed, yielding, respectively, 184, 142, and 148 grains of ashes.

These amounts are much smaller than obtained by other experimenters, and I can only attribute the different results to the following, namely:—The bottom leaves of tobacco invariably grow on or near the ground, and tobacco being of a very glutinous nature becomes strongly impregnated with the soil. This foreign matter adheres so tenaciously to the leaves that it cannot all be removed, nor can it be recognized with the naked eye. In view of this fact, it is but fair to suppose that the large amount of ashes which some have obtained may have been due, in part, at least, to the bottom leaves having been used in their experiments.

COD LIVER OIL AND FERROUS IODIDE.

The following formula for this preparation has been published in the *Nieu Tydschrift voor de Pharmacie in Nederland*, by a Commission which the Netherlands Pharmaceutical Society has appointed to examine secret remedies and specialties:—

Iodine	1 part.
Pulverized Iron	1 part.
Pale Cod Liver Oil	80 parts.

Triturate the pulverized iron in a mortar with the iodine and one-fourth of the oil, and heat the mixture in a water-bath with continual stirring, until the brown colour of the iodine has entirely disappeared and given place to a deep purple colour, showing that the ferrous iodide has been formed and dissolved. Then add the remainder of the oil, mix carefully, and after standing decant into dry bottles, which are to be completely filled, closed immediately and kept sheltered from the light.

This oil is of a purple colour and differs in taste but little from the ordinary medicinal cod liver oil. Exposed to the light it changes after a few days to a red brown colour. Although the taste is but little altered it is important to prevent this change of colour which always indicates the liberation of iodine. In well stoppered bottles the oil remains unaltered, but it is as well not to prepare too much in advance. The taste and colour furnish good criteria for its condition.

The Pharmaceutical Journal.

SATURDAY, JULY 8, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CONCENTRATED MEDICINES.

FORTUNATELY it is but seldom that we have occasion to record cases of accidental poisoning that are referable to negligence in the dispensing of prescriptions by pharmacists, or to the want of due care in the keeping of dangerous drugs, and considering how frequently potent substances such as alkaloids, etc., are now employed in medicine this circumstance furnishes evidence of the attention given by pharmacists to the dispensing of medicines.

But notwithstanding this appropriate exercise of carefulness on the part of the pharmacist there are still some possibilities of disaster such as the accidental substitution of a poisonous liniment for a mixture, either in the hands of a nurse or of patients themselves, and it would perhaps be difficult to do away with such possibilities altogether. There are, however, others which are entirely preventible; among them there is one involving very serious risk in some cases. We refer to the practice of prescribing concentrated medicines, which has been on various occasions treated of in this Journal with the object of demonstrating by argument the danger with which it is attended, and sometimes by recording the consequences to which it has given rise.

A letter which appeared in the *Lancet* on the 24th of last month under the heading of "Prescribers and Dispensers," too plainly shows that the dangerous practice to which we refer has not been wholly abandoned by medical men, and as its continuance would be no less a source of danger to patients than of perplexity to dispensers, we think it fitting to take advantage of this opportunity to urge upon medical men the desirability of its discontinuance.

In the case now referred to, two prescriptions were taken to a pharmacist in the West of London to be dispensed, which were literally as follows:

"℞ Liq. Strychniæ ℥ j. Fiat gutt.

"A teaspoonful to be added to six ounces of water. A tablespoonful to be taken twice daily before meals."

"℞ Liq. Sodæ Arseniatis ℥ j. Fiat gutt.

"A teaspoonful to be added to six ounces of water, and a tablespoonful to be taken twice daily after meals."

The pharmacist who was required to dispense these medicines felt a reluctance to do so for reasons that will readily be understood by our readers, and he adopted what we think was the proper course of calling upon the physician to express his reasons for disliking to dispense such potent remedies in that form; but, as he states, his visit was considered to be an excessive overstepping of his province.

Having thus failed to obtain consideration from the prescriber, Mr. TUPHOLME wrote to the editor of the *Lancet*, stating the difficulty he experienced as to whether he should dispense the prescription or incur the risk of offending both patient and physician, at the same time putting the questions, Whether he would be justified in refusing to dispense the medicines? Whether he would be justified in putting upon them a label with the word "Poison"? Whether his conduct in dispensing the medicines would be considered reprehensible by the public or the profession should any accident arise? And, lastly, Whether such prescribing is in accordance with professional medical ethics?

It is scarcely to be wondered at that the *Lancet* abstains from giving a specific answer to these questions, though it is admitted that an important question is raised which should be settled amicably between physicians who have to prescribe poisonous drugs and chemists who have to dispense them.

We are glad, however, to find that our medical contemporary does not hesitate to declare its opinion that the prescription of such quantities of strong solutions of the strongest poisons is most objectionable, and then proceeds to give reasons for this opinion which are so much to the point that we trust they will be duly appreciated by medical men, and have the effect of deterring them in future from the practice of prescribing concentrated medicines.

In the first place, the want of accordance in this particular instance with the instruction of the Pharmacopœia, under the head of Arseniate of Soda, that it is "to be used cautiously," is pointed out and it is held that this instruction applies even more forcibly to strychnia. A further reason for objecting to this kind of prescription is that an important part of the dispensing is left to be done by the patient or by his friends, and while the accuracy with which this is done is so important, he is directed to measure this strong solution of strychnine by the rough and variable means of a teaspoon. Equal liability to error attaches to the directions given for diluting this quantity so that the tablespoonful may contain the intended dose of strychnine. Another objection, of a more purely medical nature, consists in the length of time for which such a supply of medicine would last, nearly seven weeks, and that in the case of a medicine which acts very irregularly on different persons and requires that the patient should be frequently seen while he is taking it.

Our contemporary also urges that it is the due of chemists that dangerous medicines should be compounded by them ready for the patients' use and that for doing so they should receive a reasonable recompense, which could scarcely be the case when they supply a wholesale stock of uncompounded preparations as in this instance.

We are glad to acknowledge the spirit of fairness and consideration evinced by the foregoing remarks, and we trust they will not fail to influence medical men in such a way as to remove a fruitful source of difficulty to dispensers.

THE COUNCIL EXAMINATION PRIZES.

WE wish to call the attention of Pharmaceutical Chemists who have passed the Major examination during the present session, and who were at the time Associates of the Society, to the official notice that the examination for the above prizes (the first under the new regulations) is to be held in London and Edinburgh on Wednesday, the 26th inst. The first prize includes the PEREIRA Medal in silver, the second the Pharmaceutical Society's Medal in silver, and the third the Society's Medal in bronze. The medals are to be accompanied by presents of books of the value of about £5, £3, and £2 respectively, the gift of Mr. THOMAS HYDE HILLS. Persons intending to compete must give notice to the SECRETARY AND REGISTRAR on or before Saturday, the 15th inst.

LECTURES ON CHEMISTRY AND PHARMACY.

IT will be seen by the Report on another page that the Council, on the recommendation of the Library, Museum, and Laboratory Committee, has authorized the Professor of Chemistry and Pharmacy to raise the fees for attendance at his lectures to three guineas for a single course, four guineas for the sessional two courses, and five guineas for perpetual admission. The ground on which this alteration is made is that each course of sixty lectures has been practically increased by extending the time from an hour to an hour and a half, so that each course now comprises the matter of ninety lectures. We understand, also, that under the new arrangement of fees the Professor contemplates supplementing each course with a few evening lectures, at which he will be able to illustrate some of the subjects, such as those of polarized light, the spectroscope, etc., with experiments, for which a darkened room is required.

THE GOVERNMENT AND SCIENTIFIC RESEARCH.

THE recommendation contained in the Eighth Report of the Commission on Scientific Instruction and the Advancement of Science,* to the effect that competent investigators should sometimes receive grants in money enabling them to provide themselves with means for conducting their researches, appears to have received a practical endorsement from the Government. Some correspondence has just been published in which an offer is made by the Government on the one hand and accepted by the Royal Society on the other, of a grant of £4000 annually as an addition to the £1000 already voted annually to enable the Royal Society to defray the expenses of scientific investigations considered by a committee of the Society to be worthy of such aid. The conditions of the £1000 grant—that it should be expended in aiding investigators to provide themselves with apparatus and assistants, but never in personal payments to the investigators themselves—are to remain unaltered. But with respect to the £4000 it is intended that permission should be accorded to the Government Grant Committee of the Royal Society—which is to be enlarged so as to include the Presidents of the principal scientific bodies—to recommend in certain cases the payment of personal allowances to gentlemen during the time they are engaged in their investigations. The experiment is to be tried for five years, the Royal Society reporting annually to the Lords of the Committee of Council on Education, the department responsible to Parliament for the proper administration of the grant, on the progress made, and as to the desirability of renewing the grant. All instruments purchased for investigations with money out of this fund are to be left in the charge of the Education Department when no longer required.

* See vol. vi., p. 150.

THE REGISTRATION OF TRADE MARKS.

ACCORDING to the Act passed last session, regulating the registration of trade marks, it was provided that on and after Saturday last no person should be entitled to institute any proceeding to prevent the infringement of any trade mark until and unless such trade mark is registered pursuant to the Act. In consequence of the number of existing trade marks, and the difficulties attending their registration, it has been found impossible to complete their registration within the time specified; a Bill has therefore been introduced into Parliament to extend the time to the 1st of January, 1877, with power of still further extension by an Order in Council. The Bill has passed the Lords, and was considered in Committee in the Commons on Thursday last, when the date was again altered to the 1st of July 1877. The amendment Bill as introduced also contained a provision that the powers vested in the "Court" by the principal Act might be exercised by the Commissioners of Patents, but this was removed from the Bill in Committee.

A SUCCESSFUL PATENT MEDICINE.

THE *Temps* of the 17th ult. contains a curious report of the hearing, in a French correctional court, of a charge of swindling against a German named BAER, who had become naturalized in France, and whose name is associated with the sale of "Eau antineuralgique." This compound is alleged to cure neuralgia, prevent apoplexy, and combat epilepsy. According to the report of Dr. BERGERON, it consists of bad eau-de-vie in which tobacco previously exhausted with boiling water has been macerated; to this a little indigo is added. The remedy is sold in 4*s.* bottles, but sample bottles are considerately provided at 2*s.* 6*d.* each. In the course of his explanation the accused asserted that the water had produced "des résultats très-grands," a remark which met with the concurrence of the prosecution on the ground that the proceeds of its sale amounted to 1,800,000 francs yearly! The charge of swindling was established and the accused was sentenced to one month's imprisonment.

Transactions of the Pharmaceutical Society

MEETING OF THE COUNCIL.

Wednesday, July 5th, 1876.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present,—Messrs. Atherton, Atkins, Betty, Bottle, Cracknell, Frazer, Greenish, Hampson, Hanbury, Hills, Owen, Rimmington, Robbins, Sandford, Schacht, Shaw, and Stacey.

The minutes of the previous meeting were read and confirmed.

The SECRETARY read a letter from Mrs. Brew, of Brighton, acknowledging the letter of condolence sent to the family on the occasion of the death of Mr. Brew.

The SECRETARY also read a letter from Mr. Barnard S. Proctor, undertaking to deliver the sessional address in October next.

The SECRETARY also stated that in consequence of the acceptance of office by Mr. Stacey as a member of the Council, it would be necessary to appoint an auditor next month.

The PRESIDENT took this occasion to say a few words of welcome to Mr. Stacey on his taking his seat at the Council table, to which that gentleman briefly replied.

THE HANBURY MEMORIAL FUND.

The PRESIDENT said there was a letter from the Pharmaceutical Society of Prague, which he might read, although it did not strictly relate to the business of the Society, but to the Hanbury Memorial Fund.

Mr. GREENISH moved that the letter be entered on the minutes and published in the Journal, which was agreed to.

The following is the letter :—

"Prague, 11th June, 1876.

"To the Honourable Council of the
Pharmaceutical Society of Great Britain,
London.

"I am charged by the President of our 'Society of Bohemian Pharmacists' to notify that this Society has changed its name last time and is now called '*Pharmaceutische Gesellschaft in Prag*' (Pharmaceutical Society of Prague).

"Your Honourable Council please at once to accept my best thanks for the most honouring election of my person as one of the Vice-Presidents of the Executive Committee of the 'Hanbury Memorial Fund,' which I will endeavour to promote as much as possible. Mr. Thomas Greenish will pay for this fund to one of the Honorary Secretaries £1 1*s*. from myself (Josef Dittrich) and £1 1*s*. from the Pharmaceutical Society of Prague.

"The Pharm. Society of Prague,
In order of the President,
JOSEF DITTRICH,
Pharmacist at Prague,
No. 219, III. Bohemia.
Member of the Council."

THE MATERIA MEDICA COLLECTION OF THE LATE DANIEL HANBURY.

The PRESIDENT also read the following letter from Mr. Thomas Hanbury, relating to the botanical collection of the late Mr. Hanbury, and suggested that the offer should be gratefully accepted, on the conditions named.

"Ashburton House,
"Croydon, 29 June, 1876.

"To the President of the Pharmaceutical Society
of Great Britain.

"SIR,—My late dear brother Daniel Hanbury when near his end, gave me verbal instructions that he wished 'his herbarium to be divided between Kew, the Pharmaceutical Society, the British Museum and Professor Flückiger.'

"In taking steps to carry out this wish, I have heard many regrets expressed by the scientific friends of my late brother, that there should be any division of his Pharmaceutical collection, which being unique and *sui generis*, would it is considered greatly lose in interest by being divided and scattered. I share this opinion, and believe that had my late brother calmly considered the matter in time of health, he would have come to the same conclusion.

"With the approval of my co-executor and my other relatives, I have decided to offer the entire Pharmaceutical collection to your society, on the simple condition that it shall be kept apart, and labelled in a suitable manner to show it was formed by my late brother, and that access to the specimens and herbarium be allowed only under most careful regulations to prevent injury or loss.

"I am,
"Yours faithfully,
THOMAS HANBURY."

Mr. SANDFORD moved, and Mr. Hills seconded the following, which was carried unanimously :

"That the offer of the collection of the late Daniel Hanbury to the Pharmaceutical Society be accepted, with the best thanks of this Council to his executors, and that the letter from Mr. Thomas Hanbury be referred to the Library, Museum, and Laboratory Committee, for the purpose of making the necessary arrangements for keeping the specimens according to the wishes of the late Daniel Hanbury's representatives."

ELECTIONS.

The following being duly registered as Pharmaceutical Chemists were respectively granted a Diploma stamped with the Seal of the Society :—

Appleby, Edward Joseph.
Pain, Arthur.
Sheppard, Ebenezer.
Thomas, Henry Alma.
West, John Leaver.
Wheatly, Arthur William.
Woodland, John.

On the list of names being submitted for election to membership,

The SECRETARY drew attention to the fact that the name of a lady was included.

Mr. SANDFORD thought it was understood that when a lady applied her name should be put separately.

Mr. HAMPSON was not aware of any rule of that kind.

The VICE-PRESIDENT said the resolution was submitted in the usual form, and it was open to any one to move an amendment.

Mr. SANDFORD said he was prepared to move as on a former occasion, that the name of the lady be omitted.

Mr. BOTTLE suggested that the names be taken *seriatim*.

Mr. HAMPSON said he felt something very much akin to a sense of shame in speaking on this subject, and to find that it was necessary to re-discuss a question of this kind. He believed that the lady in question had as much right to membership as any man at the board. She was eligible according to the Act of Parliament, having passed the highest examination that the Society imposed on the candidates, and he considered that in refusing her election the Council would be acting illegally, and that probably in the future a *mandamus* from the Court of Queen's Bench would be the result. It had come to this that the Council selfishly excluded those who had a right to membership, and he believed that by so doing it was neglecting a simple duty, and acting unjustly as well as illegally. He should like to read a short passage bearing on this point from a report of a Conference held in 1867 between the Society and the United Society of Chemists and Druggists. Mr. Sandford was then president and in speaking of the word "eligibility" quoted the opinion of the solicitor that if a man were "eligible" under the Act of Parliament "they were bound to elect him, and to proceed according to the spirit of the Act." Now he contended that the spirit of the Act was decidedly in favour of the election of this lady. She had done everything which was requisite, and he felt that the Council had no right to deprive her of the privilege of membership. It was a matter of common courtesy and justice, and he hoped the election would take place.

Mr. ROBBINS contended that it was not competent for the Council to elect a lady as a member after the decision of the annual general meeting some years ago without first annulling that decision by a resolution deciding that ladies can be admitted to membership; the present mode of attempt to admit a certain lady was out of order and irregular.

Mr. OWEN did not think the Council was altogether bound by the decision of the annual meeting.

Mr. SANDFORD here formally moved an amendment that the lady be not elected. He said he was quite prepared to stand by what Mr. Hampson had read, and agreed with the definition of "eligibility" there given. It was well known that the power of election was discretionary, and cases occurred from time to time, when the discretion was exercised by refusing to elect persons whom they did not think would be fit and proper members. It was a hard thing to speak against ladies in this way, but he did not consider they would be proper members of the Society; they could not become members of the Council, or take the Presidential chair, and therefore he thought it a pity that the question had been opened again. The proper way would be to bring it before a general meeting and let the sense of the Society be taken upon it.

Mr. ATHERTON seconded the amendment. He said that ever since the Council had had the advantage of Mr. Hampson's presence this matter had been brought forward annually; and considering that year after year the Council had come to so decided a negative he rather wondered at Mr. Hampson bringing it up again.

Mr. HAMPSON protested against this being considered as his particular question.

Mr. SANDFORD: I thought you moved it.

Mr. HAMPSON: So I do. But you will please to understand that I do not bring the matter forward. It comes as it ought to come, in the usual way; the applicant has obeyed the statute, passed the examination, and seeks election in the ordinary way.

Mr. ATKINS said he should like to have the question raised by Mr. Robbins settled, whether the Council could properly elect this lady.

Mr. FRAZER asked if the President could say whether the Council would be acting illegally in electing this lady.

The PRESIDENT said he should be sorry to say it would be illegal, but he thought it would be very injudicious in the Council to do so after so strong an expression of opinion by a general meeting, without submitting the question to the members again.

Mr. FRAZER thought if the Council were entitled by law to elect this lady it was bound to do so. Her fees had been taken and she had been allowed to enter the trade, and it was now too late to stop.

Mr. BETTY pointed out that the decision of the general meeting was arrived at, not haphazard, but in consequence of the question being formally remitted to it by the Council. Therefore, although the Council might legally elect this lady, he contended most strongly that representing their constituents, morally they could not do so.

Mr. HAMPSON demurred to the statement that the question was specially referred to the general meeting, but acknowledged that he was mistaken on Mr. Bottle stating that he himself had moved a resolution for the purpose.

Mr. BETTY repeated that consistently the Council could not advance in this matter, and he should like a vote taken on this preliminary point, and afterwards, if necessary, he would give his opinion on the main question.

Mr. ATKINS agreed with Mr. Betty that the Council could not introduce such an organic change without consulting the members generally, especially after the decision which had been already come to.

Mr. SCHACHT said that although he had on former occasions voted for the admission of ladies, and still hoped that the time would shortly come when at a public meeting a vote would reverse the former decision, yet he felt that until such a vote had been given it would not be right to elect a lady as a member, and therefore he must vote for the amendment.

A vote was then taken when twelve voted for the amendment; four against it. The amendment was therefore carried. The list was then submitted with the exception of the lady's name, and the following elections took place:—

MEMBERS.

Pharmaceutical Chemists.

Appleby, Edward Joseph ......Devonport.
Pain, Arthur ....Ipswich.
Sheppard, Ebenezer ....Walsall.
West, John Leaver ....London.
Wheatly, Arthur William ......London.
Woodland, John ....Deal.

Chemist and Druggist.

Abram, Frederick William ......East Dereham.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, and being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Fiddick Thomas ....Camborne.
Hugo, Richard ....Kensington.

Modified.

Martin, Richard ....Bolton.
Saunders, Charles J. H. ....Exeter.

ASSOCIATES.

The following having passed their respective examinations, and having severally paid or tendered the subscription for the current year, were elected "Associates" of the Society:—

Adams, Charles.....................Birmingham.
Barcham, Henry ... .Hackford.
Daniel, John ....Ceibach.
Fosse, Alexander Fare............Ilfracombe.
Gregory, Walter ....Taunton.
Helmore, William Holloway ...Stratford-on-Avon.
Prebble, John George ....Folkestone.
Roberts, Edmund..................Cambridge.

Modified.

Llewelyn, Ynyr.....................Stourbridge.

The following having passed the Preliminary examination, and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Baker, Joseph Palmer............Bulwell.
Callander, William Wright......Exeter.
Cave, John Maud Perry ....Leominster.
Killick, Charles R. ....London.
Nathan, Louis Bernard ....Jersey.
Rowe, Walter ....Leicester.
Williams, Alfred Joseph ....London.

A former member was restored to his former status in the Society upon payment of the current year's subscription and a fine.

Reports of Committees.

Finance.

The report of this Committee was read and adopted, and sundry accounts ordered to be paid.

Benevolent Fund.

The report of this Committee was read, including recommendations of the following grants:—

£10 to a registered chemist and druggist in distressed circumstances. Applicant has received a former grant of like amount.

£10 to a former member, aged 55, who has had two former grants.

One application had been rejected, the person seeking assistance being in receipt of parochial relief; and another application had been ordered to stand over.

The following regulation of the Royal Agricultural Benevolent Institution had been laid before the Committee by the Secretary, who suggested that a similar regulation might with advantage be adopted:—

> "Should any subscriber, being duly qualified, hereafter become a candidate for the benefits of the Institution such number of votes should be placed to his or her credit at the first succeeding election, as should be represented by the whole amount of subscription he or she may have paid during the period of his or her enrolment as a subscriber."

The consideration of this matter had been deferred to the next meeting of the Committee.

The report and recommendations were received and adopted.

Library, Museum, and Laboratory.

The report of this Committee included the following information:—

Professor Redwood had reported that he had 51 students now attending his class; 15 perpetual, and 12 for the entire session.

Professor Bentley had reported 74 students in his class.

Professor Attfield had reported that he had had 119 entries since the commencement of the session, 56 now working.

The Librarian reported that the average attendance in the Library during the day had been 27; in the evening 9. The circulation of books had been 174 in town; country, to 28 places, 47.

The Committeee recommended the purchase of the following books from the general fund:—

Fresenius' 'Quantitative Analysis,' 7th ed., vol. 1.
Fresenius' 'Qualitative Analysis,' 9th ed.
Clowes' 'Practical and Analytical Chemistry.'
Valentin's 'Inorganic Chemistry,' 3rd ed.
Jeannel's 'Formulaire Officinal et Magistral,' 2me éd.

The Curator had reported the attendance in the Museum as being on the average 19 in the day, 5 in the evening. The stag's horns presented by the late Sir Edwin Landseer were now mounted and placed in the Museum. The Materia Medica portion of the catalogue was finally revised. The following donations to the Museum had been received:—

A series of specimens illustrating a paper on Ergot, by Professor Dragendorff of Dorpat.

A fine specimen of Bryony root, from Mr. Sturton, of Cambridge.

A number of specimens of Indian drugs, from Professor Dymock, of Bombay.

Specimen of the root of Garuleum bipinnatum, from the Cape of Good Hope, from Mr. Hyman.

With regard to the question recently raised as to the obtaining for the library certain foreign pharmaceutical journals, Mr. Greenish had reported that he had made inquiries of a firm of booksellers in Berlin who had furnished an estimate. The Committee decided to defer the consideration of this question until next month, further inquiries to be made in the meantime.

In response to the letter of Professor Redwood the Committee recommended that the fees for the Chemistry and Pharmacy course be increased to the following amounts:—

One Course	£3 3s.
An Entire Session	£4 4s.
Perpetual Admission . . .	£5 5s.

The report and recommendations of the Committee were received and adopted.

The Philadelphia Exhibition.

The President read a letter received from the American Pharmaceutical Association expressing a hope that many English pharmacists visiting the Philadelphia Exhibition would make arrangements for being present at the annual meeting of the Association in September.

Appointment of Professors and Curator for the ensuing Year.

Professor Redwood was re-appointed Professor of Chemistry and Pharmacy for the ensuing year.

Professor Bentley was re-appointed Professor of Botany and Materia Medica for the ensuing year.

Professor Attfield was re-appointed Professor of Practical Chemistry for the ensuing year.

Mr. Holmes was re-appointed Curator of the Society's Museum for the ensuing year.

House.

The report of this Committee was read and adopted. It only referred to matters of detail with regard to the house arrangements.

Law and Parliamentary.

The report of this Committee contained letters from the Solicitor detailing the steps taken in various legal proceedings. The Secretary also reported steps taken in several cases of alleged infringement of the Pharmacy Act. The Committee recommended prosecution in four cases of infringement of the provisions of the Pharmacy Act, 1868.

The report of the Committee was received and adopted.

Preliminary Examinations.

The following Superintendents and Deputy-Superintendents of written examinations at the various local centres, were appointed for the ensuing year:—

Superintendents of Examinations.

Aberdeen	Davidson, Charles.
Aberystwith	Wynne, E. P.
Barnstaple	Goss, Samuel.
Berwick-on-Tweed	Carr, William Graham.
Birmingham	Southall, William.
Boston	Pilley, Henry T.
Brighton	Gwatkin, James Thomas.
Bristol	Stoddart, W. W.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Cross, William.
Cardigan	Jones, J. E.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, R. M.
Carnarvon	Jones, John.
Cheltenham	Smith, N.
Chester	Grindley, W.
Colchester	Shenstone, J. B. B.
Darlington	Robinson, A. F.
Doncaster	Dunhill, W. W.
Dorchester	Evans, A. J.
Dumfries	Allan, William.
Dundee	Hardie, James.
Edinburgh	Mackay, John.
Exeter	Delves, George.
Glasgow	Kinninmont, A.
Guernsey	Arnold, A.
Hereford	Jennings, R.
Hull	Bell, C. B.
Inverness	Galloway, G. R.
Jersey	Ereaut, J. jun.

Leamington	Jones, S. U.
Leeds	Reynolds, R.
Leicester	Cooper, Thomas.
Lincoln	Maltby, Joseph.
Liverpool	Abraham, J.
London	Taylor, Geo. Spratt.
Lynn	Atmore, George.
Macclesfield	Bates, W. I.
Manchester	Wilkinson, W.
Newcastle	Gooderham, Rev. A.
Northampton	Bingley, J.
Norwich	Sutton, Francis.
Nottingham	Atherton, J. H.
Oxford	Prior, G. T.
Perth	Dandie, David.
Peterborough	Heanley, M.
Plymouth	Balkwill, A. P.
Portsmouth	Rastrick, R. J.
Preston	Barnes, J.
Reading	Hayward, W. G.
Salisbury	Atkins, S. R.
Scarborough	Whitfield, J.
Sheffield	Wilson, Edward.
Shrewsbury	Cross, W. G.
Southampton	Dawson, O. R.
Stafford	Averill, J.
Swansea	Brend, Thomas.
Taunton	Prince, Henry.
Truro	Serpell, S.
Worcester	Virgo, Charles.
York	Davison, R.

DEPUTY-SUPERINTENDENTS OF EXAMINATIONS.

Aberdeen	Kay, James Petrie.
Aberystwith	Vaughan, W. G.
Barnstaple	Symons, William.
Berwick-on-Tweed	Carr, Robert.
Birmingham	Churchill, Walter J.
Boston	Haller, Frederick William.
Brighton	Savage, William Wallace.
Bristol	Schacht, G. F.
Cambridge	Church, H. J.
Canterbury	Amos, D.
Cardiff	Bartleet, John.
Cardigan	Evans, C.
Carlisle	Halloway, John.
Carmarthen	Davies, R. M., jun.
Carnarvon	Hughes, Richard.
Cheltenham	Barron, William.
Chester	Hodges, W.
Colchester	Prosser, E. T.
Darlington	Hutchinson, E.
Doncaster	Shaw, H. W.
Dorchester	Durden, Henry.
Dumfries	Carruthers, R. B.
Dundee	Laird, William.
Edinburgh	Ainslie, William.
Exeter	Lake, J. H.
Glasgow	Davison, T.
Guernsey	Collenette, A.
Hereford	Parkin, T.
Hull	Baynes, J.
Inverness	Galloway, G.
Jersey	Ereaut, J.
Leamington	Davies, H.
Leeds	Smeeton, W.
Leicester	Cooper, Henry.
Lincoln	Battle, J. S.
Liverpool	Shaw, John.
London	Bremridge, Richard.
"	Knapman, J. W.
"	Holmes, E. M.
Lynn	Willis, C.
Macclesfield	Wood, R.
Manchester	Wilkinson, G.
Newcastle	Usher, J.
Northampton	Mayger, W. D.
Norwich	Corder, O.
Nottingham	Fitzhugh, R.
Oxford	Thurland, T. H.
Perth	Dandie, Robert.
Peterborough	Buckle, F. G.
Plymouth	Hearder, H. P.
Portsmouth	Rastrick, J. L.
Preston	Barnes, L. R.
Reading	Bradley, Charles.
Salisbury	Orchard, E. J.
Scarborough	Fryer, C.
Sheffield	Ward, William.
Shrewsbury	Cross, W. G. jun.
Southampton	Spearing, James.
Stafford	Averill, H. A.
Swansea	Layng, T. B.
Taunton	Gregory, G. H.
Truro	Richards, J. E.
Worcester	Lunn, Thomas.
York	Cooper, Thomas.

The VICE-PRESIDENT said the first three months of 1876, as compared with 1875, showed an increase of 195 in England in the number coming up for the Preliminary examination.

REPORT OF EXAMINATIONS.

June, 1876.

ENGLAND AND WALES.

THE COUNCIL EXAMINATION PRIZES.

Messrs. Carteighe and Linford were appointed to conduct the examination for the Council Examination Prizes to be held on Wednesday, the 26th instant.

The SECRETARY read a letter from Mr. Mackay, saying that the Council of the North British Branch had received an application from Dr. Gillespie on behalf of the Edinburgh Medical and Chirurgical Society, for the use of the Society's Rooms once a month, paying a fee of one guinea. The Council of the North British Branch had acceded to the application subject to the approval of the London Council.

A resolution was passed sanctioning the proposed arrangement.

A letter was read from a gentleman who prepares pupils for the examinations of the Society, asking that the list of successful candidates might be made known to him on the evening of the day of examination, instead of the next morning, in order to save young men from a night of suspense, and allow some of them to return to their homes a day earlier.

The SECRETARY said the list used to be exhibited in the hall on the night of the examination, but the practice had given rise to much confusion and obstruction in the hall, and it became absolutely necessary to discontinue it. The candidates were now communicated with direct from the office, and that system has been found to work satisfactorily.

The Secretary was directed to inform the gentleman referred to that the Council could not accede to his request.

THE PRELIMINARY EXAMINATIONS.

The SECRETARY submitted the following list of attendances at the different centres since the establishment of the present system :—

PRELIMINARY EXAMINATION.

List of Centres and Table of Attendances of Candidates at each Centre.

	1874. July.	1874. Oct.	1875. Jan.	1875. April.	1875. July.	1875. Oct.	1876. Jan.	1876. April.	1876. July.	Total number of attendances at each Centre.

Proceedings of Scientific Societies.

ROYAL INSTITUTION OF GREAT BRITAIN.*

THE MECHANICAL ACTION OF LIGHT.

BY W. CROOKES, F.R.S.

(Concluded from page 15.)

The speed with which a sensitive radiometer will revolve in the sun is almost incredible; and the electric light such as I have in this lantern cannot be far short of full sunshine. Here is the most sensitive instrument I have yet made, and I project its image on the screen, letting the full blaze of the electric light shine upon it. Nothing is seen but an undefined nebulous ring, which becomes at times almost invisible. The number of revolutions per second cannot be counted, but they must be several hundreds, for one candle has made it spin round forty times a second.

I have called the instrument the radiometer, because it will enable me to measure the intensity of radiation falling on it by counting the revolutions in a given time; the law being that the rapidity of revolution is inversely as the square of the distance between the light and the instrument.

When exposed to different numbers of candles at the same distance off, the speed of revolution in a given time is in proportion to the number of candles; two candles giving twice the rapidity of one candle, and three, three times, etc.

The position of the light in the horizontal plane of the instrument is of no consequence, provided the distance is not altered; thus, two candles, 1 foot off, give the same number of revolutions per second, whether they are side by side or opposite to each other. From this it follows that if the radiometer is brought into a uniformly lighted space it will continue to revolve.

It is easy to get rotation in a radiometer without having the surfaces of the discs differently coloured. Here is one having the pith discs blacked on both sides. I project its image on the screen, and there is no movement. I bring a candle near it, and shade the light from one side, when rapid rotation is produced, which is at once altered in direction by moving the shade to the other side.

I have arranged here a radiometer so that it can be made to move by a very faint light, and at the same time its rotation is easily followed by all present. In this bulb is a large six-armed radiometer carrying a mirror in its centre. The mirror is almost horizontal, but not quite so, and therefore when I throw a beam of electric light vertically downwards on to the central mirror, the light is reflected off at a slight angle, and as the instrument rotates its movement is shown by the spot of light travelling round the ceiling in a circle. Here again the fog helps us, for it gives us an imponderable beam of light moving round the room like a solid body, and saving you the trouble of looking up to the ceiling. I now set the radiometer moving round by the light of a candle, and I want to show you that coloured light does not very much interfere with the movement. I place a yellow glass in front, and the movement is scarcely diminished at all. Very deep coloured glass, you see, diminishes it a little more. Blue and green glass make it go a little slower, but still do not diminish the speed one half. I now place a screen of water in front: the instrument moves with diminished velocity, rotating with about one-fourth its original speed.

Taking the action produced by a candle flame as 100

Yellow glass reduces it to	89

* Lecture delivered on Friday, February 11, 1876.

I now move the candle a little distance off, so as to make the instrument move slower, and bring a flask of boiling water close to it. See what happens. The luminous index no longer moves steadily, but in jerks. Each disc appears to come up to the boiling water with difficulty, and to hurry past it. More and more sluggishly do they move past, until now one has failed to get by, and the luminous beam, after oscillating to and fro a few times, comes to rest. I now gradually bring the candle near. The index shows no movement. Nearer still. There is now a commencement of motion, as if the radiometer was trying to push past the resistance offered by the hot water; but it is not until I have brought the candle to within a few inches of the glass globe that rotation is recommenced. On these pith radiometers the action of dark heat is to repel the black and white surfaces almost equally, and this repulsion is so energetic as to overcome the rotation caused by the candle, and to stop the instrument.

With a radiometer constructed of a good conductor of heat, such as metal, the action of dark heat is different. Here is one of silvered copper, polished on one side and lampblacked on the other. I have set it moving with a candle slightly the normal way. Here is a glass shade heated so that it feels decidedly warm to the hand. I cover the radiometer with it, and the rotation first stops, and then recommences the reverse way. On removing the hot shade the reverse movement ceases, and normal rotation recommences.

If, however, I place a hot glass shade over a pith radiometer the arms at once revolve the normal way, as if I had exposed the instrument to light. The diametrically opposite behaviour of a pith and a metal instrument when exposed to dark heat radiated from a hot glass shade is very striking. The explanation of the action is not easy, but it depends on the fact that the metal is one of the best conductors of heat, whilst pith is one of the worst.

One more experiment with this metallic radiometer. I heat it strongly with a spirit lamp, and the arms spin round rapidly. Now the whole bulb is hot, and I remove the lamp: see what happens. The rotation quickly diminishes. Now it is at rest; and now it is spinning round just as fast the reverse way. I can procure this reverse movement only with difficulty with a pith instrument. The action is due to the metal being a good conductor of heat. As it absorbs heat it moves one way; as it radiates heat it moves the opposite way.

At first I made these instruments of the very lightest material possible, some of them not weighing more than half a grain; and where extreme sensitiveness is required lightness is essential. But the force that carries them round is quite strong enough to move a much greater weight. Thus the metallic instrument I have just experimented with weighs over 13 grains, and here is one still heavier, made of four pieces of looking-glass blacked on the silvered side, which are quickly sent round by the impact of this imponderable agent, and flash the rays of light all round the room when the electric lamp is turned on the instrument.

Before dismissing this instrument, let me show one more experiment. I place the looking-glass and the metal radiometer side by side, and, screening the light from them, they come almost to rest. Their temperature is the same as that of the room. What will happen if I suddenly chill them? I pour a few drops of ether on each of the bulbs. Both instruments begin to revolve. But notice the difference. Whilst the movement in the case of the metal radiometer is direct, that of the looking-glass instrument is reverse. And yet to a candle they both rotate the same way, the black being repelled.

Now, having found that this force would carry round a comparatively heavy weight, another useful application suggested itself. If I can carry round heavy mirrors or plates of copper, I can carry round a magnet. Here then is an instrument carrying a magnet and outside is a smaller magnet, delicately balanced in a vertical position, having the south pole at the top and the north pole at the bottom. As the inside magnet comes round, the outside magnet being delicately suspended on its centre, bows backwards and forwards, and, making contact at the bottom, carries an electric current from a battery to a Morse instrument. A ribbon of paper is drawn through the "Morse" by clockwork, and at each contact—at each revolution of the radiometer—a record is printed on the strip of paper by dots; close together if the radiometer revolves quickly, farther apart if it goes slower.

Here the inner magnet is too strong to allow the radiometer to start with a faint light without some initial impetus. Imagine the instrument to be on the top of a mountain away from everybody, and I wish to start it in the morning. Outside the bulb are a few coils of insulated copper wire, and by depressing the key for an instant I pass an electric current from the battery through them. The interior magnet is immediately deflected from its north-south position, and the impetus thus gained enables the light to keep up the rotation. In a proper meteorological instrument I should have an astatic combination inside the bulb, so that a very faint light would be sufficient to start it, but in this case I am obliged to set it going by an electric current. I have placed a candle near the magnetic radiometer. I now touch the key; the instrument immediately responds; the paper unwinds from the Morse instrument, and on it you will see dots in regular order. I put the candle 8 inches off, and the dots come wide apart. I place it 5⅝ inches off, and two dots come where one did before. I bring the candle 4 inches from the instrument, and the dots become four times as numerous, thus recording automatically the intensity of the light falling on the instrument, and proving that in this case also the radiometer obeys the law of inverse squares.

This instrument, the principle of which I have illustrated to-night, is not a mere toy or scientific curiosity, but is capable of giving much useful information in climatology. You are well aware that the temperature, the rainfall, the atmospheric pressure, the direction and force of the wind, are now carefully studied in most countries, in order to elucidate their sanitary condition, their animal and vegetable productions, and their agricultural capabilities. But one most important element, the amount of light received at any given place, has been hitherto but very crudely and approximately estimated, or rather guessed at. Yet it cannot be denied that sunlight has its effect upon life and health, vegetable, animal, and human, and that its relative amount at any place is hence a point of no small moment. The difficulty is now overcome by such an instrument as this. The radiometer may be permanently placed on some tall building, or high mountain, and, by connecting it by telegraphic wires to a central observatory, an exact account can be kept of the proportion of sunlight received in different latitudes, and at various heights above the sea level. Furthermore, our records of the comparative temperature of different places have been hitherto deficient. The temperature of a country depends partly on the amount of rays which it receives direct from the sun, and partly on the atmospheric and oceanic currents, warm or cold, which sweep over or near it. The thermometer does not discriminate between these influences; but the radiometer will enable us now to distinguish how much of the annual temperature of a place is due to the direct influence of the sun alone, and how much to the other factors above referred to.

I now come to the last question which I stated at the beginning of this discourse, "What is the amount of force exerted by radiation?" Well, I can calculate out the force in a certain way, from data supplied by this torsion apparatus. Knowing the weight of the beam, the power of the torsion fibre of glass, its time of oscillation, and the size of the surface acted on, it is not difficult to calculate the amount of force required to deflect the beam through a given angle; but I want to get a more direct measure of the force. I throw a ray of light upon one of these instruments, and it gives a push; surely it is possible to measure the amount of this push in parts of a grain. This I have succeeded in doing in the instrument behind me; but before showing the experiment I want to illustrate the principle upon which it depends. Here is a very fine glass fibre suspended from a horizontal bar, and I wish to show you the strength of it. The fibre is only a few thousandths of an inch thick; it is about 3 feet long, and at the lower end is hanging a scale-pan, weighing 100 grains. So I start with a pull of 100 grains on it. I now add little lead weights, 50 grains each, till it breaks. It bears a pull of 750 grains, but gives way when additional weight is added. You see then the great strength of a fibre of glass, so fine as to be invisible to all who are not close to it, to resist a tensile strain.

Now I will illustrate another equally important property of a glass thread, viz., its power to resist torsion. Here is a still finer glass thread, stretched horizontally between two supports: and in order to show its position I have put little jockeys of paper on it. One end is cemented firmly to a wooden block, and the other end is attached to a little instrument called a counter—a little machine for registering the number of revolutions. I now turn this handle till the fibre breaks, and the counter will tell me how many twists I have given this fibre of glass. You see it breaks at twenty revolutions. This is rather a thicker fibre than usual. I have had them bear more than 200 turns without breaking, and some that I have worked with are so fine that if I hold one of them by the end it curls itself up and floats about the room like a piece of spider's thread.

Having now illustrated these properties of glass fibres I will try to show a very delicate experiment. I want to ascertain the amount of pressure which radiation exerts on a blackened surface. I will put a ray of light on the pan of a balance, and give you its weight in grains; for I think in this Institution and before this audience I may be allowed a scientific use of the imagination, and may speak of weighing that which is not affected by gravitation.

The principle of the instrument is that of W. Ritchie's torsion balance, described by him in the 'Philosophical Transactions,' for 1830. The construction is somewhat complicated. A light beam, AB, having 2 square inches of pith, C, at one end, is balanced on a very fine fibre of glass, DD, stretched horizontally in a tube; one end of the fibre being connected with a torsion handle, E, passing through the tube, and indicating angular movements on a graduated circle. The beam is cemented to the torsion fibre, and the whole is enclosed in glass and connected with the mercury pump by a spiral tube, F, and exhausted as perfectly as possible. G is a spiral spring, to keep the fibre in a uniform state of tension. H is a piece of cocoon silk. I is a glass stopper, which is ground into the tube as perfectly as possible, and then highly polished and lubricated with melted indiarubber, which is the only substance I know that allows perfect lubrication and will still hold a vacuum. The pith, C, represents the scale-pan of the balance. The cross-beam, A B, which carries it, is cemented firmly to the thin glass fibre, D, and in the centre is a piece of mirror, K. Now the cross-beam A B, and the fibre, D, being rigidly connected together, any twist which I give to the torsion handle, E, will throw the beam out of adjustment. If, on the other hand, I place a weight on the piece of pith C, that end of the beam will fall down, and I shall have to turn the handle, E, round and round a certain number of times, until I have put sufficient torsion on the fibre, D, to lift up the beam. Now, according to the law of torsion, the force with which a perfectly elastic body like glass tends to untwist itself is directly proportional to the number of degrees through which it has been twisted; therefore, knowing how many degrees of torsion I must put on the fibre to lift up the $\frac{1}{100}$th of a grain weight, I can tell how many degrees of torsion are required to lift up any other weight; and conversely, putting an unknown weight or pressure on the pith, I can find its equivalent in grains by seeing how much torsion it is equal to. Thus, if $\frac{1}{100}$th of a grain requires 10,000 degrees of torsion, $\frac{1}{50}$th of a grain would require 20,000 degrees; and conversely, a weight which required 5000 degrees torsion would weigh $\frac{1}{200}$th of a grain. Once knowing the torsion equivalent of $\frac{1}{100}$th of a grain, the ratio of the known to the unknown weights is given by the degrees of torsion.

Having thus explained the working of the torsion balance I will proceed to the actual experiment. On the central mirror I throw a ray from the electric light, and the beam reflected on a particular spot of the ceiling will represent zero. The graduated circle, J, of the instrument also stands at zero, and the counter which I fasten on at the end, L, stands at O. The position of the spot of light reflected from the little concave mirror being noted, the torsion balance enables me to estimate the pressure or weight of a beam of light to a surprising degree of exactness. I lift up my little iron weight by means of a magnet (for working in a vacuum I am restricted in the means of manipulating), and drop it in the centre of the pith; it knocks the scale-pan down, as if I had placed a pound weight upon an ordinary balance, and the index-ray of light has flown far from the zero-point on the ceiling. I now put torsion on the fibre to bring the beam again into equilibrium. The index-ray is moving slowly back again. At last it is at zero, and on looking at the circle and counter I see that I have had to make 27 complete revolutions and 301 degrees, or $27 \times 360° + 301° = 10,021°$, before the force of torsion would balance the $\frac{1}{100}$th of a grain.

I now remove the weight from the pith-pan of my balance, and liberate the glass thread from torsion by twisting it back again. Now the spot of light on the ceiling is at zero, and the counter and index are again at O.

Having thus obtained the value of the $\frac{1}{100}$th of a grain in torsion degrees, I will get the same for the radiation from a candle. I place a lighted candle exactly six inches from the blackened surface, and on removing the screen the pith scale-pan falls down, and the index-ray again flies across the ceiling. I now turn the torsion handle, and in much less time than in the former case the ray is brought back to zero. On looking at the counter I find it registers four revolutions, and the index points to 188 degrees, making altogether $360° \times 4 + 188 = 1628°$, through which the torsion fibre has to be twisted to balance the light of the candle.

It is an easy calculation to convert this into parts of a grain weight; 10,021 torsion degrees representing 0·01 grain, 1628 torsion degrees represent 0·001624 grain.

$$10{,}021° : 0{\cdot}01 \text{ grain} :: 1628° : 0{\cdot}001624 \text{ grain}.$$

The radiation of a candle six inches off, therefore, weighs or presses the two square inches of blackened pith with a weight of 0·001624 grain. In my own laboratory, working with this torsion balance, I found that a candle six inches off gave a pressure of 0·001772 grain. The difference is only 0·000148 grain, and is fairly within the allowable limits of a discourse experiment. But this balance is capable of weighing to far greater accuracy than that. You have seen that a torsion of 10,021° balanced the hundredth of a grain. If I give the fibre one degree more twist the weight is over-balanced, as shown by the movement of the index-ray on the ceiling. Now one degree of torsion is about the $\frac{1}{10000}$th part of the whole torsion required by the $\frac{1}{100}$th grain. It represents therefore the $\frac{1}{10000}$th part of the $\frac{1}{100}$th, or the millionth part of a grain.

Divide a grain weight into a million parts, place one of them on the pan of the balance, and the beam will be instantly depressed.

Weighed in this balance the mechanical force of a candle twelve inches off was found to be 0·000444 grain; of a candle six inches off, 0·001772 grain. At half the distance the weight of radiation should be four times, or 0·001776 grain; the difference between theory and experiment being only four millionths of a grain is a sufficient proof that the indications of this instrument, like those of the apparatus previously described, follow the law of inverse squares. An examination of the differences between the separate observations and the mean shows that my estimate of the sensitiveness of this balance is not excessive, and that in practice it will safely indicate the millionth of a grain.

I have only had one opportunity of getting an observation of the weight of sunlight: it was taken on December 13th, but the sun was so obscured by thin clouds and haze that it was only equal to 10·2 candles six inches off. Calculating from this datum, it is seen that the pressure of sunshine is 2·3 tons per square mile.

But, however fair an equivalent ten candles may be for a London sun in December, a midsummer sun in a cloudless sky has a very different value. Authorities differ as to its exact equivalent, but I under-estimate it at one thousand candles twelve inches off.

Let us see what pressure this will give:—A candle twelve inches off, acting on two square inches of surface, was found equal to 0·000444 grain; the sun, equalling 1000 candles, therefore gives a pressure of 0·444000 grain; that is, equal to about 32 grains per square foot, to 2 cwt. per acre, 57 tons per square mile, or nearly three thousand million tons on the exposed surface of the globe—sufficient to knock the earth out of its orbit if it came upon it suddenly.

It may be said that a force like this must alter our ordinary ideas of gravitation; but it must be remembered that we only know the force of gravity as between bodies such as they actually exist, and we do not know what this force would be if the temperatures of the gravitating masses were to undergo a change. If the sun is gradually cooling, possibly its attractive force is increasing, but the rate will be so slow that it will probably not be detected by our present means of research.

Whilst showing this experiment I wish to have it distinctly understood that I do not attach the least importance to the actual numerical results. I simply wish to show you the marvellous sensitiveness of the apparatus with which I am accustomed to work. I may, indeed, say that I know these rough estimates to be incorrect. It must be remembered that our earth is not a lamp-blacked body enclosed in a glass case, nor is its shape such as to give the maximum of surface with the minimum of weight. The solar forces which perpetually pour on it are not simply absorbed and degraded into radiant heat, but are transformed into the various forms of motion we see around us, and into the countless forms of vegetable, animal, and human activity. The earth, it is true, is poised in vacuous space, but it is surrounded by a cushion of air; and, knowing how strongly a little air stops the movement of repulsion, it is easy to conceive that the sun's radiation through this atmospheric layer may not produce any important amount of repulsion. It is true the upper surface of our atmosphere must present a very cold front, and this might suffer repulsion by the sun; but I have said enough to show how utterly in the dark we are as to the cosmical bearings of this action of radiation, and further speculation would be but waste of time.

It may be of interest to compare these experimental results with a calculation made in 1873, before any knowledge of these facts had been made public.

Professor Clerk Maxwell, in his 'Electricity and Magnetism,' vol. ii. p. 391, writes as follows:—"The mean energy in one cubic foot of sunlight is about 0·0000000882 of a foot-pound, and the mean pressure on a square foot is 0·0000000882 of pound weight. A flat body exposed to sunlight would experience this pressure on its illuminated side only, and would therefore be repelled from the side on which the light falls."

Calculated out, this gives the pressure of sunlight equal to about $2\frac{1}{2}$ lb. per square mile. Between the $2\frac{1}{2}$ lb. deduced from calculation and the 57 tons obtained from experiment the difference is great; but not greater than is often the case between theory and experiment.

In conclusion. I beg to call especial attention to one not unimportant lesson which may be gathered from this discovery. It will be at once seen that the whole springs from the investigation of an anomaly. Such a result is by no means singular. Anomalies may be regarded as the finger-posts along the high road of research, pointing to the bye-ways which lead to further discoveries. As scientific men are well aware, our way of accounting for any given phenomenon is not always perfect. Some point is perhaps taken for granted, some peculiar circumstance is overlooked. Or else our explanation agrees with the facts not perfectly, but merely in an approximate manner, leaving a something still to be accounted for. Now these residual phenomena, these very anomalies, may become the guides to new and important revelations.

In the course of my research anomalies have sprung up in every direction. I have felt like a traveller navigating some mighty river in an unexplored continent. I have seen to the right and the left other channels opening out, all claiming investigation, and promising rich rewards of discovery for the explorer who shall trace them to their source. Time has not allowed me to undertake the whole of a task so vast and so manifold. I have felt compelled to follow out, as far as lay in my power, my original idea, passing over reluctantly the collateral questions springing up on either hand. To these I must now invite the attention of my fellow-workers in science. There is ample room for many inquirers.

Nor must we forget that the more rigidly we scrutinize our received theories, our routine explanations and interpretations of nature, and the more frankly we admit their shortcomings, the greater will be our ultimate reward. In the practical world, fortunes have been realized from the careful examination of what has been ignorantly thrown aside as refuse; no less, in the sphere of science, are reputations to be made by the patient investigation of anomalies.

Parliamentary and Law Proceedings.

Chemists' Shops and late Refreshments.

Emil Guenin and Louis Hermann were on Thursday summoned before Mr. Vaughan, at the Bow Street Police Court for keeping a refreshment-house without a licence.

Mr. Pitt, who prosecuted on behalf of the Excise, said that the defendants were conducting a chemist's shop, at No. 7, Tichborne Street, at the top of the Haymarket. The police had complained that this shop was kept open till a very late hour at night, for the sale of drinks, known under the name of American ice cream sodas; that women of bad repute frequented this place, and that disturbances had ensued. The Excise officers had, of course, no suspicion that a chemist's shop would be used as a refreshment-house; but upon these complaints they made the inquiries which resulted in this charge.

Mr. Pitt then called two Excise officers, who proved that on the 20th of December, between twelve and one at night, they had been served with these American drinks, for which they payed 6*d*. each.

For the defence, it was not denied that the drinks were sold, but they stated this was a *bonâ fide* chemist's business. If the drinks were not sold the shop would be kept open as now until two o'clock for the sale of drugs.

Mr. Vaughan, in giving judgment, said that although the shop was a chemist's shop, still, undoubtedly, it was kept open at least two or three hours every night for the purpose of supplying all comers with these American drinks. And the evidence went to prove that these comers were very numerous. Mr. Vaughan then went on to read part of Lord Justice Mellish's judgment in the case of Howes. In conclusion, he said that by that judgment he was bound to convict the defendants.

In mitigation of the full penalty of £20, Mr. Reid, for the defendants, urged that the judgment in the case of Howes was very recent, and had not yet been published, so that the defendants had not had the means of making themselves acquainted with it.

Mr. Vaughan mitigated the penalty to one-fourth —namely, £5 and costs.—*Standard.*

[*** If reference had been made to the Register of Chemists and Druggists for 1876, a copy of which has, we presume, been supplied by the Home Office for the use of the Bow Street Police Court, it would have been found that no persons bearing the names of the defendants have a right to represent themselves as being chemists and druggists.—Ed. Pharm. Journ.]

Poisoning by Carbolic Acid.

On Wednesday, June 28, an inquest was held at St. Thomas's Hospital, before Mr. Hull, in view of the body of Francis Fraser Morris, 21.

Mrs. Julia Sophia Morris said she last saw her son alive in her own house at Walworth, on Sunday evening. He came suddenly into the drawing-room looking very strange and ill. Being asked what was the matter, he said, "I have taken carbolic acid, I shall die." He did not say why he had taken the acid. She persuaded him to take some hot mustard and water, but he got rapidly worse, vomited blood, and became too ill to speak. Mr. Martin, a neighbour, summoned Dr. Simmon, the family physician, under whose advice the deceased was sent to St. Thomas's Hospital, where he died shortly afterwards.

The Rev. Eli Morris was then called, and in answer to the Coroner, said his son had for years past been subject to fits of depression. He had discharged himself from his last situation six weeks ago, but had not told any one of it, and had gone out at his usual time every morning, returned every night as usual. Carbolic acid was never used in the house.

The house surgeon having given evidence as to the effects of the poison upon the deceased, the jury returned a verdict of "Suicide while of unsound mind.—*Times.*

Poisoning by a Liniment.

A case of accidental poisoning has occurred at Heywood, near Manchester, by which an extensive ironmonger, named Robert Porter, aged 40 years, has lost his life. Deceased had been suffering from an acute attack of rheumatism. Dr. Jameson visited him, and told him he would prepare him a liniment for external application, and the deceased must send to his surgery for it. Deceased has also been taking medicine for his ailments, and it would appear that his wife was not notified of the doctor's intention to send a liniment. At half-past ten in the morning she sent to the doctor's as usual for the medicine. Her husband was then in bed, and engaged in conversation with a friend. He asked for his medicine. The wife got the bottle containing the liniment, which was labelled, "for external use only," and gave her husband a tablespoonful of the mixture, which contained belladonna. Before taking the medicine deceased remarked that it was very bad. In a few minutes afterwards deceased fell asleep. Having left the two men by themselves, about half-past eleven Mrs. Porter went to look at deceased, and noticed that he breathed heavily. She immediately went to the doctor's house, and said that her husband had been worse since he had taken the medicine. The doctor, taken aback, replied, "The bottle which I gave your boy was for external use only." Medical aid was procured as soon as possible, but deceased expired at a quarter to one o'clock.—*Manchester Courier.*

Sale of Adulterated Starch.

At the Wandsworth Police Court, on Friday, June 30, Mr. John Bain, of the Balham Co-operative Stores, appeared to answer an adjourned summons for selling to the prejudice of Mr. Samuel Smith, the inspector appointed by the Wandsworth Board of Works, a quantity of arrowroot adulterated with tapioca. In this case the analysis of the Board's analyst was disputed, and the summons was adjourned to allow of another analysis to be made in the laboratory at Somerset House.

Mr. Corsellis, clerk of the Wandsworth Board of Works, said the certificate which he produced stated that the sample was adulterated to the extent of 50 per cent. The certificate sent from Somerset House stated that it was adulterated not less than 25 per cent. He had other certificates stating that the arrowroot was adulterated.

The defendant offered no defence. He wished to absolve the stores from all blame. He sold the article under a guarantee, and it was bought under a guarantee.

Mr. Ingham said he had no doubt the defendant believed he had got a genuine article. He fined him 5*s*. and 23*s*. costs, which he could recover from the person who supplied him with it.—*Times*.

Charge of Selling Adulterated Whisky.

William Brown, spirit merchant, was charged in the Greenock Sheriff Court, on June 30, with having sold a bottle of whisky which was not of the nature, substance, or quality demanded by the purchaser.

The inspector under the Sale of Food and Drugs Act, deposed that he had received complaints regarding the quality of whisky sold in the town. Captain Grant, of H.M.S. Aurora, complained of the whisky sold to the sailors and marines of that vessel; and certain whisky taken on board was sent for analysis. It was found to be bad whisky, but as the purchaser had not intimated, when he bought the whisky, that he intended to have it analysed, a prosecution could not be instituted. In consequence of that, he took samples from shops in the habit of supplying the men of the Aurora. The shop of the defendant was one of these. The case was before the court some time ago, when it was continued for a report of analysis at Somerset House. The report from Somerset House, now read, confirmed the analysis of Mr. M'Cowan, the local analyst, and stated that the sample of whisky had been adulterated with 427 grains of hydrated sulphuric acid in the imperial gallon.

The defendant stated that he never had vitriol in his shop. Never had anything called sulphuric acid. Was well aware that neither of these was put into the whisky that was in his shop. When a cask of whisky was broached witness was in the habit of tasting it. Never observed anything peculiar about the whisky in question.

The Sheriff, in giving judgment, remarked that the defendant was not charged with having adulterated the whisky, but he was charged with having sold it in an adulterated state, and there was little doubt that the prosecution had succeeded in proving that he had done what he was charged with. He considered it a case of gross carelessness, and would pass sentence of £5 with £5 expenses.—*Greenock Telegraph*.

Notes and Queries.

[514]. GREEN OILS.—Will any reader oblige me with a formula for Lockhart's Green Oils? It is much used amongst cattle. Have tried the old white oils with subacetate of copper, but the result is not satisfactory.—F. G. Holmes.

[515]. CISTERNS FOR STORING TURPENTINE.—Mr. John Porter would be glad to receive information as to the best material for the construction of cisterns for the storing of spirit of turpentine without its becoming coloured.

[516]. BRONZE LIQUID.—W. H. L. will be glad of a recipe for making "Bronze Liquid." It contains acid. sulph., acid. mur., etc., and is used for immersing brass goods in, after which they are blackleaded and then lacquered.

[517]. GOLD LABELLING.—"Omega" will be obliged if any one can give him the *modus operandi* of Gold Labelling, also the best means of affixing Gold Paper Labels.

Suggestions.

Sir,—I wish to suggest a new measuring glass which, I think, would be of service to chemists,—that is, a tubular glass, graduated on the same principle as Mohr's burette, and holding, say 20 c.c., with lip and bottom like an ordinary measuring glass, for use when the burette is engaged with standard solution. Also, if some of our makers of evaporating dishes would adopt the plan of graduating them as well, I think they would meet with demand.

E. H. Cole.

Lichfield, July 1, 1876.

Methylated Spirit.

Sir,—In reading the letters published by you on the above subject, it seems to me that druggists, as a rule, are not aware that the licence for methylated spirit is only 10*s*. 6*d*. per annum, by taking which they, of course, can protect themselves from prosecution on account of badly made "finish," and also give greater satisfaction to the public. Besides this, by once getting fined they sink as much money at five per cent. interest as will bring in the amount of the annual licence.

Richard Sturton.

Cambridge, July 3, 1876.

[*** We have reason to believe that the case is as you suspect, but are at a loss to understand how it can be so, since the necessity for a licence is stated in the appendix to the Calendar of the Pharmaceutical Society, and the sum to be paid annually for such license is specified.—Ed. Pharm. Journ.]

S. F. Nottingham.—See a formula in the Journal for Jan. 22 last, p. 598.

H. W. B. Baker.—If you are a "Student of the Society" you ought to receive the Journal regularly as published without further payment than your annual subscription. We do not see your name in the list of Registered Apprentices and Students of the Society in the Society's Calendar.

Communications, Letters, etc., have been received from Mr. Saunders (Montreal), Dr. Morel (Ghent), Mr. Wilkinson (Manchester), Mr. Corner (Paris), Mr. Fairlie (Glasgow), Veritas, A. W. P., G. O. S.

THE DIFFERENT SYRUPS OF THE PHOSPHATES IN GENERAL USE.

BY ERNEST C. SAUNDERS.

The difference in the quality and strength of different samples of the preparation known as Parrish's chemical food, as found in the market at the present time, has been the subject of considerable discussion during the past few months, but as, with the exception of Mr. W. L. Howie in his useful and practical paper, all seem to have devoted their energies more to finding out faults in ordinary samples of the preparation than to remedying them, I venture to submit the following remarks on this article, and the somewhat similar one of Easton's syrup, which is also difficult to make and to keep in good condition. I begin with Parrish's syrup as perhaps the most difficult to make according to the ordinary formula.

The chief reason for the difference met with in the various makes of this preparation is to be found in the fact that the principal published formula, that in Parrish's 'Pharmacy,' is an utterly unpractical one. It is well known that glacial phosphoric acid uncontaminated with phosphate of soda is hardly to be found in the market at present; but even if it were, it is next to impossible to obtain a good preparation with it, as it is a monobasic acid, while the direction to add "quantum sufficit" of hydrochloric acid is exceedingly vague. But apart from this, it is evident that the formula cannot be strictly followed, as if the quantity of ferrous phosphate directed to be present in each fluid drachm of the completed syrup is attended to, 32 troy ounces of sugar will have to be made into 36 fluid ounces of syrup—a manifest impossibility; while if the quantity given as the amount of solution to be formed for the sugar to be dissolved in is adhered to, the result will be about 46 fluid ounces of syrup, which will not contain the requisite amount per drachm of iron and lime. All the formulæ at present in use seem merely modifications of that given by Parrish. In the following form the author has only followed Parrish as far as the result to be obtained is concerned, viz.—that the finished syrup shall contain in each fluid drachm 1 grain ferrous phosphate $Fe_3P_2O_8$, $2\frac{1}{2}$ grains calcic phosphate $Ca_3P_2O_8$, and traces of sodic and potassic phosphates, with free phosphoric acid.

Take of—

Iron Wire, clean, No. 20 . . .	240 grains.
Syrupy Phosphoric Acid (Spec. Grav. 1·75)	3 oz. by weight.
Water, Distilled	4 fluid ounces.

Mix the acid and water, and dissolve the wire in the mixture in a flask, loosely stopped with tow; the hydrogen evolved then protects the solution from oxidation. When all action has ceased, heat to boiling point, and filter through paper in a funnel with a long neck reaching to the bottom of a beaker containing a little syrup, which floating on the iron solution will effectually prevent any oxidation.

Slaked Lime, Fresh	923 grains.
Phosphoric Acid (Spec. Grav. 1·75)	$9\frac{1}{2}$ oz. by weight.
Water, Distilled	14 fluid ounces.

Mix the acid and water, and dissolve the lime in the mixture. Filter the solution.

Crystallized Sodic Carbonate .	54 grains.
Potassic Carbonate	72 grains.
Phosphoric Acid (Spec. Grav. 1·75)	$\frac{1}{2}$ oz. by weight.
Distilled Water	1 fluid ounce.

Dissolve and filter. Then mix all the solutions, and having added distilled water to make the solution measure 28 fluid ounces, dissolve in it with heat, sugar, $3\frac{1}{4}$; powdered cochineal, 85 grains; and strain while hot. When cold add orange flower water, 2 fluid ounces, and sufficient distilled water to make the whole measure 64 fluid ounces. The product is a nice clear syrup, entirely free from sulphate of soda, or ammonic chloride, both of which are by no means uncommon impurities, from the difficulty of washing the precipitates, when the syrup is made in the old way, while the whole process will be found very much less troublesome and tedious. Calcic hydrate is generally sufficiently pure as commonly obtained, though where the chemist has the facilities for doing it, it is best for him to make the lime himself, by igniting precipitated chalk in a crucible at a full red heat for an hour.

I may remark here, though it does not exactly bear on the subject, that the last edition (1872) of Pereira's 'Materia Medica' contains the astonishing information, on page 213, that "Hypophosphite of lime is an important constituent in Parrish's chemical food;" a statement that is liable to mislead physicians in a serious manner.

Easton's syrup, is another preparation that is frequently badly made, and very often deficient in iron. The precipitate so frequently met with, in the form of phosphate of quinine, is, I think, always owing to the use of an acid containing metaphosphoric acid. I have never been troubled with a precipitate since I have taken pains to use only orthophosphoric acid, H_3PO_4. The change in colour is due to exposure to the air, chiefly from oxidation of the iron salt, but partly to the quinine changing colour. It may be entirely avoided, as has been often remarked, by completely filling the bottles in which the syrup is kept, and corking so as to have as little air left in the bottle as possible.

No trouble will be found in making a satisfactory preparation if the following form be strictly followed, and care taken to avoid exposure to the air of the iron solution.

Take of—

Iron Wire (No. 20)	240 grains.
Phosphoric Acid (Spec. Grav. 1·75)	3 oz. by weight.
Water	4 fluid ounces.

Dissolve with the precautions directed above in the formula for Parrish's syrup.

Quinine Sulph	625 grains.
Liq. Ammon.	
Distilled Water,	
Dilute Sulphuric Acid . . .	āā q. s.

Precipitate the quinine, secundum artem, and wash on a filter with a pint of very cold distilled water, press strongly, and dissolve in half an ounce by weight of phosphoric acid, diluted with an ounce of water in which 16 grains of strychnine have been dissolved. Mix with the solution of iron, add enough distilled water to make the whole measure 10 fluid ounces, and mix thoroughly with 54 fluid ounces of simple syrup. The resulting syrup will contain in each fluid drachm 1 grain ferrous phosphate $Fe_3P_2O_8$; 1 grain quinic phosphate $(C_{20}H_{24}N_2O_2)_3 2H_3PO_4$, and $\frac{1}{32}$ grain of strychnine.

These two syrups afford good examples of two classes of syrups that present considerable difficulties in manipulation with the formulæ in general use, which, I think, are quite removed in the two just submitted. Both have now been tested on a large scale, for some time, and found very satisfactory in their products. No originality is claimed in the use of metallic iron in place of precipitated ferrous phosphate; it was, I believe, first suggested by Mr. H. W. Jones, in the columns of the *Pharmaceutical Journal*. The chief point that I would press is the importance of using tribasic (ortho) phosphoric acid, H_3PO_4; both metaphosphoric acid HPO_3, and pyrophosphoric acid $H_4P_2O_7$, if present in the acid to even a small extent, are certain to cause trouble. The precaution given as to filtering the solution of ferrous phosphate will be found useful in many other cases; a beaker full of solution of ferrous iodide filtered in a similar manner, with a layer of syrup the eighth of an inch thick floating on the surface, can be left exposed for twenty-four hours without injury to the solution. It is, of course necessary that the solution should have the greatest specific gravity.

COLOURLESS TINCTURE OF IODINE.

BY WM. H. DARLING, F.C.S.

This preparation has from time to time attracted the attention of pharmacists, and various formulæ have been offered for its preparation, which differ widely as to the results they give.

Curtmann* made a series of experiments to determine the quantity of ammonia necessary to decolorize a fixed quantity of iodine with varying quantities of alcohol, and from these experiments he proposes the following formula:—

Iodine	10 drams.
Rectified Spirit	13 fluid ounces.
Strong Solution of Ammonia	3 „

He states the result of the reaction in such a mixture to be ammonium iodide and iodate, ethyl iodide, and iodide of an ethyl substituted ammonia.

Macmillan† objects to the use of ammonia because iodide of nitrogen or some iodine substituted ammonia is formed, which he appears to think simply dissolves as a whole, and therefore the greater portion of the iodine is rendered inactive. To avoid this he proposes the replacement of the ammonia by fixed alkalies.

In the supposition that the brown precipitate dissolves as a whole he is mistaken, for it is decomposed with effervescence, more rapidly in direct sunlight, shortly after its formation.

Hager,‡ referring to the experiments of Curtmann, proposes a modification of his formula by which a colourless solution may be obtained in a short time. The decolorizing agent he uses is sodium hyposulphite. The iodine, sodium hyposulphite, and water are gently heated until colourless, when ammonia and alcohol are added. A solution so prepared, he says, contains iodide of triethyl ammonium, which decomposes in course of time into triethylamine and ethyl iodide, with sodium iodide. There is no mention of iodate, which Curtmann states is present.

By neither Curtmann nor Hager is iodoform mentioned as a constituent of a solution of decolorized iodine. Indeed, Hager's formula does not admit of its formation.

Some time ago, when preparing a quantity of the colourless tincture of iodine, and before all the alcohol was added, a few spangles or crystals were observed in the almost colourless solution. As these had not been previously noticed, curiosity was excited as to the cause and what they were. When collected upon a filter, washed with distilled water, and allowed to dry, their colour was pale yellow and their odour recalled that of iodoform.

The quantity being too small (under half-a-gram) to admit of two combustions, one for the carbon and hydrogen, and a second for the iodine, the latter alone was made by burning a known weight in a tube filled with pure lime. The iodine being precipitated by silver, the following numbers were obtained:—

Weight of substance used—0·3946 grms.
Weight of AgI obtained—0·5990 = 0·32371 of I.
„ Ag 0·0482 = 0·05668 of I.
0·38039

$$\frac{0{\cdot}38039 \times 100}{0{\cdot}3946} = 96{\cdot}39 \text{ per cent. of iodine.}$$

The molecular weight of iodoform CHI_3 is 394.

$$\frac{3 \times 127 \times 100}{394} = 96{\cdot}70 \text{ per cent. of iodine.}$$

The physical character of the substance, its odour, and finally the close agreement, a difference of 0·31 per cent. between the calculated percentage of iodine in iodoform and that found, leave little doubt that the substance in question was iodoform.

If the reaction of ammonia with iodine in the presence of alcohol, omitting the formation of iodide of nitrogen from consideration, be viewed as analogous to that of fixed alkalies, the formation of iodoform is to be expected, and if this view be correct there should be little, if any, iodate present. Its formation must be preceded by that of ammonium hypoiodite, which would react with the alcohol, of which there is an excess, producing iodoform in the same manner as calcium hypochlorite reacts with the same alcohol forming chloroform. The formation of such a compound as ammonium hypoiodite is not a matter of conjecture, for Schönbein* states that it is formed when iodine acts upon an excess of ammonia.

The efficacy of the decolorized iodine must be attributed for the most part to the iodoform it contains. This iodated compound is an almost colourless substance, which contains more than nine tenths of its weight of iodine, but how far a solution of it alone will replace the ordinary decolorized iodine must remain to be ascertained.

THE TRADE CONFERENCE AT BIRMINGHAM.

THE Conference at Birmingham has been in every respect as successful as could be expected. The programme which appeared in our advertisement columns last week comprised a number of subjects which have a special interest for the trade, and the consideration of those subjects in the shape of papers had been undertaken by men whose ability was sufficiently well known to add an additional attraction to the opportunity of discussing them under such circumstances. The announcement that Mr. REYNOLDS was to occupy the position of Chairman of the Conference also furnished assurance that the proceedings would be conducted with strict regard to order and practical requirements. Punctually at the hour fixed for the commencement of the proceedings the spacious lecture hall in Needless Alley began to fill, and before midday arrived the meeting numbered one hundred and forty persons.

Altogether there were nine papers to be read and eight subjects to be discussed, besides the introductory remarks of the Chairman and the statement by Mr. WILLIAM SOUTHALL as to the origin of the Conference and its relations to the Pharmaceutical Society. These papers are published in full in our report, and the discussion of them was so skilfully managed that the whole proceedings of the Conference were concluded within ten minutes after the time that had been fixed.

As the establishment of an ample fund for defraying ordinary expenses of management as well as extraordinary outlay in carrying on special work is one of the points most essential for the existence of such an association, this formed an important feature of the proceedings, and a sum of between £200 and £300 was subscribed, partly by those present, and partly by others who were unable to attend, the amounts ranging from a few shillings up to ten guineas. In addition to this it was decided that the annual subscription of members should be fixed at the small sum of five shillings a year, in order to offer the utmost facility for becoming a member; and to prevent inequality among the members any support given to the Association beyond this annual subscription is to be given in the form of donations, and Mr. HOLDSWORTH, who acted in the capacity of Honorary Secretary of the Conference, will receive donations to the Fund, as well as subscriptions, and will enrol members until the appointment of Secretary to the Association has been filled up.

This adoption of an extremely moderate annual subscription is we think a wise step, for it will remove any possible grounds for not joining the Association, and as we have already remarked in speaking of this project, it is essential that the Association should have the active support of the great mass of the trade. Without this it will be impossible to take any such action in regard to matters affecting trade interests as would command the approval and satisfaction of the trade at large.

The number of members already enrolled amounts to about 400, and though this may not be unsatisfactory as a commencement it is at the utmost only one twentieth of the actual numerical strength that such an association should have in order to be able to do the work contemplated. The development of the nucleus that has thus been formed, to an association which shall be capable of representing the trade and protecting its interests, because it has the general support of those engaged in the business, will be an arduous task, and it will require the most strenuous efforts of those already enrolled to bring their brethren into active co-operation with them.

We dwell upon this point not with any motive of discouraging the enterprise that has been put in motion by the Birmingham Conference, but solely because we are deeply convinced of the indispensable need for a foundation co-extensive with the trade itself in order to ensure the power of defence and guardianship which it is desired the Association shall possess and exercise. If this power should eventually be acquired, and the entire body of chemists and druggists united in the effort, as well as the desire to promote their common welfare and protect their mutual interest, another important step will have been taken in the advancement of pharmacy, and chemists and druggists will be indebted to Messrs. SOUTHALL BROS. and BARCLAY for having instigated the realization of that object of the founders of the Pharmaceutical Society which concerns the material well being of the trade in like manner as they are indebted to JACOB BELL for the services he rendered in the formation of the Society, and to the founders of the Pharmaceutical Conference for having established a means of scientific cultivation and genial intercourse which has been productive of vast improvement, both intellectually and socially.

We fully agree with the opinion that it is doubtful whether the educational and examining body which governs the practice of Pharmacy ought to run the risk of rebuff and failure that a trade association will be sure to incur. But in the same way that the formation of the Pharmaceutical Conference has served to supplement the work of the Society and make it stronger than before it seems probable that a thoroughly well supported Association for dealing with purely trade objects may also be useful in itself and in promoting the general good of pharmacy.

TRADE CONFERENCE AT BIRMINGHAM.

On Tuesday last, the 11th inst., a Trade Conference of Chemists and Druggists was held at Birmingham, in the Hall of the Young Men's Christian Association, Needless Alley, New Street. The proceedings commenced at 10 A.M.

Mr. BARCLAY (Birmingham) said: On behalf of the Provisional Committee, I have much pleasure in proposing that our friend Mr. Reynolds, of Leeds, take the chair at this meeting. I am sure we shall all agree that he is the right man in the right place. He has been already the author of one successful conference—the Pharmaceutical Conference—and I am sure that his presence here to day will add very much to the prospect of success of this Conference. Mr. Reynolds's wide experience both in trade matters and also in scientific matters entitles him to our heartiest respect and confidence; and I am sure we shall all very readily agree with any decisions he may come to in guiding the business of the meeting.

Mr. HOLDSWORTH (Birmingham) seconded the motion and it was carried unanimously.

Mr. RICHARD REYNOLDS, F.C.S., then took the chair.

Mr. JONES (Leamington): I have great pleasure in proposing the next resolution, which is that Mr. Barclay be appointed Vice-Chairman, and that Mr. Holdsworth be appointed Secretary to the Conference.

Mr. RIMMINGTON (Bradford) seconded the resolution and it was carried.

The CHAIRMAN: On the programme of this day's business you will notice a paragraph on the subject of reporting. It is stated there that as soon as the Chairman is appointed the provisional committee will recommend that the proceedings be only reported so far as the Conference deems desirable. Now, gentlemen, in a meeting of this sort—a gathering of the trade for purposes which are strictly confined to that trade, it is essential and it is for the interests of the trade that we should retain such a power in our own hands. This is not a public meeting and therefore we cannot be asking anything unreasonable to retain such a power. I am quite sure it will be with your permission that the editors and representatives of the two trade journals, the *Pharmaceutical Journal* and the *Chemist and Druggist* are admitted to these proceedings. We know that we can rely upon the discretion of the conductors of those journals. We see here their representatives and I ask you to express your approval of their being permitted to attend.

The Chairman's suggestion was unanimously approved.

The CHAIRMAN then made the following opening remarks:—

I accept the appointment to act as your chairman today as a duty owed to the common cause in which we are interested, and I offer you my grateful thanks for the personal good-will you have shown me. I would that you had placed the trust in stronger hands, so that in surveying and mapping out the features of the new subject before us you might have had the experience of some one of our leaders, entitled to be termed *facile princeps* from a combination of veteran sagacity with intimate knowledge of the steps of past legislation affecting us. The circumstances under which we meet for a day only will impress upon us the value of time, and no speaker must waste its ever-falling golden sands. I shall endeavour to fulfil this obligation to brevity. Upon the origin of the Conference we shall immediately have the pleasure of hearing a statement by Mr. William Southall, one of the gentlemen to whose energetic determination we owe this gathering. I am aware that in some quarters the initial difficulty of the movement has been the manner in which it was suggested. I need not conceal the opinion that support has been withheld in certain directions because of this mode of initiatory procedure. But, from the moment of the organization of a Provisional Committee, and even more emphatically from the time of the assembly of this Conference, the movement has been an open one, conducted on the ordinary principles of English associations. The degree of success achieved in bringing together this meeting entitles the prime movers of the Conference to our heartiest thanks. The responsibility is now ours. Let us not separate without founding an association which shall bring to a focus the latent powers of chemists and druggists in defence of their legitimate interests. Your Provisional Committee has done well in reprinting the opinions of our trade journals on the subject. We are glad to have their cordial support so far, and recognize the great power which their conductors wield in promoting agreement of opinion amongst us upon any line of policy. You will have read the remarks of the editor of the *Chemist and Druggist* upon the various reasons alleged by those who see no necessity for either a Trade Conference or a Defence Association. This criticism upon the critics has more piquancy than any phrases in which I could hope to clothe similar ideas, and I trust it will be considered by those concerned. Objectors have told us to stay our hands because already two associations exist capable of doing the work, viz. the Pharmaceutical Society and the British Pharmaceutical Conference. Gentlemen, I ought to know something about both these institutions, and the first idea recalled from the depths of my memory is that the same objection, in the same words,—aye and by the same objectors in some cases,—was brought against us when we founded the British Pharmaceutical Conference. Many a moral might be drawn from the short life history of that Conference. Do you doubt the power of chemists for effective combination? Look at that Conference, and its successful results, including its highly profitable (in two senses) 'Year-Book of Pharmacy.' It has done for the trade throughout Britain what our local associations can do for our larger towns only, in making chemists know and respect each other, and work together for their common good. But for its influence, I will venture to say that to-day's meeting would never have been held. Let me finish the subject of the British Pharmaceutical Conference before dealing with its elder sister. Its constitution is not a very rigid one, and it may assume considerable variety in aspect, according to the wish of its members. I hold that it would be an absurd position, if, when a trade question united us in feeling, we should fail to exercise some opportunity of using our influence effectively. I remember the action of the Conference at its meeting at Norwich, when it memorialized the Board of Inland Revenue on some of the abuses existing in relation to methylated spirit. But, whilst commending to members of that association the policy of not allowing this right to be lost by abeyance, I am sure that it is not feasible that the British Pharmaceutical Conference should charge itself with the general duties of a trade association. Such functions would involve a dual staff of honorary officers, for what Presidents could it find who would be "always good alike," whether recounting the advances of pharmacy, or guiding defective movements of trade policy? and for what compensatory success would the Conference part with its senior Honorary Secretary, Professor Attfield? The Pharmaceutical Society stands on a very different footing. Mr. William Southall will undertake the consideration of this subject, and I have no wish to anticipate him. Let me say, however, that so far as the Charter and the various Acts of Parliament confer power on the Society, the policy of its Council should reflect the judgment of its members. Gentlemen, I believe firmly in the representative principle of government, more especially as the intelligence of the constituents is of the higher order. Until the Society forfeits the recognition of its reasonableness, any representations which it may make upon state policy in relation to pharmacy, will, if supported in an earnest manner, be likely to receive attention from the authorities. Therefore, in the prevention of new abuses, and perhaps in the reformation of some old ones, we must recognize the power of the Pharmaceutical Society as the most potent within our command. The onus of showing cause against the exercise of this power must usually rest with the objectors to its employment. The chance of our motives being misunderstood must count for little. A body of men who have complied with the educational requirements of the state so far as have the chemists and druggists, with a very slender compensation *per contra*, have the right to be heard on any case of injustice to their order. The conclusion which I draw from these opinions is that when we have fixed upon a line of trade policy, we must take care to send to Bloomsbury Square representatives who share them, and who can give them effect. I rejoice to see amongst us to day many of our present representatives, who most fully answer this description. In relation to the duties of the Pharmaceutical Society, I should be glad if some practical suggestions come before us upon the late conviction for the sale of milk of sulphur. This case must have great interest in this district, and a miscarriage of justice will have happened if legal technicalities should prevent its being carried to a higher court. In Leeds, we had the same question raised more than a a year since, and the judgment of our stipendiary, I am happy to say, was exactly the reverse of that just given at Birmingham. The infatuation of certain public analysts is almost beyond belief. *Quis Deus vult perdere, prius dementat* is suggested by the indiscretions of some of them. That they have supplied one important reason for this Conference is beyond doubt. The subject of patent medicines will be brought before us, and this is quite justified by the various changes that have taken place in this branch of business, during the past few years; changes not only in the cost of the patent medicine licence, but in the circumstances of their distribution by retailers. Many of us would be glad of more light upon the question and I think that the exchange of information will be at present a wiser course than any very dogmatic expression of opinions. As to the recent fashion amongst fashionable people and others to take part in keeping retail shops without becoming shopkeepers there must be many here who desire to relieve their minds. I am not of the class who will offer them Job's comfort and ask *cui bono?* Freedom of trade is all very well, and it may form a general basis of our arrangements of social economy, but any precious idea of co-operation that is incorporated in the scheme of the stores would be a very poor safeguard against monopolies, as compared with the fair and equal competition from which we do not shrink. That the Government, whether liberal or conservative, should blink the question of its paid servants combining to undersell the ratepayers, shows that we live in a very free country, but the question to come forward some time must be, How long will the ratepayers submit to this? The chest of tea bought *en bloc* by the post-office clerks, and divided by them, has some historic significance, even if less important than those earlier chests that found their end in Boston Harbour. The taxgatherers of some ancient nations were noted for rapacity and unscrupulousness, but they are not recorded to have had the audacity to give their name to shops or stores. Mr. Hampson will lay before us his views upon the legal action which may be possible in relation to the stores, and I will not anticipate them. In the provinces there are social influences which may check the extension, and probably terminate the existence of many such bodies. But a general consent to put these influences into operation is needed. For the position of the question in London, I will not presume to speak, but Sir Thomas Chambers' motion on Civil Service Trading would not have been cynically counted out of the House of Commons if both London and the country had first taken counsel. The programme now in your hands details the other papers to be read by gentlemen who have been good enough to undertake this duty. The outcome of our deliberations to-day ought to be a trade association, but I will ask you to look for a moment at some of the difficulties that will surround this. They will arise, firstly, in the different views which members may take as to its functions. As age creeps slowly but surely over societies, the active becomes changed for the passive mood, but the danger of indifference is not that which I foresee as the earliest. Too much zeal is a still more mischievous quality, and it will be well that no false hopes should be raised in the minds of those who are disposed to this error. Let no one suppose that we want an association which will receive five shillings as a subscription, and will proceed forthwith to harry the subscriber's enemies and guarantee him a snug preserve. Funds will be needful, but the money need not burn our pockets until it gets transferred to those of the lawyers. If defence and not defiance be a leading principle, there will be considerable irregularity in the work to be done in different years. External circumstances will determine this to a great extent. In conclusion, gentlemen, let our discussions to day be business-like and kept to the point, each of us disposed to concession if needful for the common good, for that we wish it well we have all pledged ourselves by coming here to-day.

Mr. Barclay announced the receipt of letters of apology from some of the Liverpool delegates, Messrs. J. A. Turner, A. Redford, A. E. Tanner, J. Abraham, and D. Wharrie; from Messrs. J. R. Robinson (Dewsbury), A. W. Postans (London), J. A. Jeffrey (Cheltenham), T. Cooper (Leicester), J. M. Fairlie (Glasgow), and others. Those gentlemen expressed strong sympathy and their regret that from various reasons they were unable to be present. The circular, which was sent out to 298 local secretaries and secretaries of Chemists' Associations, was answered in the following way:—No returns as to whether a Conference was desirable or not were sent from 9 places. There were unfavourable replies from 6; indifferent 38; favourable 145. In answer to the question, Would a deputation attend from your district?—there were no returns from 7; 22 districts promised to send delegates; doubtful 30. The names of towns which were either represented at the Conference to-day, or had promised to be represented, were Liverpool, Birmingham, Leeds, Halifax, Sheffield, Leicester, York, Wolverhampton, Dewsbury, Sunderland, Taunton, Bridgewater, Hull, Exeter, Shrewsbury, Leamington, Cheltenham, Henley-on-Thames, Coventry, Rochester, Cradley, Hinckley, Riddings, Chesterfield, Derby, Bradford, Hampton-in-Arden, Clay Cross, Hay, Ruabon, Rhos-y-medre, Longton, Birkenhead, Lye, Shipley, Buxton, Oldbury, Banbury, and Bloxwich. In answer to the questions, Are there any unregistered persons practising as chemists and druggists in your district? and if so, how many?—the replies were, unregistered persons, in 21 places; none in 127 places; and no returns from 50. The various suggestions which had been made from the chemists throughout the country had been embodied in the programme which the provisional committee had already put before the Conference. The provisional committee having met, and having all the data before it decided upon the programme which had been sent to every chemist in Great Britain. A circular had also been sent to the members of the Council in London some of whom were present while others had sent letters of apology.

In the absence of Mr. William Southall, the Secretary read the following paper by that gentleman:—

The Origin of the Conference and its Relations to the Pharmaceutical Society.

If any apology be required from me as a member of the firm which has been instrumental in bringing about this Conference, I should like to say that as Local Secretary of the Pharmaceutical Society, and also as connected in business relations with a large number of druggists up and down the country, it has been my lot from time to time to hear a good deal of the troubles and grievances of our brethren. Some of these may be imaginary but others are very real, and it seemed to our firm that the time was ripe for a Conference on trade matters in general, if some one would only take the initiative. This we have done, and by way of explanation I have strung together a few notes on the general condition of the trade that may serve to explain the position we have taken. Although not very old I am old enough to remember the profession of pharmacy in a very different position from what it now is. The druggist of my early days was an old-fashioned character altogether compared with the pharmacist of the present; and although we hope the process of selection, natural or artificial, may extend a little further, we had even then advanced beyond the condition in which a first class chemist, like the preceptor of John Bell, was in the habit of subduing the too powerful properties of powdered nitre before it was fit for sale. Druggists in my early days were just taking the alarm. Mr. Hawes by his bill in Parliament had startled them out of a reposeful state, and they must either do the requisite work for themselves or it might be rather roughly done for them. At that time there were, as at present, men who were excellent pharmacists and in the quiet recessses of whose back shops important discoveries had been made and light cast upon chemistry and pharmacy, but the rank and file were but an ill-educated body, and there was a good deal that wanted rooting out as well as fresh planting. Nor was this to be wondered at, for the school at Bloomsbury Square did not yet exist, and the tutorship was confined to the back counter; Anthony Todd Thompson was the great light of materia medica, for as yet Pereira's fame had hardly reached us. The old edition of Gray's 'Supplement,' Turner's 'Chemistry,' and a few medical books, together with the Pharmacopœia, constituted the druggist's library. As yet there was no "Journal," or *Chemist and Druggist*, to diffuse, weekly or monthly, pharmaceutical "sweetness and light" through the land. The times needed a master mind, and one arose equal to the occasion. Jacob Bell, enlisting under his banner the intelligence of the trade, contended nobly against opposition from within and from without, and his efforts were ultimately crowned by the establishment of the Pharmaceutical Society and the passing of the first Pharmacy Act. Now it is not my business to trace the history of the Pharmaceutical Society, or of the chemist and druggist under the Pharmacy Act, and its various modifications; it is known more or less to most present, and it is certain that a most important change has been effected. The various Presidents of the Society may well refer in their annual addresses with pride to the results which a comparatively few years have seen effected; whilst the rising chemist of the present day may thank the Society that, through its efforts, his position is exalted from that of a mere trader to a member of an educated and scientific profession.

It is true the title is not accorded to us, but that is not of much moment. We owe more than many are perhaps willing to admit to the Pharmaceutical Society, and it is our bounden duty to support and strengthen it by all the means in our power.

Now let us refer for a moment to the chemist of thirty or thirty-five years back, and we find him very differently circumstanced from his successor. In these earlier days he was a worthy or of course sometimes an unworthy man according to his lights, but things went on very easily as far as interference from outside. He took it easily at home too, for new preparations and new "patents" did not spring up in the mushroom crop they do at present, and if people wanted new things they must wait for them.

London was then as far off from Birmingham as Paris is now, and as for small country places, they might as well have been at Timbuctoo. Then, by way of preparation for business, a shop boy could pick up a little Latin behind the counter, and in due time he acquired knowledge enough to enter business on his own account. At present responsibilities begin with his apron. He must read Cæsar and have a fair general knowledge to begin with. But I do not stay over studies, examinations etc., they are merely matters of money and brains; the money is well spent and ought to be an excellent investment in whatever way you look at it, whether by having gained ability for trade, or increased intellectual powers for the usefulness and enjoyment of life. There are, however, now-a-days responsibilities which were never thought of in old times. Let us consider a few of them. First come certain laws, which whether or no they be terrors to evil men, are certainly terrors to good ones. A conscientious pharmacist is afraid of infringing the provisions of the Sale of Poisons Act; he perhaps wakes up at night after a doubtful twopence-worth of laudanum has passed over his counter, assured that somebody has been poisoned. Then again the more careful he is to avoid the claws of the Adulteration Act, the more fearful is he lest some article should unfortunately have escaped his careful revision and be pounced upon to his eternal self-condemnation. And now, according to a recent number of the Journal, we hear of a new terror. The inspector of weights and measures sends to a druggist for a test prescription, so called, to be made up, and it is forthwith handed to the analyst, who pronounces that one article is in excess, and the unfortunate dispenser is fined 50*s.*; the case cited, however, seems to need further explanation. Now correctness is the very backbone of our position, and as honest men we are willing to have our work examined, but the analysis of a complicated mixture is not unlikely to be attended with error, and how is the ordinary chemist to defend himself unassisted? The confidence of the public is destroyed and the fine of 50*s.* may become one of £50, and it is questionable whether this accords with the intention of the legislature.

Next comes Lord Campbell's Act, which makes a man responsible in damages for the errors of his assistants as well as of himself, a most grave responsibility to the druggist. All these new responsibilities are additions by law to the serious and always increasing responsibility that naturally attaches to the proper carrying out of our business.

Let us now turn to the *quid pro quo*. Have we got it? As far as a return for our improved education goes, and in most of our internal relations which have been subjected to change, we either have it, or it is in a fair way of realization, though some may think the good time rather long in coming. Apprentices it is true are scarce, and assistants' salaries are higher, but the rise in remuneration will probably increase the supply, whilst the tendency of the examination will certainly be to restrict the number of men entering into business and at the same time the number of those in business before 1868 will continue to fall off. So far the benefits in return for our internal legislation! But how do we stand in the general way of our trade? Surely every one here will say that the pharmacist being so heavily handicapped with laws and regulations ought to be fully protected in the legitimate exercise of his calling. We find, however, that he is hustled and interfered with. The character of a chemist's business varies very much in different places; but it is impossible that he can, as a rule, make a living by dispensing and the sale of drugs alone without the addition of sundries. Here he finds that he is interfered with by the grocer, who, in addition to many articles that may be free warren, has robbed him of the sale of many—such as extract of meat—which were his own introduction. Then the haberdasher sells perfumes, a very old adjunct of a chemist's business. This, however, is all legitimate, though it may be painful in our struggle for existence; we find, however, that the grocer and others sell patent medicines containing drugs subject to the provisions of the Poisons Act. This certainly requires looking into. Then there is the Co-operative grievance, which presses heavily upon many of our brethren. For my part I always consider co-operation a mild sort of communism, and communism, whether in Paris or Westminster, means getting what you want without paying full value for it. If there must be a community of goods it should not be confined to a few shopkeeper's articles, but should be the whole thing—the red flag and common property in land above all. The aristocrats of the Haymarket might then find they had burnt their fingers. Nay, some advanced philosopher might judiciously hint at social community also, and recall the happy days when, if I recollect, Cæsar said of our ancestors, "*Uxores habent inter se communes, fratres cum fratribus.*" But you will hear presently about cooperation. Next, we have the altogether unlawful carrying on of the business by people whose names are not upon the Register. This seems to be a growing evil, and I regret to say that the efforts of the Society to put a stop to it appear to fall far short of the requirements. As local secretary I have been found fault with for inefficiency when the blame did not lie at my door. It is not, moreover, the place of any chemist, local secretary or not, to take upon himself the office of detective and virtual prosecutor; a society may do it, and upon an officer of that society, and not upon the aggrieved neighbours, should fall the duty of getting up the evidence. In connection with this arises the further question, are the laws that govern our trade such, that whilst fully protecting the public interests, they are also the best we may justly claim for our own protection? There are other matters of material import, also, well worthy of consideration, but I have said enough to show that the Conference does not come together without reason. Some will doubtless say, "The Pharmaceutical Society is the proper body to look after our interests." Well this may be so, but we require a fulcrum to move the Society; for any powerful institution that has done a great work is apt in the course of years to settle down in a comfortable state, and to inhale the pleasant aroma of finality. Therefore a little ventilation of these matters in the free air outside the walls of the city may do no harm. For my part I am most desirous that the Pharmaceutical Society should take up the work that the Conference desires to see accomplished, but I am somewhat doubtful if the great educational and examining body of our profession ought to run the risk of rebuff and failure that a trade association will certainly incur. The Pharmaceutical Conference has not only safely floated off an immense amount of scientific work from the elder society, but has left it stronger than before. Why should not a Conference that deals with trade objects purely be also successful?

To ensure success, a trade conference must not clash with the Society, but it must be largely and thoroughly supported to be of any use. At all events there is a good deal wants talking over at the present time; and to those who would say, "Better keep quiet and let these things alone," I would observe that to my mind there is a great deal of quiet wisdom and wit in the words of Dr. John Richie, at the time of the Scotch disruption. "Agitation!" said John "what good in the world was ever done without agitation? You cannot even make butter without it."

The Chairman: I think our thanks to the readers o the papers had better be made to each, and although Mr Southall has been unable to be present I am sure you will all feel much indebted to him for his paper. The arrangements made for discussion are, that the reading of a paper is not to exceed twenty minutes, and no speaker is to exceed ten minutes without the permission of the Chairman.

A Delegate suggested that discussion on Mr. Southall's paper should be deferred until some of the other papers had been read.

The Chairman approved of the suggestion, and said that unless any one desired to make any remarks he would call upon the reader of the next paper.

Mr. J. C. Thresh, F.C.S. (Buxton), read the following paper:—

The Condition of Chemists and Druggists under the Pharmacy Act.

The object of this necessarily brief and hastily compiled paper is to indicate the restrictions, responsibilities, etc., imposed upon us as a class by the Pharmacy Act of 1868; to inquire how far this Act is responsible for our grievances; to ascertain what benefits we are at present deriving from it; and to offer for discussion certain suggestions, whereby to attempt the removal of most of the grievances of which we now complain. It is notorious and certainly to be lamented that ever since the Pharmacy Act became law it has formed the subject of continual complaints, since it imposes upon our shoulders numerous burdens, for which it gives us but little in return.

When the Pharmaceutical Society first introduced the Bill it encountered a great amount of determined opposition; many real and imaginary objections were raised against it; some denied the necessity of any interference from the State, and others foresaw the results most likely to accrue from the enforcement of such a law; but the majority listened to the voice of the charmer, and believed in the brilliant future and in the immediate and prospective advantages which the Society and the advocates of the Bill predicted would accrue to the chemist and druggist should it become law.

It will materially assist us afterwards if I now briefly state the chief results which we were so confidently assured would flow from the Pharmacy Act, as we shall then the more readily discover how lamentably up to the present time it has failed to fulfil the objects for which it was promoted. The Bill was intended to secure the greater safety of the public by confining the sale of poisons and dispensing of medicines to properly qualified persons, and in return for the restrictions to be placed on the sale of these certain poisons, and in compensation for the study, for the time and money, which in future would have to be expended before any one could qualify himself to carry on the business of a chemist and druggist, we were promised—

(1) A monopoly in the sale of poisons and in the dispensing of prescriptions.

(2) That in the course of time the grocers and petty dealers who would have to be and were placed on the register, would diminish in number from death and other causes, and that thus ultimately the whole, or nearly the whole, of the dealing in drugs would be in the hands of the legitimate chemists and druggists.

(3) That in consequence of the examinations the number of young men entering the trade would decrease, and the number of chemists in proportion to the population would consequently decrease.

(4) That our ranks would in future be filled from a better class of men, and that this, together with the examinations, would confer upon the chemist a much higher status in society than he had hitherto enjoyed.

In return for these advantages, the only burden or restriction on the chemists then in business was to be the labelling certain articles after the manner specified by the Act, and the registration, etc., of the sale of certain other poisons, under pain of incurring a heavy penalty in case of neglect or wanton infringement.

It is now eight years since the Act came in force, and we have had ample time, therefore, to judge of its working, to ascertain our present condition under it, and to arrive at positive conclusions as to whether it has answered the expectations of its introducers, and the purpose for which it was passed. I think there are very few who will venture to affirm that as yet it has either secured the greater safety of the public or conferred upon us any real advantages for what we have found to be the irksome restrictions placed upon us.

First, then, is the safety of the public greater than it was before? Now the answer to this question involves answers also to the following:—

Can poisons now only be obtained of duly registered chemists and druggists?

Are prescriptions dispensed solely by competent and qualified persons?

Now the answer to both these questions is most emphatically, No. The obtaining of poison by any person and for any purpose is scarcely more difficult than it was previous to the enforcement of this Poison Bill, and the dispensing of prescriptions is not the monopoly of the chemist; and both these assertions can easily be verified. Let any one carefully examine the cases of accidental poisoning, and of suicide, and murder by means of poison, and such an one cannot fail instantly to be impressed not only with the ease with which these things can be obtained but with the almost impossibility in many cases of ascertaining when and where they were obtained. We do not wonder that this is so, for it is notorious and forms just ground for complaint that in every town and village in the kingdom we are being openly defrauded by the sale of poison or of preparations containing poisons by unregistered chemists, grocers, hucksters, and others. Instead of the number of these petty dabblers in drugs having decreased they have considerably increased, for everywhere may be found dealers in sand, blacking, and physic, who if they do not openly sell laudanum, chloroform and other poisons in the pure state, yet vend in enormous quantities mother's friend, infant's cordial, cough syrups, ointments, etc., which contain these poisons. I know certain densely populated localities in which every fifth or sixth house is a kind of shop, in almost every one of which there is sold articles of this kind. How does this state of thing affect us? It may possibly be thought convenient by some classes of the public, but it certainly is not to their benefit, and the amount of legitimate trade of which we are defrauded by these shops is almost incredible.

Again the number of men who without passing any examination or possessing any qualifications whatever are openly or covertly carrying on the trade of chemist and druggist, appears to be on the increase. Medical botanists, wholesale chemists, medical halls, drug stores, etc., are being opened out in all directions, and either the Act is unable to cope with them or, as I am inclined to think and the majority of others with me, those upon whom up to the present the duty of enforcing the Act has fallen have failed properly to enforce the Act. The Pharmaceutical Society has exhibited a truly laudable zeal in raising the standard of qualification as high as possible, and thus decreasing the number and shall I say increasing the quality of those entering our trade (or profession as many would like to call it), but I fear it is far from being generally credited with showing the same amount of zeal in protecting their interests when they have entered the trade. This, however, is a question which it would at present be useless discussing.

Many of these stores not only deal in poison but dispense prescriptions, and to obtain a trade generally begin by cutting down the prices, and thus not only compete illegally but unfairly with the legitimate chemist. There is not time to go into the various devices which these men adopt to keep as they think beyond the arm of the law; they can be considered when we are ready to vindicate our rights and eradicate the parasites. The various trade organs have frequently of late contained letters from correspondents complaining of this unfair competition and illegal trading, but they have chiefly dealt with unregistered retailers, the petty wholesale chemists rarely being mentioned, and yet in many localities these do considerably more harm that the former class. These wholesale chemists are generally assistants who have got a smattering of the so-called wholesale trade from being with some chemist who cultivated the suicidical business of supplying grocers with drugs. Many of this class keep open shop, and their wholesale dealings are made a cover for as much retailing as they can possibly do, whether it be in the sale of pickle, blacking or poison. I know instances of this kind, and I know the result it has upon the trade. People knowing that they can purchase small quantities of anything they require from these wholesale druggists, conclude they can do so at wholesale price, and to keep up this profitable delusion, the dealer reduces his prices and also his quality below that of the legitimate chemists. But this is not the only way in which we are openly defrauded by wanton infringement of the Acts designed to protect us. There are the men who, unable to compete with the established chemists who cultivate a grocers' connection, induce every little shopkeeper and huckster to deal in drugs, with ruinous result to the chemists in such localities. Towns which should support a dozen chemists in comfort afford only a bare existence to two or three. One may ask how is it that people, and working people I now more especially refer to, prefer purchasing drugs from the small shopkeepers rather than from the legitimate chemists. There are many reasons for this, one of which is that they cannot get physic from the chemist on credit, whereas by getting it where they purchase their weekly supply of food or sundries they obtain it with the same credit; but the chief reason is that it is cheaper. How is it that these small dealers can buy their few shillings worth of drugs from small wholesale druggists and yet afford to sell them for less than the chemist? These people will have a good profit upon them or they would not deal in them. The fact is the drugs sold at these shops are of the very worst description, bought at a much less price in small quantities than we can really buy genuine drugs at in large quantities. I do not make this accusation rashly, but deliberately, from an intimate knowledge of the trade and from the examination of drugs purchased from these wholesale druggists and sold by their customers. To find sweet nitre having a sp. gr. of 900 and upwards is the rule, and all the tinctures contain about half the official proportion of spirit; light carbonate of magnesia is sold as calcined, and syrup of lime blue for syrup of violets, and so on through the whole category of drugs. This question may seem at first foreign to the subject with which I am dealing, but I contend that it is not, since it is the result chiefly of the maladministration of the Pharmacy and Adulteration Acts, and I hope shortly to show how, by the proper enforcement of these Acts, nine-tenths of this infamous traffic may be stopped. But this class of so-called chemists are the source of still greater and more urgent cause of grievance by inducing the shopkeepers for the sake of increased profit to themselves to take up the sale of cough mixtures, cholera mixtures, rubbing bottles, infants' cordials, ointments, etc., so on *ad nauseam*, nearly all of which contain one or more of the poisons mentioned by the Pharmacy Act, and the exclusive sale of which is supposed to compensate the chemist and druggist for the restrictions placed upon him in his business. I have known dozens of gallons of cough mixture containing large quantities of chlorodyne or laudanum sold under the names of raspberry cough syrup, balsam of honey, and the like. Cholera mixtures invariably contain opium; so also does the infant's friend or cordial. Family ointment is usually a preparation containing white precipitate, and golden ointment a preparation with red precipitate. It must not be supposed that these cases are rare, for although flourishing more in certain localities than in others, yet there is probably not a town or village throughout the kingdom in which the rights of the chemist are not being infringed by the sale of these poisonous preparations. It is only occasionally that the attention of the public is drawn to the danger of using these medicines, as when a child is given an overdose of infant's friend, and does not recover, and then even the chemist has to stand by without defending his rights, and has to see the illegal sale of these things continued simply from the lack of some power to move the law to put an end to it.

The registration of the sale of poisons by chemists and the distinctive labelling as poison of such preparations as have not hitherto been considered such, is in itself a source often of much annoyance.

The signing of his name by the purchaser appears to be very little trouble either to him or to the retailer, but somehow or other the British public has a decided objection to signing its name, or to informing others of its intentions, consequently people look out for other places for purchasing poison where they will not be asked to sign their names or to enter into details as to the purpose for which they require them. As a consequence we find grocers and others dealing in rat and mice poisons, arsenical sheep dips, etc.; and as familiarity breeds contempt, so the evasion of the law, which at first is done surreptitiously, ultimately is done openly, to the serious loss of the chemist, who is thus again partially deprived of one of the few advantages the Pharmacy Act can confer upon him.

The subject of co-operative and civil service retailing and dispensing, I need not touch upon, as it is to be dealt with by an abler hand than mine. It is a subject worthy of serious consideration, for it more or less affects us all, since in the smaller towns many of the inhabitants are joining these societies and obtaining their drugs and medicines with their groceries.

Now let us return to the other advantages which we were to derive from this Act, namely that of the decrease in the number of chemists, and of the higher status of the trade. It is true that for some time there has been an increasing difficulty in obtaining intelligent, well educated apprentices, and one would infer that this argued a future decrease in the number of chemists. The parents of boys who can afford to give them an education fitting them to pass our Preliminary examination and thus to prosecute their future studies with a surety of success, find that for a trifling extra outlay they can place them in the medical profession; and since in the first case the result is only a chemist and druggist, whose status as yet is regarded as but little or nothing above that of his neighbours the grocers and drapers, and who if he has all his rights enjoys only the poor monopoly of the sale of a few poisons and the dispensing of medicines, in the second, the result is the enrolling of his son's name in that of an honourable profession with position and prospects far above that of a chemist. The worst result of this scarcity of respectable youths is that the poorer class of chemists are, to carry on their businesses, compelled to take as apprentices youths of whom there is not the slightest probability of their passing the examination; subsequently these are thrown upon the world as unqualified assistants, to ultimately become unqualified dealers in drugs, infringers of the law, and increasers of the illegal competition to which we are already subject. The opinion of many chemists is that the examinations are too stringent, more so than was contemplated when the Act was first framed. I hold, however, that the examinations are not a whit too stringent to prove the competency of a man to dispense and retail drugs, but I do contend that for the time and money requisite to be expended, before one can become a qualified chemist, we obtain but most disproportionately small advantages, even if the Act was fully enforced. What proportion of the average chemist's turnover is due to the sale of poisons and dispensing? Really in most cases very little. There are numerous towns, and very large towns too, where all the dispensing would not more than support a single chemist. But the further treatment of this subject would lead to a consideration of the relations of the chemist and the medical profession, which I willingly leave to some one else.

The last growl I shall utter is one upon a subject which we shall not all view in the same light. I refer to that portion of the 16th clause of the Pharmacy Act which says "nothing hereinbefore contained shall extend to or interfere with the making or dealing in patent medicines." Why, is it not equally due for the sake of the public safety and for the rights of our trade, that the sale of all patent medicines containing poisons should be subject to the same law as the sale of poisons not protected with a medicine stamp? What virtue or power is there in the government label to prevent accidental or wilful poisoning? Is it not true that a large proportion of these cases are due to the administration of these remedies? Why therefore should not their sale be restricted to the chemist, and take place exactly in the same way as the sale of any other poisonous mixture? But again this clause affords a loophole for evading the Acts, and advantage is already being taken of it to sell laudanum, paregoric and other poisons under the protection of a threehalfpenny stamp.

To the best of my ability I have now pointed out the results of the Pharmacy Act both as affecting ourselves and the public, and it is evident that a many of the grievances which we now suffer are due as much or more to the maladministration and non-enforcement of the Act as to the enforcement of it, and it is therefore necessary for us to consider (first) What means can be adapted to properly enforce the Act and protect our rights? and (second) how we can secure some more adequate recompense for own responsibilities and the restrictions placed upon us?

Now one would naturally suppose from a perusal of the Pharmacy Act, that the Pharmaceutical Society of Great Britain was the legally constituted guardian and champion of our rights, and responsible for the proper enforcements of the provisions of the Act. I am sorry to say we all know only too well that to look for help in that direction is utterly vain; for it either cannot or it will not assist us. It may be that both the chemists themselves and the Society are to blame. The latter is not supported sufficiently by the former, and as a consequence we are deserted, our distinctive title of pharmaceutical chemist is lost to us, and we are delivered over to the spoliator. Had the chemist evinced greater sympathy with the Society, and taken a more active interest in the election of its council, that council and that Society might have been made to represent every class and branch of the drug trade and have been composed of men pledged to do their utmost to protect our interests and vindicate our rights. But there is no immediate prospect of such a consummation, however devoutly it may be wished, and our only hope lies in the issue of the Conference now assembled.

The only means that I consider feasible and likely to be successful in its efforts to assist us is the formation of a trade society, which shall not be antagonistic to the Pharmaceutical Society, but which shall rather if possible act as an auxiliary to it; but if this is not possible it must be prepared to act independently of it. This society should have for its object, the defence of our rights by the enforcement of the Pharmacy Acts against all unregistered chemists, and against all shopkeepers and others who are found dealing in medicines containing poisons; to try by process of law the rights of co-operative societies to dispense and deal in poisons; to point out to the public analysts another and better field for the exercise of their abilities, namely that of investigating the quality of the drugs not sold by druggists; and to attempt to obtain such alteration of the Pharmacy Act as shall secure us increased advantages. I do not think there will be a person present who will deny the urgent necessity of some such steps being taken, and it is sincerely to be hoped that the chemists throughout the country may be roused from their lethargic state, to unite together for the common weal. There are many who would go even further than this and restrict entirely the sale of drugs to the chemist and druggist, but any one who calmly reflects on the subject will at once see that this is an object which it would be folly at present to attempt. Neither do I think it would benefit us aiming at too much, we must prove our demands to be just and moderate, and there is little doubt but that ultimately our demands would be complied with.

In conclusion let me just point out what I think would be the result of a short period of vigorous action undertaken by such a society by simply enforcing the present Pharmacy and Adulteration Acts. First by a thorough enforcement of the Pharmacy Act the sale of poisons and dispensing by unregistered men would soon be stopped. The drug stores, medical halls, etc., would have to put up their shutters or their owners make an effort, and pass the requisite examinations, and thus a large portion of our trade of which we are at present defrauded by these men would accrue to us.

The legality of co-operative dispensing could be put to the test; if illegal there would soon be an end of this grievance, and if it should prove to be legal, we should then know the worst, and could at least attempt by an alteration of the law to make it illegal.

The proper enforcement of the Adulteration Act would speedily rid us of three-fourths of that wretched competition with petty shopkeepers to which all chemists except in better class neighbourhoods are subject. It has often struck me that the inspectors would much more effectually cope with this subject if instead of always purchasing goods from the recognized dealers, as drugs of chemists, groceries of grocers, etc., they would take samples of those things not properly belonging to the business of the traders from whom they are purchased. They would thus not only be more likely to meet with cases of adulteration, but would also protect the different classes of tradesmen from unfair competition with each other.

Again, I think it would be quite possible to obtain some modification of the Pharmacy Act, so as to render it somewhat more just. This might be done by confining the sale of all patents containing poisons to the chemist, and by either extending the number of poisons in part 2 of Schedule A, or by creation of a part 3, which should contain a number of powerful remedies, such as carbolic acid, sugar of lead, nux vomica, phosphorus, lobelia, caustic, digitalis, and chloral hydrate, and all their preparations. These should only be sold by the qualified chemist, but it should be left to his discretion whether they should be labelled poison or no. These, however, are all subjects which would be taken up by the society it is proposed to form.

Let the proposal be considered as dispassionately as possible, and then whatever action we decide to take, let us unitedly strive to accomplish the purpose for which we undertake it. No local grievances, no spirit of petty jealousy or personal animosity, no trifling differences of opinion must be allowed to turn us from our purpose; we must determine to gain the favour of the gods by doing all we can for ourselves, we must keep the goal before our eyes, and swerve neither to the right nor to the left until we reach it. Let us strive to do this, and the consciousness that our efforts are not prompted by defiance, but by defence, and that our demands are just and right, will materially assist us in our endeavours, and ultimately lead us on to victory.

The Chairman: I am sure you will feel very much indebted to Mr. Thresh for his vigorous paper. We have had the pleasure of knowing Mr. Thresh for some years; I won't say a number of years, for we must speak of Mr. Thresh as one of our young able investigators. You will see how often his name occurs in the pharmaceutical and other prints, in connection with pharmaceutical science, and I am glad he has given us his clear judgment on such a question as this also. The suggestion which was made concerning Mr. Southall's paper, that it ought to be considered with some other matters yet to be brought before the Conference will apply also to this. The allusion especially to the subject of patent medicines may very properly be considered when Mr. Shaw and Mr. Arblaster give us their views on the same subjects. Some of Mr. Thresh's statements, particularly as to the abuses by small wholesale druggists acting as retailers, and also as to the quality of drugs sold by unauthorized persons, I am quite sure, are the result of his own experience, and his experience would indicate to us, even if we had not made up our minds as to what should be done or how to do it, that the collection of information is a worthy object for an association like this. I hope that we shall always bear in mind that the charter of the Pharmaceutical Society, after referring to the purpose of its education, has a definite statement that it is to be also for the protection of those who carry on the business of chemists and druggists. Let us not think that we are asking something unreasonable in asking for reasonable protection.

Mr. Edwin Yewdall (Leeds) then read the following paper:—

The Difficulties of Chemists under the Adulteration Act.

The practical working of the "Sale of Food and Drugs Act, 1875," having resulted in the prosecution of several respectable tradesmen whose previous honourable dealings lead to the supposition that they are the innocent victims of a stringent law, it has been thought that a consideration of its various sections may be interesting and productive of mutual advantage. With the object of obtaining the opinions of others I have undertaken to bring the subject before you to-day, though well aware that there are many here present who could have treated it in a much more able manner had they been invited to do so. The preamble of this Act states that it is desirable all Acts relating to the Adulteration of Food and Drugs in force at the date when this Bill became law shall be repealed, and the 1st section gives a list of these Acts, amongst which will be found the 24th section of the Pharmacy Act, the repeal of which seems to very much modify the provisions of that Act. You will remember that according to the section referred to any registered chemist and druggist selling an adulterated drug would, unless the contrary was proved, be deemed to have knowledge of such adulteration, and whilst thus rendering himself liable to the penalties of the Acts then in force for the purpose of preventing adulteration he was liable under the 26th section of the same Act to have his name erased from the Register had the Privy Council, in whom was vested the power, considered his offence deserved such further punishment. The repeal of the 24th section relieves the retail chemist of any charge of adulteration under the Pharmacy Act. Referring to the "Sale of Food and Drugs Act, 1875," the 2nd section interprets the word "Food" to mean every article used for food or drink by man other than drugs or water; also, that the term "drugs" shall include medicines for internal and external use, but it does not say for man, consequently, I presume that this term applies also to medicines for cattle. The 3rd section refers to the penalties which can be imposed for mixing any injurious ingredient with food and selling it in that condition. By the 4th section any person selling a drug to which any article has been added calculated to affect injuriously its quality or potency is liable to a penalty for the first offence of a fine for a sum not exceeding fifty pounds, and for a second or any subsequent offence of imprisonment with hard labour for a term not exceeding six months. With these heavy penalties hanging over us it is of the greatest importance that we should, if possible avoid a first conviction, especially as the success of a retail chemist depends very much indeed upon his character for supplying genuine articles. There is a provision in the next section that no person shall be liable to these penalties if he proves to the satisfaction of the Court that he did not know of the articles being mixed or adulterated and could not with reasonable diligence have obtained the knowledge. It will be observed that it is incumbent upon the retailer to be in a position to assert either from his own knowledge or from information obtained from the person of whom he purchased the article that it is genuine. To be able to speak from his own knowledge requires that he should have examined the article thoroughly, which to some chemists and druggists who have little knowledge of the use of the microscope or the process of chemical analysis, and to others who are fully employed in the usual routine work of a retail business, would be almost an impossibility; they will therefore adopt the alternative of relying upon those from whom they have purchased it, but in order to make themselves safe will probably require a warranty. How can they obtain this warranty? As the provisions of the Act apply to the wholesale dealer, it follows that if an order is given for an article and it is supplied, with it will be sent an invoice giving the quantity and name. That invoice I consider is a warranty. It is well known, however, that the sale of drugs is very slow with some retail dealers and it might happen that a drug obtained some time ago is the one respecting which action is being taken; and those who are familiar with the usual retail chemist's business are aware that when new stock is received it is often put into the store bottle in which there is perhaps some old stock obtained from another house, or if from the same source it has been so long upon the shelves, subject to the varying temperature and humid atmosphere of the shop, perhaps also exposed to direct sunlight, that it is almost inert; and yet on the ground of economy this will be mixed with that just received, thus seriously affecting its quality. Again, there are many articles which are constantly deteriorating. Under all these circumstances would it not be unfair to expect that the wholesale dealer should be held responsible for an unlimited period or even until the stock was sold,—as by improper storage the quality of a drug may be quickly altered. How long should the wholesale dealer be held responsible? To meet this difficulty, it is very probable that the wholesale dealer will, by a notice upon his invoice, intimate that he will not hold himself responsible for the genuineness of the article if it is removed from the bottle or wrapper in which it is forwarded. I have little doubt there are, in many retail shops, parcels of old drugs which have lain for years; it will be apparent to the owners of such, that for their own safety it is absolutely necessary to go through the stock, throwing out all articles of questionable character, including all powders, extracts, or similar preparations, which have become altered in their colour, smell, or taste; and if any costly article is found, respecting which there is a doubt, it will be more satisfactory to send a fair sample either to the Laboratory of the Pharmaceutical Society or to some competent analyst, of which there are many to be found in our ranks, whose practical knowledge of the various articles used as food, and also of drugs, renders them well qualified to fill the position of public analyst, providing they considered such an appointment a *quid pro quo* for relinquishing the business of a chemist and druggist. There are several articles of every-day demand, respecting which a doubt exists whether they can be sold without danger; amongst these will be found cera flav. and cera alb., which, being used in the preparation of medicines for external use, come under the definition of the term drug and therefore ought to be sold genuine, though it is a well-known fact that both are liable to sophistication. When asked for carbonate of iron, we usually supply the sesquioxide. Sapo mollis is frequently used in the preparation of linimentum saponis.

Flavouring fruit essences are artificial, and prepared in the chemists' laboratory instead of from the fruit.

Crocus in placentâ (cake saffron) is sold in large quantities in some towns, and used for similar purposes as crocus in fæno; yet it is questionable whether there is a vestige of saffron in it.

Is the retailer liable to a conviction for the sale of any of these articles under the names mentioned?

Lac sulphuris is another preparation which has already resulted in several vexatious proceedings. Respecting the last prosecution in your town, I wish to call your attention to the report in the *Pharmaceutical Journal*, which I presume is correct, and in which I observe that Mr Herbert, who appeared for the town clerk, stated that in this case it could not be pleaded that the article has been unavoidably mixed, because it was purchased in a pure state and was extensively adulterated with sulphate of lime; this adulteration having, I presume, by this statement been carried out by the defendant after he had bought it pure. If this is a correct report you will fail to see any way by which the defendant could evade the penalty, but if Mr. Herbert is wrong and the article sold was the one usually known as milk of suphur, then we are brought to a consideration of the question, What is milk of sulphur? Was the imposition of a fine in this case the proper administration of the law? I am not prepared to bring before you the whole of the correspondence which has taken place with regard to this preparation; several very eminent pharmacists have expressed an opinion that it should be considered as a separate and distinct preparation from the precipitated sulphur of the Pharmacopœia, in which opinion Dr. Redwood agrees, and there are also several most intelligent chemists, amongst whom is Dr. Attfield, who assert that the term milk of sulphur applies only to precipitated sulphur; they further argue that if an imperfect process was originally introduced for its manufacture, that process has been superseded by another in which pure sulphur only is obtained. With such a diversity of opinion we can scarcely wonder at the difficulty the learned stipendiary of this town, Mr. Kynnersley, felt in giving judgment in this case, or fail to admire his candour in expressing a hope that the question would be taken to a higher court. At the same time inasmuch as there was a doubt whether it should be considered an adulterated article or not, the English law gives the defendant the advantage of the doubt. I am disposed to think it ought to have been dismissed, yet the opportunity now afforded ought not to be allowed to pass, and as the question is one which affects the whole trade you will no doubt concur with me in thinking that the expenses attending such an appeal ought to be borne by the Pharmaceutical Society, though I must admit this Society has not received that encouragement from the trade which should have been given to it, especially by those who when danger threatens are the first to apply for assistance. If the Society refuse to take up this case, then the necessity for some trade organiza tion for obtaining a proper settlement of this and othe questions which will no doubt arise is undeniable, and it is for the purpose of considering the desirability of such a course that we are met to-day. Pending the settlement of the question, I think a label "Milk of Sulphur, prepared according to the Pharmacopœia 1724," would probably prevent any further actions, as showing that it was manufactured by a process according to which the presence of sulphate of lime was unavoidable, and therefore might be considered exempt according to the 4th clause of the 6th section. The omission of any standard of comparison up to which the pharmacist may work or by which the analyst may judge of the quality of the article submitted to him is to be regretted, from the fact that preparations bearing the same name are prepared of many different strengths; for instance, tincture of camphor, which if prepared according to the British Pharmacopœia is frequently taken with benefit. Cases are upon record in which the homœopathic tincture has produced alarming poisonous effects. Although all preparations of the British Pharmacopœia used for the dispensing or compounding of medicines according to prescriptions written since its publication must be of the strength ordered in that work, yet large quantities of drugs are sold daily by shopkeepers which are of inferior quality and in the case of preparations bearing the pharmacopœial name prepared with very weak spirit, or if of the nature of spirit of nitre mixed with water, nevertheless the want of a legal standard to judge of the qualities of these drugs and preparations is a serious obstacle in the way of any attempt to enforce the provisions of this Act against such dealers. Instead, therefore, of appointing an inspector to search for the articles we know are to be met with, would it not be better to appoint some energetic chemist as analyst, we can all obtain from our own neighbourhood specimens of the article sold, but it is not every one who has the time to examine them; if such an appointment was made, or arrangements entered into with Dr. Attfield for the same purpose, such specimens could be forwarded, and if the report showed the presence of any article restricted by the Pharmacy Act to the registered chemist and druggist, information could be given to the local inspector, and the case would be carried on by him in the usual way and without the appearance of any animosity or ill feeling on our part. It would be uncharitable to suppose that the object of the legislature was to harass the well meaning tradesman, but unfortunately if any person who, from pique or vicious disposition, or supposed injury, seeks to do a tradesman harm, this Act appears to lend a means by which he may carry out his design, unless great care is exercised. In the *Pharmaceutical Journal*, April 1, 1876, is the report of a case where a milk dealer was summoned for selling adulterated milk. Although it is not stated under which section the information was laid, I presume from the remarks of the stipendary that it was under the 6th section. Mr. Arnold pointed out that to ensure a conviction under this section it must be proved that the sale was to the prejudice of the purchaser, and as the inspector could not affirm that such was the case, he—the magistrate—would take time to consider the point. I have carefully searched in the Journal for the final decision, but have not yet met with it.

Having briefly laid before you some of the points requiring your attention, I hope due consideration will be given to them, as well as to those which may be adduced by the papers which are to follow, that some well digested scheme whereby we may avoid the penalties of this Act may be the outcoming of our meeting.

The CHAIRMAN: Our thanks are due to Mr. Yewdall for his very excellent paper on this subject, and a most important one it is. Those of us who live in the same town as Mr. Yewdall, know how important his services have been towards the organization of associations for promoting the common advantage. There can be no objection to the paper being discussed now, as I do not see any subsequent proceedings which can be taken with it. If we are to be practical, I suppose the first matter would be the consideration of the Birmingham milk of sulphur case. I should be glad if some local member would give us a little information. We have read what has been published, but it is not probably known to the meeting generally whether the person who sold this milk of sulphur was a registered chemist and druggist, or not. I should be glad to have this information, and also whether the legal technicalities which would be needful for the case to be carried to a higher court have been complied with, or whether it is now too late for such a step to be taken.

Mr. ALFRED BIRD (Birmingham) said: There have been two milk of sulphur cases, the one against Mr. J. Sumner, chemist and druggist, of Coleshill, and the other against a drysalter. As I conducted the scientific defence of Mr. Sumner, and to a successful issue, at Coleshill, we thought the same arguments and the same reasoning as was employed in the Coleshill case would suffice before our learned stipendiary. The argument which we brought forward at Coleshill was very simple. We showed distinctly that there were two preparations, and that milk of sulphur was separately quoted on the drug trade lists. I told the magistrates that I had sold milk of sulphur in my shop nearly forty years, and I should continue to sell it. The magistrates were so convinced that there were two preparations that they dismissed the summons. One of the reasons why the prosecution was resisted, was that there was a foul word in the summons, charging Mr. Sumner with fraud. I do not know, gentlemen, how you would feel, but I know how I should feel if I were charged with fraud, and I was determined in this case, regardless of expense, to hurl back the charge. We were successful, for the magistrates dismissed the case and coupled with it that Mr. Sumner did not sell a fraudulent article, but a legitimate one and was perfectly justified in so doing. When the second milk of sulphur case came on at our public office we thought that the same arguments temperately stated to our magistrate would settle the case, in fact we thought it would convince Dr. Hill. However, the result was different, and Mr. Kynnersley distinctly enunciated that the term milk of sulphur is only applicable to the precipitated sulphur of the last Pharmacopœia; that the terms are synonymous, and that if you sell the old milk of sulphur you must be good enough to put a label that there is sulphate of lime in it. I beg to say that though this unfortunate fellow who was summoned was fined a shilling he has not been able to carry on the case, for he is a very poor man and anything in the way of a reference to a higher court is a most costly proceeding. This man did not feel in a position to find money to fight the cause of the chemists and druggists, therefore the case has dropped without any appeal to the Court of Queen's Bench whatever on the point. Mr. Bird suggested that those who supplied these preparations should take particular care under what name the article is purchased. If the customer asks you for milk of sulphur, give him milk of sulphur; if he asks for precipitated sulphur, give him precipitated sulphur; then you are safe. The effect of Mr. Kynnersley's judgment has been to carry alarm and dismay into the chemists' shops throughout the whole town, and last night I had a most curious and comical instance of it. An old woman came into my shop with a tumbler glass and a spoon, and she said, "Just look here, what's this?" She was stirring away at something in the glass, and she said, "I went into a certain shop for two ounces of milk of sulphur, and this is what they gave me." She got it on Saturday night and she was still stirring at it. I asked her to give me a small portion which I tested in a spoon, and in a few moments I saw that the chemist had given her some of this unmanageable preparation. I said—"This is not milk of sulphur, you have been sold the wrong article. You look like a woman who knows how to defend yourself." I said—"Go down to the magistrates to-morrow morning and ask for Mr. Kynnersley, and just tell him your grievance, and tell him also I sent you." I do not know whether she has gone down, but I had reason to think she would. I told her first to go back to the chemist's shop and tell them she had not got the right article, when she replied, "Its no good doing that, as they would just take it away and give me something else." She said—"This is an abominable adulteration, and I don't see why a poor creature like me should be served so." I hope we shall not refuse to sell milk of sulphur when it is asked for, and that we shall not put anything on about sulphate of lime.

Mr. R. HAMPSON (London): I fully agree with what has been said about calling things by their own names. A reference has been made to the Pharmacopœia that it will be taken as the standard, and must be upheld and obeyed by chemists. Now, I hope in the future, when a time comes for another Pharmacopœia, we shall have some voice in the making of it. It is not a pressing subject now, but I feel sure it will be our interest, as well as simply just, that we should have a voice in the making of that Pharmacopœia, that we shall stand in the same position in England as upon the continent, and that the work shall be that of the pharmacists as well as of medical men. Another thought strikes me in reference to the Adulteration Act, and that is, that we have analysts appointed with very imperfect credentials. We have gentlemen no doubt very worthy, but not having the requisite skill and knowledge for their position; and it does seem exceedingly hard that examined men—chemists—should be tackled by incompetent men, and should have their reputations damaged by them. A case may come forward of adulteration, or presumed adulteration, of some article sold by a chemist, and the chemist may not have the resolution and the pluck to face it out, but may think it the best policy to abide by the analyst's statement. But what I most desire is, that in future we should bear in mind that the analyst should be a qualified analyst—an unadulterated analyst in fact—and that we should have men thoroughly qualified to undertake the responsible duties attaching to their post.

Mr. CHURCHILL (Birmingham): I think it would be well to bear in mind that our Birmingham milk of sulphur case was not directed against a chemist and druggist. The reader of the paper on the Adulteration Act suggested that in the event of such a case being brought against a chemist and druggist the defence should be undertaken by the Pharmaceutical Society. That idea has been held by many chemists, and I may state that I myself wrote to the Secretary of the Pharmaceutical Society suggesting such a view, but I received a reply that the Society was not a trade union. That seemed to point very clearly to the necessity for the formation of such an association as is now proposed.

Mr. G. ELLINOR (Sheffield): I have looked into the Pharmacopœias, especially the one of 1721, when lac sulphuris was officially named and the process given. We next find that the name was changed from lac sulphuris to sulphur præcipitatum. The present process was not adopted till 1809, therefore the name milk of sulphur applies to the present Pharmacopœia article sulphur præcipitatum. The name applies, because the name was changed before the process. I think, if you take the London Pharmacopœias as they are in the London Society's Library, and examine them, you will find there is no ground whereby you can stand with the adulterated milk of sulphur. I believe that is the only official regulation we can have, and that convictions can be obtained and will be obtained if contaminated milk of sulphur is sold either as milk of sulphur or sulphur præcipitatum. We cannot get away from the Pharmacopœias; they are the legal standards.

MR. ANDREWS (Bayswater): I am going to suggest a manner in which you may give the public what they ask for, for undoubtedly there is a demand for this adulterated —as it is termed—article. I would simply suggest that you should have a label "Milk of Sulphur—not the Precipitated Sulphur of the Pharmacopœia." Do not say adulterated with anything. Then have another label, "Precipitated Sulphur, British Pharmacopœia—such a date." I think that by this means you will escape all difficulty.

MR. G. WARD (Sheffield): I should like first of all to demur to the term "adulterated milk of sulphur." I hold it is not adulterated. I should like also to say, that the solicitor engaged in our case at Leeds, advised a label exactly such as has been recommended by the last speaker—of "Milk of Sulphur, not the Precipitated Sulphur of the British Pharmacopœia." Such a label is becoming somewhat common in our neighbourhood. There have been a great many instances in which this pure precipitated sulphur has been sold as milk of sulphur and has been returned as not being the article desired by the purchaser. A good deal of force undoubtedly rests in the remarks about the names in the Pharmacopœia but, I think, there is also some force in the custom of the trade. If I have been accustomed to buy for twenty years an article which I have known by a certain name, and which most people know by a certain name, I hold that if I go and ask for the article by the same name, the seller has a right to supply me with the article I want. That is simply what has taken place in this milk of sulphur case. Precipitated sulphur certainly is not milk of sulphur, and milk of sulphur certainly is not precipitated sulphur, according to the present Pharmacopœia, and I think the case would be established if it were taken up. I trust that it will be one of the objects of this Trade Defence Association. I am sorry to see that in some cases the advocacy of the contrary view was sought to be strengthened by the imputation of impure motives.

Mr. ELLINOR: I hope my remarks did not lead to the conclusion that I thought milk of sulphur was an adulterated article. It is a different article, and I think if the distinction is observed on our labels we shall avoid future difficulties.

Mr. WALKER (Longton): Allow me to say that some people have a very strong opinion about this milk of sulphur. On two occasions, within twenty years, I have been persuaded by friends, against my own opinion, to give up selling milk of sulphur and to sell only sulphur præcipitatum, but with very unsatisfactory results. I may say that on scores of occasions people have brought it back and have complained bitterly of being supplied with an article they did not want. It was not what they wanted; and this has been the case with other chemists who have sold pure precipitated sulphur. Where people ask for milk of sulphur they want a different article altogether, and I think all will agree they ought to be satisfied with what is known as milk of sulphur. If they ask for precipitated sulphur, let them have it; but if you supply it to them under the name of milk of sulphur they are dissatisfied, and they have not got what they want. I may mention that in my own neighbourhood certain chemists were summoned for selling milk of sulphur when precipitated sulphur was asked for. Eight or nine such cases occurred, and the defence in the case upon which the whole were decided was that they were synonmyous terms, and that when asked for precipitated sulphur we were quite justified in supplying milk of sulphur, because they were the same thing. The magistrate at once decided against that. He decided that the terms were not synonymous, that the two articles were entirely different, and that if when asked for precipitated sulphur the dealers supplied an article in which sulphate of lime was an ingredient, they broke the law, and in each case a conviction followed.

Mr. THONGER (Birmingham): I am perfectly satisfied that if the opinion of the trade was canvassed as to whether it would be wise to turn our backs on what I have no fear to call a very nasty article—the old fashioned lac sulphuris,—we should find the great majority in favour of doing so. I was told before I went into business to look at it as a nasty thing and a useless thing, and I have never had the slightest difficulty in selling the sulphur præcipitatum. I would propose that the subject should be one of the first that should be taken up by the association, and that a good plan of going to work would be first to consult some high medical authority as to whether such a society would be wise in doing its best to remove the thing altogether from the trade. If there is any value in it as a medicine it is for the medical authority to say so. That I cannot answer. If it be proved that there is some advantage in it which sulphur præcipitatum does not possess, the sale of it need not be followed with any great difficulty, I am sure.

Mr. COUNCILLOR STEAD (Leeds): Like some other gentlemen, I, after the milk of sulphur case at Leeds, sold in three instances sulphur præcipitatum, and in each case it came back.

Mr. MASON (President of the Liverpool Chemists' Association): It appears to me that the locality in which milk of sulphur is sold would in great measure decide what is to be sold for it. I agree entirely with Mr. Thonger, and I agree perhaps with the public analysts and medical men in thinking that there is not any virtue in lac sulphuris, and that one of the good re-versely, putting an unknown weight or pressure on the pith, I can find its equivalent in grains by seeing how much torsion it is equal to. Thus, if $\frac{1}{100}$th of a grain requires 10,000 degrees of torsion, $\frac{1}{50}$th of a grain would require 20,000 degrees; and conversely, a weight which required 5000 degrees torsion would weigh $\frac{1}{200}$th of a grain. Once knowing the torsion equivalent of $\frac{1}{100}$th of a grain, the ratio of the known to the unknown weights is given by the degrees of torsion.

Having thus explained the working of the torsion balance I will proceed to the actual experiment. On the central mirror I throw a ray from the electric light, and the beam reflected on a particular spot of the ceiling will represent zero. The graduated circle, J, of the instrument also stands at zero, and the counter which I fasten on at the end, L, stands at O. The position of the spot of light reflected from the little concave mirror being noted, the torsion balance enables me to estimate the pressure or weight of a beam of light to a surprising degree of exactness. I lift up my little iron weight by means of a magnet (for working in a vacuum I am restricted in the means of manipulating), and drop it in the centre of the pith; it knocks the scale-pan down, as if I had placed a pound weight upon an ordinary balance, and the index-ray of light has flown far from the zero-point on the ceiling. I now put torsion on the fibre to bring the beam again into equilibrium. The index-ray is moving slowly back again. At last it is at zero, and on looking at the circle and counter I see that I have had to make 27 complete revolutions and 301 degrees, or $27 \times 360° + 301° = 10{,}021°$, before the force of torsion would balance the $\frac{1}{100}$th of a grain.

I now remove the weight from the pith-pan of my balance, and liberate the glass thread from torsion by twisting it back again. Now the spot of light on the ceiling is at zero, and the counter and index are again at O.

Having thus obtained the value of the $\frac{1}{100}$th of a grain in torsion degrees, I will get the same for the radiation from a candle. I place a lighted candle exactly six inches from the blackened surface, and on removing the screen the pith scale-pan falls down, and the index-ray again flies across the ceiling. I now turn the torsion handle, and in much less time than in the former case the ray is brought back to zero. On looking at the counter I find it registers four revolutions, and the index points to 188 degrees, making altogether $360° \times 4 + 188 = 1628°$, through which the torsion fibre has to be twisted to balance the light of the candle.

It is an easy calculation to convert this into parts of a grain weight; 10,021 torsion degrees representing 0·01 grain, 1628 torsion degrees represent 0·001624 grain.

$$10{,}021° : 0·01 \text{ grain} :: 1628° : 0·001624 \text{ grain}.$$

The radiation of a candle six inches off, therefore, weighs or presses the two square inches of blackened pith with a weight of 0·001624 grain. In my own laboratory, working with this torsion balance, I found that a candle six inches off gave a pressure of 0·001772 grain. The difference is only 0·000148 grain, and is fairly within the allowable limits of a discourse experiment. But this balance is capable of weighing to far greater accuracy than that. You have seen that a torsion of 10,021° balanced the hundredth of a grain. If I give the fibre one degree more twist the weight is over-balanced, as shown by the movement of the index-ray on the ceiling. Now one degree of torsion is about the $\frac{1}{10000}$th part of the whole torsion required by the $\frac{1}{100}$th grain. It represents therefore the $\frac{1}{10000}$th part of the $\frac{1}{100}$th, or the millionth part of a grain.

Divide a grain weight into a million parts, place one of them on the pan of the balance, and the beam will be instantly depressed.

Weighed in this balance the mechanical force of a candle twelve inches off was found to be 0·000444 grain; of a candle six inches off, 0·001772 grain. At half the distance the weight of radiation should be four times, or 0·001776 grain; the difference between theory and experiment being only four millionths of a grain is a sufficient proof that the indications of this instrument, like those of the apparatus previously described, follow the law of inverse squares. An examination of the differences between the separate observations and the mean shows that my estimate of the sensitiveness of this balance is not excessive, and that in practice it will safely indicate the millionth of a grain.

I have only had one opportunity of getting an observation of the weight of sunlight: it was taken on December 13th, but the sun was so obscured by thin clouds and haze that it was only equal to 10·2 candles six inches off. Calculating from this datum, it is seen that the pressure of sunshine is 2·3 tons per square mile.

But, however fair an equivalent ten candles may be for a London sun in December, a midsummer sun in a cloudless sky has a very different value. Authorities differ as to its exact equivalent, but I under-estimate it at one thousand candles twelve inches off.

Let us see what pressure this will give:—A candle twelve inches off, acting on two square inches of surface, was found equal to 0·000444 grain; the sun, equalling 1000 candles, therefore gives a pressure of 0·444000 grain; that is, equal to about 32 grains per square foot, to 2 cwt. per acre, 57 tons per square mile, or nearly three thousand million tons on the exposed surface of the globe—sufficient to knock the earth out of its orbit if it came upon it suddenly.

It may be said that a force like this must alter our ordinary ideas of gravitation; but it must be remembered that we only know the force of gravity as between bodies such as they actually exist, and we do not know what this force would be if the temperatures of the gravitating masses were to undergo a change. If the sun is gradually cooling, possibly its attractive force is increasing, but the rate will be so slow that it will probably not be detected by our present means of research.

Whilst showing this experiment I wish to have it distinctly understood that I do not attach the least importance to the actual numerical results. I simply wish to show you the marvellous sensitiveness of the apparatus with which I am accustomed to work. I may, indeed, say that I know these rough estimates to be incorrect. It must be remembered that our earth is not a lamp-blacked body enclosed in a glass case, nor is its shape such as to give the maximum of surface with the minimum of weight. The solar forces which perpetually pour on it are not simply absorbed and degraded into radiant heat, but are transformed into the various forms of motion we see around us, and into the countless forms of vegetable, animal, and human activity. The earth, it is true, is poised in vacuous space, but it is surrounded by a cushion of air; and, knowing how strongly a little air stops the movement of repulsion, it is easy to conceive that the sun's radiation through this atmospheric layer may not produce any important amount of repulsion. It is true the upper surface of our atmosphere must present a very cold front, and this might suffer repulsion by the sun; but I have said enough to show how utterly in the dark we are as to the cosmical bearings of this action of radiation, and further speculation would be but waste of time.

It may be of interest to compare these experimental results with a calculation made in 1873, before any knowledge of these facts had been made public.

Professor Clerk Maxwell, in his 'Electricity and Magnetism,' vol. ii. p. 391, writes as follows:—"The mean energy in one cubic foot of sunlight is about 0·0000000882 of a foot-pound, and the mean pressure on a square foot is 0·0000000882 of pound weight. A flat body exposed to sunlight would experience this pressure on its illuminated side only, and would therefore be repelled from the side on which the light falls."

Calculated out, this gives the pressure of sunlight equal to about $2\frac{1}{2}$ lb. per square mile. Between the $2\frac{1}{2}$ lb. deduced from calculation and the 57 tons obtained from experiment the difference is great; but not greater than is often the case between theory and experiment.

In conclusion. I beg to call especial attention to one not unimportant lesson which may be gathered from this discovery. It will be at once seen that the whole springs from the investigation of an anomaly. Such a result is by no means singular. Anomalies may be regarded as the finger-posts along the high road of research, pointing to the bye-ways which lead to further discoveries. As scientific men are well aware, our way of accounting for any given phenomenon is not always perfect. Some point is perhaps taken for granted, some peculiar circumstance is overlooked. Or else our explanation agrees with the facts not perfectly, but merely in an approximate manner, leaving a something still to be accounted for. Now these residual phenomena, these very anomalies, may become the guides to new and important revelations.

In the course of my research anomalies have sprung up in every direction. I have felt like a traveller navigating some mighty river in an unexplored continent. I have seen to the right and the left other channels opening out, all claiming investigation, and promising rich rewards of discovery for the explorer who shall trace them to their source. Time has not allowed me to undertake the whole of a task so vast and so manifold. I have felt compelled to follow out, as far as lay in my power, my original idea, passing over reluctantly the collateral questions springing up on either hand. To these I must now invite the attention of my fellow-workers in science. There is ample room for many inquirers.

Nor must we forget that the more rigidly we scrutinize our received theories, our routine explanations and interpretations of nature, and the more frankly we admit their shortcomings, the greater will be our ultimate reward. In the practical world, fortunes have been realized from the careful examination of what has been ignorantly thrown aside as refuse; no less, in the sphere of science, are reputations to be made by the patient investigation of anomalies.

Parliamentary and Law Proceedings.

Chemists' Shops and late Refreshments.

Emil Guenin and Louis Hermann were on Thursday summoned before Mr. Vaughan, at the Bow Street Police Court for keeping a refreshment-house without a licence.

Mr. Pitt, who prosecuted on behalf of the Excise, said that the defendants were conducting a chemist's shop, at No. 7, Tichborne Street, at the top of the Haymarket. The police had complained that this shop was kept open till a very late hour at night, for the sale of drinks, known under the name of American ice cream sodas; that women of bad repute frequented this place, and that disturbances had ensued. The Excise officers had, of course, no suspicion that a chemist's shop would be used as a refreshment-house; but upon these complaints they made the inquiries which resulted in this charge.

Mr. Pitt then called two Excise officers, who proved that on the 20th of December, between twelve and one at night, they had been served with these American drinks, for which they payed 6*d.* each.

For the defence, it was not denied that the drinks were sold, but they stated this was a *bonâ fide* chemist's business. If the drinks were not sold the shop would be kept open as now until two o'clock for the sale of drugs.

Mr. Vaughan, in giving judgment, said that although the shop was a chemist's shop, still, undoubtedly, it was kept open at least two or three hours every night for the purpose of supplying all comers with these American drinks. And the evidence went to prove that these comers were very numerous. Mr. Vaughan then went on to read part of Lord Justice Mellish's judgment in the case of Howes. In conclusion, he said that by that judgment he was bound to convict the defendants.

In mitigation of the full penalty of £20, Mr. Reid, for the defendants, urged that the judgment in the case of Howes was very recent, and had not yet been published, so that the defendants had not had the means of making themselves acquainted with it.

Mr. Vaughan mitigated the penalty to one-fourth—namely, £5 and costs.—*Standard.*

[*** If reference had been made to the Register of Chemists and Druggists for 1876, a copy of which has, we presume, been supplied by the Home Office for the use of the Bow Street Police Court, it would have been found that no persons bearing the names of the defendants have a right to represent themselves as being chemists and druggists.—Ed. Pharm. Journ.]

Poisoning by Carbolic Acid.

On Wednesday, June 28, an inquest was held at St. Thomas's Hospital, before Mr. Hull, in view of the body of Francis Fraser Morris, 21.

Mrs. Julia Sophia Morris said she last saw her son alive in her own house at Walworth, on Sunday evening. He came suddenly into the drawing-room looking very strange and ill. Being asked what was the matter, he said, "I have taken carbolic acid, I shall die." He did not say why he had taken the acid. She persuaded him to take some hot mustard and water, but he got rapidly worse, vomited blood, and became too ill to speak. Mr. Martin, a neighbour, summoned Dr. Simmon, the family physician, under whose advice the deceased was sent to St. Thomas's Hospital, where he died shortly afterwards.

The Rev. Eli Morris was then called, and in answer to the Coroner, said his son had for years past been subject to fits of depression. He had discharged himself from his last situation six weeks ago, but had not told any one of it, and had gone out at his usual time every morning, returned every night as usual. Carbolic acid was never used in the house.

The house surgeon having given evidence as to the effects of the poison upon the deceased, the jury returned a verdict of "Suicide while of unsound mind."—*Times.*

Poisoning by a Liniment.

A case of accidental poisoning has occurred at Heywood, near Manchester, by which an extensive ironmonger, named Robert Porter, aged 40 years, has lost his life. Deceased had been suffering from an acute attack of rheumatism. Dr. Jameson visited him, and told him he would prepare him a liniment for external application, and the deceased must send to his surgery for it. Deceased has also been taking medicine for his ailments, and it would appear that his wife was not notified of the doctor's intention to send a liniment. At half-past ten in the morning she sent to the doctor's as usual for the medicine. Her husband was then in bed, and engaged in conversation with a friend. He asked for his medicine. The wife got the bottle containing the liniment, which was labelled, "for external use only," and gave her husband a tablespoonful of the mixture, which contained belladonna. Before taking the medicine deceased remarked that it was very bad. In a few minutes afterwards deceased fell asleep. Having left the two men by themselves, about half-past eleven Mrs. Porter went to look at deceased, and noticed that he breathed heavily. She immediately went to the doctor's house, and said that her husband had been worse since he had taken the medicine. The doctor, taken aback, replied, "The bottle which I gave your boy was for external use only." Medical aid was procured as soon as possible, but deceased expired at a quarter to one o'clock.—*Manchester Courier.*

SALE OF ADULTERATED STARCH.

At the Wandsworth Police Court, on Friday, June 30, Mr. John Bain, of the Balham Co-operative Stores, appeared to answer an adjourned summons for selling to the prejudice of Mr. Samuel Smith, the inspector appointed by the Wandsworth Board of Works, a quantity of arrowroot adulterated with tapioca. In this case the analysis of the Board's analyst was disputed, and the summons was adjourned to allow of another analysis to be made in the laboratory at Somerset House.

Mr. Corsellis, clerk of the Wandsworth Board of Works, said the certificate which he produced stated that the sample was adulterated to the extent of 50 per cent. The certificate sent from Somerset House stated that it was adulterated not less than 25 per cent. He had other certificates stating that the arrowroot was adulterated.

The defendant offered no defence. He wished to absolve the stores from all blame. He sold the article under a guarantee, and it was bought under a guarantee.

Mr. Ingham said he had no doubt the defendant believed he had got a genuine article. He fined him 5s. and 23s. costs, which he could recover from the person who supplied him with it.—*Times.*

CHARGE OF SELLING ADULTERATED WHISKY.

William Brown, spirit merchant, was charged in the Greenock Sheriff Court, on June 30, with having sold a bottle of whisky which was not of the nature, substance, or quality demanded by the purchaser.

The inspector under the Sale of Food and Drugs Act, deposed that he had received complaints regarding the quality of whisky sold in the town. Captain Grant, of H.M.S. Aurora, complained of the whisky sold to the sailors and marines of that vessel; and certain whisky taken on board was sent for analysis. It was found to be bad whisky, but as the purchaser had not intimated, when he bought the whisky, that he intended to have it analysed, a prosecution could not be instituted. In consequence of that, he took samples from shops in the habit of supplying the men of the Aurora. The shop of the defendant was one of these. The case was before the court some time ago, when it was continued for a report of analysis at Somerset House. The report from Somerset House, now read, confirmed the analysis of Mr. M'Cowan, the local analyst, and stated that the sample of whisky had been adulterated with 427 grains of hydrated sulphuric acid in the imperial gallon.

The defendant stated that he never had vitriol in his shop. Never had anything called sulphuric acid. Was well aware that neither of these was put into the whisky that was in his shop. When a cask of whisky was broached witness was in the habit of tasting it. Never observed anything peculiar about the whisky in question.

The Sheriff, in giving judgment, remarked that the defendant was not charged with having adulterated the whisky, but he was charged with having sold it in an adulterated state, and there was little doubt that the prosecution had succeeded in proving that he had done what he was charged with. He considered it a case of gross carelessness, and would pass sentence of £5 with £5 expenses.—*Greenock Telegraph.*

Notes and Queries.

[514]. GREEN OILS.—Will any reader oblige me with a formula for Lockhart's Green Oils? It is much used amongst cattle. Have tried the old white oils with subacetate of copper, but the result is not satisfactory.—F. G. HOLMES.

[515]. CISTERNS FOR STORING TURPENTINE.—Mr. JOHN PORTER would be glad to receive information as to the best material for the construction of cisterns for the storing of spirit of turpentine without its becoming coloured.

[516]. BRONZE LIQUID.—W. H. L. will be glad of a recipe for making "Bronze Liquid." It contains acid. sulph., acid. mur., etc., and is used for immersing brass goods in, after which they are blackleaded and then lacquered.

[517]. GOLD LABELLING.—"OMEGA" will be obliged if any one can give him the *modus operandi* of Gold Labelling, also the best means of affixing Gold Paper Labels.

SUGGESTIONS.

Sir,—I wish to suggest a new measuring glass which, I think, would be of service to chemists,—that is, a tubular glass, graduated on the same principle as Mohr's burette, and holding, say 20 c.c., with lip and bottom like an ordinary measuring glass, for use when the burette is engaged with standard solution. Also, if some of our makers of evaporating dishes would adopt the plan of graduating them as well, I think they would meet with demand.

E. H. COLE.

Lichfield, July 1, 1876.

METHYLATED SPIRIT.

Sir,—In reading the letters published by you on the above subject, it seems to me that druggists, as a rule, are not aware that the licence for methylated spirit is only 10s. 6d. per annum, by taking which they, of course, can protect themselves from prosecution on account of badly made "finish," and also give greater satisfaction to the public. Besides this, by once getting fined they sink as much money at five per cent. interest as will bring in the amount of the annual licence.

RICHARD STURTON.

Cambridge, July 3, 1876.

[*** We have reason to believe that the case is as you suspect, but are at a loss to understand how it can be so, since the necessity for a licence is stated in the appendix to the Calendar of the Pharmaceutical Society, and the sum to be paid annually for such license is specified.—ED. PHARM. JOURN.]

THE DIFFERENT SYRUPS OF THE PHOSPHATES IN GENERAL USE.

BY ERNEST C. SAUNDERS.

The difference in the quality and strength of different samples of the preparation known as Parrish's chemical food, as found in the market at the present time, has been the subject of considerable discussion during the past few months, but as, with the exception of Mr. W. L. Howie in his useful and practical paper, all seem to have devoted their energies more to finding out faults in ordinary samples of the preparation than to remedying them, I venture to submit the following remarks on this article, and the somewhat similar one of Easton's syrup, which is also difficult to make and to keep in good condition. I begin with Parrish's syrup as perhaps the most difficult to make according to the ordinary formula.

The chief reason for the difference met with in the various makes of this preparation is to be found in the fact that the principal published formula, that in Parrish's 'Pharmacy,' is an utterly unpractical one. It is well known that glacial phosphoric acid uncontaminated with phosphate of soda is hardly to be found in the market at present; but even if it were, it is next to impossible to obtain a good preparation with it, as it is a monobasic acid, while the direction to add "quantum sufficit" of hydrochloric acid is exceedingly vague. But apart from this, it is evident that the formula cannot be strictly followed, as if the quantity of ferrous phosphate directed to be present in each fluid drachm of the completed syrup is attended to, 32 troy ounces of sugar will have to be made into 36 fluid ounces of syrup—a manifest impossibility; while if the quantity given as the amount of solution to be formed for the sugar to be dissolved in is adhered to, the result will be about 46 fluid ounces of syrup, which will not contain the requisite amount per drachm of iron and lime. All the formulæ at present in use seem merely modifications of that given by Parrish. In the following form the author has only followed Parrish as far as the result to be obtained is concerned, viz.—that the finished syrup shall contain in each fluid drachm 1 grain ferrous phosphate $Fe_3P_2O_8$, $2\frac{1}{2}$ grains calcic phosphate $Ca_3P_2O_8$, and traces of sodic and potassic phosphates, with free phosphoric acid.

Take of—

Iron Wire, clean, No. 20 . . .	240 grains.
Syrupy Phosphoric Acid (Spec. Grav. 1·75)	3 oz. by weight.
Water, Distilled	4 fluid ounces.

Mix the acid and water, and dissolve the wire in the mixture in a flask, loosely stopped with tow; the hydrogen evolved then protects the solution from oxidation. When all action has ceased, heat to boiling point, and filter through paper in a funnel with a long neck reaching to the bottom of a beaker containing a little syrup, which floating on the iron solution will effectually prevent any oxidation.

Slaked Lime, Fresh	923 grains.
Phosphoric Acid (Spec. Grav. 1·75)	$9\frac{1}{2}$ oz. by weight.
Water, Distilled	14 fluid ounces.

Mix the acid and water, and dissolve the lime in the mixture. Filter the solution.

Crystallized Sodic Carbonate .	54 grains.
Potassic Carbonate	72 grains.
Phosphoric Acid (Spec. Grav. 1·75)	½ oz. by weight.
Distilled Water	1 fluid ounce.

Dissolve and filter. Then mix all the solutions, and having added distilled water to make the solution measure 28 fluid ounces, dissolve in it with heat, sugar, $3\frac{1}{4}$; powdered cochineal, 85 grains; and strain while hot. When cold add orange flower water, 2 fluid ounces, and sufficient distilled water to make the whole measure 64 fluid ounces. The product is a nice clear syrup, entirely free from sulphate of soda, or ammonic chloride, both of which are by no means uncommon impurities, from the difficulty of washing the precipitates, when the syrup is made in the old way, while the whole process will be found very much less troublesome and tedious. Calcic hydrate is generally sufficiently pure as commonly obtained, though where the chemist has the facilities for doing it, it is best for him to make the lime himself, by igniting precipitated chalk in a crucible at a full red heat for an hour.

I may remark here, though it does not exactly bear on the subject, that the last edition (1872) of Pereira's 'Materia Medica' contains the astonishing information, on page 213, that "Hypophosphite of lime is an important constituent in Parrish's chemical food;" a statement that is liable to mislead physicians in a serious manner.

Easton's syrup, is another preparation that is frequently badly made, and very often deficient in iron. The precipitate so frequently met with, in the form of phosphate of quinine, is, I think, always owing to the use of an acid containing metaphosphoric acid. I have never been troubled with a precipitate since I have taken pains to use only orthophosphoric acid, H_3PO_4. The change in colour is due to exposure to the air, chiefly from oxidation of the iron salt, but partly to the quinine changing colour. It may be entirely avoided, as has been often remarked, by completely filling the bottles in which the syrup is kept, and corking so as to have as little air left in the bottle as possible.

No trouble will be found in making a satisfactory preparation if the following form be strictly followed, and care taken to avoid exposure to the air of the iron solution.

Take of—

Iron Wire (No. 20)	240 grains.
Phosphoric Acid (Spec. Grav. 1·75)	3 oz. by weight.
Water	4 fluid ounces.

Dissolve with the precautions directed above in the formula for Parrish's syrup.

Quinine Sulph	625 grains.
Liq. Ammon.	
Distilled Water,	
Dilute Sulphuric Acid . . .	āā q. s.

Precipitate the quinine, secundum artem, and wash on a filter with a pint of very cold distilled water, press strongly, and dissolve in half an ounce by weight of phosphoric acid, diluted with an ounce of water in which 16 grains of strychnine have been dissolved. Mix with the solution of iron, add enough distilled water to make the whole measure 10 fluid ounces, and mix thoroughly with 54 fluid ounces of simple syrup. The resulting syrup will contain in each fluid drachm 1 grain ferrous phosphate $Fe_3P_2O_8$; 1 grain quinic phosphate $(C_{20}H_{24}N_2O_2)_3 2H_3PO_4$, and $\frac{1}{32}$ grain of strychnine.

These two syrups afford good examples of two classes of syrups that present considerable difficulties in manipulation with the formulæ in general use, which, I think, are quite removed in the two just submitted. Both have now been tested on a large scale, for some time, and found very satisfactory in their products. No originality is claimed in the use of metallic iron in place of precipitated ferrous phosphate; it was, I believe, first suggested by Mr. H. W. Jones, in the columns of the *Pharmaceutical Journal*. The chief point that I would press is the importance of using tribasic (ortho) phosphoric acid, H_3PO_4; both metaphosphoric acid HPO_3, and pyrophosphoric acid $H_4P_2O_7$, if present in the acid to even a small extent, are certain to cause trouble. The precaution given as to filtering the solution of ferrous phosphate will be found useful in many other cases; a beaker full of solution of ferrous iodide filtered in a similar manner, with a layer of syrup the eighth of an inch thick floating on the surface, can be left exposed for twenty-four hours without injury to the solution. It is, of course necessary that the solution should have the greatest specific gravity.

COLOURLESS TINCTURE OF IODINE.

BY WM. H. DARLING, F.C.S.

This preparation has from time to time attracted the attention of pharmacists, and various formulæ have been offered for its preparation, which differ widely as to the results they give.

Curtmann* made a series of experiments to determine the quantity of ammonia necessary to decolorize a fixed quantity of iodine with varying quantities of alcohol, and from these experiments he proposes the following formula:—

Iodine	10 drams.
Rectified Spirit	13 fluid ounces.
Strong Solution of Ammonia	3 „

He states the result of the reaction in such a mixture to be ammonium iodide and iodate, ethyl iodide, and iodide of an ethyl substituted ammonia.

Macmillan† objects to the use of ammonia because iodide of nitrogen or some iodine substituted ammonia is formed, which he appears to think simply dissolves as a whole, and therefore the greater portion of the iodine is rendered inactive. To avoid this he proposes the replacement of the ammonia by fixed alkalies.

In the supposition that the brown precipitate dissolves as a whole he is mistaken, for it is decomposed with effervescence, more rapidly in direct sunlight, shortly after its formation.

Hager,‡ referring to the experiments of Curtmann, proposes a modification of his formula by which a colourless solution may be obtained in a short time. The decolorizing agent he uses is sodium hyposulphite. The iodine, sodium hyposulphite, and water are gently heated until colourless, when ammonia and alcohol are added. A solution so prepared, he says, contains iodide of triethyl ammonium, which decomposes in course of time into triethylamine and ethyl iodide, with sodium iodide. There is no mention of iodate, which Curtmann states is present.

By neither Curtmann nor Hager is iodoform mentioned as a constituent of a solution of decolorized iodine. Indeed, Hager's formula does not admit of its formation.

Some time ago, when preparing a quantity of the colourless tincture of iodine, and before all the alcohol was added, a few spangles or crystals were observed in the almost colourless solution. As these had not been previously noticed, curiosity was excited as to the cause and what they were. When collected upon a filter, washed with distilled water, and allowed to dry, their colour was pale yellow and their odour recalled that of iodoform.

The quantity being too small (under half-a-gram) to admit of two combustions, one for the carbon and hydrogen, and a second for the iodine, the latter alone was made by burning a known weight in a tube filled with pure lime. The iodine being precipitated by silver, the following numbers were obtained:—

Weight of substance used—0·3946 grms.
Weight of AgI obtained—0·5990 = 0·32371 of I.
„ Ag 0·0482 = 0·05668 of I.

0·38039

$$\frac{0{\cdot}38039 \times 100}{0{\cdot}3946} = 96{\cdot}39 \text{ per cent. of iodine.}$$

The molecular weight of iodoform CHI_3 is 394.

$$\frac{3 \times 127 \times 100}{394} = 96{\cdot}70 \text{ per cent. of iodine.}$$

The physical character of the substance, its odour, and finally the close agreement, a difference of 0·31 per cent. between the calculated percentage of iodine in iodoform and that found, leave little doubt that the substance in question was iodoform.

If the reaction of ammonia with iodine in the presence of alcohol, omitting the formation of iodide of nitrogen from consideration, be viewed as analogous to that of fixed alkalies, the formation of iodoform is to be expected, and if this view be correct there should be little, if any, iodate present. Its formation must be preceded by that of ammonium hypoiodite, which would react with the alcohol, of which there is an excess, producing iodoform in the same manner as calcium hypochlorite reacts with the same alcohol forming chloroform. The formation of such a compound as ammonium hypoiodite is not a matter of conjecture, for Schönbein* states that it is formed when iodine acts upon an excess of ammonia.

The efficacy of the decolorized iodine must be attributed for the most part to the iodoform it contains. This iodated compound is an almost colourless substance, which contains more than nine tenths of its weight of iodine, but how far a solution of it alone will replace the ordinary decolorized iodine must remain to be ascertained.

THE TRADE CONFERENCE AT BIRMINGHAM.

THE Conference at Birmingham has been in every respect as successful as could be expected. The programme which appeared in our advertisement columns last week comprised a number of subjects which have a special interest for the trade, and the consideration of those subjects in the shape of papers had been undertaken by men whose ability was sufficiently well known to add an additional attraction to the opportunity of discussing them under such circumstances. The announcement that Mr. REYNOLDS was to occupy the position of Chairman of the Conference also furnished assurance that the proceedings would be conducted with strict regard to order and practical requirements. Punctually at the hour fixed for the commencement of the proceedings the spacious lecture hall in Needless Alley began to fill, and before midday arrived the meeting numbered one hundred and forty persons.

Altogether there were nine papers to be read and eight subjects to be discussed, besides the introductory remarks of the Chairman and the statement by Mr. WILLIAM SOUTHALL as to the origin of the Conference and its relations to the Pharmaceutical Society. These papers are published in full in our report, and the discussion of them was so skilfully managed that the whole proceedings of the Conference were concluded within ten minutes after the time that had been fixed.

As the establishment of an ample fund for defraying ordinary expenses of management as well as extraordinary outlay in carrying on special work is one of the points most essential for the existence of such an association, this formed an important feature of the proceedings, and a sum of between £200 and £300 was subscribed, partly by those present, and partly by others who were unable to attend, the amounts ranging from a few shillings up to ten guineas. In addition to this it was decided that the annual subscription of members should be fixed at the small sum of five shillings a year, in order to offer the utmost facility for becoming a member; and to prevent inequality among the members any support given to the Association beyond this annual subscription is to be given in the form of donations, and Mr. HOLDSWORTH, who acted in the capacity of Honorary Secretary of the Conference, will receive donations to the Fund, as well as subscriptions, and will enrol members until the appointment of Secretary to the Association has been filled up.

This adoption of an extremely moderate annual subscription is we think a wise step, for it will remove any possible grounds for not joining the Association, and as we have already remarked in speaking of this project, it is essential that the Association should have the active support of the great mass of the trade. Without this it will be impossible to take any such action in regard to matters affecting trade interests as would command the approval and satisfaction of the trade at large.

The number of members already enrolled amounts to about 400, and though this may not be unsatisfactory as a commencement it is at the utmost only one twentieth of the actual numerical strength that such an association should have in order to be able to do the work contemplated. The development of the nucleus that has thus been formed, to an association which shall be capable of representing the trade and protecting its interests, because it has the general support of those engaged in the business, will be an arduous task, and it will require the most strenuous efforts of those already enrolled to bring their brethren into active co-operation with them.

We dwell upon this point not with any motive of discouraging the enterprise that has been put in motion by the Birmingham Conference, but solely because we are deeply convinced of the indispensable need for a foundation co-extensive with the trade itself in order to ensure the power of defence and guardianship which it is desired the Association shall possess and exercise. If this power should eventually be acquired, and the entire body of chemists and druggists united in the effort, as well as the desire to promote their common welfare and protect their mutual interest, another important step will have been taken in the advancement of pharmacy, and chemists and druggists will be indebted to Messrs. SOUTHALL BROS. and BARCLAY for having instigated the realization of that object of the founders of the Pharmaceutical Society which concerns the material well being of the trade in like manner as they are indebted to JACOB BELL for the services he rendered in the formation of the Society, and to the founders of the Pharmaceutical Conference for having established a means of scientific cultivation and genial intercourse which has been productive of vast improvement, both intellectually and socially.

We fully agree with the opinion that it is doubtful whether the educational and examining body which governs the practice of Pharmacy ought to run the risk of rebuff and failure that a trade association will be sure to incur. But in the same way that the formation of the Pharmaceutical Conference has served to supplement the work of the Society and make it stronger than before it seems probable that a thoroughly well supported Association for dealing with purely trade objects may also be useful in itself and in promoting the general good of pharmacy.

TRADE CONFERENCE AT BIRMINGHAM.

On Tuesday last, the 11th inst., a Trade Conference of Chemists and Druggists was held at Birmingham, in the Hall of the Young Men's Christian Association, Needless Alley, New Street. The proceedings commenced at 10 A.M.

Mr. BARCLAY (Birmingham) said: On behalf of the Provisional Committee, I have much pleasure in proposing that our friend Mr. Reynolds, of Leeds, take the chair at this meeting. I am sure we shall all agree that he is the right man in the right place. He has been already the author of one successful conference—the Pharmaceutical Conference—and I am sure that his presence here to day will add very much to the prospect of success of this Conference. Mr. Reynolds's wide experience both in trade matters and also in scientific matters entitles him to our heartiest respect and confidence; and I am sure we shall all very readily agree with any decisions he may come to in guiding the business of the meeting.

Mr. HOLDSWORTH (Birmingham) seconded the motion and it was carried unanimously.

Mr. RICHARD REYNOLDS, F.C.S., then took the chair.

Mr. JONES (Leamington): I have great pleasure in proposing the next resolution, which is that Mr. Barclay be appointed Vice-Chairman, and that Mr. Holdsworth be appointed Secretary to the Conference.

Mr. RIMMINGTON (Bradford) seconded the resolution and it was carried.

The CHAIRMAN: On the programme of this day's business you will notice a paragraph on the subject of reporting. It is stated there that as soon as the Chairman is appointed the provisional committee will recommend that the proceedings be only reported so far as the Conference deems desirable. Now, gentlemen, in a meeting of this sort—a gathering of the trade for purposes which are strictly confined to that trade, it is essential and it is for the interests of the trade that we should retain such a power in our own hands. This is not a public meeting and therefore we cannot be asking anything unreasonable to retain such a power. I am quite sure it will be with your permission that the editors and representatives of the two trade journals, the *Pharmaceutical Journal* and the *Chemist and Druggist* are admitted to these proceedings. We know that we can rely upon the discretion of the conductors of those journals. We see here their representatives and I ask you to express your approval of their being permitted to attend.

The Chairman's suggestion was unanimously approved.

The CHAIRMAN then made the following opening remarks:—

I accept the appointment to act as your chairman today as a duty owed to the common cause in which we are interested, and I offer you my grateful thanks for the personal good-will you have shown me. I would that you had placed the trust in stronger hands, so that in surveying and mapping out the features of the new subject before us you might have had the experience of some one of our leaders, entitled to be termed *facile princeps* from a combination of veteran sagacity with intimate knowledge of the steps of past legislation affecting us. The circumstances under which we meet for a day only will impress upon us the value of time, and no speaker must waste its ever-falling golden sands. I shall endeavour to fulfil this obligation to brevity. Upon the origin of the Conference we shall immediately have the pleasure of hearing a statement by Mr. William Southall, one of the gentlemen to whose energetic determination we owe this gathering. I am aware that in some quarters the initial difficulty of the movement has been the manner in which it was suggested. I need not conceal the opinion that support has been withheld in certain directions because of this mode of initiatory procedure. But, from the moment of the organization of a Provisional Committee, and even more emphatically from the time of the assembly of this Conference, the movement has been an open one, conducted on the ordinary principles of English associations. The degree of success achieved in bringing together this meeting entitles the prime movers of the Conference to our heartiest thanks. The responsibility is now ours. Let us not separate without founding an association which shall bring to a focus the latent powers of chemists and druggists in defence of their legitimate interests. Your Provisional Committee has done well in reprinting the opinions of our trade journals on the subject. We are glad to have their cordial support so far, and recognize the great power which their conductors wield in promoting agreement of opinion amongst us upon any line of policy. You will have read the remarks of the editor of the *Chemist and Druggist* upon the various reasons alleged by those who see no necessity for either a Trade Conference or a Defence Association. This criticism upon the critics has more piquancy than any phrases in which I could hope to clothe similar ideas, and I trust it will be considered by those concerned. Objectors have told us to stay our hands because already two associations exist capable of doing the work, viz. the Pharmaceutical Society and the British Pharmaceutical Conference. Gentlemen, I ought to know something about both these institutions, and the first idea recalled from the depths of my memory is that the same objection, in the same words,—aye and by the same objectors in some cases,—was brought against us when we founded the British Pharmaceutical Conference. Many a moral might be drawn from the short life history of that Conference. Do you doubt the power of chemists for effective combination? Look at that Conference, and its successful results, including its highly profitable (in two senses) 'Year-Book of Pharmacy.' It has done for the trade throughout Britain what our local associations can do for our larger towns only, in making chemists know and respect each other, and work together for their common good. But for its influence, I will venture to say that to-day's meeting would never have been held. Let me finish the subject of the British Pharmaceutical Conference before dealing with its elder sister. Its constitution is not a very rigid one, and it may assume considerable variety in aspect, according to the wish of its members. I hold that it would be an absurd position, if, when a trade question united us in feeling, we should fail to exercise some opportunity of using our influence effectively. I remember the action of the Conference at its meeting at Norwich, when it memorialized the Board of Inland Revenue on some of the abuses existing in relation to methylated spirit. But, whilst commending to members of that association the policy of not allowing this right to be lost by abeyance, I am sure that it is not feasible that the British Pharmaceutical Conference should charge itself with the general duties of a trade association. Such functions would involve a dual staff of honorary officers, for what Presidents could it find who would be "always good alike," whether recounting the advances of pharmacy, or guiding defective movements of trade policy? and for what compensatory success would the Conference part with its senior Honorary Secretary, Professor Attfield? The Pharmaceutical Society stands on a very different footing. Mr. William Southall will undertake the consideration of this subject, and I have no wish to anticipate him. Let me say, however, that so far as the Charter and the various Acts of Parliament confer power on the Society, the policy of its Council should reflect the judgment of its members. Gentlemen, I believe firmly in the representative principle of government, more especially as the intelligence of the constituents is of the higher order. Until the Society forfeits the recognition of its reasonableness, any representations which it may make upon state policy in relation to pharmacy, will, if supported in an earnest manner, be likely to receive attention from the authorities. Therefore, in the prevention of new abuses, and perhaps in the reformation of some old ones, we must recognize the power of the Pharmaceutical Society as the most potent within our command. The onus of showing cause against the exercise of this power must usually rest with the objectors to its employment. The chance of our motives being misunderstood must count for little. A body of men who have complied with the educational requirements of the state so far as have the chemists and druggists, with a very slender compensation *per contra*, have the right to be heard on any case of injustice to their order. The conclusion which I draw from these opinions is that when we have fixed upon a line of trade policy, we must take care to send to Bloomsbury Square representatives who share them, and who can give them effect. I rejoice to see amongst us to day many of our present representatives, who most fully answer this description. In relation to the duties of the Pharmaceutical Society, I should be glad if some practical suggestions come before us upon the late conviction for the sale of milk of sulphur. This case must have great interest in this district, and a miscarriage of justice will have happened if legal technicalities should prevent its being carried to a higher court. In Leeds, we had the same question raised more than a a year since, and the judgment of our stipendiary, I am happy to say, was exactly the reverse of that just given at Birmingham. The infatuation of certain public analysts is almost beyond belief. *Quis Deus vult perdere, prius dementat* is suggested by the indiscretions of some of them. That they have supplied one important reason for this Conference is beyond doubt. The subject of patent medicines will be brought before us, and this is quite justified by the various changes that have taken place in this branch of business, during the past few years; changes not only in the cost of the patent medicine licence, but in the circumstances of their distribution by retailers. Many of us would be glad of more light upon the question and I think that the exchange of information will be at present a wiser course than any very dogmatic expression of opinions. As to the recent fashion amongst fashionable people and others to take part in keeping retail shops without becoming shopkeepers there must be many here who desire to relieve their minds. I am not of the class who will offer them Job's comfort and ask *cui bono?* Freedom of trade is all very well, and it may form a general basis of our arrangements of social economy, but any precious idea of co-operation that is incorporated in the scheme of the stores would be a very poor safeguard against monopolies, as compared with the fair and equal competition from which we do not shrink. That the Government, whether liberal or conservative, should blink the question of its paid servants combining to undersell the ratepayers, shows that we live in a very free country, but the question to come forward some time must be, How long will the ratepayers submit to this? The chest of tea bought *en bloc* by the post-office clerks, and divided by them, has some historic significance, even if less important than those earlier chests that found their end in Boston Harbour. The taxgatherers of some ancient nations were noted for rapacity and unscrupulousness, but they are not recorded to have had the audacity to give their name to shops or stores. Mr. Hampson will lay before us his views upon the legal action which may be possible in relation to the stores, and I will not anticipate them. In the provinces there are social influences which may check the extension, and probably terminate the existence of many such bodies. But a general consent to put these influences into operation is needed. For the position of the question in London, I will not presume to speak, but Sir Thomas Chambers' motion on Civil Service Trading would not have been cynically counted out of the House of Commons if both London and the country had first taken counsel. The programme now in your hands details the other papers to be read by gentlemen who have been good enough to undertake this duty. The outcome of our deliberations to-day ought to be a trade association, but I will ask you to look for a moment at some of the difficulties that will surround this. They will arise, firstly, in the different views which members may take as to its functions. As age creeps slowly but surely over societies, the active becomes changed for the passive mood, but the danger of indifference is not that which I foresee as the earliest. Too much zeal is a still more mischievous quality, and it will be well that no false hopes should be raised in the minds of those who are disposed to this error. Let no one suppose that we want an association which will receive five shillings as a subscription, and will proceed forthwith to harry the subscriber's enemies and guarantee him a snug preserve. Funds will be needful, but the money need not burn our pockets until it gets transferred to those of the lawyers. If defence and not defiance be a leading principle, there will be considerable irregularity in the work to be done in different years. External circumstances will determine this to a great extent. In conclusion, gentlemen, let our discussions to day be business-like and kept to the point, each of us disposed to concession if needful for the common good, for that we wish it well we have all pledged ourselves by coming here to-day.

Mr. Barclay announced the receipt of letters of apology from some of the Liverpool delegates, Messrs. J. A. Turner, A. Redford, A. E. Tanner, J. Abraham, and D. Wharrie; from Messrs. J. R. Robinson (Dewsbury), A. W. Postans (London), J. A. Jeffrey (Cheltenham), T. Cooper (Leicester), J. M. Fairlie (Glasgow), and others. Those gentlemen expressed strong sympathy and their regret that from various reasons they were unable to be present. The circular, which was sent out to 298 local secretaries and secretaries of Chemists' Associations, was answered in the following way:—No returns as to whether a Conference was desirable or not were sent from 9 places. There were unfavourable replies from 6; indifferent 38; favourable 145. In answer to the question, Would a deputation attend from your district?—there were no returns from 7; 22 districts promised to send delegates; doubtful 30. The names of towns which were either represented at the Conference to-day, or had promised to be represented, were Liverpool, Birmingham, Leeds, Halifax, Sheffield, Leicester, York, Wolverhampton, Dewsbury, Sunderland, Taunton, Bridgewater, Hull, Exeter, Shrewsbury, Leamington, Cheltenham, Henley-on-Thames, Coventry, Rochester, Cradley, Hinckley, Riddings, Chesterfield, Derby, Bradford, Hampton-in-Arden, Clay Cross, Hay, Ruabon, Rhos-y-medre, Longton, Birkenhead, Lye, Shipley, Buxton, Oldbury, Banbury, and Bloxwich. In answer to the questions, Are there any unregistered persons practising as chemists and druggists in your district? and if so, how many?—the replies were, unregistered persons, in 21 places; none in 127 places; and no returns from 50. The various suggestions which had been made from the chemists throughout the country had been embodied in the programme which the provisional committee had already put before the Conference. The provisional committee having met and having all the data before it decided upon the programme which had been sent to every chemist in Great Britain. A circular had also been sent to the members of the Council in London some of whom were present while others had sent letters of apology.

In the absence of Mr. William Southall, the Secretary read the following paper by that gentleman:—

The Origin of the Conference and its Relations to the Pharmaceutical Society.

If any apology be required from me as a member of the firm which has been instrumental in bringing about this Conference, I should like to say that as Local Secretary of the Pharmaceutical Society, and also as connected in business relations with a large number of druggists up and down the country, it has been my lot from time to time to hear a good deal of the troubles and grievances of our brethren. Some of these may be imaginary but others are very real, and it seemed to our firm that the time was ripe for a Conference on trade matters in general, if some one would only take the initiative. This we have done, and by way of explanation I have strung together a few notes on the general condition of the trade that may serve to explain the position we have taken. Although not very old I am old enough to remember the profession of pharmacy in a very different position from what it now is. The druggist of my early days was an old-fashioned character altogether compared with the pharmacist of the present; and although we hope the process of selection, natural or artificial, may extend a little further, we had even then advanced beyond the condition in which a first class chemist, like the preceptor of John Bell, was in the habit of subduing the too powerful properties of powdered nitre before it was fit for sale. Druggists in my early days were just taking the alarm. Mr. Hawes by his bill in Parliament had startled them out of a reposeful state, and they must either do the requisite work for themselves or it might be rather roughly done for them. At that time there were, as at present, men who were excellent pharmacists and in the quiet recessses of whose back shops important discoveries had been made and light cast upon chemistry and pharmacy, but the rank and file were but an ill-educated body, and there was a good deal that wanted rooting out as well as fresh planting. Nor was this to be wondered at, for the school at Bloomsbury Square did not yet exist, and the tutorship was confined to the back counter; Anthony Todd Thompson was the great light of materia medica, for as yet Pereira's fame had hardly reached us. The old edition of Gray's 'Supplement,' Turner's 'Chemistry,' and a few medical books, together with the Pharmacopœia, constituted the druggist's library. As yet there was no "Journal," or *Chemist and Druggist*, to diffuse, weekly or monthly, pharmaceutical "sweetness and light" through the land. The times needed a master mind, and one arose equal to the occasion. Jacob Bell, enlisting under his banner the intelligence of the trade, contended nobly against opposition from within and from without, and his efforts were ultimately crowned by the establishment of the Pharmaceutical Society and the passing of the first Pharmacy Act. Now it is not my business to trace the history of the Pharmaceutical Society, or of the chemist and druggist under the Pharmacy Act, and its various modifications; it is known more or less to most present, and it is certain that a most important change has been effected. The various Presidents of the Society may well refer in their annual addresses with pride to the results which a comparatively few years have seen effected; whilst the rising chemist of the present day may thank the Society that, through its efforts, his position is exalted from that of a mere trader to a member of an educated and scientific profession.

It is true the title is not accorded to us, but that is not of much moment. We owe more than many are perhaps willing to admit to the Pharmaceutical Society, and it is our bounden duty to support and strengthen it by all the means in our power.

Now let us refer for a moment to the chemist of thirty or thirty-five years back, and we find him very differently circumstanced from his successor. In these earlier days he was a worthy or of course sometimes an unworthy man according to his lights, but things went on very easily as far as interference from outside. He took it easily at home too, for new preparations and new "patents" did not spring up in the mushroom crop they do at present, and if people wanted new things they must wait for them.

London was then as far off from Birmingham as Paris is now, and as for small country places, they might as well have been at Timbuctoo. Then, by way of preparation for business, a shop boy could pick up a little Latin behind the counter, and in due time he acquired knowledge enough to enter business on his own account. At present responsibilities begin with his apron. He must read Cæsar and have a fair general knowledge to begin with. But I do not stay over studies, examinations, etc., they are merely matters of money and brains; the money is well spent and ought to be an excellent investment in whatever way you look at it, whether by having gained ability for trade, or increased intellectual powers for the usefulness and enjoyment of life. There are, however, now-a-days responsibilities which were never thought of in old times. Let us consider a few of them. First come certain laws, which whether or no they be terrors to evil men, are certainly terrors to good ones. A conscientious pharmacist is afraid of infringing the provisions of the Sale of Poisons Act; he perhaps wakes up at night after a doubtful twopence-worth of laudanum has passed over his counter, assured that somebody has been poisoned. Then again the more careful he is to avoid the claws of the Adulteration Act, the more fearful is he lest some article should unfortunately have escaped his careful revision and be pounced upon to his eternal self-condemnation. And now, according to a recent number of the Journal, we hear of a new terror. The inspector of weights and measures sends to a druggist for a test prescription, so called, to be made up, and it is forthwith handed to the analyst, who pronounces that one article is in excess, and the unfortunate dispenser is fined 50*s.*; the case cited, however, seems to need further explanation. Now correctness is the very backbone of our position, and as honest men we are willing to have our work examined, but the analysis of a complicated mixture is not unlikely to be attended with error, and how is the ordinary chemist to defend himself unassisted? The confidence of the public is destroyed and the fine of 50*s.* may become one of £50, and it is questionable whether this accords with the intention of the legislature.

Next comes Lord Campbell's Act, which makes a man responsible in damages for the errors of his assistants as well as of himself, a most grave responsibility to the druggist. All these new responsibilities are additions by law to the serious and always increasing responsibility that naturally attaches to the proper carrying out of our business.

Let us now turn to the *quid pro quo*. Have we got it? As far as a return for our improved education goes, and in most of our internal relations which have been subjected to change, we either have it, or it is in a fair way of realization, though some may think the good time rather long in coming. Apprentices it is true are scarce, and assistants' salaries are higher, but the rise in remuneration will probably increase the supply, whilst the tendency of the examination will certainly be to restrict the number of men entering into business and at the same time the number of those in business before 1868 will continue to fall off. So far the benefits in return for our internal legislation! But how do we stand in the general way of our trade? Surely every one here will say that the pharmacist being so heavily handicapped with laws and regulations ought to be fully protected in the legitimate exercise of his calling. We find, however, that he is hustled and interfered with. The character of a chemist's business varies very much in different places, but it is impossible that he can, as a rule, make a living by dispensing and the sale of drugs alone without the addition of sundries. Here he finds that he is interfered with by the grocer, who, in addition to many articles that may be free warren, has robbed him of the sale of many—such as extract of meat—which were his own introduction. Then the haberdasher sells perfumes, a very old adjunct of a chemist's business. This, however, is all legitimate, though it may be painful in our struggle for existence; we find, however, that the grocer and others sell patent medicines containing drugs subject to the provisions of the Poisons Act. This certainly requires looking into. Then there is the Co-operative grievance, which presses heavily upon many of our brethren. For my part I always consider co-operation a mild sort of communism, and communism, whether in Paris or Westminster, means getting what you want without paying full value for it. If there must be a community of goods it should not be confined to a few shopkeeper's articles, but should be the whole thing—the red flag and common property in land above all. The aristocrats of the Haymarket might then find they had burnt their fingers. Nay, some advanced philosopher might judiciously hint at social community also, and recall the happy days when, if I recollect, Cæsar said of our ancestors, "*Uxores habent inter se communes, fratres cum fratribus.*" But you will hear presently about cooperation. Next, we have the altogether unlawful carrying on of the business by people whose names are not upon the Register. This seems to be a growing evil, and I regret to say that the efforts of the Society to put a stop to it appear to fall far short of the requirements. As local secretary I have been found fault with for inefficiency when the blame did not lie at my door. It is not, moreover, the place of any chemist, local secretary or not, to take upon himself the office of detective and virtual prosecutor; a society may do it, and upon an officer of that society, and not upon the aggrieved neighbours, should fall the duty of getting up the evidence. In connection with this arises the further question, are the laws that govern our trade such, that whilst fully protecting the public interests, they are also the best we may justly claim for our own protection? There are other matters of material import, also, well worthy of consideration, but I have said enough to show that the Conference does not come together without reason. Some will doubtless say, "The Pharmaceutical Society is the proper body to look after our interests." Well this may be so, but we require a fulcrum to move the Society; for any powerful institution that has done a great work is apt in the course of years to settle down in a comfortable state, and to inhale the pleasant aroma of finality. Therefore a little ventilation of these matters in the free air outside the walls of the city may do no harm. For my part I am most desirous that the Pharmaceutical Society should take up the work that the Conference desires to see accomplished, but I am somewhat doubtful if the great educational and examining body of our profession ought to run the risk of rebuff and failure that a trade association will certainly incur. The Pharmaceutical Conference has not only safely floated off an immense amount of scientific work from the elder society, but has left it stronger than before. Why should not a Conference that deals with trade objects purely be also successful?

To ensure success, a trade conference must not clash with the Society, but it must be largely and thoroughly supported to be of any use. At all events there is a good deal wants talking over at the present time; and to those who would say, "Better keep quiet and let these things alone," I would observe that to my mind there is a great deal of quiet wisdom and wit in the words of Dr. John Richie, at the time of the Scotch disruption. "Agitation!" said John "what good in the world was ever done without agitation? You cannot even make butter without it."

The CHAIRMAN: I think our thanks to the readers o the papers had better be made to each, and although Mr Southall has been unable to be present I am sure you will all feel much indebted to him for his paper. The arrangements made for discussion are, that the reading of a paper is not to exceed twenty minutes, and no speaker is to exceed ten minutes without the permission of the Chairman.

A DELEGATE suggested that discussion on Mr. Southall's paper should be deferred until some of the other papers had been read.

The CHAIRMAN approved of the suggestion, and said that unless any one desired to make any remarks he would call upon the reader of the next paper.

Mr. J. C. THRESH, F.C.S. (Buxton), read the following paper:—

THE CONDITION OF CHEMISTS AND DRUGGISTS UNDER THE PHARMACY ACT.

The object of this necessarily brief and hastily compiled paper is to indicate the restrictions, responsibilities, etc., imposed upon us as a class by the Pharmacy Act of 1868; to inquire how far this Act is responsible for our grievances; to ascertain what benefits we are at present deriving from it; and to offer for discussion certain suggestions, whereby to attempt the removal of most of the grievances of which we now complain. It is notorious and certainly to be lamented that ever since the Pharmacy Act became law it has formed the subject of continual complaints, since it imposes upon our shoulders numerous burdens, for which it gives us but little in return.

When the Pharmaceutical Society first introduced the Bill it encountered a great amount of determined opposition; many real and imaginary objections were raised against it; some denied the necessity of any interference from the State, and others foresaw the results most likely to accrue from the enforcement of such a law; but the majority listened to the voice of the charmer, and believed in the brilliant future and in the immediate and prospective advantages which the Society and the advocates of the Bill predicted would accrue to the chemist and druggist should it become law.

It will materially assist us afterwards if I now briefly state the chief results which we were so confidently assured would flow from the Pharmacy Act, as we shall then the more readily discover how lamentably up to the present time it has failed to fulfil the objects for which it was promoted. The Bill was intended to secure the greater safety of the public by confining the sale of poisons and dispensing of medicines to properly qualified persons, and in return for the restrictions to be placed on the sale of these certain poisons, and in compensation for the study, for the time and money, which in future would have to be expended before any one could qualify himself to carry on the business of a chemist and druggist, we were promised—

(1) A monopoly in the sale of poisons and in the dispensing of prescriptions.

(2) That in the course of time the grocers and petty dealers who would have to be and were placed on the register, would diminish in number from death and other causes, and that thus ultimately the whole, or nearly the whole, of the dealing in drugs would be in the hands of the legitimate chemists and druggists.

(3) That in consequence of the examinations the number of young men entering the trade would decrease, and the number of chemists in proportion to the population would consequently decrease.

(4) That our ranks would in future be filled from a better class of men, and that this, together with the examinations, would confer upon the chemist a much higher status in society than he had hitherto enjoyed.

In return for these advantages, the only burden or restriction on the chemists then in business was to be the labelling certain articles after the manner specified by the Act, and the registration, etc., of the sale of certain other poisons, under pain of incurring a heavy penalty in case of neglect or wanton infringement.

It is now eight years since the Act came in force, and we have had ample time, therefore, to judge of its working, to ascertain our present condition under it, and to arrive at positive conclusions as to whether it has answered the expectations of its introducers, and the purpose for which it was passed. I think there are very few who will venture to affirm that as yet it has either secured the greater safety of the public or conferred upon us any real advantages for what we have found to be the irksome restrictions placed upon us.

First, then, is the safety of the public greater than it was before? Now the answer to this question involves answers also to the following:—

Can poisons now only be obtained of duly registered chemists and druggists?

Are prescriptions dispensed solely by competent and qualified persons?

Now the answer to both these questions is most emphatically, No. The obtaining of poison by any person and for any purpose is scarcely more difficult than it was previous to the enforcement of this Poison Bill, and the dispensing of prescriptions is not the monopoly of the chemist; and both these assertions can easily be verified. Let any one carefully examine the cases of accidental poisoning, and of suicide, and murder by means of poison, and such an one cannot fail instantly to be impressed not only with the ease with which these things can be obtained but with the almost impossibility in many cases of ascertaining when and where they were obtained. We do not wonder that this is so, for it is notorious and forms just ground for complaint that in every town and village in the kingdom we are being openly defrauded by the sale of poison or of preparations containing poisons by unregistered chemists, grocers, hucksters, and others. Instead of the number of these petty dabblers in drugs having decreased they have considerably increased, for everywhere may be found dealers in sand, blacking, and physic, who if they do not openly sell laudanum, chloroform and other poisons in the pure state, yet vend in enormous quantities mother's friend, infant's cordial, cough syrups, ointments, etc., which contain these poisons. I know certain densely populated localities in which every fifth or sixth house is a kind of shop, in almost every one of which there is sold articles of this kind. How does this state of thing affect us? It may possibly be thought convenient by some classes of the public, but it certainly is not to their benefit, and the amount of legitimate trade of which we are defrauded by these shops is almost incredible.

Again the number of men who without passing any examination or possessing any qualifications whatever are openly or covertly carrying on the trade of chemist and druggist, appears to be on the increase. Medical botanists, wholesale chemists, medical halls, drug stores, etc., are being opened out in all directions, and either the Act is unable to cope with them or, as I am inclined to think and the majority of others with me, those upon whom up to the present the duty of enforcing the Act has fallen have failed properly to enforce the Act. The Pharmaceutical Society has exhibited a truly laudable zeal in raising the standard of qualification as high as possible, and thus decreasing the number and shall I say increasing the quality of those entering our trade (or profession as many would like to call it), but I fear it is far from being generally credited with showing the same amount of zeal in protecting their interests when they have entered the trade. This, however, is a question which it would at present be useless discussing.

Many of these stores not only deal in poison but dispense prescriptions, and to obtain a trade generally begin by cutting down the prices, and thus not only compete illegally but unfairly with the legitimate chemist. There is not time to go into the various devices which these men adopt to keep as they think beyond the arm of the law; they can be considered when we are ready to vindicate our rights and eradicate the parasites. The various trade organs have frequently of late contained letters from correspondents complaining of this unfair competition and illegal trading, but they have chiefly dealt with unregistered retailers, the petty wholesale chemists rarely being mentioned, and yet in many localities these do considerably more harm that the former class. These wholesale chemists are generally assistants who have got a smattering of the so-called wholesale trade from being with some chemist who cultivated the suicidical business of supplying grocers with drugs. Many of this class keep open shop, and their wholesale dealings are made a cover for as much retailing as they can possibly do, whether it be in the sale of pickle, blacking or poison. I know instances of this kind, and I know the result it has upon the trade. People knowing that they can purchase small quantities of anything they require from these wholesale druggists, conclude they can do so at wholesale price, and to keep up this profitable delusion, the dealer reduces his prices and also his quality below that of the legitimate chemists. But this is not the only way in which we are openly defrauded by wanton infringement of the Acts designed to protect us. There are the men who, unable to compete with the established chemists who cultivate a grocers' connection, induce every little shopkeeper and huckster to deal in drugs, with ruinous result to the chemists in such localities. Towns which should support a dozen chemists in comfort afford only a bare existence to two or three. One may ask how is it that people, and working people I now more especially refer to, prefer purchasing drugs from the small shopkeepers rather than from the legitimate chemists. There are many reasons for this, one of which is that they cannot get physic from the chemist on credit, whereas by getting it where they purchase their weekly supply of food or sundries they obtain it with the same credit; but the chief reason is that it is cheaper. How is it that these small dealers can buy their few shillings worth of drugs from small wholesale druggists and yet afford to sell them for less than the chemist? These people will have a good profit upon them or they would not deal in them. The fact is the drugs sold at these shops are of the very worst description, bought at a much less price in small quantities than we can really buy genuine drugs at in large quantities. I do not make this accusation rashly, but deliberately, from an intimate knowledge of the trade and from the examination of drugs purchased from these wholesale druggists and sold by their customers. To find sweet nitre having a sp. gr. of 900 and upwards is the rule, and all the tinctures contain about half the official proportion of spirit; light carbonate of magnesia is sold as calcined, and syrup of lime blue for syrup of violets, and so on through the whole category of drugs. This question may seem at first foreign to the subject with which I am dealing, but I contend that it is not, since it is the result chiefly of the maladministration of the Pharmacy and Adulteration Acts, and I hope shortly to show how, by the proper enforcement of these Acts, nine-tenths of this infamous traffic may be stopped. But this class of so-called chemists are the source of still greater and more urgent cause of grievance by inducing the shopkeepers for the sake of increased profit to themselves to take up the sale of cough mixtures, cholera mixtures, rubbing bottles, infants' cordials, ointments, etc., so on *ad nauseam*, nearly all of which contain one or more of the poisons mentioned by the Pharmacy Act, and the exclusive sale of which is supposed to compensate the chemist and druggist for the restrictions placed upon him in his business. I have known dozens of gallons of cough mixture containing large quantities of chlorodyne or laudanum sold under the names of raspberry cough syrup, balsam of honey, and the like. Cholera mixtures invariably contain opium; so also does the infant's friend or cordial. Family ointment is usually a preparation containing white precipitate, and golden ointment a preparation with red precipitate. It must not be supposed that these cases are rare, for although flourishing more in certain localities than in others, yet there is probably not a town or village throughout the kingdom in which the rights of the chemist are not being infringed by the sale of these poisonous preparations. It is only occasionally that the attention of the public is drawn to the danger of using these medicines, as when a child is given an overdose of infant's friend, and does not recover, and then even the chemist has to stand by without defending his rights, and has to see the illegal sale of these things continued simply from the lack of some power to move the law to put an end to it.

The registration of the sale of poisons by chemists and the distinctive labelling as poison of such preparations as have not hitherto been considered such, is in itself a source often of much annoyance.

The signing of his name by the purchaser appears to be very little trouble either to him or to the retailer, but somehow or other the British public has a decided objection to signing its name, or to informing others of its intentions, consequently people look out for other places for purchasing poison where they will not be asked to sign their names or to enter into details as to the purpose for which they require them. As a consequence we find grocers and others dealing in rat and mice poisons, arsenical sheep dips, etc.; and as familiarity breeds contempt, so the evasion of the law, which at first is done surreptitiously, ultimately is done openly, to the serious loss of the chemist, who is thus again partially deprived of one of the few advantages the Pharmacy Act can confer upon him.

The subject of co-operative and civil service retailing and dispensing, I need not touch upon, as it is to be dealt with by an abler hand than mine. It is a subject worthy of serious consideration, for it more or less affects us all, since in the smaller towns many of the inhabitants are joining these societies and obtaining their drugs and medicines with their groceries.

Now let us return to the other advantages which we were to derive from this Act, namely that of the decrease in the number of chemists, and of the higher status of the trade. It is true that for some time there has been an increasing difficulty in obtaining intelligent, well educated apprentices, and one would infer that this argued a future decrease in the number of chemists. The parents of boys who can afford to give them an education fitting them to pass our Preliminary examination and thus to prosecute their future studies with a surety of success, find that for a trifling extra outlay they can place them in the medical profession; and since in the first case the result is only a chemist and druggist, whose status as yet is regarded as but little or nothing above that of his neighbours the grocers and drapers, and who if he has all his rights enjoys only the poor monopoly of the sale of a few poisons and the dispensing of medicines, in the second, the result is the enrolling of his son's name in that of an honourable profession with position and prospects far above that of a chemist. The worst result of this scarcity of respectable youths is that the poorer class of chemists are, to carry on their businesses, compelled to take as apprentices youths of whom there is not the slightest probability of their passing the examination; subsequently these are thrown upon the world as unqualified assistants, to ultimately become unqualified dealers in drugs, infringers of the law, and increasers of the illegal competition to which we are already subject. The opinion of many chemists is that the examinations are too stringent, more so than was contemplated when the Act was first framed. I hold, however, that the examinations are not a whit too stringent to prove the competency of a man to dispense and retail drugs, but I do contend that for the time and money requisite to be expended, before one can become a qualified chemist, we obtain but most disproportionately small advantages, even if the Act was fully enforced. What proportion of the average chemist's turnover is due to the sale of poisons and dispensing? Really in most cases very little. There are numerous towns, and very large towns too, where all the dispensing would not more than support a single chemist. But the further treatment of this subject would lead to a consideration of the relations of the chemist and the medical profession, which I willingly leave to some one else.

The last growl I shall utter is one upon a subject which we shall not all view in the same light. I refer to that portion of the 16th clause of the Pharmacy Act which says "nothing hereinbefore contained shall extend to or interfere with the making or dealing in patent medicines." Why, is it not equally due for the sake of the public safety and for the rights of our trade, that the sale of all patent medicines containing poisons should be subject to the same law as the sale of poisons not protected with a medicine stamp? What virtue or power is there in the government label to prevent accidental or wilful poisoning? Is it not true that a large proportion of these cases are due to the administration of these remedies? Why therefore should not their sale be restricted to the chemist, and take place exactly in the same way as the sale of any other poisonous mixture? But again this clause affords a loophole for evading the Acts, and advantage is already being taken of it to sell laudanum, paregoric and other poisons under the protection of a threehalfpenny stamp.

To the best of my ability I have now pointed out the results of the Pharmacy Act both as affecting ourselves and the public, and it is evident that a many of the grievances which we now suffer are due as much or more to the maladministration and non-enforcement of the Act as to the enforcement of it, and it is therefore necessary for us to consider (first) What means can be adapted to properly enforce the Act and protect our rights? and (second) how we can secure some more adequate recompense for own responsibilities and the restrictions placed upon us?

Now one would naturally suppose from a perusal of the Pharmacy Act, that the Pharmaceutical Society of Great Britain was the legally constituted guardian and champion of our rights, and responsible for the proper enforcements of the provisions of the Act. I am sorry to say we all know only too well that to look for help in that direction is utterly vain; for it either cannot or it will not assist us. It may be that both the chemists themselves and the Society are to blame. The latter is not supported sufficiently by the former, and as a consequence we are deserted, our distinctive title of pharmaceutical chemist is lost to us, and we are delivered over to the spoliator. Had the chemist evinced greater sympathy with the Society, and taken a more active interest in the election of its council, that council and that Society might have been made to represent every class and branch of the drug trade and have been composed of men pledged to do their utmost to protect our interests and vindicate our rights. But there is no immediate prospect of such a consummation, however devoutly it may be wished, and our only hope lies in the issue of the Conference now assembled.

The only means that I consider feasible and likely to be successful in its efforts to assist us is the formation of a trade society, which shall not be antagonistic to the Pharmaceutical Society, but which shall rather if possible act as an auxiliary to it; but if this is not possible it must be prepared to act independently of it. This society should have for its object, the defence of our rights by the enforcement of the Pharmacy Acts against all unregistered chemists, and against all shopkeepers and others who are found dealing in medicines containing poisons; to try by process of law the rights of co-operative societies to dispense and deal in poisons; to point out to the public analysts another and better field for the exercise of their abilities, namely that of investigating the quality of the drugs not sold by druggists; and to attempt to obtain such alteration of the Pharmacy Act as shall secure us increased advantages. I do not think there will be a person present who will deny the urgent necessity of some such steps being taken, and it is sincerely to be hoped that the chemists throughout the country may be roused from their lethargic state, to unite together for the common weal. There are many who would go even further than this and restrict entirely the sale of drugs to the chemist and druggist, but any one who calmly reflects on the subject will at once see that this is an object which it would be folly at present to attempt. Neither do I think it would benefit us aiming at too much, we must prove our demands to be just and moderate, and there is little doubt but that ultimately our demands would be complied with.

In conclusion let me just point out what I think would be the result of a short period of vigorous action undertaken by such a society by simply enforcing the present Pharmacy and Adulteration Acts. First by a thorough enforcement of the Pharmacy Act the sale of poisons and dispensing by unregistered men would soon be stopped. The drug stores, medical halls, etc., would have to put up their shutters or their owners make an effort, and pass the requisite examinations, and thus a large portion of our trade of which we are at present defrauded by these men would accrue to us.

The legality of co-operative dispensing could be put to the test; if illegal there would soon be an end of this grievance, and if it should prove to be legal, we should then know the worst, and could at least attempt by an alteration of the law to make it illegal.

The proper enforcement of the Adulteration Act would speedily rid us of three-fourths of that wretched competition with petty shopkeepers to which all chemists except in better class neighbourhoods are subject. It has often struck me that the inspectors would much more effectually cope with this subject if instead of always purchasing goods from the recognized dealers, as drugs of chemists, groceries of grocers, etc., they would take samples of those things not properly belonging to the business of the traders from whom they are purchased. They would thus not only be more likely to meet with cases of adulteration, but would also protect the different classes of tradesmen from unfair competition with each other.

Again, I think it would be quite possible to obtain some modification of the Pharmacy Act, so as to render it somewhat more just. This might be done by confining the sale of all patents containing poisons to the chemist, and by either extending the number of poisons in part 2 of Schedule A, or by creation of a part 3, which should contain a number of powerful remedies, such as carbolic acid, sugar of lead, nux vomica, phosphorus, lobelia, caustic, digitalis, and chloral hydrate, and all their preparations. These should only be sold by the qualified chemist, but it should be left to his discretion whether they should be labelled poison or no. These, however, are all subjects which would be taken up by the society it is proposed to form.

Let the proposal be considered as dispassionately as possible, and then whatever action we decide to take, let us unitedly strive to accomplish the purpose for which we undertake it. No local grievances, no spirit of petty jealousy or personal animosity, no trifling differences of opinion must be allowed to turn us from our purpose; we must determine to gain the favour of the gods by doing all we can for ourselves, we must keep the goal before our eyes, and swerve neither to the right nor to the left until we reach it. Let us strive to do this, and the consciousness that our efforts are not prompted by defiance, but by defence, and that our demands are just and right, will materially assist us in our endeavours, and ultimately lead us on to victory.

The CHAIRMAN: I am sure you will feel very much indebted to Mr. Thresh for his vigorous paper. We have had the pleasure of knowing Mr. Thresh for some years; I won't say a number of years, for we must speak of Mr. Thresh as one of our young able investigators. You will see how often his name occurs in the pharmaceutical and other prints, in connection with pharmaceutical science, and I am glad he has given us his clear judgment on such a question as this also. The suggestion which was made concerning Mr. Southall's paper, that it ought to be considered with some other matters yet to be brought before the Conference will apply also to this. The allusion especially to the subject of patent medicines may very properly be considered when Mr. Shaw and Mr. Arblaster give us their views on the same subjects. Some of Mr. Thresh's statements, particularly as to the abuses by small wholesale druggists acting as retailers, and also as to the quality of drugs sold by unauthorized persons, I am quite sure, are the result of his own experience, and his experience would indicate to us, even if we had not made up our minds as to what should be done or how to do it, that the collection of information is a worthy object for an association like this. I hope that we shall always bear in mind that the charter of the Pharmaceutical Society, after referring to the purpose of its education, has a definite statement that it is to be also for the protection of those who carry on the business of chemists and druggists. Let us not think that we are asking something unreasonable in asking for reasonable protection.

Mr. EDWIN YEWDALL (Leeds) then read the following paper:—

THE DIFFICULTIES OF CHEMISTS UNDER THE ADULTERATION ACT.

The practical working of the "Sale of Food and Drugs Act, 1875," having resulted in the prosecution of several respectable tradesmen whose previous honourable dealings lead to the supposition that they are the innocent victims of a stringent law, it has been thought that a consideration of its various sections may be interesting and productive of mutual advantage. With the object of obtaining the opinions of others I have undertaken to bring the subject before you to-day, though well aware that there are many here present who could have treated it in a much more able manner had they been invited to do so. The preamble of this Act states that it is desirable all Acts relating to the Adulteration of Food and Drugs in force at the date when this Bill became law shall be repealed, and the 1st section gives a list of these Acts, amongst which will be found the 24th section of the Pharmacy Act, the repeal of which seems to very much modify the provisions of that Act. You will remember that according to the section referred to any registered chemist and druggist selling an adulterated drug would, unless the contrary was proved, be deemed to have knowledge of such adulteration, and whilst thus rendering himself liable to the penalties of the Acts then in force for the purpose of preventing adulteration he was liable under the 26th section of the same Act to have his name erased from the Register had the Privy Council, in whom was vested the power, considered his offence deserved such further punishment. The repeal of the 24th section relieves the retail chemist of any charge of adulteration under the Pharmacy Act. Referring to the "Sale of Food and Drugs Act, 1875," the 2nd section interprets the word "Food" to mean every article used for food or drink by man other than drugs or water; also, that the term "drugs" shall include medicines for internal and external use, but it does not say for man, consequently, I presume that this term applies also to medicines for cattle. The 3rd section refers to the penalties which can be imposed for mixing any injurious ingredient with food and selling it in that condition. By the 4th section any person selling a drug to which any article has been added calculated to affect injuriously its quality or potency is liable to a penalty for the first offence of a fine for a sum not exceeding fifty pounds, and for a second or any subsequent offence of imprisonment with hard labour for a term not exceeding six months. With these heavy penalties hanging over us it is of the greatest importance that we should if possible avoid a first conviction, especially as the success of a retail chemist depends very much indeed upon his character for supplying genuine articles. There is a provision in the next section that no person shall be liable to these penalties if he proves to the satisfaction of the Court that he did not know of the articles being mixed or adulterated and could not with reasonable diligence have obtained the knowledge. It will be observed that it is incumbent upon the retailer to be in a position to assert either from his own knowledge or from information obtained from the person of whom he purchased the article that it is genuine. To be able to speak from his own knowledge requires that he should have examined the article thoroughly, which to some chemists and druggists who have little knowledge of the use of the microscope or the process of chemical analysis, and to others who are fully employed in the usual routine work of a retail business, would be almost an impossibility; they will therefore adopt the alternative of relying upon those from whom they have purchased it, but in order to make themselves safe will probably require a warranty. How can they obtain this warranty? As the provisions of the Act apply to the wholesale dealer, it follows that if an order is given for an article and it is supplied, with it will be sent an invoice giving the quantity and name. That invoice I consider is a warranty. It is well known, however, that the sale of drugs is very slow with some retail dealers and it might happen that a drug obtained some time ago is the one respecting which action is being taken; and those who are familiar with the usual retail chemist's business are aware that when new stock is received it is often put into the store bottle in which there is perhaps some old stock obtained from another house, or if from the same source it has been so long upon the shelves, subject to the varying temperature and humid atmosphere of the shop, perhaps also exposed to direct sunlight, that it is almost inert; and yet on the ground of economy this will be mixed with that just received, thus seriously affecting its quality. Again, there are many articles which are constantly deteriorating. Under all these circumstances would it not be unfair to expect that the wholesale dealer should be held responsible for an unlimited period or even until the stock was sold,—as by improper storage the quality of a drug may be quickly altered. How long should the wholesale dealer be held responsible? To meet this difficulty, it is very probable that the wholesale dealer will, by a notice upon his invoice, intimate that he will not hold himself responsible for the genuineness of the article if it is removed from the bottle or wrapper in which it is forwarded. I have little doubt there are, in many retail shops, parcels of old drugs which have lain for years; it will be apparent to the owners of such, that for their own safety it is absolutely necessary to go through the stock, throwing out all articles of questionable character, including all powders, extracts, or similar preparations, which have become altered in their colour, smell, or taste; and if any costly article is found, respecting which there is a doubt, it will be more satisfactory to send a fair sample either to the Laboratory of the Pharmaceutical Society or to some competent analyst, of which there are many to be found in our ranks, whose practical knowledge of the various articles used as food, and also of drugs, renders them well qualified to fill the position of public analyst, providing they considered such an appointment a *quid pro quo* for relinquishing the business of a chemist and druggist. There are several articles of every-day demand, respecting which a doubt exists whether they can be sold without danger; amongst these will be found cera flav. and cera alb., which, being used in the preparation of medicines for external use, come under the definition of the term drug and therefore ought to be sold genuine, though it is a well-known fact that both are liable to sophistication. When asked for carbonate of iron, we usually supply the sesquioxide. Sapo mollis is frequently used in the preparation of linimentum saponis.

Flavouring fruit essences are artificial, and prepared in the chemists' laboratory instead of from the fruit.

Crocus in placentâ (cake saffron) is sold in large quantities in some towns, and used for similar purposes as crocus in fœno; yet it is questionable whether there is a vestige of saffron in it.

Is the retailer liable to a conviction for the sale of any of these articles under the names mentioned?

Lac sulphuris is another preparation which has already resulted in several vexatious proceedings. Respecting the last prosecution in your town, I wish to call your attention to the report in the *Pharmaceutical Journal*, which I presume is correct, and in which I observe that Mr Herbert, who appeared for the town clerk, stated that in this case it could not be pleaded that the article has been unavoidably mixed, because it was purchased in a pure state and was extensively adulterated with sulphate of lime; this adulteration having, I presume, by this statement been carried out by the defendant after he had bought it pure. If this is a correct report you will fail to see any way by which the defendant could evade the penalty, but if Mr. Herbert is wrong and the article sold was the one usually known as milk of suphur, then we are brought to a consideration of the question, What is milk of sulphur? Was the imposition of a fine in this case the proper administration of the law? I am not prepared to bring before you the whole of the correspondence which has taken place with regard to this preparation; several very eminent pharmacists have expressed an opinion that it should be considered as a separate and distinct preparation from the precipitated sulphur of the Pharmacopœia, in which opinion Dr. Redwood agrees, and there are also several most intelligent chemists, amongst whom is Dr. Attfield, who assert that the term milk of sulphur applies only to precipitated sulphur; they further argue that if an imperfect process was originally introduced for its manufacture, that process has been superseded by another in which pure sulphur only is obtained. With such a diversity of opinion we can scarcely wonder at the difficulty the learned stipendiary of this town, Mr. Kynnersley, felt in giving judgment in this case, or fail to admire his candour in expressing a hope that the question would be taken to a higher court. At the same time inasmuch as there was a doubt whether it should be considered an adulterated article or not, the English law gives the defendant the advantage of the doubt. I am disposed to think it ought to have been dismissed, yet the opportunity now afforded ought not to be allowed to pass, and as the question is one which affects the whole trade you will no doubt concur with me in thinking that the expenses attending such an appeal ought to be borne by the Pharmaceutical Society, though I must admit this Society has not received that encouragement from the trade which should have been given to it, especially by those who when danger threatens are the first to apply for assistance. If the Society refuse to take up this case, then the necessity for some trade organization for obtaining a proper settlement of this and othe questions which will no doubt arise is undeniable, and it is for the purpose of considering the desirability of such a course that we are met to-day. Pending the settlement of the question, I think a label "Milk of Sulphur, prepared according to the Pharmacopœia 1724," would probably prevent any further actions, as showing that it was manufactured by a process according to which the presence of sulphate of lime was unavoidable, and therefore might be considered exempt according to the 4th clause of the 6th section. The omission of any standard of comparison up to which the pharmacist may work or by which the analyst may judge of the quality of the article submitted to him is to be regretted, from the fact that preparations bearing the same name are prepared of many different strengths; for instance, tincture of camphor, which if prepared according to the British Pharmacopœia is frequently taken with benefit. Cases are upon record in which the homœopathic tincture has produced alarming poisonous effects. Although all preparations of the British Pharmacopœia used for the dispensing or compounding of medicines according to prescriptions written since its publication must be of the strength ordered in that work, yet large quantities of drugs are sold daily by shopkeepers which are of inferior quality and in the case of preparations bearing the pharmacopœial name prepared with very weak spirit, or if of the nature of spirit of nitre mixed with water, nevertheless the want of a legal standard to judge of the qualities of these drugs and preparations is a serious obstacle in the way of any attempt to enforce the provisions of this Act against such dealers. Instead, therefore, of appointing an inspector to search for the articles we know are to be met with, would it not be better to appoint some energetic chemist as analyst, we can all obtain from our own neighbourhood specimens of the article sold, but it is not every one who has the time to examine them; if such an appointment was made, or arrangements entered into with Dr. Attfield for the same purpose, such specimens could be forwarded, and if the report showed the presence of any article restricted by the Pharmacy Act to the registered chemist and druggist, information could be given to the local inspector, and the case would be carried on by him in the usual way and without the appearance of any animosity or ill feeling on our part. It would be uncharitable to suppose that the object of the legislature was to harass the well meaning tradesman, but unfortunately if any person who, from pique or vicious disposition, or supposed injury, seeks to do a tradesman harm, this Act appears to lend a means by which he may carry out his design, unless great care is exercised. In the *Pharmaceutical Journal*, April 1, 1876, is the report of a case where a milk dealer was summoned for selling adulterated milk. Although it is not stated under which section the information was laid, I presume from the remarks of the stipendary that it was under the 6th section. Mr. Arnold pointed out that to ensure a conviction under this section it must be proved that the sale was to the prejudice of the purchaser, and as the inspector could not affirm that such was the case, he—the magistrate—would take time to consider the point. I have carefully searched in the Journal for the final decision, but have not yet met with it.

Having briefly laid before you some of the points requiring your attention, I hope due consideration will be given to them, as well as to those which may be adduced by the papers which are to follow, that some well digested scheme whereby we may avoid the penalties of this Act may be the outcoming of our meeting.

The CHAIRMAN: Our thanks are due to Mr. Yewdall for his very excellent paper on this subject, and a most important one it is. Those of us who live in the same town as Mr. Yewdall, know how important his services have been towards the organization of associations for promoting the common advantage. There can be no objection to the paper being discussed now, as I do not see any subsequent proceedings which can be taken with it. If we are to be practical, I suppose the first matter would be the consideration of the Birmingham milk of sulphur case. I should be glad if some local member would give us a little information. We have read what has been published, but it is not probably known to the meeting generally whether the person who sold this milk of sulphur was a registered chemist and druggist, or not. I should be glad to have this information, and also whether the legal technicalities which would be needful for the case to be carried to a higher court have been complied with, or whether it is now too late for such a step to be taken.

Mr. ALFRED BIRD (Birmingham) said: There have been two milk of sulphur cases, the one against Mr. J. Sumner, chemist and druggist, of Coleshill, and the other against a drysalter. As I conducted the scientific defence of Mr. Sumner, and to a successful issue, at Coleshill, we thought the same arguments and the same reasoning as was employed in the Coleshill case would suffice before our learned stipendiary. The argument which we brought forward at Coleshill was very simple. We showed distinctly that there were two preparations, and that milk of sulphur was separately quoted on the drug trade lists. I told the magistrates that I had sold milk of sulphur in my shop nearly forty years, and I should continue to sell it. The magistrates were so convinced that there were two preparations that they dismissed the summons. One of the reasons why the prosecution was resisted, was that there was a foul word in the summons, charging Mr. Sumner with fraud. I do not know, gentlemen, how you would feel, but I know how I should feel if I were charged with fraud, and I was determined in this case, regardless of expense, to hurl back the charge. We were successful, for the magistrates dismissed the case and coupled with it that Mr. Sumner did not sell a fraudulent article, but a legitimate one and was perfectly justified in so doing. When the second milk of sulphur case came on at our public office we thought that the same arguments temperately stated to our magistrate would settle the case, in fact we thought it would convince Dr. Hill. However, the result was different, and Mr. Kynnersley distinctly enunciated that the term milk of sulphur is only applicable to the precipitated sulphur of the last Pharmacopœia; that the terms are synonymous, and that if you sell the old milk of sulphur you must be good enough to put a label that there is sulphate of lime in it. I beg to say that though this unfortunate fellow who was summoned was fined a shilling he has not been able to carry on the case, for he is a very poor man and anything in the way of a reference to a higher court is a most costly proceeding. This man did not feel in a position to find money to fight the cause of the chemists and druggists, therefore the case has dropped without any appeal to the Court of Queen's Bench whatever on the point. Mr. Bird suggested that those who supplied these preparations should take particular care under what name the article is purchased. If the customer asks you for milk of sulphur, give him milk of sulphur; if he asks for precipitated sulphur, give him precipitated sulphur; then you are safe. The effect of Mr. Kynnersley's judgment has been to carry alarm and dismay into the chemists' shops throughout the whole town, and last night I had a most curious and comical instance of it. An old woman came into my shop with a tumbler glass and a spoon, and she said, "Just look here, what's this?" She was stirring away at something in the glass, and she said, "I went into a certain shop for two ounces of milk of sulphur, and this is what they gave me." She got it on Saturday night and she was still stirring at it. I asked her to give me a small portion which I tested in a spoon, and in a few moments I saw that the chemist had given her some of this unmanageable preparation. I said—"This is not milk of sulphur, you have been sold the wrong article. You look like a woman who knows how to defend yourself." I said—"Go down to the magistrates to-morrow morning and ask for Mr. Kynnersley, and just tell him your grievance, and tell him also I sent you." I do not know whether she has gone down, but I had reason to think she would. I told her first to go back to the chemist's shop and tell them she had not got the right article, when she replied, "Its no good doing that, as they would just take it away and give me something else." She said—"This is an abominable adulteration, and I don't see why a poor creature like me should be served so." I hope we shall not refuse to sell milk of sulphur when it is asked for, and that we shall not put anything on about sulphate of lime.

Mr. R. HAMPSON (London): I fully agree with what has been said about calling things by their own names. A reference has been made to the Pharmacopœia that it will be taken as the standard, and must be upheld and obeyed by chemists. Now, I hope in the future, when a time comes for another Pharmacopœia, we shall have some voice in the making of it. It is not a pressing subject now, but I feel sure it will be our interest, as well as simply just, that we should have a voice in the making of that Pharmacopœia, that we shall stand in the same position in England as upon the continent, and that the work shall be that of the pharmacists as well as of medical men. Another thought strikes me in reference to the Adulteration Act, and that is, that we have analysts appointed with very imperfect credentials. We have gentlemen no doubt very worthy, but not having the requisite skill and knowledge for their position; and it does seem exceedingly hard that examined men—chemists—should be tackled by incompetent men, and should have their reputations damaged by them. A case may come forward of adulteration, or presumed adulteration, of some article sold by a chemist, and the chemist may not have the resolution and the pluck to face it out, but may think it the best policy to abide by the analyst's statement. But what I most desire is, that in future we should bear in mind that the analyst should be a qualified analyst—an unadulterated analyst in fact—and that we should have men thoroughly qualified to undertake the responsible duties attaching to their post.

Mr. CHURCHILL (Birmingham): I think it would be well to bear in mind that our Birmingham milk of sulphur case was not directed against a chemist and druggist. The reader of the paper on the Adulteration Act suggested that in the event of such a case being brought against a chemist and druggist the defence should be undertaken by the Pharmaceutical Society. That idea has been held by many chemists, and I may state that I myself wrote to the Secretary of the Pharmaceutical Society suggesting such a view, but I received a reply that the Society was not a trade union. That seemed to point very clearly to the necessity for the formation of such an association as is now proposed.

Mr. G. ELLINOR (Sheffield): I have looked into the Pharmacopœias, especially the one of 1721, when lac sulphuris was officially named and the process given. We next find that the name was changed from lac sulphuris to sulphur præcipitatum. The present process was not adopted till 1809, therefore the name milk of sulphur applies to the present Pharmacopœia article sulphur præcipitatum. The name applies, because the name was changed before the process. I think, if you take the London Pharmacopœias as they are in the London Society's Library, and examine them, you will find there is no ground whereby you can stand with the adulterated milk of sulphur. I believe that is the only official regulation we can have, and that convictions can be obtained and will be obtained if contaminated milk of sulphur is sold either as milk of sulphur or sulphur præcipitatum. We cannot get away from the Pharmacopœias; they are the legal standards.

MR. ANDREWS (Bayswater): I am going to suggest a manner in which you may give the public what they ask for, for undoubtedly there is a demand for this adulterated —as it is termed—article. I would simply suggest that you should have a label "Milk of Sulphur—not the Precipitated Sulphur of the Pharmacopœia." Do not say adulterated with anything. Then have another label, "Precipitated Sulphur, British Pharmacopœia—such a date." I think that by this means you will escape all difficulty.

MR. G. WARD (Sheffield): I should like first of all to demur to the term "adulterated milk of sulphur." I hold it is not adulterated. I should like also to say, that the solicitor engaged in our case at Leeds, advised a label exactly such as has been recommended by the last speaker—of "Milk of Sulphur, not the Precipitated Sulphur of the British Pharmacopœia." Such a label is becoming somewhat common in our neighbourhood. There have been a great many instances in which this pure precipitated sulphur has been sold as milk of sulphur and has been returned as not being the article desired by the purchaser. A good deal of force undoubtedly rests in the remarks about the names in the Pharmacopœia but, I think, there is also some force in the custom of the trade. If I have been accustomed to buy for twenty years an article which I have known by a certain name, and which most people know by a certain name, I hold that if I go and ask for the article by the same name, the seller has a right to supply me with the article I want. That is simply what has taken place in this milk of sulphur case. Precipitated sulphur certainly is not milk of sulphur, and milk of sulphur certainly is not precipitated sulphur, according to the present Pharmacopœia, and I think the case would be established if it were taken up. I trust that it will be one of the objects of this Trade Defence Association. I am sorry to see that in some cases the advocacy of the contrary view was sought to be strengthened by the imputation of impure motives.

Mr. ELLINOR: I hope my remarks did not lead to the conclusion that I thought milk of sulphur was an adulterated article. It is a different article, and I think if the distinction is observed on our labels we shall avoid future difficulties.

Mr. WALKER (Longton): Allow me to say that some people have a very strong opinion about this milk of sulphur. On two occasions, within twenty years, I have been persuaded by friends, against my own opinion, to give up selling milk of sulphur and to sell only sulphur præcipitatum, but with very unsatisfactory results. I may say that on scores of occasions people have brought it back and have complained bitterly of being supplied with an article they did not want. It was not what they wanted; and this has been the case with other chemists who have sold pure precipitated sulphur. Where people ask for milk of sulphur they want a different article altogether, and I think all will agree they ought to be satisfied with what is known as milk of sulphur. If they ask for precipitated sulphur, let them have it; but if you supply it to them under the name of milk of sulphur they are dissatisfied, and they have not got what they want. I may mention that in my own neighbourhood certain chemists were summoned for selling milk of sulphur when precipitated sulphur was asked for. Eight or nine such cases occurred, and the defence in the case upon which the whole were decided was that they were synonmyous terms, and that when asked for precipitated sulphur we were quite justified in supplying milk of sulphur, because they were the same thing. The magistrate at once decided against that. He decided that the terms were not synonymous, that the two articles were entirely different, and that if when asked for precipitated sulphur the dealers supplied an article in which sulphate of lime was an ingredient, they broke the law, and in each case a conviction followed.

Mr. THONGER (Birmingham): I am perfectly satisfied that if the opinion of the trade was canvassed as to whether it would be wise to turn our backs on what I have no fear to call a very nasty article—the old fashioned lac sulphuris,—we should find the great majority in favour of doing so. I was told before I went into business to look at it as a nasty thing and a useless thing, and I have never had the slightest difficulty in selling the sulphur præcipitatum. I would propose that the subject should be one of the first that should be taken up by the association, and that a good plan of going to work would be first to consult some high medical authority as to whether such a society would be wise in doing its best to remove the thing altogether from the trade. If there is any value in it as a medicine it is for the medical authority to say so. That I cannot answer. If it be proved that there is some advantage in it which sulphur præcipitatum does not possess, the sale of it need not be followed with any great difficulty, I am sure.

Mr. COUNCILLOR STEAD (Leeds): Like some other gentlemen, I, after the milk of sulphur case at Leeds, sold in three instances sulphur præcipitatum, and in each case it came back.

Mr. MASON (President of the Liverpool Chemists' Association): It appears to me that the locality in which milk of sulphur is sold would in great measure decide what is to be sold for it. I agree entirely with Mr. Thonger, and I agree perhaps with the public analysts and medical men in thinking that there is not any virtue in lac sulphuris, and that one of the good results which may come from the Adulteration Actis to put away its sale. I was most amused when I heard of the first milk of sulphur prosecution; my wife read it to me, and while she was so doing she said, "If they wanted cream of sulphur, why did not they ask for cream of sulphur?" I do not know whether it is known as cream of sulphur anywhere, but I believe there is some distinction of the kind in Guernsey, and that they ask for milk of sulphur if they want lac sulphuris, and for cream of sulphur if they want sulphur præcipitatum.

Mr. CUBLEY (Sheffield): I think a question has arisen which should be looked into with the greatest care, and that is the necessity of having the Pharmacopœia as the standard of purity. I am afraid the question of milk of sulphur is one of those where, after all, the greatest profit will go into the pockets of the lawyers. But I think it should be our duty, as far as we possibly can go, to see that everything should be as nearly as possible to the Pharmacopœia. I say so for this reason, and this reason only, that however you may put the sale of drugs by further enactments into the hands of the chemists only, there would be behind them, for vending by unlicensed persons, the calomel, milk of sulphur, and other things which may not be mentioned in the Pharmacopœia. If any further restriction is to be made as to the sale of drugs you would have to take the Pharmacopœia as the standard of purity. It is not in the wish to make no difference between milk of sulphur and precipitated sulphur that I would hold to it, but it is that we should endeavour, if possible, to get the principal articles of the Pharmacopœia into our hands. If, however, we raise a lot of these dual articles, there will be the more to be left in the hands of unlicensed people.

Mr. ELLINOR: If we do not combine the old and new names together we shall have great difficulty in getting convictions against small shopkeepers. Where there are two names in the Pharmacopœia, we must take them as synonymous.

Mr. BIRD: We are bound, in dispensing prescriptions, and medical men are bound in writing them, to adhere to our codex and to it alone; and we must not say that the old and the new names are synonymous.

Mr. THRESH: I would suggest that in any future Pharmacopœia it would be advisable to increase the number of synonyms.

Mr. AYRES (Bridgwater): I think, as a practical man of business, that we cannot get over the fact that a demand by the public exists for lac sulphuris. The article is in demand, and in certain localities it has a very considerable sale. In our associations at Taunton and Bridgwater we have adopted a label declaring the actual article as it exists. We, as individuals, do not create the demand; the public come to us for the article, and we supply to them the article to which they have been accustomed.

The CHAIRMAN in closing the discussion said: Any proposal to place in the hands of the medical authorities the decision as to what should be an article of sale or should be forbidden to Englishmen would be to open up some of the principles of the liberty of the subject a great deal wider than we propose to discuss. The customs of the purchaser have a right to be considered. It is not a question merely of synonyms. On that, perhaps, we might have no great difficulty but we have to admit that the two things are different, that it is because they are different that prosecutions have taken place, and that the public say that they wish to have what they and their forefathers have been accustomed to. I think that the chemists would be disposed for the sake of avoiding trouble and annoyance, to give up a trifling gain from the sale of a particular article, but still there is a principle concerned which if we were to disregard altogether might be applied to other matters, so that we must still maintain that we have a perfect right to go on honestly selling the article which the public ask for. A very useful suggestion of Mr. Hampson's should be borne in mind, and that is, that it is one more reason why pharmacists should be consulted in the formation of all parts of the Pharmacopœia.

Mr. J. T. SLUGG, F.R.A.S., read the following paper on:—

THE CASE OF WIDOWS AND TRUSTEES UNDER THE PHARMACY ACT, 1868.

This is soon told. By clause 1 of this Act it is made unlawful for any person to carry on the business of a chemist and druggist whose name is not on the register; and by the 11th clause, on the death of a chemist and druggist his name is to be removed therefrom. By the 16th clause certain exceptions are made to the operation of the 1st clause, and it is there enacted that "upon the decease of any chemist and druggist actually in business at the time of his death, it shall be lawful for any executor, administrator or trustee of the estate of such chemist and druggist to continue such business if and so long only as such business shall be *bonâ fide* conducted by a duly qualified assistant." In 1873 the Council of the Pharmaceutical Society obtained the opinion of their solicitor as to the right interpretation of this clause, from which it appears that in the case of the death of a man who has made a will appointing executors, and creating certain trusts, providing, for instance, that the business shall be carried on for the benefit of the widow or children, so long as the trust exists the executors may carry it on. But the strangest thing is that no one's name will appear on the register in connection with such business. The very essence of the Act appears to be complete and unexceptional registration, and yet it allows numberless executors in various parts of the kingdom to carry on the business without registration of any kind. Hence to this extent, which may be a large one, the register will be incomplete, and will not show the actual number of chemists and druggists in business. Here is one glaring instance of the incompleteness of the Act. But a still more glaring one,—and a most unjust effect of this incompleteness,—is the following, that the widow of a druggist cannot carry on the business for herself. If the husband should leave his business to his widow for her absolute benefit and appoint her sole executrix, she could only carry it on until his debts were paid, or the business sold, and not a day longer. The day she puts the profit into her own pocket she breaks the law. Exactly the same results follow if the husband dies intestate, and the wife takes out letters of administration. What a hardship this is, will be seen from a consideration of cases like the following, which is mentioned as a type of many others. The writer intimately knew the parties—a druggist and his wife without children. The wife who was much the younger, took an active part in the business, and in course of time became the more popular of the two. She acquired quite as competent a knowledge of it in every respect as the husband, and was even more trusted than he by the public. Since the Act was passed the husband has died, leaving his little all to his wife for her maintenance, fondly hoping she would have the profits of the business she had helped to build up, for her support. She was only allowed to continue the business till she had paid the debts due at his decease, and was then compelled to sell it. So that notwithstanding her intimate acquaintance with the business, equal in all respects to that of her husband, and her perfect competency to carry it on, she could not do so even with the aid of a legally qualified assistant. The extreme stringency of the Act in this respect appears very illogical when contrasted with its incongruous and absurd laxity in another. For a druggist once having his name on the register may open any number of shops in any number of towns, and if he chooses may appoint an apprentice or a porter, or any person, whether much or little qualified, to manage each shop. Of course it is admitted that self-interest would lead to the appointment of managers with some qualification, but the law in question, which is so absurdly strict in one point, goes to the opposite extreme in another, and makes no provision for the adequate management of any of the branch shops a druggist may be the proprietor of. The writer believes that if an executor, who in all probability knows nothing of the business, may carry it on by the aid of a qualified assistant, a widow, who in many cases knows something of it, may be allowed to do the same for her own benefit, on similar conditions.

The CHAIRMAN: The meeting is much obliged to Mr. Slugg for his lucid explanation of a matter which many have not looked into very carefully. The matter is one most interesting to us and I shall be glad to hear any remarks.

Mr. RADLEY (Sheffield): There is one point to which I should like to call attention. The Council of the Pharmaceutical Society is the body entrusted with seeing that the law is carried out, and in no case has the Council taken action to oppress any widow. I believe a feeling of tenderness and compassion has always been felt towards a widow.

Mr. RIMMINGTON: I think it is only an anomaly of the Act.

Mr. HOLDSWORTH: I think that what has been advanced will show that it will be very wise for a druggist to make his will. I apprehend in the case of a man being in the position Mr. Slugg has referred to, the difficulty would not have happened if there had been a nominal executorship, and somebody had been appointed trustee to carry on the business for his widow. At all events it would be well for gentlemen who wish to leave their businesses to their widows to look into the matter.

Mr. R. G. JONES (Lye): Two trustees are required. I had a legal opinion on that point.

Mr. SLUGG: And then comes the difficulty of getting two gentlemen from mere friendship's sake to bear the responsibility which does rest upon anybody carrying on a druggist's shop.

Mr. DYER (Halifax) said: The question is a very difficult one. The more we look into the operation of the clause of the Act in question, the more we shall see how detrimentally it may operate against descendants of members of the trade. It is one of those questions which I think this Society should put its shoulder to the wheel to set right. One of my friends has suggested what would be the position of an executor employed in one of these trusteeships, who is not registered, administering poisons with fatal results. What would be the result to the persons implicated under such circumstances?

Mr. DAVISON (York): I should like to ask one question—Whether any parties except the Council of the Pharmaceutical Society are in a position to set the law in motion according to the clause read? We have no evidence that the Council of the Pharmaceutical Society has ever taken any action whatever against widows; the local associations for very obvious reasons never liked to appear in these matters; therefore if no other individuals have any right or power to insist on the provisions of the clause being carried out, it is evident the clause is likely to be quite inoperative.

Mr. ANDREWS: I think it is quite within the power of any one to take action to cause the clause to be carried out. I do not think there is anything which touches the interest of the druggists more closely than the settlement of the affairs of their families. I can tell of a case in London where very great injustice was done to the widow of a pharmacist who thought she had succeeded to a good business. She asked the Secretary of the Pharmaceutical Society whether it was legal for her to carry it on. She was told that it was not, and she was obliged to sell the business for a sum about equal to what the annual income would have been. While a widow may not carry on her late husband's business any registered chemist may set up any number of businesses all over the country and put any one he pleases in charge of them, competent or incompetent. Here is a glaring iujustice which ought to be remedied, and I think some substantive resolution ought to be carried by this meeting affirming that something should be done. When I went to consult my solicitor some time ago he said that the Act was very badly drawn, that you may do almost what you like, but that if you want to be in a secure position you must get two gentlemen to act as trustees; and therein consists the difficulty.

Mr. WOOTTON (Editor of the *Chemist and Druggist*): I should like to say, that so far as the business of a chemist and druggist approaches a profession, this clause is no injustice; because when a surgeon dies you cannot claim that his practice shall be retained by his widow, with any number of trustees. His practice dies with him; and so it must be with the professional part of a chemist and druggist's trade. At the same time, there is no doubt a great deal of property in a trade business, in reference to which there is much opportunity for rectifying the Act.

Mr. HAMPSON: I should not like to do anything injurious to women, but we ought to bear in mind that it was the intention of the legislature that the owner of the shop should be an examined person; and if we attempt to amend the Act in an opposite direction, we shall do injury instead of good. We ought to bear steadily in mind that the owner of poisons should be a responsible person. The widow, unfortunately, does not occupy that position. It is one of those unfortunate things in connection with this Act which occur in almost every kind of legislation—that there is personal hardship inflicted somewhere.

Mr. SLUGG: The executor is not an examined person.

Mr. HAMPSON said the object of an executorship was simply to wind up the concern. It was never intended that the executors should carry on the business in perpetuity.

Mr. A. BIRD: Would it not meet the difficulty by allowing ladies to pass the pharmaceutical examination? If the wife had been examined, she would then be in a position to carry on the business. Is not that some reason for allowing ladies to pass our higher examination? I say in my judgment that it is.

A DELEGATE: They can pass.

Mr. BARCLAY: I should like to advise any chemist who has not made his will, that it would scarcely be wise for him to make it in such a way as that his widow should carry on his business after him. I have known several cases throughout the country, and in almost every case the business has suffered. Instead of the business continuing a lucrative one as it was when carried on by the chemist himself, it has in the hands of a manager suffered considerably. I know a few exceptions where a manager has carried on a business satisfactorily, but they are quite the exception. It was only the other week I was consulted by a widow who was left some six months ago with a capital businesg in a neighbourhood where there was very little competition, and where one would have thought that the business could have been carried on by means of an ordinary assistant. In six months she had had three or four assistants, and just now the business is in such a condition that she is obliged to sell it—it is slipping away entirely from her, and she is in the greatest extremity about getting a manager, and altogether it is a most lamentable thing. She has been teased and worried during the last six months to such an extent that she would be glad to get rid of it almost at any price. Looking at the matter in a benevolent view certainly widows ought to have the privilege which executors are allowed, yet at the same time I should like to give the Conference, as the result of my experience, that it is not wise to make arrangements for widows to carry on the business as a rule. There is another point which ought not to be lost sight of, and that is that in the carrying on of businesses by widows and executors there is a loophole for illegal competition. I think there are many businesses carried on professedly by executors, which are really carried on by unregistered persons for their own benefit. As the Pharmaceutical Society does not appear to have pushed the matter, I should think the object of Mr. Slugg will be gained without pressing the matter further.

The CHAIRMAN: The discussion of this matter in a calm and dispassionate way cannot fail to do good by letting us all know the position of the law. Although manifest hardships may occur to the individual in some cases, which would at first dispose us to seek an alteration of the law that would permit greater latitude, I think there is great force in such suggestions as have been given us by Mr. Barclay. In the interest of the widows it probably is better that they should leave property of such a risky and responsible nature as this. We must recollect that in addition to the difficulties which any business may have there are liabilities under Lord Campbell's Act which apply specially to this trade. In view of this, and of the abuses by unauthorized persons, it is very doubtful whether it is in the interest of the general body that we should have much extension of the powers of widows. There are cases of wills being made which would give a widow power to continue a business two or three years in anticipation of the coming of age of a son. It appears that for this there should be some protection, but that a business should be carried on by a widow for a long period he did not think was particularly desirable.

The Conference then adjourned for luncheon and were entertained by the Birmingham Chemists' Association at the Midland Hotel. On resuming,

Mr. JOHN HARRISON (Sunderland) read a paper on —

JURIES.

Although the subject I have to bring before you is one of great practical importance to every chemist, yet I am happy to say that I shall not require to trespass long upon your time, as the reasonableness of the proposition I shall advance is so clear that very few words on my part will be required to enlist your sympathies with me.

The principle by which the members of certain professions are exempted from jury service on account of the peculiar character of their duties is a very ancient one, and has been so frequently adopted by Parliament that no defence of it is required on the present occasion. Since the year 1513 surgeons have been exempt from such service, and in the year 1694 this exemption was extended to apothecaries, for the following reason, which I quote from the Act by which the extension of the Act of 1513 was enacted:—

"Whereas the art of apothecaries is of great and general use and benefit by reason of their constant and necessary assistance to his Majesty's subjects, which should oblige them to attend solely to the duties of their profession."

It was no doubt felt at the time that as the physician and surgeon who prescribed the medicine were free from service on juries that it was only the correct logical consequence that he who compounded the medicine should be likewise free.

Public opinion in this country is proverbial for the slow rate of its growth, and it is perhaps therefore not a matter for surprise that nothing more was done in making further extensions of this principle in our own direction until the year 1862, when pharmaceutical chemists were included in the lists of those entitled to exemption from jury service, and they, observe, not because they were pharmaceutical chemists, but being a registered body and only able to obtain registration by passing a recognized system of examination there was no difficulty in limiting the privilege to those who were really entitled to it. Chemists and druggists were not included in the provisions of this Act, simply on account of the difficulty it was felt would occur in defining who were and who were not entitled to it.

This difficulty has, however, been removed by the Pharmacy Act of 1868, and every one now who aspires to the rank of chemist must reach it through the examination room.

My contention is, therefore, that as the whole of the members of our profession, whether pharmaceutical or not, must be registered, and when so registered discharge the same duties and incur the same responsibilities, so they ought also to be accorded the same protection. This contention will I imagine be at once conceded, as I trust there is no necessity at this advanced period of the nineteenth century to argue that equal conditions should entail equal rights.

The reasonableness of this proposition is so clear to my own mind that I can only account for the fact that it did not receive legislative sanction at the time of the passing of the Pharmacy Act, 1868, by supposing that it must have been overlooked or that it was withheld by Parliament simply because it was not asked for by those most interested in it. I am strengthened in this conclusion by comparing the principle upon which both the Act of 1694 and that of 1868 are based. You will have observed from the quotation which I made from the Act of 1694 that its principle was that persons engaged in the dispensing of medicines should give their personal attention to the same, for it speaks of "their constant and necessary assistance," and you will find that in the Pharmacy Act, 1868, the same principle is acted upon, for in the 17th clause, after defining what the penalties shall be for certain offences against the Act, it is enacted "and for the purposes of this section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller." Now it is very clear from this that the intention of the Legislature has been that a chemist's business shall enjoy the continual personal supervision of the chemist himself, and I ask where is the consistency to lay down such a principle in one Act of Parliament and enforce the contrary by another Act, even to perform so important a duty as that of a juryman.

I need not trouble you with any instances of the hardships the present law entails, there will be plenty of such instances present to the mind of each one of you. The immortal Dickens has supplied in his trial of Bardell *v.* Pickwick such an one, which may differ somewhat in degree but certainly not in kind from realities which take place daily amongst us.

On two recent occasions have our claims been before Parliament. In 1872 Sir John, now Lord Coleridge, and again, in 1874, Mr. Lopes, introduced bills dealing with the juries question, and in the last bill were clauses exempting chemists from service on juries. In both cases, however, the bills failed to make their way through the Parliament, not, however, I am glad to say, from any opposition to the clauses especially interesting to ourselves, but on account of objections raised to other portions of the measures.

I think we should now proceed on a new basis, and not wait for so simple an act of justice until such time as the whole jury question can be dealt with, but urge upon Government or some private member to introduce a bill by which the provisions of the Juries Act, 1862, may be extended to all chemists and druggists.

And I hope that this Conference will not only express with a decided voice its dissatisfaction with the present unequal state of the law, but will also place the question in a favourable position for its successful agitation, and of this I am firmly convinced that, if it be taken up with spirit and prosecuted with zeal, its justice and reasonableness will ensure for it a speedy success.

The CHAIRMAN: I feel sure we shall all feel under an obligation to Mr. Harrison for his paper on the subject of juries. He expects to have your general consent, but there may be some remarks to be made.

Mr. BARNET (Rochester): I was engaged with many persons at the time of the Amended Pharmacy Act in getting the amendments, and one point which we pressed on the attention of the government was that we should be exempted from serving on juries, and the answer which was given was that they could not afford to spare so many intelligent men.

Mr. A. BIRD: I think there is a good deal of force in the able paper which has been read but there is one point I think we should not overlook. There does appear to me a sort of slinking, a sort of moral cowardice, in not being prepared on suitable occasions to assist our fellow countrymen in the difficult operations of doing justice. Although I think it is desirable that those who are engaged in dispensing medicines should be to a certain extent exempt, I think it would be desirable that they should have the option of serving on juries, as there may be cases where it would be of the greatest consequence to have a good chemist and druggist on the jury. I think it should be optional. If a chemist declines to serve he should not be called upon, but if he is willing to serve the country would receive benefit from his services.

Mr. SLUGG: I am very glad the subject has been taken up by the Conference because I have always considered it a great injustice that while members of the Pharmaceutical Society should be exempt the ordinary chemist and druggist could not be.

The CHAIRMAN: Not members of the Society; you mean pharmaceutical chemists?

Mr. SLUGG: Well, pharmaceutical chemist really means nothing, because men who were in business at the passing of the first Act were on certain payments made pharmaceutical chemists. I know the case of an ostler who groomed the horses of a surgeon and was occasionally called into the surgery and so obtained a knowledge of drugs. When that Act was passed he became a pharmaceutical chemist, having previously set up in business. I think it a great injustice that men of that kind should be exempt from serving on juries while I am not.

Mr. HAMPSON: As a pharmaceutical chemist I coincide with a great deal of what has been said. I think that as the legislature in its wisdom compels a certain standard of examination as a condition of entrance to the trade those so exempt are entitled to all the advantages which accrue to pharmaceutical chemists. With respect to the option of serving or not serving on juries I think the proposition that they should have the option is certainly a desirable one. It would be a pity if intelligent men should not have an opportunity of serving on juries if they think proper. I should certainly support any proposition which should exempt a properly registered druggist from being obliged to serve.

Mr. ARBLASTER (Birmingham): I am afraid the returning officer would find it very awkward in serving notices if chemists and druggists were to have an option.

Mr. ELLINOR: I think it is only right chemists and druggists should be exempt from serving on juries, seeing that many of them are not able to leave their business without getting a temporary assistant. They had no one regularly to manage for them, and as they were held responsible for any accidents or mistakes of those they employ, I think they should be exempt.

Mr. DELVES (Exeter): Speaking as a Major man, and especially in answer to Mr. Slugg, I may say that the only advantage we have in passing our examination is exemption from juries. I don't wish to speak as to the merits or demerits of others.

Mr. DYER (Halifax): If it would be competent for us I should like to propose a resolution that the Pharmaceutical Society be requested as soon as possible to procure the exemption of chemists and druggists from the liability of serving on juries. I believe there is no point upon which there is greater unanimity among the registered chemists and druggists throughout the country than that they ought to be exempt.

Mr. HARRISON: I rise for the purpose of seconding the resolution. When the pharmaceutical chemists were exempted it was not because they were pharmaceutical chemists but because they were registered. Now we are registered I contend we ought to enjoy the same exemption.

Mr. BIRD asked the mover of the resolution to amend it by adding the word "optional."

The CHAIRMAN explained the manner in which the jury lists were compiled, pointing out that exempted persons were omitted from those lists on their claiming exemption. It was from the lists that juries were summoned. If any chemist wished to be called upon to serve it would be necessary that there should be no claim for exemption by himself nor by anyone on his behalf.

Mr. ANDREWS moved as an amendment, "That in the opinion of this meeting, it is most desirable that chemists and druggists be exempted from serving on juries, and that as soon as possible the attention of the trade association be devoted to the purpose."

Mr. BIRD: I beg to move an amendment that the word optional be a portion of that amendment.

Mr. JONES (Leamington): I have been anxious that all members of the trade should be exempt, because there are many of our brethren who have not the means of obtaining an assistant. I hope Mr. Bird will not press his amendment as regards it being optional. I hope the legislature will release us entirely, or that it may be optional only as a matter of favour. In Leamington, I have been asked by the summoning officer whether I would act on a jury as a favour in certain cases where it was thought desirable to have a chemist or two.

Mr. BIRD: All I wish is that registered chemists and druggists should not be absolutely disqualified from serving

Mr. JONES: They are not disqualified from serving.

Mr. ANDREWS: I have had a like experience to Mr. Jones. We should not be disqualified in any way.

Mr. BIRD withdrew his amendment, and the amendment of Mr. Andrews, being accepted by the mover of the resolution, was carried unanimously.

Mr. R. HAMPSON read the following:—

CIVIL SERVICE AND CO-OPERATIVE STORES.

BY R. HAMPSON.

This subject which has revolved in the mind of the trade for a considerable time, is at length likely to receive adequate and unfettered discussion. It has been a forbidden one to ventilate in the pages of the *Pharmaceutical Journal*, and at the annual meetings of the Society it has been mentioned with bated breath, as if this particular question was so involved and peculiar that neither discussion would throw light upon it, nor deliberation help to remove it from our path.

The main plea uttered by presumably intelligent men for all this folly of silence and reticence was that a public discussion on the illegality of the co-operative stores, would simply result in gratuitously advertising them to the public, and would otherwise do no good. This plea can no longer be advanced. The stores still abound and flourish, and the pernicious example set in the metropolis is bearing the expected fruit in the provinces.

The time has come when the assumed and hollow decorum of silence investing this subject must be utterly broken through and put aside, and the question—notwithstanding the inordinate apathy and patience that clings to the trade in reference to it—be fought out to the best issue that remains for it.

It is not needful for me to bring you detailed evidence as to the number of the stores in which the Act of Parliament is infringed and set at nought, or a precise estimate of the amount of damage done by them to the legitimate trader. It is admitted by all, except perhaps some of the so-called *élite* of the trade, who may possibly be unaffected, that the injury done is great and increasing, and that in some cases the result is absolute despair and ruin.

If discussion be stifled elsewhere, here at any rate there will be liberty of speech, ending I hope in deliberate counsel and action. Some persons in their commendable desire to raise the so-called status of our business seem to forget that the true basis of the fabric they would build is that of a prosperous and contented trade; and they would appear to be utterly oblivious of the fact that without a proportionate money compensation to the trader, this status is merely attenuated moonshine.

When the Pharmacy Act had passed, those who had worked with unselfish zeal for the enactment gave vent to much jubilant feeling. They had fair grounds for so doing. They spoke as if the panacea of pharmacy had at length been found. The President occupying the chair at the time, our much esteemed Mr. Sandford, publicly stated, and he only gave expression to the prevailing hope, "that as no man could in future commence business without passing an examination, there could be no doubt that the status of pharmacy would be improved." The reverse of this expected result time has proved to be true. The Act of 1868 is now openly set at defiance, not only by illegal traders of the ordinary stamp, but by large wealthy and influential bodies of traders who tag on a department of pharmacy as they would one of millinery in the midst of a heterogeneous mass of mixed trades, and in this manner openly break the law, not only by serving their own members but the public at large.

I do not intend to enter into the question of the right or equity of civil officers of the state to become traders to the detriment and ruin of the ordinary trader, who has to contribute in the shape of taxes to their support, but I shall confine myself to the question of the right and legality of co-operative trades "keeping open shop for the sale and dispensing of poisons."

Our trade has been legislated for because of its exceptional character. It is subjected to clearly defined state restrictions and regulations which affect all its members, and as a consequence we are quite justified in taking distinct and well assured grounds of criticism in dealing with the question of co-operative stores. Our stand-point totally differs from that occupied by the ordinary trader, who is not subject to legal restrictions or onerous regulations.

It cannot have entered into the head of either the registrar, or any other person interested in pharmacy, that whilst the Pharmacy Act of 1868 was deliberately intended by the wisdom of Parliament, and in the interest of the public, to prevent and punish the illegal trader who opened "shop for the retailing and dispensing or compounding of poisons" without having first passed the legal examination, that a large number of persons putting their capital together were to be exempt from the operations of the statute.

It is admitted, and sundry convictions in courts of law prove the fact, that an uncertificated person keeping a qualified assistant cannot assume the title of chemist and druggist or its equivalent, "or sell or keep an open shop for the retailing, dispensing or compounding of poisons" without breaking the law. Surely both law and equity are infringed and common sense outraged if a number of unqualified persons keeping open shop (although they employ a qualified assistant as their servant) are permitted to "retail, dispense, and compound poisons" with impunity, whilst an individual is held liable to a conviction in a court of law for doing precisely the same thing.

If there exists a reason or cause for this unequal and partial interpretation of the law it is too profoundly occult and mysterious for my discovery.

The infringement of the law and of our legal privileges, of which we justly complain and of which we demand the rectification, should have been immediately called into question and put to the legal test.

Years are quickly passing away and the Pharmaceutical Society, supported by the money of the legal traders and the fees of the examined men, is yet asleep and dumb, and the safety of the public and our own legitimate trade interests, both of which are trusts the Society is bound to take cognizance of, are apparently forgotten and neglected.

But some of the members, whose sentiments would almost lead me to doubt their fealty to the Society, have assumed that the public might consider that their safety was not in any way imperilled, if the drug departments of the stores are managed by qualified assistants.

The interpretation of the statute in the courts of law is testimony in an opposite direction.

A grocer or any ordinary tradesman keeping a qualified assistant, has been held to be thoroughly unfit to have the ownership and control of a chemist's business; and a person unable to pass the technical examination in his business, yet trained by years of experience to practical knowledge, is also held to be an illegal trader, notwithstanding that he may employ a qualified assistant to help him in the conduct of his business; and even the poor widow's shop as been closed in obedience to the same law.

The Act has likewise been legally construed, that a partnership, consisting of a qualified and unqualified person, cannot legally exist.

Is it to be supposed therefore, that if these interpretations of the statute be warrantable and consistent with the true interests of the public, that the public safety is well and legally conserved in the drug departments of an unwieldy store, one perhaps of ten or twenty departments, where there is no one possessed of the requisite training and knowledge to overlook and control the qualified servant or to bear the great and unceasing responsibility that attaches to the properly qualified employer and owner?

The intention of the statute is, that the owner of the drugs and poisons should be the carefully instructed and legally qualified and responsible person, and to him mainly the public looks for safety and not to the qualified assistant.

There is another aspect of this very pressing question to which I must ask your attention.

The second object contemplated by pharmaceutical legislation was the conservation of the interests of the legal trader. The words of the charter assign as its special object, "the protection of those who carry on the business of chemists and druggists."

If this specific object were not so formally stated in the charter of incorporation as it is, the provisions for restricting the trade in poisons, as clearly set forth in the Act of 1868, denote that the legally qualified person is entitled to the full benefit from all the legal trading coincident with the carrying out of the enactment.

This is a just and dignified claim, however much it may be the fashion in some quarters to deny or doubt it.

Before the passing of the Act of 1868, there was much said about the vested interests of those already in business, and of those who had voluntarily passed the examinations of the Pharmaceutical Society. These claims were reasonably advanced and entertained.

If there were vested interests acknowledged and claims to be considered before the Act had passed into law, there are greater and more pressing claims and better established interests belonging to the legally qualified men to be urged now. They are the natural and anticipated growths arising out of the operations of our state-regulated and restricted trade, and the vested interests may be represented as the expenditure of much time, money, energy, and intelligence in obedience to the system directed by law. And I maintain that it is strictly equitable and in perfect accordance with the spirit and letter of the law, that the fairly earned equivalent in trade should be reaped only by the legitimate trader.

These claims and interests I wish most fervently still to entrust to the quickened guardianship and conscience of the Pharmaceutical Society, and I hope they may not be ignored or forgotten.

Should these our interests and claims, however, remain unheeded or inadequately recognized, the Society will be called upon to justify its existence afresh, on grounds not to be found in the statutes; it will lose the prestige that is attached to its good name, and become an unpopular and effete body.

I would not have accepted the unenviable responsibility of introducing this subject for your consideration had I not deeply felt that the stability of our calling and the safety of the Pharmaceutical Society were deeply endangered by the evil that prevails unchallenged in our midst.

The continued existence of the evil arising from this most gross infringement of the law and of our legal privileges, will have the effect of stunting the growth of pharmaceutical knowledge, as well as causing the impoverishment of the trade to which we are attached.

It is our duty to request the Pharmaceutical Society, to whom I trust we desire most faithful allegiance, to resolve upon a course of prompt resolute action. The sooner this obligation is undertaken the better, as the lapse of valuable time increases the evil and renders the position in every way more difficult and doubtful. If upon the test being fairly made it should be found there exists some unexpected legal flaw or weakness in the Act of Parliament, which inadvertently permits the existence for the time being of the excrescence we would uproot, we must be prepared to ask of the legislature an amendment of the law upon the fair and already accepted grounds of enlightened expediency—namely, "the safety of the public, and the protection of those who carry on the business of chemists and druggists."

A period of absolute finality in pharmaceutical legislation has certainly not yet arrived, that we need hesitate or fear to approach Parliament, if we should find it necessary, with the open and honourable request that our Act shall be so far amended as to carry out more completely the objects for which it was originally framed.

The present crisis is one of singular doubt, embarassment and dissatisfaction. It is admitted on all hands that a glaring and grievous evil exists that cuts at the root of the Pharmacy Act—an evil which, if allowed complete development, will to a great degree render worthless and obsolete the legislation which we have been accustomed to look upon with so much satisfaction, and which was earned after the expenditure of much zeal and toil.

We assume that the Act of 1868 is strong enough to put an end to the evil of which we complain, yet there appears to be a total absence of the necessary public spirit and resolution in the Pharmaceutical Society to enable it to take up the leadership which devolves upon it, so as to bring this question to a satisfactory issue.

I deeply regret that I have found it necessary—occupying, as I do, so close a connection with the Society—to speak thus plainly of the institution to which I feel sincere regard; but he is not a friend who covers up and conceals the danger which menaces the Society, in polite phrases and useless encomiums.

The CHAIRMAN: There has certainly been no case in which our obligation can be greater than it is to Mr. Hampson. He has treated the question with great judgment, and in a most convincing manner.

Mr. SLUGG: While Mr. Hampson was speaking I could not exclude the idea from my mind that if the able reasoning contained in the first part of his paper was transferred to the brief of an able advocate and addressed to the Court of Queen's Bench I think it would convince the judges that the sale of poisons and the dispensing of prescriptions are illegal on the part of the societies to whom reference has been made. At the same time I admit that the whole question is one full of difficulty. It is, however, worth discussing, and I compliment Mr. Hampson on the great ability with which he has brought the subject before us. I repeat that if his able argument could be transferred to the brief of an able advocate it would convince a jury. During the last twenty years a great change has taken place in the drug trade, of Manchester at all events. There are fewer drugs sold now than ever, and more patent medicines. All drugs seem to be crystallizing themselves in the shape of patent medicines. The sale of these is a very important item in the druggist's business.

Mr. MYERS (Hull): I beg to submit the following resolution:—"That this Conference of chemists and druggists urges upon the Pharmaceutical Society the necessity of testing the legality of the co-operative societies selling and dispensing poisons." I believe myself, as other speakers have expressed it, that if a proper brief were constructed by a gentleman of Mr. Hampson's capabilities, and such a case were taken up by the Pharmaceutical Society and brought into a court of justice, we should put a stop to these co-operative stores dispensing and selling poisons.

Councillor STEAD (Leeds): I have great pleasure in seconding the resolution moved by Mr. Myers. The subject before us is called on the programme "Civil Service and Co-operative Stores." I do not know what the co-operative stores do in the south, and though I am not going to justify the action of one in Leeds, it occupies a position which, in contrast to that of the Civil Service, is that of honest men. They do not dispense but they sell ordinary drugs. You cannot obtain from them a box of Cockle's pills under 1*s.* 1½*d.*, but if you go to the Civil Service you can get them for 11½*d.* Perhaps the service is not altogether to blame, for I remember somebody boasting that he and others had sent to a wholesale chemist and bought half a dozen boxes of Cockle's pills for 4*s.* 6*d.*, and divided them amongst them. At the Leeds co-operative store, which was originated by working men, you cannot buy a bottle of medicine one penny cheaper than the usual price. They are honest traders because they charge the usual price and divide the profits among them. We had one society which whether its liabilities were limited or not its trade certainly had been, and I hope to see the other follow its example. I am sorry to see the one now standing in Leeds is supported by men who might well set a better example, and is actually supported by middle class shopkeepers. If we were to band ourselves together, as certain of the chemists of Leeds have done and who have eschewed certain solicitors, certain doctors, as well, I am sorry to say, as clergymen, both Dissenting and Church, who are subscribers and shareholders in these companies, we might give them a Roland for an Oliver, and stop the supplies to them if they stop the supplies to us. I have great pleasure under the circumstances in supporting the resolution.

Mr. JERVIS: May I ask whether it it has been well considered that these stores have not the same privileges as a club?

The CHAIRMAN: There is no doubt about it, that there is a great deal that is hollow and a sham. There are five shilling tickets given as a sort of proof of membership, which are lent about by one person to another, and in consequence of that being the case, I do not think the claim to be a club could be sustained.

Mr. JERVIS: It cannot, and if the matter were followed up I have no doubt we should obtain some success.

Mr. SOUTHALL: And there are some which profess and call themselves Limited Companies.

Mr. READE (Wolverhampton): With regard to this motion which is before you, I think you would be decidedly very likely to gain the point if you confined the restriction to their selling and dispensing poisons and prescriptions. That is a point I think we should dwell upon in any memorial upon the subject. I think there has been some decision lately which would strengthen a view of that kind. The London and North Western Railway Company at Crewe have until lately been manufacturing engines to sell. Now their powers, while they enable them to manufacture all they require, are found not to warrant them in selling, and I think there is some analogy between the two cases. These societies may have a perfect right to dispense for themselves, but not to sell to others.

Mr. RIMMINGTON: In the railway case objection was taken by some shareholder on the ground that trading in engines was likely to turn out disastrously to the Company. In the present case, unless we can get a member of some co-operative store to object as to the conduct of the business, there is no analogy between the two cases.

The CHAIRMAN: I think I may put a case which will act as an illustration. A few weeks ago there was an injunction brought against Price's Candle Company, for having given a holiday to the workpeople. It was by a shareholder who wished to show he was suffering damage by this holiday having been given to the workpeople, as, consequently, the dividend was diminished. I am told he was a clergyman, and had once been chaplain to the company. I think it shows that it is the shareholders who generally move in these matters. Of course the gentleman in that case was very properly defeated.

Mr. READE: I do not see at present where the analogy fails. These people are doing, to a certain extent, what they have a right to do, but beyond that point they have no right to go, and I think we, as a body, are the people to point where they should go and where they should stop. We may say, "You shall make what you like for yourselves, but not for the public. The law will prevent you."

Mr. DYER: They don't sell to the general public.

Mr. RIMMINGTON: Some of them.

Mr. ELLINOR: I would suggest another way of getting out of the difficulty; and that is, all members of firms should be registered, and none should be allowed to enter into any partnership, or any benefit, or any society without they are registered.

Mr. RADLEY: I should like to move an amendment to the proposition; not that I disagree with the feeling of the meeting, but I think this association—if it can be considered such—can take up the subject, and let it be relegated to the committee of the association. That is what I propose instead of the other resolution. The amendment is—"That this question be remitted to the Committee of the Association, to take action such as they may be advised." I think we now can act independently, and I should like the matter to be carefully gone into by the committee of the association.

Mr. ANDREWS: As a tradesman in the West-end of London, I am very much interested in this question, and although I go almost entirely with Mr. Hampson in his very able paper, yet I am afraid the resolution as it now stands would be productive of no good whatever. It is well that this meeting should consider whether we should not go to the root of the evil, and see whether something cannot be done to prevent civil service stores dispensing, because, as the law now stands nothing can. The action must come from the House of Commons, your action must be on its Members, not on the Council of the Pharmaceutical Society.

Mr. BIRD seconded Mr. Radley's amendment.

Mr. HAMPSON replying said: I feel considerable delicacy in reference to this question, but I believe that the resolution as proposed is a straightforward course. I do not attack the Council at all; I attack the Society, and the Society is responsible for the action of the Council. Even supposing we are beaten in this matter shall we be worse off? The position I take is simply this, that the Pharmaceutical Society is bound to take action if it receives our money at all. If we allow this system to continue we are setting an example of illicit trading, and if we do not take action against these it is not just to prosecute individuals. I think it is unjust to prosecute individuals and permit these great sharks to remain untouched. It is thoroughly unjust to shut up the widow's shop or prevent a small trader from selling a pennyworth of laudanum when we allow these great stores to start up and defy a law which was made for the safety of the public and for the protection of legitimate trade. I believe it is our duty to take the matter in hand. If the Pharmaceutical Society does not do it I believe we ought to do it, and I would sooner resign my seat on the Council to-morrow than continue to occupy a position of such ignominy as a member of the Council, and if my advocacy of this cause should compromise my position on this Council, I would resign my position to-morrow. I feel that the protection of the small trader does not affect your large West-end shops but to a trifling degree, but it affects the man who has just passed his Major standard, who having passed that standard expects to obtain the public confidence, but who, without he has set up his shop at a rent of perhaps £100 a year, finds the trade is cut from beneath his feet and he can scarcely keep the wolf from the door. This is a humiliating position for the Society to occupy. I maintain that this is the work of the Society and if the Association can help the Society in carrying forward the prosecution it is its duty to do so.

Mr. RADLEY withdrew his amendment and the resolution was carried unanimously.

Mr. G. A. CUBLEY (Sheffield) then read the following paper:—

NECESSITY FOR A CHEMISTS' ASSOCIATION.

The subject I have undertaken to bring before your notice is "The Necessity for a Chemists' Trade Association." This must of itself have been sufficiently shown by the papers already discussed; for in each one, and in those to follow, the remedy offered to the evils complained of, is trade combination. In each case if any good is to be effected it will be accomplished, not by individual effort but by a union of the members of the trade bound together for mutual defence and protection. It is the old, old story over again of the bundle of sticks, with its antiquated, but equally true moral "Union is Strength."

It has no doubt occurred to many of us that our parent society and governing body, the Pharmaceutical Society, should or ought to be able to take up each of the questions discussed to day and many others that will arise from time to time, but whether from apathy on the part of the Society or the individual chemist, those questions affecting our trade have been kept in the background, and those respecting our professional attainments and knowledge have been mostly attended to.

It has been examinations and regulations regarding us as a profession that have hitherto been the chief object of attention, whilst the defence of our trade and of our daily living has been left alone, for the single efforts of some particularly aggrieved member. Although this is not altogether satisfactory it has been productive of some good, and it has been the means of drawing us together here, to end in what we hope will be an Association that can defend us from all undue pressure and preserve intact our trade and privileges. Many amongst us believe it to be an anomaly, nay an injustice, that although we as a trade number some 14,000, we are governed as to examination and trade restrictions by about one-fifth of the whole body.

It may be easily said, "Oh! it's your own fault. If you wish, you can pay your entrance fee and a guinea a year, become members of the Society, and thus help to govern yourselves." That is quite true, and no doubt it would be well for all to do so and thus have a voice in the election of those who virtually govern us. Yet every one does not like to pay for what hitherto has appeared to him to be merely an examining and restrictive body; a body that has paid very little attention to the protection of its trade interests.

It is in no spirit of opposition to the Pharmaceutical Society that we are met here to-day, but as it seems to be thoroughly understood in high quarters (I will quote the organ of the Pharmaceutical Society,—the Journal) that "there are under existing conditions so many difficulties in the way of obtaining the requisite precise information necessary for dealing with particular cases, that without the aid of some organization, the chances of escaping detection are greatly in favour of those who systematically infringe the Act,"—then I am sure you will coincide with me, that we must help to remove those "difficulties," get the required information, and finally, do away with the existing conditions that prevent our being protected in the responsible trade we pursue.

But it is not only against infringements of the Act that a trade association would be useful; there are the cases where we have to defend ourselves from undue and unjust attacks from other sources. There are prosecutions of druggists under the Medical Act. What is more unjust than that any dabbler in herbs, or pretentious quack can physic at will, whilst a druggist is sought to be restrained from giving a dose of a drug he has been acquainted with a life time; or that a doctor's errand lad, when he has grown a little, should be made a dispenser, and finally, when too big or wanting too much wages, should be turned adrift amongst us to start a shop, a mere blind for quackery, for the illegal sale of poisons. I will venture to say that there is more harm done in prescribing by the setting up of one of these places than by a score of establishments conducted by properly apprenticed and educated chemists. What the medical men complain of, they to a great extent must thank themselves for. We can never forego our just right to be able to give over our counter a dose of medicine when asked for. This would be one object that a trade association could properly defend, and which could give the answer of the whole trade, that the only settlement possible of the dispute between the doctor and the chemist shall be on this basis. You prescribe and not dispense; and we will dispense and not prescribe. Then there are prosecutions, and vexatious ones, under the Adulteration Act, that require to be protected against. I am sure no one here would defend adulteration; our object as honest tradesmen (having in view the responsible position we hold) is, and ever ought to be, to adhere to the highest standard of purity; yet we ought to resist any prosecution founded upon a merely legal quibble. In these cases it can be hardly expected that the Pharmaceutical Society will at once take them up. But if it does not, pressure must be put upon it, and it is through the medium of a trade association that the pressure can be put; or it would be by a trade association that such attacks could be resisted. How easily and quickly we could acquaint the Society and the country of the feeling of the trade upon any particular subject, if in each important town or district there was a branch of such an association!

We must remember that in case of a society founded upon charter and Act of Parliament, action is slow and deliberate; that I believe is rightly so. It is difficult for it to act quickly, for no step can be taken except through the authorized channels, and in the case of the Pharmaceutical Society we know that the feeling that naturally has most weight is that of its members; perhaps they are less affected as a body by the evils we complain of than the rest of the members of the trade, therefore an outside body that shall be able rapidly and easily (by its freedom from legislative restriction) to express and give force to the opinion and wants of the whole trade, will, I believe, not only be of the highest benefit to chemists generally, but to the Pharmaceutical Society itself. There is one thing I cannot endeavour too often and too deeply to impress upon you, that we are tradesmen. Tradesmen no doubt requiring an almost professional education, and with responsibilities far beyond those of other trades, yet tradesmen still; it is in the endeavour to make our calling into a purely professional one, where so great a danger lies. It would be to leave the substance to grasp at the shadow. It is constantly dinned into our ears that it is derogation in our position to sell this, that, or the other; but I would hold (it may be I am alone in the opinion) that it is no disgrace to us to sell any one thing so long as we do it honestly and fairly. If we are to go on much further, as some wish, we shall merely take the place of the old apothecary, and leave to spring up behind us a new body of men who will occupy the position that the majority of us now hold, and they untrammeled by Act of Parliament and not subject to examinations. Therefore, it will be far better for us to join a defence association, having regard to our trade interest, and leave the Pharmaceutical Society the duties it is more adapted to, whilst we should be able from time to time to make known to it the wants of the bulk of the trade, to restrain it when tying our hands too tightly by causing it to put new action into the powers it possesses for our benefit, so we both may mutually benefit each other. But if left uninfluenced by a trade association there is danger of the Society going to sleep, regardless of the interest of the whole of the trade.

It is easy so long as things go on quietly and the balance-sheet is pretty good, for the Society to feel that all is well, and yet for us to know that there are plenty of cases where attention is wanted. The Society would be all the better for an association to wake it up a bit now and then.

But we must look still further. The time will come when some alterations of the Pharmacy Act must be required, even if there is not already a necessity for it. There are further extensions of the schedule of poisons. Such questions as confining the sale of drugs to registered persons only, the appointing inspectors to discover illicit trading by unqualified persons and sale of poison by them. There is the constitution of the Council, for we must remember that eventually if the Pharmacy Act remains unaltered the Council will be elected from pharmaceutical chemists only, members being chemists and druggists will die out, and then the trade would be governed by a council elected from a very small proportion of the entire body. Here then is another field for a protective association to enter upon. Another class of questions a trade association alone could entertain is that of a price current, a trade mark for prescriptions, early closing, defence against co-operative stores, against the sale of patent medicines and drugs by grocers, and, if needful, combination against those who supply them with patent medicines, and drugs. Here is a case where the Society could not possibly interfere, but where we, if combined together could at once make ourselves felt. This is what is doubtlessly wanted by the provisional committee when they say it would also be within its functions to take active measures in such ways as it is deemed desirable for their legitimate trade interests.

There is yet another and that a most important office we can combine together for, that is for mutual relief in cases of accident. We all know that being human we are liable, however well our establishments may be organized, however careful we may be personally in the discharge of our duties, however highly trained and qualified ourselves and our assistants may be, at some unfavoured moment, and through some untoward train of circumstances, to the occurrence of an accident, injurious, perhaps fatal to our customer, and of untold disgrace and pecuniary damage to ourselves. Here again the association could be made useful, not to cover any wilful neglect, or guilty carelessness, but to aid and protect any one who may be accidentally the unwilling and unconscious means of a distressing and painful accident.

I think I have pointed out plenty of work to do; but how and by whom is it to be done? It will never be accomplished by men talking and writing, or by men grumbling and complaining each one about his own particular and private grievance. It can only be done by banding together; by mutual support with united energy.

It is only as an united body we can make ourselves felt and heard.

Let us urge upon each and all to join together with us in removing the difficulties that lie before us; in punishing those encroachments on our well earned privileges, in resisting all oppressive and injurious attempts on our freedom of trade, and in combining together for our mutual support and advancement. It is not merely meeting and talking together that will do us good; it is systematic and wide spread organization that will enable us to defend ourselves from all attacks. If we separate from this place without laying the foundation of a trade association, our time will have been merely spent in having had an enjoyable meeting and, perhaps, making a few new agreeable friends. But as far as the trade at large is concerned it will have been time wasted. It has not been my duty to point out how this organization is to be effected. It has only been to show how necessary and urgent it is to be done. It cannot be done without each one putting his shoulder to the wheel by influencing all with whom he comes in contact, also by that test, a great support in liberal contribution to start with. Then come the details of organization, and after that the fruits of being a firmly united body. I know that I have left out many points that might have been touched upon, that I might have urged more strongly and placed more decidedly before you the advantages ages that will result from union. These, I trust, will be gone into and made clearer by those who follow me, but the object that I have had in view will be accomplished and my duty fulfilled, if I have in any way shown you the necessity for a Chemists' Trade Association.

The CHAIRMAN: The paper Mr. Cubley has been good enough to put before us must certainly in many respects be considered the paper of the day. It is one which will bear practical results. If gentlemen are convinced by his argument they will soon have an opportunity of showing their convictions in a very tangible shape by voting for a resolution which will be moved upon this subject.

Mr. RADLEY: I have been very much pleased with the paper which has been read to us. I have great pleasure in moving that we have an association, in the following terms:—"That this meeting of delegates from Liverpool, Birmingham, Leeds, and Halifax, Sheffield, Leicester, York, Wolverhampton, Dewsbury, Sunderland, Taunton, Bridgwater, Hull, Exeter, Shrewsbury, etc., also for members of the trade from several other towns, is of opinion that it is necessary to establish a chemists and druggists' association for the protection of trade interests, and to defend druggists and chemists from illegal and vexatious applications of the Adulteration Act, also that those present agreeing with the objects in view, now form themselves into an association, having the following constitution:—This Association shall be styled the Chemists and Druggists' Trade Association; that the management of the Association shall be in the hands of a committee, consisting of a president, treasurer, honorary secretary, and other members named in the following list, with power to add to their number; that the minimum subscription of members shall be 5*s.* per annum, and that larger subscriptions shall be invited; that a meeting of members shall be held, to which the committee shall present the report of the year's proceedings, and the treasurer his financial statement; that the officers shall be elected annually at this meeting; that Mr. S. U. Jones of Leamington be elected President for the ensuing year, Mr. T. Barclay Vice-President, Mr. W. Southall (Birmingham) Treasurer; and that the members of the provisional committee and the following gentlemen be the Committee:—Messrs. F. Andrews (London), H. Barnaby (Rochester), C. B. Bell (Hull), W. B. Clarke (Leicester), Clifton (Derby), G. A. Cubley (Sheffield), R. Davison (York), W. Dyer (Halifax), F. Earle (Hull), W. Fleeming (Wolverhampton), Frost (Derby), Greaves (Chesterfield), Greenish (London), J. Harrison (Sunderland), J. Jessop (Halifax), S. S. Johnson (Manchester), A. H. Mason (Liverpool), F. Parsons (Leicester), W. V. Radley (Sheffield). Reade (Wolverhampton), B. Shaw (Halifax), J. C. Thresh (Buxton), and A. C. Wootton (London)."

Mr. CROSSBY (Shrewsbury): I think that to have different amounts of subscriptions would be to place some of the members of the association in an invidious position. I think that I should fix the subscription, and if 5*s.* is not sufficient fix it at 10*s.*, only let one member of the association be as good as another. Mr. Bird mentioned that the Grocers' Association had an absolute subscription of one guinea per annum, which was not found too much to supply funds in the defence of costly prosecutions.

Mr. ANDREWS: Whatever the subscription is it should be a uniform one. I think it would be invidious to have a rising scale.

Mr. CUBLEY: I might say that if you adhere to the 5*s.*, you would probably be better off, because one association ought to include the whole of the country. We ought to have the whole of the 14.000, druggists who are on the register, and if we keep our minimum subscription low, we shall have greater chance of including the whole of them, there are many amongst the druggists in the smaller districts, and the poorer districts of larger towns, to whom 10*s.* or a guinea would be a large sum. If we can unite a large body their little subscriptions will amount to a large sum. With regard to the Grocers' Association which has been mentioned, that is the Association of one town only, and our object is to have a trade association of the whole country.

Mr. BELL: I must say I support the subscription of 5*s.* per annum. I have had some experience in getting up the East Yorkshire Association, and I must confess I found the small subscriptions come in better than the large ones.

The CHAIRMAN: Do you wish the 5*s.* to be the minimum or the absolute subscription?

Mr. BELL: I would say absolute the first year and if more was required I would appeal to the liberality of the members afterwards.

A DELEGATE (from Taunton) said: The unanimous opinion of those whom he represented was that an absolute sum of 5*s.* as an annual subscription shonld be the subscription for the Association.

Mr. CHURCHILL: I have been engaged talking among many gentlemen during the afternoon and I find many not only prepared to give us a handsome donation but also to give us a subscription much larger than 5*s.*, and I cannot see that any harm would result from receiving a larger subscription than 5*s.* It is simply as a sort of annual donation. There are many chemists who may be thankful that they have good businesses and good incomes and can afford to give a fair sum to an association like this, but there are, on the other hand, unfortunately many chemists who have small businesses, who just manage to make a living, and who stand in need of defence, and they cannot afford to pay more than this 5s. I think the association would be very unwise not to accept larger subscriptions than 5s., but I think this minimum amount should be as small as possible. I do not think the fact of a member being a minimum subscriber should at all be to his detriment. None but the Secretary and officers would know who were the minimum and who were the maximum subscribers.

Mr. NICHOLSON (Sunderland): I think the fact of there being two subscriptions would tend to keep many away who would otherwise join.

Mr. THONGER: I rise just to say that my opinion agrees with that of the friend who spoke last. From what experience I have had I think it would be very foolish to have two rates of subscription. Many of the small chemists would be altogether deterred from giving the smaller sum of five shiliings, and would not join the society. It would be for the rest of us to give donations at any time, but I do feel strongly that we should have one subscription, and that subscription the sum of five shillings.

Mr. ANDREWS moved an amendment, "That the subscription be five shillings, and if any gentleman desired to give more than that he could give it in the form of a donation."

Mr. CROSS seconded this, and it was carried by a large majority.

The general resolution was amended in this particular, and also carried; after which Mr. Jones, the President-elect, took the chair. Having thanked the Conference for the honour they had done him, he called upon the reader of the next paper.

Mr. JESSOP (Halifax), read a paper by Mr. B. SHAW, on

PATENT MEDICINE LEGISLATION.

Although the misadventures arising from the careless or injudicious use of patent medicines are not, to judge from the reports that appear, so numerous as those which follow mistakes made by ignorant or temporarily incompetent persons in the dispensing of medicines, yet there have been recently cases of poisoning of the former class so startling as to attract public and general attention, and to call up a demand for protection. At present there is no remedy at law, or at least no power of blame laying in the event of death, subsequent to taking a patent medicine or nostrum. Its composition is for all practical purposes known only to the maker. It is quite possible that in some cases, through careless mixing or want of due precaution at the time of putting up a secret medicine, that its composition is variable, and that too in respect of the most active of its ingredients. I name chlorodyne to indicate how easily variability might occur under such conditions. But the composition being secret and the article having the protection of a Government stamp, the public have no safeguard in the item of variability of nature, and therefore of power and efficacy, in a so-called patent medicine.

It is equally helpless in respect of there being an unsafe quantity of a powerful medicine, such as opium, chloroform, chloral, antimony, etc., in each dose, as ordered in the directions attached to a patent medicine, even provided the conditions producing variability have been absent.

It is well for our own interest, therefore, to cast about and ascertain whether it is feasible to frame suggestions for legislation on this important matter which, if made law, would not restrict the profits of those who prepare safe nostrums, appreciated by the public, and yet at the same time afford some safeguard against the lamentable accidents which have occurred through the indiscreet use of patent medicines containing powerful drugs or chemicals.

In the first place, let the name patent medicine as applied to a secret remedy be a reality instead of a misnomer, as it is at present.

This change seems to require the submission to a properly constituted authority of a form of specification as to nature and composition, in many respects corresponding to what is required before protection or letters patent are granted in the arts. Let this authority be a Board of Commissioners sitting in London, and paid by the Inland Revenue. There is room for much discussion as to the powers to be delegated to, and exercised by, these officers. What profession should they be chosen from? Should they have the right to refuse any proposal for a secret medicine, licence, or patent, that they deemed undesirable, or to require an alteration to be made either in formula or size of dose for safety's sake before they issued their licence?

The dealers in nostrums consisting mainly of the registered chemists of the country would naturally look with a strong foreboding of ill, were a Board of Commissioners in patents for medicine to be chosen solely from the medical profession. The writer is disposed to think that a number of public analysts or professional chemists would be preferable to a board composed of medical practitioners only, or one of trading chemists only, or to a mixed board of persons from both these classes.

In setting the patent medicine business on a new footing, the proposed Commissioners would have to deal with existing patent medicines, and thus come in contact with vested interests at once. Let all makers of nostrums now in the market be compelled to name all the ingredients in their several preparations, and to state the proportion of the most active in the maximum dose, as set forth in their directions for use. Let this be a private procedure before the board either by personal appearance or affidavit.

The Commissioners shall then certify what medicines, the composition of which having been duly declared unto them, may be sold freely, and in case of powerful medicines such as Jeremie's solution of opium, James's powder, chlorodyne, Hunter's solution of chloral etc., shall state in a schedule what medicines shall be registered at the time of sale in the same way as a poison in schedule 1 of the Pharmacy Act, 1868, requires registration.

It should also be binding on all makers of secret medicines to state distinctly on the outside wrapper round their several preparations whether they require registration or not.

The Commissioners should admit all patent medicines that are before the public by a date specified, to licence or letters patent when they have duly lodged their specification of composition, to make and sell their nostrums, and they should demand for the same a fee of five pounds.

So far as relating to existing patents; and I would suggest a similar application and granting of licence to persons desiring to introduce medicaments to the public, with this difference, that ten pounds shall be demanded in their case.

The protection to be granted by suggested licence should be continued for ten years, at the end of which the holder of the licence should have the option of renewing it for a term of the same length, on payment of a fee of five pounds. In regard to any nostrums the licence for making which has expired and not been renewed, the Commissioners shall make public the specifications of such secret medicines. Such action would give a respectable funeral to patents whose popularity had declined, and enable those partial thereto to have a fair imitation prepared by their own chemist.

Let the retail sale of patent medicines be restricted to pharmaceutical chemists, and registered chemists and druggists, and apothecaries keeping open shop, who are the proper persons under the Pharmacy Act to register and retail poisons and preparations containing them.

The licence to retail should, as things are at present, be raised to a guinea for the whole country. Should the sale be secured to chemists only, and should there be an early prospect of this, either keep it at five shillings, or better still—abolish it altogether.

The payment of fees on obtaining letters patent by makers would, I think, be a mild but effectual check against the universal quackery that has of late prevailed, and would also restrain the wholesale rush of nostrums under the eyes and nose of the public, a rush which is far from being convenient or desirable, whether the convenience of the dealer or the service of his customers be considered. In case of misadventure through the careless use of a patent remedy, the police authorities should purchase a sealed-up, unopened bottle, box, or parcel of the same medicine at the same shop, where that had been bought, the taking of which was alleged to have caused illness or death. This bottle, box, or parcel should then be transmitted by the police with a certificate to the Board of Commissioners, and the contents thereof be analysed by them. And in case the medicine should be found to contain a greater proportion of the most active ingredients as stated in the specification supplied by the maker to the Board, and in case that proportion in the maximum does exceed the true proportion as stated therein in the degree of one-half additional or upwards, or if the preparation should be found to contain a powerful drug or chemical not stated in said specification, the maker, not the seller, should be liable to a fine of large amount not less than £20 and not more than £100, one half of which should go to the revenue and the remainder to the unfortunate subject of the mishap, or his or her representatives. No analysis should be made or any proceeding set on foot in respect of accident from using a nostrum, unless it can be proved that the patient took or had given not more than a maximum dose of the remedy as directed by the label or circular attached thereto at the time of purchase. The Inland Revenue authorities have pushed the use of medicine stamps in many cases to an extreme; and I think it quite consistent with the plan sketched out for a new system, to suggest further that only where a secret medicine shall be recommended for internal use by man, shall its manufacture require a licence or letters patent!

The registration of the more potent remedies would very likely throw a certain amount of suspicion upon them, and the public would avoid them to some extent, and thus the sale thereof and the dangers possible to result from their use or misuse would lessen together. At the same time the more harmless ones, not requiring that ceremony, would become still more popular.

No secret medicine should have licence or protection if the price of the smallest size, less the stamp, were below a shilling.

The payment of fees for licence would certainly help to rid us of the tiresome little patents. I am not prepared to advocate the abolition of the stamp at present, and as for joining the medical men, the rank and file thereof would certainly not have much regard for our interest, and would be more likely to seek the abolition of the secret medicine business itself.

Seeing we have the safety and welfare of the general public to secure in this matter, I can suggest no other plan with reference to secret remedies prepared abroad than the application for license and submission of specification in every respect identical with the one sketched out for British nostrums.

The sale having been restricted to the classes before named, any others retailing patents shall be liable to be sued and fined in the way and degree that unregistered chemists are liable to prosecution.

Let us not forget in conclusion that no code of regulations or system of license and registration, however elaborate will prevent a person of intemperate habits, the subject of mania, delirium or ignorance taking a dangerous dose by accident or of intention; yet if the business in these secret medicines, the names and prices of which are indeed legion, be somewhat hedged about, the use of some of these may in case of accidental suffering or decease be traced from the taking, back to the sale; and if the evidence as relates to the physic be made clear, it is so much towards the adjustment of the balance held by the blinded divinity. What though the life of the taker be departed, if the scruples of the legal mind be laid to rest!

Mr. C. J. Arblaster (Birmingham) read the following paper on the same subject.

Patent Medicines.

That what may be called the patent medicine question is largely engaging the attention of the chemists of the country is, I think, well known to all here present, and that it is one deserving of this attention is, I think, equally admitted. In a pecuniary point of view, the returns in some districts from the sale of patent medicines form no inconsiderable part of the gross return in the business of a chemist, and it is not to be wondered at, that when he finds a large portion of his trade is being taken by others under cover of the Patent Medicine Act, he feels himself somewhat aggrieved. It would take too much time to mention all the grievances under which, whether rightly or wrongly, he considers that he suffers. I am informed, however, and can readily believe that in some districts tinct. opii is largely prepared with methylated spirit, and sold under an assumed name by others than registered chemists, under the provisions of the Patent Medicine Act. Preparations again of that useful but very dangerous chemical, chloral, are largely retailed and bid fair to become as destructive in their continued use to the Englishman, as absinthe is to the Frenchman. These and the sales of powerful external applications, prepared with the deadly aconite, belladonna, etc., demand, not only in the interest of the public but also in that of the registered chemist, some alteration of the law. If this meeting can find a remedy for this and other evils, it will, I think, ensure to this association the support of the great majority of the trade. Let us look then at the present state of the law in relation to these matters. In the year 1868, an Act of Parliament was passed entitled the Pharmacy Act, and I am pleased to see here to-day so many that are fully acquainted with its main provisions. In the preamble of this Act there are one or two points that I wish prominently to bring before you. I will not take up the time of this meeting by reading at length its different provisions, but under correction state in a few words the main points to which I more particularly beg to draw your attention. The first line then contains this important declaration, "Whereas it is deemed expedient for the safety of the public that persons keeping open shop for the retailing of poisons, etc., should be duly qualified." Secondly, "That persons should be those as shall be deemed to be such by the Council of the Pharmaceutical Society, with the consent of the Privy Council." Thirdly, "That nothing in this Act shall extend to, or interfere with, the making or vending of patent medicines." These three points then are all that I think that we have to consider in discussing this question. Here I would just notice in passing, the anomaly that one clause of the Act, for the safety of the public, prevents all but registered chemists from selling poisons, and allows it to these only under the greatest restrictions, and another clause permits (under cover of a paper stamp) unqualified persons to sell poisons (in any quantity), and these too of the most virulent character, without any restriction whatever. I do not find fault with this Act of Parliament, for in some respects it has, I believe, by decreasing the facilities for obtaining the more common poisons been productive of good, but I do say that it is wrong in principle to place restrictions on the sale of such things by qualified persons, and at the same time take away those restrictions when poisons are sold under other names by unqualified persons. I would then reiterate these main features of the Pharmacy Act that have to be considered:—The safety of the public; the sale of poisons by chemists only; and the sales of patent medicines. The safety of the public is its main consideration, and *not* the well-being of the chemist; and in my opinion if we are to succeed in getting an amendment of this Act, it must be by giving as our main reasons that the safety of the public demands it.

The next point is this: "Are poisons pure and simple sold by chemists only?" This question must I think be answered in the negative, and here it is that a powerful organization, which I trust to see this day formed, would be of the greatest benefit to the registered chemist. The third point is already answered in the instances that I have given of evasions of this Act under cover of the stamp duty. Before proceeding to suggest a remedy for these evils, it will be well just to notice some of the various antidotes that have been made public. One suggests that the law of France, by which the makers of patent medicines are bound to furnish the proper authorities with their formulæ for the same, and by which also all vendors of the same must be registered pharmaceutists, should be put in operation here. This in our free trade England would, I think, be found impracticable to get passed into law. Another would confine the sale of all patent medicines to chemists only. Some would do away with the so-called patent medicines and licence for sale; but here I am afraid that it would be found a difficult matter to persuade any government to relinquish a tax collected so easily and at so small a cost, and which at the same time contributes so large a sum as £100,000 to the revenue. Other suggestions have been made, but I will not detain you with more, but proceed at once to state what should be the remedy for this unsatisfactory state of things. I start then with this proposition, "That if it be considered expedient for the safety of the public that certain poisons and their preparations should be sold by registered chemists only, that it is equally expedient that patent medicines containing such poisons should also be sold by chemists only." The safety of the public would be by this means assured, as much as it now is in respect to the sales of other poisons. The patent medicine maker is our last point, and to him I would say this, "You shall make a declaration to a proper authority that your proprietary article contains one of the scheduled poisons,"—I would respect his private formula and not ask which it is,—"place upon the same a label the same or somewhat similar to those introduced on the passing of the Pharmacy Act, reading as follows: 'In conformity with the sale of Poisons Act, 1868, this preparation must be labelled poison, but its composition remains unaltered with this addition. This article may only be sold by a registered chemist.'" By so doing you respect the rights of the makers of patent medicines, you show that the medicine is one requiring care in its use, and you also keep in the hands of chemists the sale of articles, which by some of the clauses of this Act, were deemed to be poisons. Whether, in conclusion, the sale of such should be registered; whether the poison list might not be largely extended; whether patent medicine licences in the future might not be fairly confined to those that are supposed, at any rate, to know somewhat of the action of drugs and chemicals, are subjects which may be considered at a future time. For the present I beg to thank you for so kindly listening to these remarks, and if they are productive of any good, I shall feel amply repaid for any trouble that I have taken in the matter.

The Secretary read the following paper by Mr. Fairlie, of Glasgow:—

On the Medical Acts in their Relation to Chemists and Druggists.

It was at first suggested that the title of this paper should be "On the Apothecaries Act in its Relation to Chemists and Druggists.' On making inquiry for a copy of the Apothecaries Act, however, I found it was out of print, and as that Act does not apply to Scotland, and thinking that any paper on such a subject should bring out the relations between medicine and pharmacy north of the Tweed, I suggested that the words "Medical Acts" should be substituted for "Apothecaries Act." It will not be possible, however, in the short space of time at our disposal, to refer to all the medical acts that have been passed from time to time, all of which have no doubt more or less relationship to the dispenser; even if time did permit it would still be impossible, as we were told the medical acts are so numerous that it would be difficult to say whether even the half of them could be procured.

For our purpose, therefore, it will be necessary to refer specially to three Acts of Parliament, all of which have direct reference to the pharmacist. First, the Apothecaries Act of 1815; second, the Glasgow Medical Act, obtained about the seventeenth century; and the Medical Act of 1858.

During the sixteenth and seventeenth centuries the position of the apothecary in England seems to have been somewhat similar to that of the chemist and druggist of the present day; from various causes, however, they gradually adopted the practice of physic in conjunction with their dispensing business. The College of Physicians endeavoured to put a stop to this, and after a long and hard struggle, both in the law courts and in Parliament, the apothecaries ultimately established for themselves the right to treat diseases.

About this time, also, a schism took place in the College of Physicians, one party establishing a number of dispensaries for the supply of medicines, and being placed in the charge of parties who were neither physicians nor apothecaries, there gradually sprung from this class the body since known as chemists and druggists.

In 1815, the Society of Apothecaries, with consent of the College of Physicians, got a bill passed entitled "The Apothecaries Act," appropriate enough when it is considered that it gave power to the Apothecaries' Society not only to examine and grant licences to practice as apothecaries, which was proved to be practically that of the physician, for the distinction between the two had been almost entirely lost sight of, but also to one and the same person to practise pharmacy as well. Anomalous as this may seem, it is borne out much more clearly when it is remembered that the same Act created a corporate body of physicians, who affirmed that the practice of medicine should have no connection with the practice of pharmacy. Why the College of Physicians gave their assent to such an Act cannot now be explained; probably they were not so watchful of their interests as the chemists and druggists were, for the history of the passing of this measure, meagre as it is, brings out clearly that but for the firm stand taken by the then chemists and druggists, their occupation would have been gone. We learn from a most interesting volume on the "Unity of Medicine" by Dr. Davies, that a petition was presented by the druggists against the Bill, and which was the cause of some delay in its becoming law; that petition no doubt would set forth the kind of business carried on by chemists and druggists, and appears to have resulted in the adding of the 28th section, which provides that nothing in the Act shall interfere with the "buying, compounding, dispensing, preparing and vending of drugs by chemists and druggists." How the apothecaries might have acted, had this clause not been inserted, it would be unsafe to predict, but if their recent conduct with regard to counter prescribing by the druggist may be taken as a criterion, it would most certainly not have been their fault if the chemist and druggist had not been altogether extinguished. There is a common saying in broad Scotland "that every man should stick to his last," that is to say that whatever trade or profession a man adopts, he should adhere to it, and the inference is that it is unfair for the joiner for example, to interfere with the legitimate work of the cartwright, or the mason with that of the sculptor. Tradesmen doing so are looked down upon by their fellow-workmen, and why gentlemen of education and refinement should continue to usurp the best things of two professions, unless it is that having been brought up like those amphibious animals which live partly in water and partly on land, they cannot rid themselves of the old habits, is more than one can comprehend.

But badly as you are situated with the apothecaries in England and Wales, your position is not so bad as in certain parts of Scotland. So far as I can learn, the diplomas granted generally by the medical schools in Scotland, confer the right with them to practise pharmacy, and in this way the Scotch medical practitioners have ever been the controlling power in the drug business. It is only in the north of Scotland, however, where this is felt to any great extent at the present time. In Edinburgh, Dundee, Aberdeen, Greenock, Perth, and other large towns, there are few surgeons who keep open shop; whether it is that in these towns they originally wrought under a different law in respect to medicine and pharmacy, or whether it is there being a better class of inhabitants, or that a better understanding exists between the physician and the pharmacist, I am not aware; but things are conducted far differently from that in and around Glasgow. In the former places the physician attends to his practice, and leaves the dispensing almost entirely to the chemist and druggist. In the north of Scotland however, the great bulk of the retail drug business is carried on by surgeons. This state of matters has no doubt arisen from the fact that the faculty of physicians and surgeons of Glasgow, by charter granted by King James VI. of Scotland (James I. of England) in 1599, and confirmed by the Scottish Parliament in 1672, were empowered to examine all persons and license them to practise as physicians, surgeons, and apothecaries in the city of Glasgow, and the counties of Lanark, Dunbarton, Renfrew, and Ayr. The names of three parties are given in the original charter, namely, Peter Low, Robert Hamilton, and William Spany, who are designated as a physician, a surgeon, and an apothecary. It will thus be seen that the faculty of physicians of Glasgow adopted a much wiser course, in their own interest, than did the College of Physicians of London. For about 200 years the Glasgow faculty continued to examine and license apothecaries as well as physicians and surgeons, but as there were no restrictions on the latter also practising as apothecaries, surgery and pharmacy were generally combined, only a very few from time to time confining themselves solely to pharmacy. It is a curious coincidence worthy of record, that some of the clauses in this old Scottish Act have a most striking resemblance to some of those in the Pharmacy Act of 1868, especially the regulations regarding the registration of poisons, and the pharmaceutical examinations, and but that they are worded in the ancient "Doric," I should have been disposed to quote some of them here. A good many years ago the faculty ceased to license for the simple qualification of apothecary, and at present there is only one gentleman in the business in Glasgow, known to have been examined and licensed by the faculty under this Act; and a druggist who made application to be examined previous to the passing of the Pharmacy Act was refused; very probably the faculty had profited by the state of affairs in England and Wales, and took the most effectual mode of preventing the apothecary from usurping the physician's office, by cutting off the supply altogether, and retaining in their own hands the practice of pharmacy—hence the very backward condition of pure pharmacy in the West of Scotland, and the curious anomaly of duly qualified medical practitioners carrying on in conjunction with their practice as physicians a mixed trade in drugs, patent medicines, confections and tobaccos. In 1850 the faculty of physicians and surgeons of Glasgow procured an Act "for better regulating their privileges, and amending their charter." Amongst its provisions the principal are those relating to the exclusive privileges enjoyed previously by the faculty, giving liberty to duly qualified physicians and surgeons from other faculties to practise within their bounds, and also granting them power to enable their licentiates to practise beyond the prescribed bounds. No reference is made in this Act either to pharmacy or apothecaries, but as by the sixth section they retain the powers contained in the original charter, they continue to include the practice of pharmacy in their licentiates' diplomas, though we understand that by a bye-law, the "Fellows" of the faculty have to sign a declaration to the effect that they will have no connection with any secret remedy or in the dispensing of medicines. The "Licentiates" however, that is, those who hold the minor qualification, are by far the most numerous; they, with the large numbers of medical practitioners from the universities and various other medical schools and colleges, have completely overrun the next country with "Surgeries" and "Apothecary Halls." I have been unable to obtain the precise number of open shops in the district, and the exact proportions kept by druggists and by doctors, but the numbers given generally are about one druggist to two surgeons with open shops. The injustice of this arrangement, however, lies in the fact that the druggist is expected to be constantly behind his counter, while it is impossible for a medical practitioner to do so, and in the great majority of cases those surgeons' shops are left in charge of mere boys and often girls.

In the midst of this state of matters both in England and Scotland, the question naturally arises can any step be taken to get dispensing done by chemists only? My answer is, Yes! And the first step seems to be that we should organize a strong union of druggists of all parts of the kingdom, with an energetic executive representative of the various sections of the trade, as well as the different districts of the country. This formed, they should at once put themselves into communication with the General Medical Council created by the Medical Act of 1858 and with whom now rests most of the matters appertaining to medicine and pharmacy. It seems to me that they have power under the Act to remedy very many of the evils we are suffering under at present; for instance, if it was made known to the General Council that certain medical men were surreptitiously aiding unregistered druggists to keep open shops for the sale of poisons, as is the case by several in Glasgow, it would surely be their duty to investigate the matter and probably deal with the parties. Then I think they ought to prevent that system of attaching unintelligible names to compound mixtures, I refer to the "Mist. Comp.", "Lin. Co." "Ung. Rub." "Pil. Asiatici," a class of prescriptions, which are a frequent annoyance to some chemists who do not care to enter into secret alliances with medical practitioners. And referring to secret alliances I believe the telegraph has been brought into requisition, that a wire reaches the chemist's shop from the physician's consulting room in some towns in Scotland; the medicine being sent up to the doctor while the patient is waiting, and in this way the physician procures a profit on the drugs as well as his consulting fee, and is saved the degradation of keeping an open shop. Any druggist carrying on such an arrangement as that must be driven into it by fear that the physician will open an "Apothecary Hall," and take away all his trade. The question, therefore, comes to be, are the practices I have indicated not an evasion of the Medical Act of 1858? The fifty-fifth clause provides that "nothing in this Act contained shall extend or be construed to extend to prejudice or in any way to affect the lawful occupation, trade, or business of chemists and druggists and dentists, so far as the same extends to selling, compounding, or dispensing medicines." Is this clause not a sufficient preventive against such things as I have been referring to? for are they not extending both directly and indirectly to the prejudice of the legitimate and upright druggist? It seems to me that we have an admirable case to present. All that is wanted is united sympathy and action amongst ourselves, because if we are not united as one man all our efforts will be futile, and I would here call upon my brothers in trade to rouse themselves from their apathy and indifference. Why should pharmacists be under the necessity of humbling themselves before the medical profession? Why can they not as a body show something of that spirit of independence which has made our country what it is, and emancipate themselves once and for ever from the tyranny and injustice of those of them at least who would keep us down, for they are not all alike, and there are many honourable men amongst them. I say we ought to free ourselves from such, who if they had the power would prevent our progress not only as individuals but as a class. Failing any good result arising from negotiation with the Medical Council, probably we may have to approach Parliament, a course I would be disposed to make the last resort, however. The question would then come, that suppose chemists obtained for the future the sole right to dispense, should physicians who have at present a vested interest in the drug business be allowed to keep open shop with unregistered assistants? Most assuredly not. This I apprehend is the great grievance of the druggist, as against the apothecary in England; at all events it is the point upon which the druggists in the west of Scotland feel most keenly, and we most firmly maintain that if a medical practitioner is to be allowed to compete with the chemist at all, both must be put on an equality. We must, however, bear in mind that the medical men interested in this will also have their say, and will advance objections against the druggists; as for example, that a chemist has no right to dispense a prescription whenever it is presented for the purpose. Some physicians hold that the prescription is not the property of the patient, and that the druggist has no right to repeat the recipe without the written order of the physician. If medical men can get the public to concur in this arrangement I presume that the druggist would not object; but until they can get the people generally convinced that they must not take a single dose of medicine without previously consulting the physician, the druggist must also maintain his right to dispense any prescription that is presented to him.

Then there is the vexed question of counter-prescribing, and this point appears to me to lead to one of the most powerful arguments why we should have a strong society of chemists and druggists, if it were for nothing else than defensive objects; for with Baron Bramwell's decision flaunting us in the face, and observing the temper of some of the correspondents to the medical press, we cannot fail to see that without some definite and united action on our part there may be no end of prosecutions and harassment. But with a powerful Society, prepared for any emergency, to defend the rights of the druggist, even the "Medical Defence Association" will hesitate before risking another similar prosecution. But have chemists and druggists the right to prescribe simple medicines? Personally I avoid it as much as possible, but I believe that in some districts it is impossible to avoid it, and it is therefore our bounden duty to maintain the just rights of every section of the business. So long as the druggist makes no charge for his advice the medical profession have no cause of complaint. Where, I wonder, would they stop in preventing one person from making a recommendation or a suggestion to another, and how could they draw the line? I fancy they would require to suppress Dr. Buchan's works, and all books of the "family doctor" description. The public will have gratuitous advice; and far better that they should be permitted to consult a conscientious druggist than that they should be driven to ignorant quacks.

In conclusion, I have to express the hope that nothing will be done at this meeting in antagonism to the Pharmaceutical Society, and if a separate organization is formed it will be to co-operate harmoniously with it in all that affects the interests of the trade at large. Our mission as a Conference is an educational one; the end and aim must be improvement, and for us as members of one body to endeavour to leave to our successors a legacy they may not be ashamed of. We are not perfect ourselves; many of us interfere in our business with other traders, and while smarting under the opposition of medical practitioners and unregistered persons we must bear in mind that "charity begins at home." Let us therefore endeavour, as far as in us lies, to purify our own profession; and thus acting out the principle of doing to others as we would wish to be done by, we may rest from our labours confident in this,—that we have done what we could.

The CHAIRMAN: You have heard a very able paper by Mr. Fairlie, and I am sorry he is not here in person to receive the thanks to which he is entitled.

Mr. JONES (The Lye): With reference to chemists prescribing, we should like to give up the risk of prescribing if the medical men would give up dispensing. There is a population where I reside of between 7000 and 8000 inhabitants, and during the summer I have had forty, and even fifty, persons come to me in twenty-four hours with diarrhœa. They say that they could not find a medical man nearer than Stourbridge, and that if they sent to him he would not come. There is another question which often arises; a chemist is often called up in the night by a surgeon to dispense medicine, and having obtained it, he expects you to charge him the very lowest possible amount,—such an amount that I would not get up for, but for consideration for a person who might be suffering. Only recently a surgeon came to me for an 8oz. of mixture and a box of pills, and tendered me the respectable amount of 10*d*. I thanked him, and politely told him he might put it in the poor-box.

The CHAIRMAN: I think you deserve very great credit for having had the moral courage to tell him so.

Mr. HAMPSON: The business of this Conference having come to an end I think there is one duty we must not forget. I refer to the exertions and the skill which have been used by the firm of Messrs. Southall, Brothers, and Barclay. It is impossible to forget that through their agency or intervention we have now this trade association. I have much pleasure in moving that our thanks are due to Messrs. Southall, Brothers, and Barclay.

Mr. RADLEY seconded the motion, and it was carried unanimously.

Mr. BARCLAY: I am sorry our senior partner is not able to respond to the vote of thanks. We felt that it was a very hazardous undertaking to call this Conference, and if it had ended in failure we should have felt it most acutely but having gauged the feelings of the trade throughout the country we felt that this must be a successful Conference. We felt that there was a very deep feeling in the country that something must be done, and that if only an opportunity were given men would come from all quarters as they have come today. We have been blamed in some quarters for not consulting others before we took this step. But my experience in such matters is, that when you have made up your mind that a cause is right, the thing is to do yourself what is needed and do it the best way you can, and you are most likely to be successful. I am quite sure if we had gone to many quarters we should have had cold water thrown upon it, and very likely our own enthusiasm would have been damped in such a way as to have prevented the Conference etc., going forward. Success is the great thing, and I am very glad indeed to congratulate the chemists of Great Britain on the successful results of this Conference. There is every prospect that with such an excellent chairman, and such a committee good work may be done.

Mr. GREENISH proposed "That the best thanks of the meeting be given to Mr. Reynolds for the manner in which he has filled the chair."

Mr. RIMMINGTON seconded the motion, which was carried unanimously.

Mr. REYNOLDS: Mr. President and Gentlemen,—I thank you most heartily for the expression of your thanks and your approval of any efforts I have made for this common cause of ours. I am glad to hear that there is between £200 and £300 guaranteed towards our new association. It really does not appear to be so serious a thing to get up an association when you have thoroughly gauged public opinion. The associations we already possess we have used, I believe, for the public good. Some of them have been used for political and educational work, for the advancement of pharmacy, and this one may very fairly be used for the promotion of our legitimate trade interest.

The Conference then broke up.

The following journals have been received:—The 'British Medical Journal,' July 8; the 'Medical Times and Gazette,' July 8; the 'Lancet,' July 8; the 'London Medical Record,' July 8; 'Medical Press and Circular,' July 8; 'Nature,' July 8; 'Chemical News,' July 8; 'Gardners' Chronicle,' July 8; the 'Grocer,' July 8; 'Journal of the Society of Arts,' July 8; 'Grocery News,' July 8; 'Produce Markets Review,' July 8; Practical Magazine,' for July.

BOOKS, PAMPHLETS, ETC., RECEIVED.

HANDBOOK OF RURAL SANITARY SCIENCE. Edited by LORY MARSH, M.D., London: Smith, Elder and Co. 1876. From the Publishers

A COURSE OF PRACTICAL CHEMISTRY. Arranged for the Use of Medical Students. By WILLIAM ODLING, M.B., F.R.S. Fifth Edition. London: Longmans, Green and Co. 1876. From the Publishers.

Notes and Queries.

CHLORAL CREAM.—The following formula for "Chloral Cream" appears in the *Répertoire de Pharmacie* for June 25:

White Sugar, finely powdered	100	grams
Chloral Hydrate	5	"
Water	15	"

Dissolve the chloral hydrate in the water and mix the sugar by trituration in a mortar. Flavour it with either artificial essence of pine apples (butyrate of ethyl-oxide) or with essence of peppermint. The preparation contains 50 centigrams of chloral hydrate in 12 grams, or about a teaspoonful. It is semi-fluid, and beautifully white. It can be dissolved to form a syrup by the addition of water. After a time, however, a liquid layer forms at the top, which contains a larger proportion of chloral hydrate than that underneath.

SOLUBILITY OF SALICYLIC ACID.—According to M. Cassan (*Rep. Pharm.*, June 25, p. 353), the solubility of salicylic acid in water or alcohol is considerably increased by ammonium citrate. Two grams of salicylic acid will dissolve readily in 120 grams of water if 2·5 or 3 grams of ammonium citrate be added. The ammonium citrate, which may be prepared by saturating solution of ammonia with solution of citric acid, is said not to communicate an unpleasant taste or interfere with the action of the medicament.

ALBUMINATE OF SANTONIN AND SODA.—According to Pavesi a combination of santonin and sodium bicarbonate with soluble albumen forms a good vermifuge. The preparation is made by heating together 1 part of santonin, 4 parts of sodium bicarbonate, and 2 parts of dried soluble albumen, with sufficient water, to 60° or 70° C., until the whole is dissolved, and then evaporating with a gentle heat to dryness. The "albuminate of santonin and soda" forms white shining scales, soluble in water. Mineral acids precipitate the santonin and albumen, with disengagement of carbonic acid. Pavesi states that the use of this preparation is not followed by coloured vision as in the case where santonin is used alone.—*L'Union Pharmaceutique*, May, 1876.

"CONCENTRATED MEDICINES."

Sir,—Only a few weeks since one of these ill-advised and perplexing mixtures was ordered for a lady. "Two tablespoonfuls to be mixed in half a pint of water (8 ozs.), and two tablespoonfuls to be taken three times a day."

The lady, according to directions received, very carefully measured the quantity, and in compliance with the doctor's orders transferred it into an eight ounce bottle, filling it up with water, and from this she took the dose ordered, placing the bottle on a sideboard. So far all was right, but on going for the second dose, and being in a hurry, she poured out a dose of the concentrated medicine and swallowed it off before she found out her mistake, which she only discovered by a severe burning in the throat, and by a sense approaching to suffocation. As the dose taken contained nearly 4 drams of sp. am. ar. and 2 drams of spts. chloroform, with a quantity of potass. bromid. and very little water, this was not much to be wondered at.

For myself I do not think that the dispenser incurs any moral or legal responsibility in sending out these medicines, such responsibility resting entirely upon the prescriber. All the dispenser can do is to make the directions as distinct as possible, and to point out to the patient the necessity for care.

My reason for troubling you with the present case is because it is one strongly pointing out the danger attending this plan of prescribing. The lady in question is one of the most intelligent, clear-headed, business-like women I have ever met with. The bottle sent had a very large prominent label affixed to it by myself, with the words "Concentrated Mixture" as well as the directions, and yet the mistake was made, demonstrating to my mind most distinctly the great risk that must always arise from medical men advocating and encouraging private dispensing.

What is the object of ordering these "Concentrated Medicines?" The unjustly saving the pockets of the patients at the expense of the dispenser. And these are the men, forsooth, who rise up against the chemists and druggists for dispensing on their own account. The present style of things cannot last long; we shall not quietly submit to be crushed out of existence.

"ONE WHO HAS KNOWN THE DRUG TRADE MORE THAN THIRTY YEARS."

THE BENEVOLENT FUND.

Sir,—In view of the approaching election of annuitants on the Benevolent Fund, I would wish to suggest that subscribers should refrain from recording their votes in favour of candidates who canvass them by means of post-cards or circulars, as it is obvious that candidates who are in a position to do this are those who least need the grants.

If a few subscribers would intimate their intention through the columns of your Journal of acting in this manner I am of opinion that much would be done to eliminate this objectionable practice.

I notice with pleasure in this week's *Pharmaceutical Journal* a recommendation from the Secretary that former subscribers who, from reduced circumstances, are compelled to apply to the Fund for assistance, should have a number of votes placed to their credit corresponding to the total amount of their subscriptions. I am confident all will admit the justice of such a proceeding.

Norwich, July 10, 1876.

H. NORVICUS.

C. Jarvis.—We cannot say; apply to the authorities at Apothecaries' Hall or the College of Surgeons.

"*A Student at the Square.*"—The quotation from the Calendar, as given by you, is correct; we believe no limitation is intended. If you wish for an official exposition of the regulation you should apply to the Secretary.

W. T. E.—European honey is said to be at times adulterated with glucose, molasses, flour potato meal, dextrin, tragacanth, etc. According to the last report of the adulteration committee of the American Pharmaceutical Association most of the so called strained honey sold in the United States is made by melting cane or other sugar in a decoction of slippery elm bark, or in a solution of gum and starch, Cuban honey being used for flavouring.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. Muter, Mr. E. Saunders, Mr. Beall, Mr. Strongitharm, "Country Pharmaceutical Chemist," "Enitar," "An Associate," "Tau," H. H.

NOTES ON BRAZILIAN DRUGS.*

SICOPIRA (BOWDICHIA MAJOR, Mart.).

BY DR. THEODOR PECKHOLT,

Apothecary to the Imperial Brazilian Court.

The *Bowdichia major* is an imposing primeval forest tree, called by the Brazilians "Subupira," "Sebipira," "Sebupira," and "Sicopira," the latter two names being used especially in the provinces of Rio and Minas Geraes. It was first described by Pison as "Cebipira-guassu," and afterwards by Marcgrave as "Carubai-merim." Dr. Von Martius named it in his 'Reise' *Sebipira major*, and afterwards, in the 'Flora Brasiliensis,' *Bowdichia major*.

The dense, heavy, very resinous wood is much esteemed for building, and a decoction is used as an antisyphilitic. Occasionally when some of the old trunks are felled a dark yellow liquid that froths strongly and has a bitter taste flows from the hollow sap-wood; this is called by the woodcutters "Cerveja de Sicopira (Sicopira beer), and is popularly used for disorders of the stomach. The stem bark has been indicated as possessing therapeutic properties, but the author has not found any special result following its administration. The root bark, however, which has a still greater therapeutic reputation, the author thinks actually deserves a place in the materia medica.

The root bark obtained from trees growing in the Campos district, upon the so-called capoes (tree-islands) is most esteemed. According to the quality of the soil the root bark is red-brown or flesh-coloured, and is known by the natives as "Sicopira vermellia" or "Sicopira branca;" the latter comes almost exclusively from the Campos district, and is the most valued. For the last nine years it has been prescribed by Brazilian physicians in cases of syphilis and rheumatism, but mostly in affections of the skin (psoriasis, etc.). The people use a decoction, an ounce of root bark to a pint, taken in tablespoonfuls, and externally a strong decoction as a lotion. The late Dr. De Mattos, who introduced its use officially and published a memoir upon the subject, prescribed principally a tincture (one part bark and four parts alcohol) and an alcoholic extract. One part by weight of the tincture was mixed with ten of simple syrup, and a tablespoonful three times daily was the dose for an adult. The spirituous extract was made up into pills, each containing 0·15 gram, three to six of which were taken daily. The administration of the pills in skin affections has been observed at first to intensify the disease, which afterwards gradually disappears.

In the spring the trees are pierced by insects, and there flows out a thick light-brown juice which quickly hardens in the air, and forms pieces resembling Senegal gum. This gum is called by the Brazilians "Gomma de Sicopira," and consists in 1000 parts of—

Green fatty matter	0·278
Light-brown acid resin	30·000
Brown resin, containing tannin	11·252
Tannin precipitating ferric salts green	29·258
Glucose	traces.
Gum	310·500
Bassorin-like substance	440·600
Moisture	137·000
Inorganic substances	39·020
Loss	2·090

The gum is used against diarrhœa. The result of an examination of this gum was published by the author in 1872.* This he now supplements by the following notes on the wood and root bark:—

100 grams of air-dried wood sawdust lost 12·652 grams of moisture and yielded 6·400 grams of ash. The sawdust was treated with various solvents, and extracted with acidulated water, and an aqueous decoction was treated with lead acetate, but no crystalline product was obtained. The ethereal extract yielded a red resin which was insoluble in dilute alcohol, but very soluble in 80 per cent. alcohol as well as in alkalies. By soda solution the resin was coloured superficially green and then dissolved with a brown colour; from which solution it was again precipitated in flocks by acids. Treatment of the sawdust exhausted by ether with alcohol gave only a trace of a brown resin. The sawdust boiled with water gave a dirty yellow decoction, which upon evaporation yielded a brown extract having a disagreeable taste, having for its principal constituents a tannin colouring iron salts green, gum, and colouring and extractive matters.

In 1000 parts of air-dried sawdust was found—

Moisture	126·520
Acid resin soluble in ether	7·490
Resin insoluble in alkalies and ether	10·009
Tannin, gum, and extractive	30·000
Fibre	825·981

When boiled with alum and water and treated with a solution of ammonium carbonate a product is obtained which upon drying forms a beautiful orange yellow powder very useful in water-colour painting. When a solution of sodium carbonate is used instead of ammonium carbonate the product is not so bright.

In consequence of the belief of the Brazilians in the therapeutic value of the stem bark, the author made an examination of it. No crystalline product was obtained, but the constituents of the wood, gum and root bark were found to be partially present, the stem bark being richest of all in tannin.

Dr. Mattos was in the habit of prescribing only the root bark and its preparations, and preferred that the root bark used should be collected from trees growing in the Campos district, and especially in the diamond territory in the province of Minas Geraes. The author, therefore, examined root bark from that locality, and obtained from it an organic crystalline body. The supply being limited he also experimented with root-bark from the province of Rio Janeiro, and found the same constituents, including the crystalline principle, "Sicopirinum," but as the Campos root bark appears to contain it in larger proportion, it may be, if this crystalline body is the active principle, that Dr. Mattos was right in thinking that variety the most active.

The Rio sample of bark was obtained from a forest tree under the superintendence of Dr. Peckholt himself. Besides the colossal tap root the tree had very wide-spreading rootlets, which frequently almost appeared through the surface of the soil, and so were most convenient for the work of removing the bark. Most of the rootlets ended in a kind of

* From "Mittheilungen aus der Materia Medica Brasiliensis" (Zeitschrift d. algemenien österreichischen Apotheker-Vereines, July, p. 290).

* *Archiv der Pharmacie*, 1872, p. 37.

knob, or sometimes three to six knobs united like a rosette. The knobs were of a long oval shape, tapering off very thin at both ends, about 20 c.m. long and 7 c.m. in diameter, and weighed on the average 380 grams. They were covered with a thin pale yellow pellicle, which peeled of as in the mandioc. The underlying bark was like the ordinary root bark, yellow and smooth externally, orange yellow in section, and 5 mm. thick. The knob-like swellings, after being freed from bark, consisted of a solid, thick fibred, very tough woody substance, resembling ivory, and probably capable of being put to technical use. Whether the trees in the Campos district possess similar knobs, the author has not been able to learn.

100 grams of fresh root bark lost 62·773 grams of moisture. The powder of the dried bark was completely exhausted with absolute ether, the ethereal solution distilled, and the red brown resinous residue treated with 32° alcohol as long as anything was dissolved; there was left a crystalline residue which the author has named Sicopirinum.

The alcoholic solution distilled and evaporated to dryness yielded a reddish-brown resin (α Sicopira resin). The bark exhausted with ether was dried until the smell of ether was no longer perceptible and repeatedly exhausted with boiling absolute alcohol, the united extracts distilled, and the residue after being evaporated to dryness treated with distilled water as long as any dissolved. The portion insoluble in water was β Sicopira resin.

The aqueous solution after treatment with lead acetate yielded tannin precipitating iron salts green, and an extractive matter having an intensely bitter taste, similar to gentian bitter.

The bark after having been extracted with ether and alcohol was then treated with alcohol; but it gave only a very small yield of an insipid extract.

100 grams of dried root bark gave about 16 grams of alcoholic extract, which was prepared by repeatedly extracting the powder with boiling 80 per cent. alcohol.

α Sicopira resin, when perfectly dry, is viscous, cannot be pulverized and may be kneaded in hot water. It is of a reddish-brown colour, without smell, tasteless at first, with a bitter after-taste. Heated on platinum foil it melts to clear liquid; it inflames and burns with an odourless but cough-provoking smoke, leaving no residue. Alcohol dissolves it easily, the solution forming with water an emulsion-like liquid, which is coloured violet red by perchloride of iron. It is insoluble in alkalies, and is very different from the resin soluble in ether from the wood sawdust.

β Sicopira resin is a yellow-brown resin, which when dried can be easily pulverized and forms a dark yellow powder. It is insoluble in ether, very soluble in alcohol, soluble in akalies, and forms with metallic salts precipitates of metallic resinates.

The bitter substance is soluble in water and alcohol and is precipitated from the solutions by tannin; with iron salts it gives a blood red colour.

In 1000 grams of fresh root bark the following constituents were found:—

Moisture	627·730
Starch	19·830
Albumen	1·830
α Sicopira resin	12·340
β Sicopira resin	66·433
Sicopirinum (cryst.)	0·190
Sicopira tannin matters	8·350
Bitter and extractive matters	91·047
Gum, etc.	36·690
Fibre	135·560

Sicopirinum forms conglomerations of acicular crystals resembling poppy seeds. The crystals have a bitter slightly pungent taste and a faintly alkaline reaction. They are soluble in absolute alcohol and may be purified by repeated solution and recrystallization from it in the presence of animal charcoal. Heated on platinum foil they melt to a clear liquid, and burn without residue. They are soluble in ether and boiling alcohol, but water only dissolves traces. When treated with sulphuric acid there is a formation of glucose.

An elementary analysis of sicopirinum made for the author by Dr. Geuther, of Jena, gave results closely corresponding with the formula $C_{16}H_{12}O_5$.

When sicopirinum has been dried over sulphuric acid it loses no more at 100° C.

Whether sicopirinum is the active principle against skin affections has yet to be tested by experiment.

THE ALOIN OF BARBADOES ALOES.*

BY DR. ERNST SCHMIDT, UNIVERSITY LABORATORY, HALLE.

The first specimen of aloin examined by the author was obtained from an English manufacturer, and was supposed to have been prepared from Barbadoes aloes. After recrystallization from alcohol this aloin agreed in physical characters with the aloin originally described by Stenhouse, but the results of its analysis exhibited considerable discrepancies. The author therefore induced Mr. Liebelt to prepare some of the crystalline principle from a well marked specimen of Barbadoes aloes and to examine its characters more closely.

Of the different processes which have been recommended for the preparation of aloin the method proposed by Tilden ('Year-Book of Pharmacy, 1870'), was found to give the most satisfactory results. According to this method the aloes crushed small is dissolved in nine or ten times its weight of boiling water acidified with sulphuric acid. After cooling and standing for a few hours the clear liquid is decanted from the resin and evaporated. The concentrated solution deposits a mass of yellow crystals which can be purified by washing, pressure, and recrystallization from hot spirit. After several recrystallizations the aloin is obtained in the form of beautiful yellow needles which are pretty soluble in water and in alcohol, but soluble with difficulty in ether.

The melting point was found to vary according as the crystals contain water or not. The crystals melt between 70° and 80°, and the anhydrous substance at 146°—148° (Stenhouse 150°).

Aloin contains water of crystallization which it loses completely when left over sulphuric acid or when dried at 100°. The quantity of water present, however, is by no means constant, for not only do different preparations differ from one another, but even the same material according to the concentration and temperature of the solution from which it is deposited.

* Abstracted from the *Archiv der Pharmacie*, vol. v., No. 6, 1876.

The air dried substance heated to 100° lost in three experiments—

I.	II.	III.
5·89	6·77	7·01

per cent. of water.

Another product lost under similar circumstances—

IV.
11·93

per cent. of water.

In another case the first crop of crystals dried in the air then at 100° lost—

V.	VI.	VII.	VIII.
11·56	11·89	11·79	11·60

Whilst a subsequent deposit of crystals gave the following percentages:—

IX.	X.	XI.	XII.	XIII.
13·76	14·04	14·29	13·90	14·01

Some aloin exposed for a long time over sulphuric acid lost 13·44 per cent. of water, a loss which was not increased by afterwards heating it to 100°.

It appears from these results that aloin is capable of uniting with water of crystallization in several proportions which depend upon the temperature and state of concentration of the solution from which it is obtained.

According to the formula $C_{15}H_{16}O_7$—

One molecule of water requires .	5·52 per cent.
Two molecules	10·46 „
Three molecules	14·91 „

With the formula $C_{16}H_{18}O_7$—

One molecule of water requires .	5·29 per cent.
Two molecules	10·11 „
Three molecules	14·44 „

It seems, therefore, that aloin may crystallize with either one, two, or three molecules of water.

This variation of the water agrees with the observations of Flückiger upon the aloin of Zanzibar aloes, a substance which, according to Tilden, is isomeric with the aloin of Barbadoes.

Mr. Liebelt made numerous combustions of the aloin dried at 100°, and the percentages of carbon and hydrogen obtained by him are as follows:—

	I	II.	II.	IV.
C	58·68	58·30	58·41	58·33
H	5·73	5·71	5·71	5·47
	V.	VI.	VII.	VIII.
C	58·42	58·48	58·17	58·66
H	5·57	5·70	5·33	5·23
	IX.	X.	XI.	Mean.
C	58·66	58·33	58·71	58·46
H	5·81	5·84	5·69	5·61

With these data there is a choice between two empirical formulæ $C_{15}H_{16}O_7$ which requires

C 58·44
H 5·19

and $C_{15}H_{17}O_7$ for which the percentages must be—

C 58·25
H 5·50

Various considerations seemed to indicate that the former of these two expressions should be adopted, especially as von Sommaruga and Egger had obtained similar results with the aloin of Socotrine aloes.

Nevertheless this formula cannot be accepted. Soon after the publication of Mr. Liebelt's analytical results in the *Berichte d. Deutsch. Ges. zu Berlin* (November, 1875), the author became acquainted with the paper read by Dr. Tilden before the British Pharmaceutical Conference in August, 1875. In that paper the formula $C_{16}H_{18}O_7$ is proposed on the basis of analytical results obtained with the aloin and with its chloro-, bromo- and acetyl substitution derivatives.

These results led the author to recrystallize the aloin in his possession and to submit it again to analysis, this time drying it in a vacuum. The results showed that Mr. Liebelt's analyses had furnished somewhat too little carbon. The following numbers were obtained:—

	I.	II.	III.	IV.	Mean Schmidt.
C	59·31	59·45	58·96	59·19	59.23
H	5·39	5·63	6·08	5·34	5·61

The formula $C_{16}H_{18}O_7$ requires—

C 59·62 per cent.
H 5·59 „ „

This formula therefore seems to be established.

The author's results with the bromo- and chloro-derivatives, however, do not entirely agree with those described by Tilden.

When an aqueous solution of aloin is mixed with excess of bromine water a copious yellow precipitate is obtained, as long ago shown by Stenhouse. This yellow precipitate dried and crystallized from alcohol yields beautiful yellow needles. This compound, however, is not a homogeneous substance, for it seems to contain not only tribromaloin, which is the chief product, but also small quantities of compounds richer as well as poorer in bromine, which are very difficult to separate on account of their almost equal solubility. Although several preparations were made, especially by the introduction of aloin solution into excess of bromine water, and the composition of these specimens was not altered by repeated crystallization, the analytical results were found to agree sometimes with the formula

$$C_{15}\genfrac{}{}{0pt}{}{H_{13}}{Br_3}O_7$$

sometimes with the formula

$$C_{16}\genfrac{}{}{0pt}{}{H_{15}}{Br_3}O_7$$

All these brominated compounds exhibit much greater stability than pure aloin. They crystallize readily from alcohol in golden needles which are almost insoluble in water and in ether. The melting point appears to be at 190° to 191°. Bromaloin also contains water of crystallization.

The air-dried substance lost at 100° the following quantities per cent.:—

I.	II.	III.	IV.	V.
9·00	9·22	9·06	11·93	10·56

A variation in the amount of water is exhibited here as in the case of pure aloin. The formula $C_{16}\genfrac{}{}{0pt}{}{H_{15}}{Br_3}O_7$ with $3\,H_2O$ requires 8·81 per cent. of water, with $4H_2O$ 11·41 per cent.

The substance dried at 100° gave when burnt with chromate of lead the following percentages of carbon and hydrogen. The bromine was determined by the method of Carius.

	I.	II.	III.	IV.	V.
C	33·36	33·38	33·49	33·17	33·13
H	3·17	2·76	2·89	2·93	3·06
Br	43·31	43·38	43·60	43·63	43·70

	VI.	VII.	VIII.	IX.	X.	XI.
C	33·47	33·84	33·71	35·15	34·27	34·24
H	2·69	2·70	3·02	2·97	3·11	2·01
Br	43·47	43·22	——	41·44	43·08	

The following percentages are required for the two formulæ referred to

	$C_{15}H_{13}Br_3O_7$	$C_{16}H_{15}Br_3O_7$
C	33·03	34·34
H	2·39	2·68
Br	44·03	42·93

The author has not been successful in producing from aloin a definite chlorinated product by the action of chlorine either in the gaseous form or in aqueous solution. But by the action of potassic chlorate and hydrochloric acid, according to Tilden's process, a yellow substance was obtained which crystallizes in beautiful needles. The analysis of this compound, however, led to numbers which vary still more than those obtained in the analysis of the corresponding brominated derivative. The percentages of chlorine obtained were as follows:—

I.	II.	III.	IV.	V.
23·02	24·47	25·67	25·55	26·83

The formula $C_{16}H_{15}Cl_3O_7$ requires 25·03 per cent.

The author finds that barbaloin when digested with nitric acid yields chrysammic, picric, oxalic and carbonic acids.

The action of zinc dust when heated with aloin has already been observed by Graebe and Liebermann, who obtained a hydrocarbon which they believed to be anthracene. As, however, it is not clear as to which kind of aloin these chemists operated upon the author has repeated the experiment with Barbadoes aloin, and finds that the hydrocarbon derived from this source is principally methyl-anthracene.

The melting point was at 210°–202°. By oxidation with chromic acid dissolved in acetic acid it furnished anthracene mono-carbonic acid (melting point 281) soluble in ammonia, also a small quantity of a body having the properties of anthraquinone. The melting point of this latter was, however, not constant (210° to 240°) and it may, therefore, be assumed that it consisted of a mixture of anthraquinone and methyl-anthraquinone. Whether this anthraquinone is a product of the decomposition of methyl-anthracene or is formed by the direct oxidation of a small quantity of anthracene cannot be at present determined. The quantity of methyl-anthracene obtainable from barbaloin is exceedingly small (about 1 part of the hydrocarbon from 200 of the aloin), so that the aloin can scarcely be regarded as a direct derivative of methyl-anthracene.

The author is not at present continuing his experiments upon the oxidation of aloin, having been informed by Professor von Sommaruga and Dr. Tilden that they are already occupied in a similar investigation.

PERSIAN INSECT POWDER.*

BY R. ROTHER.

The powdered flowers of *Pyrethrum caucasicum, roseum,* etc., have in the course of a few years attained celebrity as an insecticide.

The non-poisonous character of the powder widens its range of application to an unlimited extent, and places it prominently above the numerous often highly poisonous substances used for the same purposes. Its general use has, however, been restricted by reason of its costliness. This feature, though, is becoming less apparent year by year, and bids fair to come to a normal basis very soon.

Persian insect powder is analogous in its action to Cocculus Indicus. Its contact promptly stupefies, and, if prolonged, death rapidly ensues. It appears to be harmless to the larger animals, but if much of its dust is inhaled, dizziness will result. That the substance must possess medicinal virtues cannot be questioned, and probably before long will be largely employed otherwise than as a vermin destroyer.

The powder has never been thoroughly investigated. It was found not to contain an alkaloid nor santonin, so that its virtues were ascribed to the volatile oil it contains. Early last summer the writer made a preliminary examination of it, and, by operating upon 3500 grains of the powder obtained results which were recently confirmed by a second experiment upon 20 ounces of the material, but an altogether thorough investigation was cut short by an accident, through which most of the material was lost.

The writer found that an aqueous percolate, as also an aqueous ammoniacal one, when treated with chloroform, ether and benzine, gave no indications of an alkaloid soluble in these liquids. Three acid bodies were, however, isolated. An oleo-resinous greenish-yellow acid, which the writer denominates Persicein, was found having the odour of the powder and its sub-bitter taste. It is, however, not the active principle of the plant. This acid resin is soluble in ether, alcohol and benzine, but insoluble in chloroform; it is instantly dissolved by ammonia and the fixed alkalies, from which acids in not too dilute solutions precipitate it milky white. It is somewhat soluble in water, imparting a greenish-yellow colour and its characteristic odour and bitter taste. It forms insoluble salts with the heavy metals.

A second acid was found; it has a light-brown colour and is nearly insoluble in cold water, slightly soluble in hot. It is soluble in alcohol, with a red-brown colour; but insoluble in chloroform, ether and benzine; water reprecipitates it from the alcoholic solution. It forms soluble salts of dark brown-red colour with ammonia and the fixed alkalies; acids, again, precipitate it from the solutions of its salts. Strong sulphuric acid dissolves it with dark-brown colour; the addition of water precipitates it from this solution unchanged. Strong nitric acid acts on it with great energy, liberating nitrogen tetroxide in profusion, yielding a deep yellow solution, and an insoluble yellow acid, probably a nitro-acid. This new acid is soluble in alkalies, from which acids again precipitate it. The yellow nitric solution was not examined. The writer designates this second acid as Persiretin. The powder was found to contain 4·3 per cent. of it. It is not the active principle, but a decomposition product of it.

A third and very soluble acid was found. This body the writer names Persicin. It is a glucoside, and is split by boiling with acids into persiretin and glucose. It appears to be a polybasic acid, forming an insoluble and a soluble lead salt. It is remarkable for having a pleasant odour resembling that of fresh honey. This acid is exceedingly unstable; contact with dilute chlorhydric acid in the cold or evaporation of its solution, or of its salts, converts it into persiretin and glucose. It is, therefore, almost impossible to obtain the free acid dry in a pure state. The colour of persicin is, in solution, light wine-red, and that of its neutral salts dark wine-red.

Plumbic acetate does not precipitate its neutral solutions, but diplumbic acetate produces a voluminous greenish-white precipitate. Excess of persicin dissolves the neutral lead salt, forming a pale yellow solution, which on evaporation yields an amorphous mass insoluble in alcohol, which latter also precipitates the salt from its aqueous solution in yellowish-white curdy flakes.

The acid potassium salt of persicin can be crystallized;

* From *The Druggists' Circular and Chemical Gazette,* July, 1876.

it is also soluble in alcohol. The neutral salt is apparently amorphous, and but sparingly soluble in alcohol. Persicin gives a fresh-coloured precipitate with argentic nitrate, which is insoluble in acetic acid, but soluble in ammonia. Persicin is soluble in alcohol, but insoluble in chloroform, ether and benzine. It is apparently the active principle of the plant.

The investigation was conducted by percolating the powder first with water, then with water containing ammonia. The aqueous percolate yielded nothing to chloroform. Addition of chlorhydric acid threw down the persiretin. After filtration, ammonia gave a crystalline precipitate of ammonio-magnesian phosphate.

The ammoniacal percolate had a ruby-red colour. Addition of chlorhydric acid precipitated persiretin in great abundance, showing that the small amount extracted by water in the first percolation existed in combination with some base, but that the most of it is uncombined. The acid filtrate was then treated with ammonia in excess, united with the first filtrate and the whole evaporated on a water-bath to a syrupy liquid. This residue, now having an acid reaction, was treated with alcohol, which produced a gummy precipitate and a dark red liquid. The solution was evaporated on a water-bath to expel the alcohol, slightly diluted with water and shaken with ether. The ethereal solution on spontaneous evaporation yielded a residue of persicein. The aqueous residue was now shaken with chloroform, which after decantation and evaporation left no residue. The aqueous liquid was then treated with benzine, which took up the ether and chloroform held in solution; on evaporation no appreciable residue was left, thus showing the probable absence of alkaloids.

The liquid from which the benzine had been decanted was treated with chlorhydric acid, producing a slight turbidness; shaken with ether, it dissolved, and the yellowish ethereal solution yielded on evaporation more of the persicein. This result shows that the persicein taken up by the ether in the first instance had parted with the ammonia during the evaporation, and that the remainder could only be removed after its liberation by the chlorhydric acid.

The red acid liquid was now mixed with the filtered solution of the matter precipitated by the alcohol, neutralized with ammonia and treated with diplumbic acetate as long as a precipitate formed; this was collected, washed and treated with dilute sulphuric acid in slight excess, whereby the persicin was liberated, and the peculiar honey odour at once became perceptible. On evaporation on a water-bath, a red acid residue was obtained; however, it was much contaminated with insoluble persiretin, into which a part of the persicin had been converted. The fresh solution of the persicin, neutralized with potassium hydrate and boiled with Fehling's solutions, yields an emerald-green liquid, but no cuprous oxide. If the solution is, however, first boiled a few moments with dilute chlorhydric acid until it becomes turbid, then neutralized and boiled with Fehling's solutions, cuprous oxide is profusely precipitated. This makes it evident that persicin is a glucoside, decomposable into persiretin and glucose.

THE USE OF ARNICA.

Strong opinions having been expressed by various writers that the external application of arnica is not only valueless but often positively noxious, and that arnica lotion applied to excoriations sometimes occasions severe outbreaks of acute inflammation, Dr. Patze, of Washington, has published the following remarks on the subject in *New Remedies* for June:—

"Though the German name for Arnica is *Wohlverleih*—weal-bestowing—it deserves this name only under the condition that it be properly applied, for it has not only its well defined indications, but also such serious, terrifying contra-indications that German governments, especially the Prussian, classing arnica among the acria, have already more than fifty years ago, issued laws to their apothecaries prohibiting its sale, except on prescriptions from authorized physicians.

"Experiments with arnica on horses have, according to Schuchardt, rendered the following results: small doses accelerated the pulse, raised the temperature of the skin, increased the secretion of urine, and caused tremor of the muscles. The violence of these phenomena increased with the augmentation of the dose, causing frequent evacuations of fæces and urine, violent tremor, accelerated respiration and prostration. Injections of an infusion of arnica-flowers into the veins caused considerable excitation, soon followed by intense languidness, vertigo, and even death, and on examination the organs of the chest and abdomen, the cerebrum and spine were found engorged with blood.

"In man the series of symptoms are the following: any part of the arnica-plant applied to the skin causes an itching, burning sensation, accompanied by redness; though its fragrance is agreeable, it will, in closer proximity, cause sneezing, so much so, that the Savoyards are using it instead of snuff. Small doses of 4 to 10 grains exert an irritating effect on the fauces and larynx, on the stomach and the alimentary canal, manifesting itself by a burning, scratching sensation, cardialgia, abdominal pains, nausea, belching, vomiting, frequent evacuations, the circulation is accelerated, accompanied by increase of warmth of the body, the secretions are increased, especially those of the urine, the skin and the lungs. The continued use of the arnica will cause numbness of the head, vertigo, mental depression, restless sleep, oppression of the lungs, jerking pains, like electric strokes, in the extremities, etc.; increase of the dose will aggravate all these phenomena, especially the affections of the brain.

"The hot infusion acts more severely than the tincture, and the flowers are more exciting than the root. This series of symptoms indicates that arnica may find its place in all those diseases which manifest a character of torpor, wherever an acceleration of the circulation is desirable, in order to remove and scatter stagnating humours.

"Arnica is in Germany so extensively, so frequently used, that some apothecaries have to keep the infusion, by the quart, on hand, preparing it every morning fresh, (℥ j of the flowers steeped for 15 minutes in 6 ounces of boiling water). It has maintained its old reputation as *Wohlverleih* in a variety of cases, especially where the vitality of the nerve-centres, brain and spine, is oppressed, in extravasations, paralyses consequent upon apoplectic strokes, rheumatism, catarrh, pleurisy and pneumonia, in traumatic commotions of the brain, in typhoid fevers with torpor and paralytic affections, etc.

"The external use of arnica is very limited, and especially contraindicated in recent traumatic cases; it should never be applied before all tendency to inflammation is removed by the antiphlogistic applications; it can therefore seldom find its place before the lapse of seven days after the injury; then, and not before then, the tincture, properly diluted in combination with other remedies for the stimulation of the capillary vessels may be applied, perhaps like this: ℞ Tincturæ flor. Arnicæ ℥ ss, Aceti ℥ ss, Aq. Camphoræ ℥ vj d. g. for external use."

THE PHARMACEUTICAL PREPARATIONS OF PHYSOSTIGMA.*

BY GEORGE W. KENNEDY.

One of the subjects suggested by the American Pharmaceutical Association was an essay on Calabar Bean, giving the readiest method of obtaining the various pharmaceutical preparations and isolating its active principle.

* Read at the fifth session of the American Pharmaceutical Association.

In response to the above query, the writer reports the following as being as easy and simple a process for the various pharmaceutical preparations of Physostigma venenosum, in my opinion, as can be offered for your acceptance. I experimented with various menstrua of alcoholic strength, and none of them gave the satisfaction as the one I herewith present for your consideration. Most of the preparations of Calabar bean that have heretofore been manufactured were made of strong alcohol, with very few exceptions. Our deceased colabourer, Professor William Procter, recommended a menstruum composed of seven fluid ounces of alcohol, and three fluid ounces of water, and one troy ounce of bean, which makes a half-pint of tincture when the preparation is completed.

I do not favour the use of strong alcoholic preparations, so long as a weaker alcohol will answer the same purpose. Physostigma is the active principle of the bean, a certain per cent. of which is soluble in water; and, knowing this to be the case, I therefore recommend a menstruum composed of alcohol and water for the different preparations, and used in the proportions of three (3) parts alcohol and one (1) part water; and, as the seeds are so tenacious, I would also recommend a preliminary maceration of the drug before proceeding with the percolation, otherwise the exhaustion will be imperfect. The following embraces all the preparations of the bean that I am acquainted with, solid extract, fluid extract, tincture, calabarized paper, and calabarized gelatin, besides the alkaloidal principle physostigmia.

Extractum Physostigmatis.

Take of	Calabar Bean in moderately fine powder	12 troy ounces.
„ „	Alcohol (95 per cent.) . . .	9 fluid „
„ „	Water (distilled)	3 „ „
„ „	Glycerin	1 „ „

Mix the alcohol, water, and glycerin together; moisten the powder with five fluid ounces of the mixture, pack in a conical glass percolator, and cover the surface of the powder with a disk of paper; pour on the balance of the mixture, cork the percolator, and cover closely, and set aside in a moderately warm place for four days, after which remove the cork, and proceed with the percolation, with a menstruum composed of three parts alcohol and one part water, until completely exhausted; distil off the alcohol, and evaporate in a porcelain vessel by means of a water-bath to the proper consistence. The object of the glycerin is to keep the extract in a soft condition, which makes it more convenient for manipulation, and especially when it forms one of the component parts of a pill mass.

Extractum Physostigmatis Fluidum.

Take of	Calabar Bean in moderately fine powder	16 troy ounces.
„ „	Alcohol (95 per cent.) . . .	12 fluid „
„ „	Water (distilled)	4 „ „

Moisten the powder with six fluid ounces of the above menstruum, pack in a conical glass percolator, after which cover the surface of the powder with a disk of paper, and pour upon it a sufficient quantity of the menstruum until the liquid begins to drop from the percolator; then close the lower aperture with a cork, and cover closely, and set aside in a moderately warm place for four days, after which the cork should be removed, and more menstruum added until thoroughly exhausted, the first twelve ounces being reserved, and the balance to be evaporated to four fluid ounces, and mixed with the reserved portion, and after standing a few days should be filtered through paper. This preparation is but little used in our locality, and I believe but little used anywhere else, but makes an excellent preparation to prepare calabarized paper or calabarized gelatin.

Tinctura Physostigmatis.

Take of	Calabar Bean in moderately fine powder	4 troy ounces.
„ „	Alcohol (95 per cent.) . . .	24 fluid „
„ „	Water (distilled)	8 „ „

Mix the alcohol and water; moisten the powder with two fluid ounces of the menstruum; pack in a conical glass percolator, and cover the surface of the powder with a disk of paper, and pour six fluid ounces of the above menstruum on it; cork, and cover the percolator closely, and allow it to remain in this condition four days, after which remove the cork, and proceed with the percolation and with the same menstruum until two pints of tincture are obtained, which will be found sufficient to thoroughly exhaust the bean. Some of the formulas which have been published for making this preparation contain a much larger proportion of the bean. My object in making it four troy ounces to the quart of tincture is so that it will conform in the proportion of solid material with most other tinctures.

Calabarized Paper.

This is readily prepared by taking paper deprived of its size—thin letter-paper, not ruled, is the best—and the size got rid of by boiling in water and drying. By dipping the paper three or four times in the fluid extract, of which I have given you a formula, and drying it after each immersion, the paper will be impregnated with a sufficient amount of the extract to perform the necessary service when applied to the eye. This plan of obtaining the effects of Calabar bean is objectionable, by being inconvenient, as it necessitates the removal of the paper subsequently. Calabarized gelatin is a much preferble preparation, and I would recommend the following formula:—

Calabarized Gelatin

Gelatin	30 grains.
Water (distilled)	2 fluid ounces.
Glycerin	gtt. xx.
Fluid extract Physostigma . .	♏c.

Make a solution of the gelatin in the water and glycerin, and, while the solution is still warm, filter through paper in a warm funnel; add the fluid extract, and evaporate. When it is evaporated to the proper consistence, spread on a glass plate or marble slab, with edges slightly raised, and with perfectly even surface, and place another glass plate or slab on top, which will keep it even and smooth; when it is hard enough, remove the plates, and divide into one hundred equal squares of about an eighth of an inch square, or as some might perhaps prefer, in circular form. The object here of the glycerin is to prevent its brittleness. The slabs should be slightly greased and warm, so as to prevent the shrinking and sticking of the gelatin. One of these small disks, containing about one grain of the bean, placed in the eye, will be immediately dissolved by the secretions, and the remedial agent absorbed, and the effects of the bean produced.

Physostigmia

I obtained by treating the extract as prepared according to the formula given, with a small quantity of dilute sulphuric acid, and diluting the mixture with water, filtering, and supersaturating with ammonium carbonate. The whole is now shaken with strong ether, and the ethereal solution which contains the alkaloid is separated after standing, which yields on evaporation the physostigmia in an impure condition, being contaminated with a red foreign matter, which obstinately adheres to it, and requires repeated solution in ether and crystallization to remove all the impurities.

NOTE ON CARVOL.*

BY F. A. FLUCKIGER.

Volckel, in 1840, pointed out that oil of cumin consisted of a hydrocarbon and a portion containing oxygen, to which Berzelius afterwards gave the name of carvol. This body was more minutely examined by Schweizer in 1841. He found that upon treatment with caustic potash, glacial acetic acid or iodine it undergoes a remarkable change; that it is specially soluble in potash, acquiring a very acrid taste, for which reason Schweizer designated the product carvacrol. When in 1842 Claus prepared camphor creosote by boiling camphor with iodine, Schweizer at once recognized its analogy with carvacrol. In 1844 he also obtained this compound by similar treatment of oil of *Thuja occidentalis*. Since then the methods of obtaining this body—at present looked upon as oxycymol, but probably more correctly oxycymene—have been multiplied. Pott obtained it by melting potassium cymensulphonate with potassium hydrate, the cymene employed being prepared by the action of phosphorsulphide upon camphor. H. Müller melted caustic soda with sodium cymensulphonate with the same result, the cymene (cymol) having been obtained from the oil of ajowan fruit (*Ammi Copticum*, L. = *Ptychotis Ajowan* and *P. coptica*, D.C.).

It now appears probable that cymene can be obtained by suitable treatment from any of the essential oils having the composition $C_{10}H_{16}$, as well as from many, if not all, that differ by the addition of O or OH_2, and the chemical identity of cymene from the most diverse sources may now be accepted; but the optical properties of this substance have hitherto only attracted the attention of Schiff and Guareschi. It remained to be seen whether cymene from other sources possessed for instance the same rotatory property as that prepared from cumin oil by Guareschi. The author thinks that this property will generally be found wanting in artificial cymenes, whether prepared synthetically or by reduction of $C_{10}H_{16}$, $C_{10}H_{16}O$, or $C_{10}H_{18}O$. Probably oxycymene is always without optic action, carvacrol prepared by the author from oil of cumin being without rotatory power. The author points out that oxycymene differs from carvol in being permanently coloured green by alcoholic perchloride of iron, refracting light strongly, not penetrating the cork so readily, and not giving the creaking noise peculiar to carvol and other thin volatile oils when rubbed against the side of a glass vessel.

Carvol is the only oil that, as noticed by Varrentrapp in 1849, combines directly with SH_2. The author has used a slight modification of Varrentrapp's method in testing whether carvol is as limited in its distribution in nature as the corresponding hydrocarbon, cymene or cymol. The oil to be tested is diluted with one-fourth its volume of alcohol (sp. gr. ·830) and then saturated with sulphuretted hydrogen. Upon the addition of only a little concentrated ammonia, or better still absolute alcohol saturated with ammonia, it solidifies to a crystalline paste of carvol sulphydrate $(C_{10}H_{14}O)_2SH_2$, or $C_{20}H_{30}O_2S$. Pure carvol is not necessary to the obtaining of this product; it is yielded by both the crude and rectified cumin oil of commerce. If the crystallization does not take place immediately it can be rapidly induced by the passage of a few bubbles of sulphuretted hydrogen. The crystals can be washed with cold alcohol and after further purification by recrystallization they have neither smell nor taste. They can be decomposed by gently heating with alcoholic soda, and upon dilution with hot water pure carvol separates.

Carvol from cumin oil rotates the polarized beam strongly to the *right*, giving with a column of liquid 25 mm. long, in a Wild's polaristrobometer, and with the sodium light, a deviation of not less than 15·6°. The hydrocarbon of cumin oil, carvene, is very strongly dextrogyre, to the extent of 26·8° under the same conditions.

Bolley had stated that in distilling oil of curcuma he had found the portion passing over 230° and between 250° C. to give upon analysis results closely corresponding to the formula $C_{10}H_{14}O$, whilst its behaviour with sulphide of ammonium pointed to its being an isomer with carvol. The author, however, failed to get from curcuma oil a product corresponding either in boiling point or composition with carvol; and four different portions, equally with the crude oil, failed to give the crystals $C_{20}H_{30}O_2S$.

The author next examined oil of myrrh, which, according to Ruikoldt's analysis, agreed in composition with carvol. An oil prepared by him from good myrrh, under the conditions above mentioned, rotated 15° to the *left* and yielded no sulphuretted hydrogen compound. Further its elementary analysis did not correspond with carvol. Herr Buri found in the crude oil C=84·70, H=9·98 per cent.; and in the principal portion, distilling between 262° and 263°, C=84·70, H=10·26. The formula $C_{22}H_{32}O$ would require C=84·62, H=10·25, O=5·13.

Oils of the composition of $C_{10}H_{14}O$ have been reported with more or less probability as present in oil of nutmeg and eucalyptus oil. Gladstone had already shown that the elements of the first formed no combination with oil of nutmeg, and this the author confirms, and gives the same report of oil of mace, his experiments having been made with samples distilled by himself. Neither did he obtain carvol sulphydrate from a commercial eucalyptus oil.

Oil of dill fruit (*Anethum graveolens*) yielded to Gladstone a portion behaving like the carvol of cumin oil, and the chemical identity of the two oils has been established by Nietzki. The author finds it unnecessary to separate the carvol, as the crude oil gives an abundant yield of crystals, $C_{20}H_{30}O_2S$. The carvols from the two oils also correspond in their optical properties. They do not differ more in smell than many sorts of turpentine oil or oil of citron and oil of lemon.

The author examined a sample of oil of *Mentha crispa* and found it to rotate 9·3° to the *left*. Treated with sulphuretted hydrogen it gave the crystals $C_{20}H_{30}O_2S$. The liquid portion, after separation of the alcohol and sulphuretted hydrogen by a gentle heat, amounted to about 70 per cent. of the crude oil, and showed a diminished rotatory power (7·0° to the left). The portion not acted upon by sulphuretted hydrogen gradually deposited crystals in the cold, and upon continuing the passage of sulphuretted hydrogen, adding a little ammonia, a thick oil separated, which, after washing, formed a vitreous mass ($C_{20}H_{30}S_3$, or $(C_{10}H_{14}S)_2SH_2$), the hydrothion sulphocarvol or thiocarvum first obtained by Varrentrapp from cumin oil carvol. This compound, so very rich in sulphur, has at first an agreeable spicy smell, but when purified is odourless.

As the oil of *Mentha crispa* rotated the plane of polarization to the left, it would result that the carvol it contained would also have a lævogyre action, although chemically it was perfectly identical with carvol from cumin oil. The author had supposed that the rotatory powers of the two carvols might be equal, but exercised in opposite directions. Examined, however, under the same conditions as those before mentioned for cumin carvol the crisped mint carvol showed a deviation to the *left* of about 9° only. It would be interesting to compare these two carvols still more closely, as the author thinks that that from crisped mint would probably also yield an oxycymene (carvacrol) without optical action, as well as other derivatives identical with those from cumin carvol.

The author has not met with carvol in any other case, although he has examined a large number of essential oils.

* Abstract of a paper read before the Berlin Chemical Society, from the *Berichte d. Deutsch. chem. Gesselsch.*, ix. 468.

OFFICINAL TINCTURES.

A Contribution to the Literature of the Proposed International Pharmacopœia.*

BY B. F. MCINTYRE.

The difficulty of finding a feasible method of solving the question of a universal standard of formulæ is evidenced by the comments in pharmaceutical journals, medical publications, and reports of societies abroad and at home.

The necessity of a universal standard is marked when we examine the French Codex, British, German, and United States Pharmacopœias with reference to correspondence of proportions in formulas of the same name and medicinal character. The urgency of investigation and comparison of Galenical formulas has received special emphasis during the past year by a publication from the German apothecaries' union of New York, giving the comparative strength of many preparations in the German and United States Pharmacopœias. The tincture calculations found therein are based on proportion of drug to *measure* of menstruum or finished tincture.

Weights and measures of the several pharmacopœias are apt to confuse, and a reform is needed in the directions of parts by weight. This system prevents errors when the weights used have a uniform relative value.

The impracticability of framing an international codex as a substitute for national standards cannot be questioned, but the revisions made occasionally in their standards admit of an opportunity to harmonize and level down discrepancies in formulas, and also to adopt well-tested improvements in pharmaceutical science. Classes of preparations and new remedies tried and found of intrinsic value will advance from national to international endorsement, as secondary preparations are promoted to primary in the U. S. P., when found worthy of transfer.

Percolation, when conducted with moderate care and skill, is an unexceptionable process; but when the conditions are the reverse, maceration with the full quantity of menstruum, as directed by the German and French Pharmacopœias, is preferable. The question of pressing from the dregs all of the adhering tincture is medicinally unimportant, as the tincture has throughout a uniform strength.

The British Pharmacopœia directs maceration of the drug with only a portion of the menstruum, the residue to be freed from tincture and extractive by percolation with fresh spirit until a prescribed measure is obtained.

The German process would be more in harmony with other authorities if a definite measure or weight of tincture could be got from the specified parts of drug; the difference now is considerable where force from hand-screw or hydraulic press is applied to the expression of marc or residue. This, however, is only an economic point for consideration. The loss may be seen in the annexed table, by comparing the actual weight of tincture obtained from the drug after maceration, with the theoretical quantity, or the proportional medicinal strength of the finished tincture given in the next column.

In the experiments tabulated below, the manipulations directed by, and characteristic of, the several pharmacopœias were followed, though the menstruum for the exhaustion of the drug was disregarded, except when they were of the same spirit strength as that designated in the U. S. Pharmacopœia. This was necessary in order to sustain the object of this paper, the finding of the exact parts by weight of drug in parts by weight of tincture; the determinations being based on repeated experiments and calculations made from weighings of hundreds of gallons of officinal tinctures.

As the German Pharmacopœia specifies that tincture of belladonna and digitalis be prepared from the fresh herb, calculation was made for loss in the drying of the herb, and the powdered drug was used instead.

* Read before the Alumni Association of the College of Pharmacy, New York.

‡ One fluid drachm of Tincture of Iron. U.S.P contains 3·53 grains of oxide of iron. One fluid drachm of the same tincture, B.P., contains 3·90 grains of ferric oxide.

‖ Parts by weight of tincture actually obtained from one part by weight of the drug.

† Parts by weight containing the active principles of one part by weight of the drug.

* Tinctures directed to be made by maceration.

Several gummy and resinous tinctures in the U. S. Pharmacopœia are made by maceration without special directions concerning the amount of tincture to be got from the drug; in these instances, if the filtered tincture was less in measure than the menstruum employed, the residue on the filter was percolated with fresh spirit until the measure was obtained.

The tincture of aconite root, given in the table with the French Codex tinctures, is unofficinal; the formula used was that recommended in Dorvault's *L'Officine*. All the Codex tinctures are made in accordance with the system of weight by parts.

Some are directed to be made by maceration, and a great number by percolation. The second process is nearly indentical with that of the United States Pharmacopœia. Such of the tinctures as are made by maceration are in the table marked (*).

A brief study of the table will show a startling exhibit of variations in the strength of several of the dangerous tinctures, whilst the difference between many of the more important ones, including a few that are considered as requiring particular precaution in dispensing, is so slight, that no serious confusion would arise, were they revised so as to correspond with each other.

Nothing but a lingering prejudice against innovation, and an antique veneration for traditional formulas need prevent a systematic and wholesome reform in the direction of a simple and scientific basis for our pharmaceutical authorities to stand upon.

IMPURITIES IN THE HYPOPHOSPHITES OF SODA AND LIME.*

BY M. PATROUILLARD.

The hypophosphites soluble in water may be recognized by the following characters:—They reduce, by the aid of a gentle heat, salts of binoxide of mercury and those of silver, and more readily if the liquor contain a little hydrochloric or sulphuric acid. With bichloride of mercury they form a white precipitate of protochloride, or sometimes the colour is grey from the presence of metallic mercury through the more complete reduction of the chloride. With nitrate of silver, even in a neutral liquid, there is produced a dark-brown precipitate of phosphide of silver mixed with reduced silver.

Dry hypophosphites of the alkalies and of the alkaline earths, heated carefully in a test tube are decomposed giving off phosphuretted hydrogen which inflames spontaneously within the tube and burns with a pale greenish flame, depositing on the sides an orange-yellow or brownish body. Lastly, heated slightly with concentrated nitric acid an active effervescence is suddenly produced, accompanied by an abundant evolution of nitrous vapour. These experiments should be made carefully upon small portions of the substance, in consequence of the violence of the reactions.

Hypophosphite of soda is white, usually amorphous, although it can be obtained crystalline, inodorous, deliquescent, and completely soluble in water and even concentrated alcohol. One part dissolves in about two parts of water and in fifteen parts of 90° alcohol.

The impurities which this salt sometimes contains are due to want of care in its preparation. To obtain it it is usual to decompose hypophosphite of baryta with sulphate of soda, insoluble sulphate of baryta being formed and hypophosphite of soda, which remains in solution. If the sulphate of soda is not used in sufficient quantity, undecomposed hypophosphite of baryta remains mixed with the hypophosphite of soda, giving when tested with sulphate of soda a white precipitate insoluble in hydrochloric acid. If on the other hand an excess of sulphate of soda is used, and this is the more frequent case, the salt gives with chloride of barium the same precipitate of sulphate of barium. When treated with 90° alcohol a residue of sulphate of soda is left. The author reports that he has met with notable proportions of sulphate of soda in commercial hypophosphite of soda.

The residue insoluble in alcohol may also contain phosphate of soda formed during the evaporation of the solution of the hypophosphite. In this case the residue dissolved in distilled water gives with neutral nitrate of silver a yellow precipitate very soluble in nitric acid and in ammonia.

Hypophosphite of lime is white, unaltered by exposure to the air, soluble in about six parts of distilled water and insoluble in alcohol. The salt is rarely completely soluble in water, because in its preparation, during the evaporation of the solution, there is always formation of phosphite and consecutively of phosphate of lime. When triturated with water it ought to dissolve without giving off the alliaceous odour characteristic of phosphuretted hydrogen. The solution of hypophosphite of lime acidulated by acetic acid should give with oxalate of ammonia a white precipitate insoluble in acetic acid in excess, but soluble in hydrochloric acid. The same solution should not precipitate upon the addition of sulphate of lime, as that might show the presence of a baryta salt: neither should it precipitate with chloride of barium.

CHEMICAL INVESTIGATION OF SASSY-TREE BARK.*

(*Erythrophlœum guineense.*)

BY N. GALLOIS AND E. HARDY.

The Sassy-tree (*Erythrophlœum guineense*, G. Don) is a tall tree belonging to the Leguminosæ, sub-class Cæsalpinieæ, and a native of West Africa. Its wood is very hard and enduring and is not attacked by ants. The bark is used by the natives to poison their arrows and to prepare an ordeal drink for criminals. It is met with in irregular flat reddish brown pieces, with a rough surface. It is hard, fibrous, and odourless, and its pulverization is provocative of sneezing. A specimen of this bark has been examined by the authors, who have succeeded in extracting from it an alkaloid.

The powdered bark was exhausted by repeated macerations for three days in cold 90 per cent. alcohol slightly acidulated with hydrochloric acid. The tinctures were united and filtered and the greater part was distilled over from a water-bath; the remainder was then evaporated at a low temperature. A red brown extract was thus obtained rich in resinous matter. This was treated five or six times with lukewarm distilled water, and the liquor cooled, filtered and evaporated in a water-bath. When suitably concentrated it was again allowed to cool, decanted, saturated with ammonia, and poured into four or five times its volume of acetic ether, from which any acid present had been previously removed. After shaking several times the ether was removed by means of a funnel having a robinet. The aqueous solution was then exhausted a second time with four times its volume of acetic ether. The ethereal solutions were filtered, evaporated in a water-bath at a low temperature and the yellowish residue treated several times with cold distilled water. The aqueous solution was filtered and allowed to evaporate in vacuum of an air pump. Another process employed was that of Stas, with the substitution of acetic ether for ordinary ether after the saturation with carbonate of soda.

A substance was thus obtained that was soluble in water, and gave a yellowish red precipitate with iodine and iodide of potassium, white with the double iodide of mercury and potassium, yellow with iodide of bismuth and cadmium, white flocculent precipitate with iodide of

* *Journal de Pharmacie et de Chemie* [4], xxiv, 25.

cadmium and potassium, yellowish with bichromate of potash, white with bichloride of mercury, white with chloride of palladium, and a dirty yellowish green with phosphomolybdic acid. To the alkaloid thus indicated the authors have given the name "erythrophleine."

Erythrophleine is described as being colourless, crystalline, and soluble in water, alcohol, amylic alcohol, and acetic ether. It is only slightly, or not at all, soluble in sulphuric ether, chloroform and benzol. It combines with acids to form salts; the hydrochlorate is colourless and crystalline and gives a white crystalline precipitate with potash solution. The approach even of a rod dipped in ammonia to a concentrated solution causes an immediate formation of an opaque white precipitate, crystalline under the microscope. In contact with permanganate of potash and sulphuric acid erythrophleine develops a violet colour, less intense than that given by strychnine, and soon becoming dusky.

Erythrophleine is a very energetic poison, quickly paralysing the action of the heart. Its effects are retarded by curare.

A fruit and a leaf of *Erythrophlœum coumenga* were also examined by the authors, who found indications of an alkaloid very nearly allied to or identical with that present in *E. guineense.*

THE DECAY OF FRUITS.*

At a recent meeting of the *Gesellschaft naturforschenden Freunde zu Berlin*, Dr. Brefeld reported the results of his investigations on the decay of fruits. He says it is a universally recognized fact that a rotten apple will infect a sound one with which it may be in contact. We cannot conceive infection in the absence of an active agent producing it, and calling forth and determining the form of this phenomenon. These investigations embraced the examination of rotten fruits of various kinds from the most widely diverse localities, and at different seasons of the year. The tissue was invariably found to be exhausted and withered, the cells had lost their turgidity, the contents were contracted, and the cell-sap dispersed in the inter-cellular spaces. With certain exceptions, alluded to below, Brefeld found the entire mass of cells permeated in all directions by the easily seen spawn of fungi, but the threads were merely interlaced among the cells, never piercing the cells themselves. The fungi present belong to very common moulds of two distinct kinds; one with broad, dense tubes without partitions, the other with narrower, frequently septate tubes, both being very much branched. The former consisted mainly of *Mucor stolonifer*, more rarely of *M. racemosus*, and the latter of *Botrytis cinerea* and *Penicillium glaucum.* There seems to be no doubt that these parasites are nourished by the cell-sap which has escaped into the inter-cellular spaces; but the most important question for elucidation was whether these fungi are the cause of decay, or simply accompanying conditions. To determine this point, several series of experiments were undertaken with the pure fungus and perfectly sound fruit. Spores were thickly sprinkled over sound fruit, and, to make the experiment more conclusive, the spores were conveyed to the fruit in water, and the fruit afterwards placed under a bell-glass in a moist atmosphere. As might have been expected, the fruit remained sound, the spores failing to germinate altogether, or germinating only very sparingly. In consequence of the absence of a nourishing fluid, the spores possessed no power to attack the tissues of the fruit.

A second series of experiments was instituted, in which the spores were dipped in a nourishing solution of fruit pulp, in which they could germinate and form a mycelium, and this was laid on sound fruit with a pencil. Soon some of the fruits began to show here and there, in the least protected places, symptoms of decay, spreading with varying degrees of rapidity over the whole fruit. Nothing was easier to observe than that the penetrating fungus was actually the cause of the decay. Another set of experiments more fully proved this to be the case. Some sound apples were artificially wounded, and infected with the spores, which grew and spread in the same manner. Other sound, bruised, but not infected apples showed no symptoms of decay. From a large number of experiments it was found that the more unripe the fruit, and the denser its tissue, the less power the fungus had of taking possession of it; but with the increase of saccharine matter, and the decrease of acids, the fruit becomes more susceptible. Unripe fruit artificially infected with fungus did not decay, as the fungus did not find a suitable host. Concerning the relative rate of growth of the fungi named above it was found that *Mucor stolonifer* was by far the most rapid. Pears infected with this fungus become thoroughly decomposed in a few days, and, strange to say, no outward trace of it is usually discernible before the whole interior is destroyed. Now arises the question, Do fungi always cause the decay of fruit? This is easily answered in the negative, for many pears, and in a still more striking manner the medlar, exhibit a kind of spontaneous decay, equally as rapid in its course as is the case where moulds are present. This kind of decay is what we find in a "sleepy" pear and a blet medlar, in which, according to Brefeld, there is no fungus present. Otherwise the decomposition of the tissue proceeds in exactly the same manner in both cases. The foregoing extracts fully confirm practical experience, and suggest the means for preventing the spread of these insidious organisms—the moulds—in the fruit room.

* From the *Gardeners' Chronicle*, July 15, 1876.

The Pharmaceutical Journal.

SATURDAY, JULY 22, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, *17, Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary, 17, Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACISTS' DANGERS.

IF a non-pharmaceutist had been present last week in the room at Birmingham when Mr. WILLIAM SOUTHALL described the conscientious pharmacist as waking up in the night after a doubtful two-pence worth of laudanum has passed over his counter, assured that somebody has been poisoned, he might pardonably have looked upon the statement as a little dramatic colouring But pharmacists themselves know that even if their slumbers are as a rule unbroken this is not to be attributed to the absence of disturbing possibilities, and that scarcely a day passes without fresh evidence of the supreme necessity for the exercise of almost superhuman vigilance in carrying on the operations of a pharmacy. Two cases have recently been published, one in England and the other in France, in neither of which was there wanting what an ordinary tradesman would call carefulness, yet a little oversight in each nearly resulted in death, and in one case brought very disagreeable consequences to the pharmacist. We think it may be useful to put both of them on record.

The English case was the misreading of a badly written prescription, the result being an illustration on a human subject of probably the extreme amount of nitrobenzol that can be taken in forty-eight hours without inducing death. The details have been published by Dr. THOMAS STEVENSON in a pamphlet illustrated by a lithograph of the prescription. A young man having consulted a physician for a pain in the chest and troublesome cough, received the following prescription with a request to have it dispensed by a particular druggist:—

℞ Benzole rect., ʒij
OL Menth. pip., ʒss
OL Olivæ, ℥x, gutt. xxx. t.d.s.

The medicine was dispensed and taken and the cough was relieved. Three months afterwards, the patient thinking he had occasion to take the medicine again had it made up by another chemist. Here, however, obscure caligraphy exercised a disturbing influence, and the "Benzole *rect.*" of the prescription, which a medical contemporary fairly describes as a curiosity in the way of illegibility, was read "Benzole *nit.*" and dispensed accordingly. After taking equal to 23 minims of nitrobenzol in forty-eight hours, the patient was compelled to leave business, but on his way home fell senseless in the street and was carried into Guy's Hospital apparently dead, although we are glad to add he subsequently recovered.

We quite indorse the opinion of the *Lancet* that here the pharmacist—who, indeed, remarked on the largeness of the dose—was not to blame, and that the accident was due to the "homicidal handwriting" of the prescriber. It appears that the word "*rect.*" was so written as to exactly resemble "*nit.*" with the exception that the "*i*" was not dotted, but neither was any "*i*" in the prescription. In fact so specious was the resemblance that when the prescription was produced those who saw it, including Dr. STEVENSON, thought nitrobenzol had been prescribed, and the truth was not discovered until the chemist who first made up the prescription having been communicated with his greater familiarity with the prescriber's caligraphy enabled him to show the correct construction of the prescription. We are also glad to see that our contemporary strongly condemns the "practice of relying on a particular chemist to interpret bad writing."

The other case to which we referred was the dispensing of arseniate of soda for phosphate of soda, arising apparently from using up odd stock without previous examination. A French lady having received a prescription ordering ten packets of phosphate of soda, each containing one gram, sent it to be dispensed at a Paris pharmacy. Shortly after taking the contents of one of the packets in milk the lady was seized with violent symptoms of poisoning, and an examination of the remaining packets showed that they contained arseniate of soda.

After the recovery of the lady, the chemist was prosecuted before the *tribunal correctionnel* for having caused involuntary damage through neglect of the law providing that all poisons in a pharmacy shall be kept under lock and key. One of his pupils was also included in the charge. The offence was acknowledged, but in extenuation it was urged that the poison had been taken by the pupil out of a bottle labelled "phosphate de soude," which had been lying unused in a cabinet from the time when the business had been bought from the present proprietor's predecesor three years before. The tribunal, however, decided that the accident had resulted from "imprudence, inattention, négligence et inobservation des règlements." It therefore sentenced the principal defendant to suffer one month's imprisonment and pay a penalty of one hundred francs and the pupil to one month's imprisonment and a penalty of fifty francs. Besides this, both the defendants were ordered to pay two thousand francs *dommages intérêts.* This judgment appears to be a rather severe one, but the case is a fresh illustration of the necessity for the careful supervision of old stock by new proprietors.

FRENCH PROPRIETARY ARTICLES.

A FORTNIGHT since we quoted a statement respecting the sale of a French *spécialité*, the figures in which were almost suggestive of exaggeration. The last number of the *Bulletin Commercial*, however, contains fresh evidence of the enormous value (to the proprietors) of some of these preparations in France. It is stated that upon the death of M. BOYER of the Rue Taranne, the interest in his "Eau de Melisse" was sold for 1,264,000 francs, and that another *spécialité*, the "Liqueur des Bénédictines de Fecamp," has recently been sold for 1,400,000 francs. Under these circumstances it is not surprising to find that French financiers are desirous of making the citizens of this El Dorado contribute more freely towards the taxation of the country. A M. LORGERIL is particularly enthusiastic in this direction, and has recently been urging upon the Minister of Finance, for the third or fourth time, the possibility of raising untold millions (of francs) by a tax on *spécialités*. M. LEON SAY confesses to being in the position of a second TANTALUS, unable to drink of the stream that is running past him, because—he is in want of a definition. He has consulted the learned societies as to what constitutes a *spécialité*, but without success, and his last hope now rests upon a commission. Perhaps he and the commission may be assisted by a suggestion made during the debate that a *spécialité* is anything that speculates upon human stupidity!

XANTHIUM SPINOSUM AS A PREVENTIVE OF HYDROPHOBIA.

IN a letter published in a recent number of Professor GUBLER'S *Journal de Thérapeutique* another addition is made to the already formidable list of prophylactics against hydrophobia. Dr. GRZYMALA, of Krivoe Ozeroe, Podolie, reports that during the last ten years he has treated at least one hundred cases—in human subjects as well as beasts—of bites by hydrophobic animals with the powdered leaves of *Xanthium spinosum*, with success in every case except one, although cases of bites inflicted at the same time, but treated in other ways, had terminated in death. The drug is described as possessing sudorific, sialagogue, and slightly diuretic properties, but less pronounced than those of jaborandi. The dose for an adult is 60 centigrams of dry powder of the leaves, repeated three times a day and continued during three weeks; to children under twelve years half the quantity is given.

EVOLUTION OF OXYGEN BY VALLISNERIA SPIRALIS.

MR. STANTON, in a letter to *Nature*, invites confirmation of the following observation. He says that if a blade of *Vallisneria spiralis* be cut or broken and held under water in sunlight, there is a rapid evolution from the broken end of bubbles of oxygen gas which can be collected by filling a test tube with water and allowing the gas to displace the water. Mr. STANTON states that in this way he has collected about a cubic inch of oxygen from one blade in eight hours. After forty-eight hours the pores of the broken blade close up and a fresh fracture is necessary to restore the evolution.

POISONING BY VIRGINIAN CREEPER.

THE details of two cases of poisoning by the well-known Virginian Creeper or American Ivy (*Ampelopsis hederacea*) have been communicated to the medical papers by Mr. BERNAYS, of Chatham. The sufferers were two children, aged respectively 2½ and 5 years, who had chewed some leaves of the plant, swallowing only the juice. They were quickly seized with violent vomiting and purging, with considerable tenesmus; then collapse, sweating and faint pulse; followed by deep sleep for two hours from which they were aroused by a return of the vomiting and purging. Milk, with some rum mixed in it, was freely administered, under which treatment the children soon recovered; but four hours after the commencement of the attack there was still considerable dilatation of the pupil.

CINCHONA EXPERIMENTS BY THE JAPANESE.

IN the last quarterly report respecting the Dutch Government Cinchona Plantations in Java, it is stated that an attempt is to be made to acclimatize the cinchona in Japan. An application has been received from the Japanese Government for a supply of young plants for the purpose, and a selection of specimens of the best varieties in the Dutch plantations has accordingly been forwarded.

WE learn that H.R.H. the PRINCE of WALES has enriched the Kew Museum by the presentation of a large number of specimens of seeds and fruits of economic or medicinal value, as well as of condiments, drugs, grains, etc., from Southern India, collected during his recent tour in that country.

THE fifth session of the French Association for the Advancement of Science is to be held next month at Clermont-Ferrand. The local committee includes a large number of medical men and pharmacists. The opening meeting is to be held on the 18th of August and the congress is to close on the 27th.

THE Office of Registrar of the General Medical Council having become vacant through the resignation of Dr. HAWKINS, advertisements have appeared inviting applications for the appointment, which will be made by the Executive Committee in October next. The salary is £500 a year.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

July 12th, 1876.

Present—Messrs. Ainslie, Borland, Buchanan, Gilmour, Kemp, Kinninmont, and Young.

Professor Maclagan was present on behalf of the Privy Council.

MAJOR EXAMINATION.

One candidate was examined, and passed, and was declared qualified to be registered as a Pharmaceutical Chemist.

Baikie, Peter........................Belfast.

MINOR EXAMINATION.

Ten candidates were examined. *Three* failed. The following *seven* passed and were declared qualified to be registered as Chemists and Druggists:—

Fowler, Donald.......................Inverness.
Laurie, John..........................Ipswich.
Lees, David...........................St. Andrew's.
Pittuck, Frederick William ...Hebburn.
Roberts, Joseph......................Liverpool.
Robertson, Andrew.................Markinch.
Veitch, Andrew.......................Shildon.

MODIFIED EXAMINATION.

Four candidates were examined. *Two* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Johnstone, Robert ....Langholm.
Thorburn, Henry W. ....Bishop Auckland.

July 13th, 1876.

Present—Messrs. Ainslie, Borland, Buchanan, Gilmour, Kemp, Kinninmont, and Young.

Professor Maclagan was present on behalf of the Privy Council.

MINOR EXAMINATION.

Nine candidates were examined. *Six* failed. The following *three* passed, and were declared qualified to be registered as Chemists and Druggists:—

Frazer, Alexander ....Liverpool.
Harris, Evan William ....Aberavon.
Weddell, George ....Kelso.

EXAMINATIONS IN LONDON.

July 12th, 1876.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Taylor, and Umney.

MAJOR EXAMINATION.

Sixteen candidates were examined. *Five* failed. The following *eleven* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Allen, Charles Bowen ....Penzance.
Bennett, Charles ....Bristol.
Best, John William ....Darlington.
Bowen, John William ....Handsworth.
Dimmock, Augustus Frederick .London.
Dymott, Frank ....Southampton.
Hunt, Arthur ....London.
Milton, Thomas Clement.........Exeter.
Newbury, Samuel..................Dorking.
Severs, Samuel Thomas ....Leeds.
Wright, Thomas David ....Lancaster.

MINOR EXAMINATION.

Twelve candidates were examined. *Three* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Cooper, John.........................Newcastle-under-Lyne.
Goodall, William Anthony ......Clifton.
Hollick, Richard ....Birmingham.
Johnson, William Henry.........Nuneaton.
Madden, Ronald George ....London.
Trevaskis, George Marrack ...London.
Walker, George......................Liverpool.
Widdowson, Reuben ....Nottingham.
Wilkinson-Newsholme, Geo. T. Huddersfield.

PRELIMINARY EXAMINATION.

The undermentioned Certificates were received in lieu of the Society's examination:—

Certificate of the University of Oxford.

Powell, Ernest George Burrup. Cheltenham.

Certificate of the Royal College of Surgeons in Ireland.

Goodchild, Thomas Archibald...Belfast.

July 13th, 1876.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor, and Umney.

MAJOR EXAMINATION.

Seventeen candidates were examined. *Eight* failed. The following *nine* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Amoore, Lewis Perigoe ....Hastings.
Bessant, Frederick Railton......Hampstead.
Glegg, John ....Edinburgh.
Haworth, Benjamin Henry......Manchester.
Hicks, William Thomas ....Ipswich.
Jones, James Parry...............Newcastle.
Lewis, David.........................Cardigan.
Newton, Alfred Henry ....Kenilworth.
Weddell, Arthur ....Stamford.

MINOR EXAMINATION.

Ten candidates were examined. *Four* failed. The following *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Babb, James ....Taunton.
Collingwood, John Henry ......Little Gonerby.
Craske, Thomas Augustus ......Tunbridge Wells.
Stacey, Peter.........................London.
Wallas, Thomas Irwin............Carlisle.
Wardle, William Stephens ......London.

July 14th, 1876.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor, and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-seven candidates were examined. *Nine* failed. The following *eighteen* passed, and were declared qualified to be registered as Chemists aud Druggists:—

Alpe, Robert Bird ....East Dereham.
Bevan, Edward......................Swansea.
Clayton, Thomas ....Malton.
Collitt, William ....Gainsborough.
Davies, John.........................Carmarthen.
Evans, Thomas.....................Cwmbach.
Hart, James Connorton ....Horselydown.
Harrington, John Stephen .. ...London.
Jones, Richard Edward ....London.

Kendall, John ....Truro.
Knight, Lindsey ....Cheltenham.
Owen, Griffith Charles Roose ...Carnarvon.
Place, Frederick William.........Knutsford.
Ridgley, Thomas ....Newport, I. of W.
Robinson, Thomas Dexter ......Bedford.
Rumsey, James Window.........Crickhowell.
Treweeks, Richard Harwood ...Pembroke.
Truman, Henry Vernon ....Nottingham.

July 18*th*, 1876.

Present—Mr. Williams, President; Messrs. Allchin, Benger, Carteighe, Corder, Gale, Haselden, Linford, Moss, Schweitzer, Southall, Taylor, and Umney.

MINOR EXAMINATION.

Twenty-seven candidates were examined. *Seventeen* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barron, William ....Leamington.
Ferguson, William Harry ......London.
Foggon, George......................Newcastle-on-Tyne.
Ford, Horace Sidney ... .Southsea.
Hughes, Benjamin Longmore...Chichester.
Jones, Thomas Mantle............Stafford.
Jones, William Henry......... ..Landport.
Lowe, William Foulkes ....Rock Ferry.
Wade, Robert Brady ....Shoreham.
Wastie, Francis.....................London.

July 19*th*, 1876.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor, and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty candidates were examined. *Twelve* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Abraham, Alfred Clay............Liverpool.
Allen, Joseph John William ...Haverstock Hill.
Carr, John Allen ....Lancaster.
Cocker, Robert Benjamin ......London.
Fargher, Henry Spencer ....Warrington.
Gall, Alfred ... .Woodbridge.
Nichols, Frederic Bulstrode ...Chelsea.
Tompsett, Leighton Stovold ...Strood.

MODIFIED EXAMINATION.

Six candidates were examined. *Three* failed. The following *three* passed, and were declared qualified to be registered as Chemists and Druggists:—

Goucher, Levi Tom ... .Manchester.
Morgan, John ....Poonah.
Williams, William David ......Salisbury.

PRELIMINARY EXAMINATION.

July 3*rd*, 1876.

Three hundred and two candidates presented themselves for examination, of whom *one hundred and twenty-eight* failed. The following *one hundred and seventy-four* passed, and have been duly registered as Apprentices or Students (arranged alphabetically):—

Adams, Thomas Edwin, jun. ...Liverpool.
Arthur, John........................Chesterfield.
Ashburner, Isaac ....Broughton-in-Furness.
Atkinson, John Lancelot ....Pickering.
Barton, Francis.....................Guernsey.
Benson, George William ....Bradford.
Bishop, Cecil.......................Brading.
Blyton, Thomas Bage ....Manchester.
Bolton, William Edward.........Rochester.
Bowering, John ....Taunton.
Brown, Richard ....Rochester.
Brown, Thomas ....Hull.
Burchell, Robert Henry ....Kettering.
Butterfield, Joseph William ...Blackburn.
Caton, Edwin Charles ....Shepherd's Bush.
Charles, Frank Henry............Pontypool.
Christie, Peter Crombie ....Aberdeen.
Christien, Frederick Joseph ...Bury St. Edmund's.
Clague, Thomas Maltby ....Douglas.
Cleland, Andrew Hutcheson ...Eastwood.
Cock, Charles Maidwell ....Shipdham.
Cooper, Albert ....Huntingdon.
Cooper, George Dodd ....Brightlingsea.
Corfield, Edward ....Birmingham.
Coverdale, George ... .Leeds.
Cowpe, John........................Southwell.
Cowx, Wilfred Henry Russell...Birmingham.
Crompton, Wm. Wolstenholme...Bury.
Crosby, Robert.....................Sunderland.
Cullwick, Herbert Ernest ......Knighton.
Cuthbert, George Bennard ......Caistor.
Cutts, Joseph Nix ....Chesterfield.
Dawson, Arthur Robert ....Southampton.
Dewes, George ....Wolverhampton.
Dunbar, George ....Dumfries.
East, William Alfred ....Princes Risboro.
Elliott, William Atherton ......Macclesfield.
Emerson, Henry Wall ....West Hartlepool.

The Questions for Examination were as follows:—

(*Time allowed: Three hours for the three subjects.*)

I. LATIN.

1. Translate into English:—Flumen est Arar, quod per fines Haeduorum et Sequanorum in Rhodanum influit, incredibili lenitate, ita ut oculis, in utram partem fluat, judicari non possit. Id Helvetii ratibus ac lintribus junctis transibant. Ubi per exploratores Caesar certior factus est tres jam partes copiarum Helvetios id flumen traduxisse, quartam vero partem citra flumen Ararim reliquam esse, de tertia vigilia cum legionibus tribus e castris profectus ad eam partem pervenit, quae nondum flumen transierat.

2. Parse *quod, utram;* and decline *flumen, ratibus. tribus.*

3. Give the present, perfect, supine, and infinitive of the active forms of the following verbs: *fluat, junctis, transibant, traduxisse, pervenit.*

4. In what case is (*a*) the *manner*, (*b*) the *time*, (*c*) the *place* of an action put? Give *one* example of each.

II. ARITHMETIC.

(The working of these questions, as well as the answers must be written out in full.)

5. Multiply 716804 by 360; divide the product by 180, and express the quotient in *words.*

6. Of 21 people, 13 lose £116. 7*s.* 8*d.* *each*, and 8 lose £23. 0*s.* 9*d.* *each*; what is the average loss per man?

7. A bankrupt whose debts amount to £2653 10*s.* 6*d.* pays 6*s.* $3\frac{1}{2}$*d.* in the pound; what is the value of his effects?

8. Find the value of $\dfrac{4\frac{4}{15} \text{ of } 2\frac{5}{8}}{5\frac{1}{5}-4\frac{1}{2}}$; and of $1\frac{7}{8}$ of 10*s.* 6*d.*—$\frac{3}{4}$ of 2*s.* 6*d.* + £$\frac{1}{12}$ — $\frac{1}{14}$ of 21*s.*

9. Divide 172·9 by ·142 to three places of decimals; and express $\cdot 00\dot{4}\dot{9}$ as a vulgar fraction.

III. ENGLISH.

10. Write the following nouns in the plural number; *loaf, hoof, staff, hero, focus, genus, crisis;* and give the feminine forms of *hart, peacock, votary, fox.*

11. How are adjectives inflected? Give the superlative degree of *good, bad, little, lively;* and convert the following adjectives into adverbs: *first, pretty, good, hopeless.*

12. Parse the following lines:—

"Now Jove suspends his golden scales in air,
Weighs the men's wits against the lady's hair."

13. Give a short account of Cardinal Wolsey, Mary Queen of Scots, or Sir Walter Scott (*one* only); *or*, give a brief description of some scientific discovery or invention of the present century.

The following is a list of the Centres at which the examination was held, showing the number of Candidates examined at each Centre, and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A lecture was delivered at the rooms of the above Association, Halford Street, Leicester, on Tuesday evening, July 10th, 1876, by Mr. Joseph Young. Subject, "Specific Gravity." The President, Mr. W. B. Baron, occupied the chair.

The lecturer proceeded first to impress upon his hearers the necessity of thoroughly comprehending what is meant by the term specific gravity, and the various rules and laws which govern this particular branch of science; secondly to explain methods of taking specific gravities under the many varying conditions which necessarily arise.

The specific gravity of liquids was first taken into consideration, the lecturer illustrating his remarks by specimen bottles brought for the purpose, together with the method of procedure requisite in connection with each, the advantages and disadvantages being clearly demonstrated.

The specific gravity of substances by weight in water was next referred to, and a very interesting explanation of the hydrostatic balance given, also the manner of taking a specific gravity by means of the hydrometer. This plan, however, the lecturer pointed out is subject to many inaccuracies and should not be adopted when anything like a true result is required. The specific gravity of fragments or powders was next treated of at considerable length, and the different process each individual chemical or fragment would require indicated.

The lecturer next showed the way to procure a specific gravity when the substance to be operated upon is soluble in water, and the caution and rules to be observed; also when the article is in a mass and sinks in water, and on the other hand when it will not sink.

With regard to the arithmetical part of the subject, enabling students to express the result arrived at upon paper or in their note books, after referring to the means adopted by various scientific gentlemen, the lecturer, said he always resorted to the one containing the least figures, giving illustrations.

In conclusion the more important facts were impressed upon the members present, the lecturer stating he did not expect them to acquire a substantial knowledge of this important branch of science by simply listening to one lecture, but if only he was enabled to introduce them to the subject, especially as such a knowledge is so indispensible to each student of pharmacy, he should feel that he had done some good, in being present with them that evening.

The lecture, which occupied an hour and a quarter in delivery, was listened to with special interest and pleasure.

The President then proposed a vote of thanks to the lecturer, which was seconded by Mr. Thirlby, and carried unanimously.

Proceedings of Scientific Societies.

PARIS SOCIETE DE PHARMACIE.

At a meeting of this Society held on the 7th of June, under the presidency of M. Coulier, a report was read from a commission appointed to consider a proposition by M. Bussey, to form a Scientific Union of the Pharmacists of France. The report, which approved of the project and included a scheme for the regulation of the proposed society, was ordered to be printed and circulated among the members.

The Testing of Commercial Oils.

An instrument for determining the purity of commercial oils, constructed by M. A. Pinchon, and named by him a thermic areometer, was exhibited and explained. It consists of an areometer containing in a reservoir above the ballast bulb a small mercurial thermometer. Above this again is a fine stem graduated to correspond with the distance to which the instrument is immersed at different temperatures in a sample of pure oil. The test is made in a glass vessel through the sides of which the reading of the thermometer can be observed. The areometer being plunged into the oil, it is allowed to float in it for a little while until the thermometer indicates its true temperature. The degree on the graduated stem which corresponds with the surface of the oil is then noted, and this, if the oil be pure, should correspond with the degree shown by the mercury in the thermometer. Any difference between the two would be evidence of an adulteration. Thus if the temperature indicated be 20° C., the mark on the stem to which the areometer sinks in the oil should be 20 also. It will be seen that a separate areometer would be required for each kind of oil to be tested.

The following table will show the amount of the variation caused by an admixture of 25 parts of different oils with 75 parts of olive oil :—

Admixture.	Stem.	Thermometer.	Difference.
Sesame Oil	17·5	19·5	2
Poppy Oil.........	16·0	19·5	3·5
Nut Oil..............	13·0	16·5	3·5
Purified Colza Oil...	20·0	22·0	2·0

The following table shows the difference in the indications when an instrument constructed for olive oil is used for other liquids :—

Liquid.	Stem.	Thermometer.	Difference.
Leg of Beef Fat ...	22·5	17·0	5·5
Nut Oil..............	10·5	12·0	1·5
Purified Colza Oil...	19·5	15·5	4·0
Oleic Acid (commercial)	35·5	16·0	19·5
Oleic Acid (from distillation)	42·0	15·0	27·0

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee.

17, Bloomsbury Square, London, on July 5th, 1876, at 10 A.M.

Present :—Professor Redwood, *President*; Messrs. Frazer, Williams, Carteighe and Schacht, *Treasurer*; Professor Attfield, *Honorary Secretary*; and Mr. Davies, *Assistant-Secretary*.

Thirteen candidates were elected to membership.

The names of several members whose subscriptions were more than two years in arrear, and to whom repeated applications had been made by the Secretaries, were removed from the lists of members.

Twenty-six subjects proposed for research were received and considered.

Professor Attfield suggested that some competent member should be employed to revise and somewhat elaborate the "subjects for papers," named in the current list issued by the Conference. In the course of thirteen years the Conference had proposed some two hundred subjects, for research, of which nearly one hundred had been investigated, resulting papers forming about one third of the three hundred papers which had been read at the Twelve Annual Meetings of the Conference. The one hundred or so of subjects now on the list, especially the fifty or sixty which had been down for several years, required careful revision, information concerning any work already accomplished being added to each subject, and some hints given as to the direction which further investigation should take. Probably a few of the subjects might now be excluded from the list altogether. The Secretaries were ordered to give effect to the suggestion.

The Editor reported good progress in the preparation of the MS. of the 'Year-Book of Pharmacy for 1876.'

Professor Attfield reported that since the previous meeting, he had issued about 2500 copies of the current Year-Book. He also presented an analysis of his cash-book for the year ending, June 30, 1876, as follows :—

Parliamentary and Law Proceedings.

PAPER PRESENTED TO PARLIAMENT.

The Analysis of Butter.

The following "Report made to the Board of Inland Revenue by the Principal of the Chemical Laboratory, Somerset House, on experiments conducted by him for the Analysis of Butter," bearing the signature of J. Bell, has been included in a return made to the House of Commons.

We have deemed it desirable to institute special investigations into the chemical composition of a variety of commodities of ordinary consumption including the article butter.

At the time that these investigations were commenced there was a great difference of opinion among chemists as to the possibility of detecting the adulteration of butter, so far as related to the admixture of foreign fats. These divergent views were notably expressed in the scientific evidence on the adulteration of food given before a Committee of the House of Commons. Some chemists of considerable repute held that there were no means of detecting foreign fats in butter, and that it would be easy to make up a factitious butter which would baffle all attempts at analysis, so far as the then known tests would apply. Others, on the other hand, maintained that by certain empirical methods, such as taking the melting point of the fat, or determining its degree of solubility in mixtures of alcohol and ether, foreign fats could with certainty be detected.

It was in these circumstance that we undertook the investigation of butter, and we commenced by fairly trying all the methods of butter analysis that had been suggested, and which appeared to afford any hope of assisting in the solution of the question.

One of the methods most recently suggested was to estimate the amount of fixed fatty acids which a butter would yield. This test, which was devised by Messrs. Angell and Hehner, and which is based upon the fact that genuine butter contains a less amount of these fixed acids than other animal or vegetable fats, was the nearest approach to the solution of the question which had been made. But their standard of purity, which was founded upon the analyses of a few samples obtained from one part of the country and about one time of the year, was looked upon with suspicion, and met with but little acceptance from analysts, so that the test for some time practically fell into abeyance.

It was found, however, that although the test was sound in principle, it involved a somewhat difficult chemical process in its application, and required a considerable amount of manipulative skill to carry it out. We, therefore, directed our attention to the devising of a more simple and more easily applied test, and in this, I think, we have succeeded.

This method consists in the determination of the specific gravity of the butter fat in the liquid condition at 100° Fahrenheit. We are not aware that this method had ever before been applied in the analysis of butter. It is true that there had been an endeavour to determine the specific gravity of some of the constituents of butter fat when in the solid condition, but no useful result had been arrived at; in fact, the results were rather misleading than otherwise.

In applying the specific gravity test to butter, the curd, salt, and water are first removed, and the density of the melted fat at 100° Fahrenheit is taken in an ordinary specific gravity bottle. The bottle used for the purpose was of a pear shape, into which could be inserted the bulb of a sensitive thermometer, the mercurial portion of which extended nearly the whole depth of the bottle. The temperature of 100° Fahrenheit was adopted, as at that temperature nearly all the animal and vegetable fats likely to be used as butter adulterants assume the liquid state.

It will be seen from Table I. that the specific gravity of ordinary animal fats varies from 902·83 to 904·56, while the specific gravity of butter fat, as exhibited in Table II., rarely falls below 910, the usual range being from about 911 to 913. There is thus a material difference between the specific gravity of butter fat and that of ordinary commercial animal fats, and it is obvious that this difference affords a satisfactory basis upon which to found an additional test for determining the purity of butter.

It may be useful to describe here briefly the difference between the composition of ordinary animal fats and that of butter fat. The former consist of a mixture of stearic, palmitic, and oleic acids, in combination with glycerin, and as these acids are insoluble in water, and not readily volatilized, they are commonly called "fixed" fatty acids, in contradistinction to other fatty acids which are either volatile or soluble in water, such as butyric, caproic, caprylic, etc., acids. Butter fat also consists of fatty acids in combination with glycerin, but while by far the larger proportion of the acids are of a "fixed" nature, there are invariably present several of those which are volatile or soluble in water, and it is to the latter, the most important of which is butyric acid, that the characteristic taste and smell of butter are chiefly due. In rich butters the proportion of the volatile acids is comparatively large, the specific gravity of the fat is high, and the percentage of "fixed" fatty acids is correspondingly low.

In getting samples of butter we purposely selected a wide range, so as to obtain as far as possible fair representative specimens of the different variations that occur in the composition of genuine butters produced under different conditions. In short, the samples may be taken to fairly represent the various qualities of butter as made and brought to market by farmers both in England and Ireland. Every care was exercised by the Board's local officers in procuring them, and there can be no question whatever as to their being genuine.

Table I.—Results of Analyses of Animal Fats.

Description of Sample.	Specific Gravity at 100° Fahrenheit.	Percentage of fixed Fatty Acids.
Mutton Suet	902·83	95·86
Beef Suet	903·72	95·91
Fine Lard	903·84	96·20
Dripping (Commercial)	904·56	94·67
Mutton Dripping (Genuine) ..	903·97	95·48

Table II.—Results of the Analysis of 117 Samples of Butter.

The whole of the samples in Table II. have been tested by the specific gravity method, and it will be seen from the results that while a few samples were very poor in quality, and a few others exceptionally rich, the great bulk examined were found to possess considerable uniformity of composition, the principal variations being apparently due to a difference in the method of manufacture, the different seasons of the year when made, and the various modes of feeding. As might be expected, some of the poorest butters were produced by, and obtained from, small farmers in Ireland, at a time when there was very little grass and food was scarce.

It was also noticed, so far as the investigation could be carried out, that the butter was relatively poorer in its essential constituents when the food was chiefly cotton and oil-cake, than was the case when roots and grass formed the staple food.

When the fixed fatty acids test referred to is accurately performed, the correspondence between the amount of these acids and the specific gravity of the fat is so close that it is possible to predicate within a few tenths one result from the determination of the other. Owing to the pressure of other duties the proportion of fixed fatty acids in each sample was not ascertained, but a sufficient number of determinations have been made to establish the fact of this correspondence, as will be seen in Table II. in the column headed "Percentage of fixed Fatty Acids." A little variation may sometimes arise from the fact that the several fixed fatty acids are not always present in different butters in exactly the same proportion.

As the estimation of the fixed fatty acids is a lengthy process attended with difficulty, and, without great care, nearly always with a measure of uncertainty, and as on the other hand the specific gravity of the butter fat can be ascertained with ease and rapidity by any person of ordinary skill, it will be seen that an important additional factor in the analysis of butter has been furnished to chemists. The specific gravity of a fat may be repeated with but slight variation, which in several successive weighings will not exceed from ·02 to ·05 of a grain.

A noticeable feature in the results recorded in Table II. is the great variation in the quantity of water in the different butters, the lowest being 4·15 per cent. and the highest 20·75 per cent. The Devon and Dorset butters, which usually stand so high in the market, were found to contain in nearly all cases a high percentage of water, and No. 15, which was procured from the dairy of a private gentleman, contained as much as 16·99 per cent., and a second sample, recently obtained from the same source, contained 15·70 per cent.

Various attempts have been made by chemists to separate the glycerides of the fatty acids in butter, but without success. We have experimented in the same direction by treating butter fat with different solvents such as alcohol, mixtures of alcohol and ether, and ether alone, but the fractional parts still remained esentially a butter.

The following is an outline of the process which we adopted to separate the component fats of butter. A quantity amounting to four hundred and sixty grams was treated successively with twice its volume of alcohol of 92 per cent; the alcoholic solution on evaporation gave nine grams of an oily fat which yielded 79·7 per cent. of fixed fatty acids, the remainder consisting of glycerin and the volatile acids.

The butter fat insoluble in alcohol was next treated with twice its volume of warm ether, and allowed to stand for several hours. A white crystalline fat separated, which was thrown on a filter and washed with a small quantity of ether. The ether was evaporated from both portions, and the specific gravity and fixed fatty acids determined. The crystalline fat, weighing 90 grams, had a specific gravity of 909·55, and gave 89·50 per cent. of fixed fatty acids. The soluble fat, weighing 350 grams, had a specific gravity of 912·35, and yielded 87·95 per cent. of fixed fatty acids.

The portion soluble in ether was then treated with a mixture of alcohol and ether. Nearly one-half of the fat passed into solution. Both portions were freed from alcohol and ether. The soluble gave 86·50 per cent. of fixed fatty acids, and the insoluble 88·62 per cent.

We then proceeded synthetically, by adding to a mixture of beef-suet fat and dripping a given percentage of prepared butyrate of glycerin; 8 per cent. of the butyrin was dissolved in a fat of a specific gravity of 902·99 by the aid of heat. The specific gravity of the mixture at 100° Fahrenheit was 910·39. The mixture, when treated with alcohol, as in the preceding experiment, was almost completely freed from butyrin, as was shown by the residual fat giving a specific gravity of 903·44. The extractive by alcohol contained a little olein derived from the fat.

The conclusion which may be drawn from these results is that, contrary to the statement made by Berthelot and others, compounds of butyric and the other volatile acids present in butter with glycerin do not exist as simple glycerides, but are in all probability present in a complex form, the radicals of the volatile fatty acids being combined with glycerin and the fixed fatty acids in the same molecule to form compound ethereal salts.

It may be noted here as remarkable that the portion dissolved out with alcohol in the first experiment yields an amount of fixed fatty acids bearing out this theory. We purpose following up this part of the investigation, which appears to possess considerable scientific interest.

There is another point of interest which we have in some measure elucidated, and which has reference to the deterioration which certain butters undergo when kept in small quantities in glass or earthenware vessels. We have found that whilst some of the finest and best prepared butters undergo little or no change, there is in others a gradual disappearance of the characteristic principles of butter, and a consequent assimilation to the constitution of an ordinary animal fat. This change, which appears to be due to an incipient fermentation, and is generally accompanied by the development of fungi is probably caused either by the use of sour cream or by insufficient care in making the butter.

The following Table III. exhibits the amount of depreciation which different samples of butter have undergone in the respective time stated :—

Table III.—Analysis of Butter after Keeping.

As cases may occur where the melting point becomes of primary importance this test is never overlooked in the analysis of a reputed butter.

In determining the melting point we found that more uniform results were obtained if the butter fat were suddenly cooled by plunging the small platinum capsule containing it into ice water.

A small portion of the fat which had a somewhat vitreous appearance was taken up on the loop of a platinum wire and introduced into a beaker of water placed in a porcelain dish, and the loop brought close to the bulb of a thermometer. The temperature of the water was slowly raised and the temperature read off immediately the fat assumed the liquid condition.

Obituary.

Notice has been received of the death of the following:—

On the 28th of June, 1876, Mr. William Wilson, Pharmaceutical Chemist, Lowther Street, Groves, York. Aged 57 years. Mr. Wilson had been a Member of the Pharmaceutical Society since 1854.

On the 8th of July, 1876, Mr. Daniel Walker Scott, Chemist and Druggist, Sowerby Bridge. Aged 29 years.

On the 10th of July, 1876, Mr. William Baxter, Chemist and Druggist, of Leeds Road, Bradford. Aged 37 years.

On the 11th of July, 1876, Mr. Alfred Boyle, Chemist and Druggist, Poplar Dispensary. Aged 35 years.

On the 15th of July, 1876, Mr. Thomas Stocker, Chemist and Druggist, St. Ives. Aged 63 years.

BOOKS, PAMPHLETS, ETC., RECEIVED.

METHYLATED SPIRIT.

Sir,—I differ from Mr. Sturton as to druggists generally not being aware of the methylated spirit licence being only ten shillings.

An important clause in the Methylated Spirit Act prohibits licences being granted to retailers of spirits, wines, and sweets. So many druggists have embarked in the wine trade, Foreign and British, that in country districts the combination of these two trades is general.

As regards the sale of "finish" it would be better if druggists discontinued the sale of it, unless it is implicitly prepared according to the excise directions. But owing to the imperfect manner in which "finish" burns I am afraid that in many instances a deficiency of gum is a wilful omission in order to prevent complaints. I have seen several samples of "finish"—sold as such—which have contained the barest traces of gums or resins, and regret that I am unable to attribute such sales altogether to ignorance.

In all matters relating to the excise absolute integrity and the greatest care are essential. Where such are observed no litigation need be feared.

A COUNTRY PHARMACEUTICAL CHEMIST.

T. Colton (Selby).—We shall be happy to publish the information if you will furnish us with it.

E. B. J.—The best solvent of cantharidin is chloroform. It dissolves in 34 parts of cold ether, and in fixed and volatile oils. Are you satisfied as to the purity of the cantharadin?

The Trade Conference at Birmingham.—We are requested to say that the representative of Rochester, Chatham and district, was Mr. H. Barnaby, *not* Mr. Barnet as reported in last week's Journal.

"*Minor*" (who should have sent his name and address). We think the subject has been sufficiently discussed for the present.

W. Bray.—*Sherardia arvensis.*

"*Tau*" (Clifton).—(1) *Senecio Jacobæa;* (2) *Sedum,*—the species cannot be determined without the leaves; (3) *Malva moschata;* (4) *Galium Mollugo;* (5) *Scrophularia nodulosa;* (6) *Stachys Betonica;* (7) *Origanum vulgare;* (8) *Centaurea nigra,*—white variety; (9) *Teucrium Scorodonia;* (10) *Cotyledon umbilicus;* (11) *Scabiosa Columbaria;* (12) *Eupatorium cannabinum.* In future please limit your specimens to six.

H. H.—*Asclepias syriaca:* not a native plant.

"*Enitar.*"—The Flora may be obtained through Mr. J. W. N. Keyes, Bedford Street, Plymouth. The Curator would be happy to give you any information respecting Devonshire plants.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Balkwill, Mr. A. N. Palmer, Mr. Barnaby, Mr. Colton, E. A. T., "Minor," "Student."

THE UNION OF CHOLRAL HYDRATE AND CAMPHOR.

BY ERNEST C. SAUNDERS, MONTREAL.

It has long been known that a mixture of hydrate of chloral and camphor, in equal parts, formed a liquid, but it has, I believe, never been settled as to whether the result is due to chemical combination or to the solvent power of one article over the other. The following notes of an investigation into the subject may be interesting, and throw some light upon it.

Four ounces of chloral hydrate and the same weight of camphor, in lumps, were put into a bottle and allowed to stand, being occasionally shaken. In forty eight hours both were completely liquefied, forming a syrupy fluid, smelling of both ingredients, and of specific gravity 1·243. Five ounces of this were placed in a flask, fitted with a wide tube leading into a receiver immersed in ice-cold water, and having a thermometer passed through the cork, the bulb reaching into the liquid. Heat being applied, the temperature rose to 224° F. at which point the liquid boiled freely. The temperature rose gradually up to 300°, from which point it rose more rapidly to 402°, when the liquid distilled unchanged. The distillate was separated into two parts, the first being collected up to 300°, the other being that which passed over between that point and 402°. The vapour which passed over at this temperature solidified in the tube before reaching the receiver.

The first distillate was a soft greenish mass, consisting of small crystals mixed with liquid. It was found to consist of chloral hydrate, with a very small quantity of camphor, and owed the colour to a minute quantity of a greenish oil, apparently the result of some chemical action having taken place between the chloral and camphor. This oil could not be obtained in sufficient quantity to be examined.

The second distillate was a thick oily liquid, having a pungent odour of chloral hydrate. It combined with a small proportion of water, but was insoluble in a larger quantity. It was miscible with alcohol, of specific gravity ·937 and ·838 in all proportions, and proved to be hydrate of chloral with about enough camphor to liquefy it.

The residue in the flask, which boiled at 402°, was found to solidify at 248°, and was almost insoluble in water, but freely soluble in alcohol, sp. gr. ·838, was plainly camphor.

The original solution was decomposed by water, the camphor floating on the surface, while the filtered liquid gave abundant evidence of chloral hydrate on being tested.

Judging from these facts, it would seem certain that no chemical action takes place when the two articles are mixed in the cold. Both are volatile at ordinary temperatures, and the following experiment, which was performed to ascertain which was the solvent, conclusively proves that it is the vapours which act upon each other. Two lumps, one of chloral hydrate and one of camphor, were placed about an inch apart on a porcelain plate, and covered with a bell glass. In fifteen minutes the surface of the camphor was quite damp, but the chloral was quite dry. In three hours the chloral was still dry, while the camphor was quite wet and standing in the midst of liquid. In twelve hours the liquid had reached the chloral, the upper surface of which was still dry, while in twenty hours both lumps were half liquefied, and the inner surface of the bell glass was covered with moisture. This would almost seem to point out that the vapour of the chloral was the solvent, but it was found while one part of camphor would form a permanent liquid with three and a half parts of chloral hydrate, one part of chloral dissolved by the aid of heat with two parts of camphor solidified to a soft crystalline mass when cold, from the camphor crystallizing. It is most probable that the camphor is the solvent, which would also seem likely, as camphor is an essential oil, and is known to render other bodies fluid. The change of colour, with the formation of an oily liquid would seem to point to chemical action occurring when the mixture is subjected to strong heat.

The following notes of the solubility of the mixture in various articles may be serviceable to any who are called upon to dispense it, or to physicians who feel inclined to try the effects of it.

It is miscible in all proportions with alcohol, sp. gr. ·838, bisulphide of carbon, ether, and olive oil. It is soluble in eleven parts of alcohol, sp. g. ·937. It is insoluble in water. It forms a clear mixture with one and a half parts of chloroform, but a further addition of three parts of chloroform renders it turbid. Camphor forms a permanent liquid with three times its weight of chloral hydrate. The experiments were conducted with the atmosphere at a temperature of about 80°; the fact is mentioned as it may have influenced the solubility slightly.

LABORATORY NOTES ON THE DETERMINATION OF QUININE IN THE PRESENCE OF CERTAIN OTHER SUBSTANCES, AND ESPECIALLY IN "FERRI ET QUINIÆ CITRAS."

BY ALFRED NEOBARD PALMER.

The chemist is often required to determine the quinine in pharmaceutical preparations wherein the alkaloid is associated with other substances—such as glycerin, sugar, citrate of ammonium, etc.—and it then becomes important for him to know whether the presence of the substances just named at all interferes with the accuracy of his determination of the quinine when that determination is effected by shaking up the fluid with ether or chloroform after the quinine has been precipitated with an alkali. Moreover, still following this method of analysis, it sometimes becomes necessary, in the case of certain cinchona preparations, to add considerable excess of the alkali, so as either to re-dissolve some of the substances other than quinine precipitated together with the latter, or to render the line of separation between the aqueous layer and the chloroformic or ethereal layer quite clear and well-defined. And here, again, the analyst desires to know whether, in the presence of this possibly large excess of alkali, he still gets in his chloroformic or ethereal layer all the quinine that exists in the fluid operated upon. I have at various times made experiments with a view of satisfying myself upon some of these points, and since the appearance of Mr. Allen's interesting paper* have continued these as well as made two or

* *Pharm. Journ.*, June 3rd, 1876, p. 964.

three additional ones on the determination of quinine with *chloroform* in presence of sugar, Mr. Allen having confined himself to its determination under these conditions with *ether*. The result of these experiments I now present.

In all cases where the simple and rapid method of estimation above referred to can be employed I am now accustomed to use a pear shaped glass separating vessel, which may be obtained of apparatus dealers, of about four ounces capacity, the pear stalk being represented by a short tube provided with a tight-fitting stopper, while at the opposite end of the vessel, representing the top of the pear core, is another stoppered opening. Through this last opening fluids are poured into the separating vessel: by the tube they are run out of it. I will now describe distinctly my course of procedure in these experiments. Let us suppose we have a solution of sulphate of quinine, and we make two estimations of it—one by ether and one by chloroform The tube-cock of the separating vessel being closed, a measured volume of the solution to be examined was run in; then (out of a burette) the alkali; lastly, ether or chloroform was poured in, the whole well shaken, and set aside for at least two or three hours. When ether was used the underlying watery layer was drawn off down to the stop-cock; then a little water poured into the glass vessel, the stopper (which was of course removed while the watery layer was being drawn off) inserted; the whole well shaken and set aside for another two or three hours. The watery layer was now drawn off to the last drop down to the very bottom of the tube, and the ethereal layer run off through a small filter into a weighed dish; a little more ether was shaken up in the vessel and run into the dish in the same way: the ether in the latter evaporated, and the residue dried at about 270° F.,* and weighed. When chloroform was used, after the underlying layer was drawn off down to the tube-cock through a small filter into the dish below more chloroform was poured into the vessel, well shaken up, and after two hours drawn off down to the last drop through the filter, and evaporated with the first layer.

When the substances, whose effect on the accuracy of the quinine-determination was to be studied were present, these were added in solution to the sulphate of quinine solution and thoroughly mixed therewith previous to the addition of the alkali.

I have entered into these details so that my method of procedure and allusions hereafter may be clearly apprehended.

I may say further that in all my experiments specially prepared and quite pure sulphate of quinine and well washed ether and chloroform were alone employed.

I find then that, working under these conditions—

1. Whether the precipitant be ammonia, potash, or soda, whether added in slight or in large excess, whether the quinine solvent be ether or chloroform is quite indifferent. In any case, and in all cases the actual quantity of quinine present in the fluid operated upon is obtained.

2. The association of sugar or of glycerine with the quinine in the fluid under examination does not in any way affect the accuracy of the process when the precipitated quinine is dissolved by shaking up the mixture with *chloroform*, and drying the residue of evaporation of the latter at 260°-270° *until its weight is constant*. Mr. Allen has shown that *ether* also in the presence of sugar takes up all the quinine thrown down by an alkali. I believe this is also the case in the presence of glycerine. In one experiment undertaken with a view to satisfy myself hereon I recovered all the quinine present but in a second only ·1 grm. out of ·106 grm. It is possible, however, that in the latter case a little of the ether was spilled. I have had neither time nor inducement to proceed any further with the investigation of this particular point.

3. Nor does any loss of quinine occur when it is determined in presence of citrate of ammonium, so long as chloroform is the solvent employed.

4. But when in this last case ether is substituted for chloroform, the ethereal layer contains only a portion of the quinine present, the remainder being held entangled in the aqueous layer, from which it can be extracted by shaking the latter with chloroform, and this is still so even when the aqueous and watery layers are allowed to remain in contact for so long a time as eighteen hours. I may say that in such cases the aqueous layer, which tastes very bitter, has always a strongly ethereal smell; and from this fact as well as from other circumstances, I am inclined to think that the ethereal solution is rather mechanically entangled in the aqueous layer than that the quinine is chemically retained by it. But, however to be explained, about the fact of the retention of part of the quinine under these circumstances by the solution of citrate of ammonium, there can be no doubt at all. In one experiment 6·5 per cent. of the quinine was thus retained; in a second experiment 12·1 per cent.; in a third, 13·8; in a fourth, 37·5 per cent.; in a fifth, 50 per cent. It seemed to me that the percentage retained varied with the *strength* of the citrate of ammonium solution as distinguished from the *volume* of the latter. But I am not sure of this.

"Ferri et Quiniæ Citras" is sometimes estimated by shaking a solution of the substance with ether after addition of excess of ammonia, and weighing the residue obtained on evaporating the ethereal layer. But "Ferri et Quiniæ Citras," contains citrate of ammonium, and ether (as the results described above show) is incompetent (or at least cannot be relied on) to remove all the quinine which is precipitated in a solution of that salt. We are not therefore surprised to find "Ferri et Quiniæ Citras," when estimated by this process, showing very low percentages of quinine. If the alkalized aqueous layer which has been shaken with ether be tasted it will nearly always be found very bitter, and, if shaken up with chloroform, will yield to the latter an additional quantity of quinine. In three cases recorded in my note-book chloroform extracted an additional 2 per cent. or thereabouts of quinine, in each case the ethereal and aqueous layers having been allowed to remain in contact for several hours before the underlying layer was drawn off.

The same experimental results, however, that condemn beforehand the use of *ether* for the determination of quinine in "Ferri et Quiniæ Citras" indicate at the same time the employment of *chloroform* for

* The residue of quinine left on evaporating an ethereal or chloroformic solution of quinine on the water-bath does not contain a constant percentage of water. I cannot agree with Mr. Allen when he implies that the "ether residue" is always hydrated to the extent of 4·28 per cent. Constant results can only be obtained by weighing the residue after drying at 260°—270° F.

that purpose. When a watery solution of from 8 to 12 grains of the sample, contained in the "pear-shaped evaporating vessel," is *strongly* alkalized with ammonia, twice shaken with chloroform, and treated in the way described above, the whole of the quinine contained in the citrate will be found in the two chloroformic layers. The process, thus carried out, for accuracy, simplicity, and rapidity, leaves nothing to be desired. After the precipitated quinine has been shaken up in the separating vessel with chloroform, the latter need not remain longer than half an hour before being drawn off. The addition of the ammonia to *strong* rather than *faint* alkalinity is rendered necessary by a fact to be referred to presently, while this excess, as we already know, in no way affects the accuracy of the determination. Of course, if a preliminary experiment should show that only a portion of the alkaloid precipitated from the citrate, on addition of ammonia, is dissolved when shaken with a suitable quantity of ether, the total alkaloid obtained by this method will have to be dissolved in dilute acid, and the amount of quinine therein determined by any of the approved processes. Citrate of ammonium being absent from this solution, ether may now be relied on for taking up all the quinine precipitated in it, and unless employed in too great excess, for separating this from the other cinchona alkaloids present.

Samples of "Ferri et Quiniæ Citras," yielding by the chloroform method of analysis just described 13 per cent. of pure waterless quinine, will answer to the pharmacopœia tests; but the citrate sold as "P.B." of the best makers seldom contains less than 14 per cent. And when the substance referred to is made according to the process of manufacture recommended in the pharmacopœia, I do not think a much higher percentage of quinine than this will in general be obtained. Four samples of different makers (all of them of high repute and standing) gave, by the chloroform method, 14, 14·2, 14·4, and 15·37 per cent. respectively of the pure dry alkaloid.

When by addition (from a burette) of a dilute solution of ammonia to an aqueous solution of "Ferri et Quiniæ Citras," the latter has become distinctly alkaline to red litmus paper, further addition of ammonia gives a further precipitate of quinine, and this will continue until at last often more than twice the volume of ammoniacal solution has been added that was added at first. In one case further addition of ammonia to ferro-quinic citrate solution, after the latter already turned red litmus paper dipped into it distinctly blue, precipitated an additional 4·6 per cent., and in another case an additional 3 per cent. of quinine.

The method of estimating "Ferri et Quiniæ Citras" recommended in the pharmacopœia cannot be said to be at all satisfactory. If the indications of litmus paper be alone attended to, the "slight excess of ammonia" there prescribed may be, as we have seen, *too slight* to precipitate all the quinine present. We are not told, moreover, whether the precipitate so obtained when collected on the filter is to be washed or not: if washed, some of the quinine will be dissolved out by the wash-water; but, if unwashed, it will retain a very great deal of the solution in which it is precipitated, the ammonium and iron citrates of which will then be reckoned as quinine. In one experiment, the unwashed precipitate obtained from 50 grains of a sample of "Ferri et Quiniæ Citras" containing 13 per cent. quinine having been collected on a small filter, and allowed to drain in the funnel for forty-eight hours, was found, after drying, to weigh 8·2 grains; the filtrate (somewhat short of a fluid ounce in volume) yielding to chloroform an additional ·4 grain of quinine. Now as only 6·5 grains of quinine were present altogether, and of this ·4 grain was contained in the filtrate, there could have been upon the filter no more than 6·1 grains: 8·2 grains were however indicated, which quantity therefore consisted of 2·1 grains of citrates of iron and ammonium and 6·1 grains of quinine. At another time in the case of a sample containing 14·4 per cent. quinine, when the filter, with the precipitate from 50 grains upon it, instead of being drained in the funnel, was placed upon several folds of blotting paper to remove superfluous moisture, the precipitate was found to weigh 9·5 grains. But since the filtrate contained dissolved ·3 grain of quinine, there could not have been upon the filter more than 6·9 grains of the alkaloid, which were therefore here associated with 2·6 grains of foreign substances. Results more nearly approaching accuracy may be obtained by pressing the precipitate repeatedly between folds of blotting paper, and still more nearly by transferring it to a weighed capsule which is then slightly warmed: the quinine will immediately shrink upon itself and set free the greater part (about three-fourths) of the retained solution of the citrates, which may be easily poured off, the residual quinine being then dried and weighed. But our precipitate will not now amount to the 8 grains which the pharmacopœia requires. And it will still fail to represent the quantity of quinine actually present in 50 grains of the sample, since, on the one hand, it will retain even now about ½ grain or ¾ grain of iron and ammonium citrates, and will be deficient, on the other, in respect of the quinine dissolved in the filtrate and lost in other ways. It is true that these two opposite sources of error will sometimes balance each other. But we may well be impatient of a process giving results that are only approximately accurate, when in that by chloroform we have one which is as absolutely trustworthy as it is simple in application and rapid in execution.

CHEMICAL CONSTITUENTS OF ANGELICA ROOT.*

BY CARL BRUNNER.

The following analysis of angelica root was given many years ago by John:—300 parts contain—colourless volatile oil of a penetrating odour, 2 parts; resin, with sour taste, 20; other extractives, 87·5; gum, 100·5; inulin, 12; product soluble in caustic alkali, probably combined with albumin, 22; woody tissue, with a trace of matter soluble in potash, 90; water, 16 parts. Similar figures were also obtained by Buchholz and Brandes, who found six per cent. of "angelica balsam." This product was afterwards found by A. Buchner to contain an agreeably smelling, camphoraceous, essential oil, a volatile acid, a waxy substance, an amorphous resin, and a crystallizable principle, analogous to imperatorin and peucedanin, to which he applied the term *angelicin*. The author prepared this substance from fifty pounds of root, grown near Schweinfurt; after complete extraction with boiling alcohol, and evaporation of the extract, 1090 grams of "balsam" separated, insoluble in water, whilst an aqueous

* *Journal of the Chemical Society* for June, from the *Neues Repert.* xxiv. 641.

liquid was also obtained, on which the balsam floated; this liquid was found to contain *cane sugar*, the values 73·2 and 73·04 being obtained by the polariscope, whilst the specific rotatory power given in text-books is 73·84.

The "balsam" thus obtained was heated with aqueous caustic potash (500 grams balsam, 180 of solid caustic potash), until a homogeneous, brownish-red, thick fluid was obtained; on distillation this furnished a small quantity of an ethereal oil; when this ceased coming over the residue was evaporated to a thick syrup, and dissolved in water. After standing all night and filtering, a minute quantity of insoluble matter was obtained, possibly *angelica wax*. The liquid did not deposit crystals of angelicin on standing, wherefore it was again evaporated, and the residue treated with alcohol, whereby much resin was left undissolved; the filtrate was saturated with carbonic acid, to remove potash, and the filtrate from the crystals of potassium carbonate evaporated to a small bulk, and then treated with ether as long as the latter became coloured; by spontaneous evaporation the ethereal extract gave a smeary residue, containing a few crystals; this residue became much more crystalline on stirring it up with alcohol, and again leaving it to evaporate spontaneously; finally the mother-liquors were removed by the filter pump, and washing with 80 per cent. spirit. The crystals of angelicin thus obtained weighed, after purification by recrystallization, only about 0·8 gram.

This small yield appeared to be due to the fact that the roots employed had been dried in an oven; from 30 pounds of air-dried roots a much larger yield was obtained by the same process; finally about 4 grams of pure angelicin were isolated, constituting fine white silky plates, destitute of taste and odour; slightly soluble in cold, more so in hot alcohol, and readily soluble in ether, chloroform, carbon disulphide, benzene, oil of turpentine, and warm olive oil. On analysis this substance gave numbers agreeing with the formula, $C_{18}H_{30}O$; from these figures, and the general properties of the substance, it appeared to be identical with the *hydrocarotin* of Husemann; it melts at 126·5 to yellowish oily drops, which solidify at 118° to an amorphous mass, soluble in alcohol and ether, but not crystallizing from those solutions (the original substance crystallizes readily in forms belonging to the monoclinic system). Concentrated hydrochloric acid does not change angelicin, but fuming nitric acid dissolves it with evolution of gas; concentrated sulphuric acid dissolves it to a red fluid, depositing brownish-white flakes on dilution with water; fusion with caustic potash, and treatment with bromine give rise to the formation of amorphous coloured products.

The resin insoluble in alcohol, obtained as above described, was fused with caustic potash in a silver dish; the product dissolved in water and acidulated with sulphuric acid evolved acetic, butyric, and other fatty acids, and the aqueous liquid yielded to ether a mixture of two substances, separable by addition of lead acetate. The precipitate thus thrown down gave, after decomposition by sulphuretted hydrogen, a small quantity of a crystalline acid, colouring ferric chloride green, the colouration becoming deep red on further addition of sodium carbonate. With silver nitrate this gave no precipitate, but on further addition of ammonia immediate reduction ensued; hence this product was doubtless *protocatechuic acid*. The filtrate from the lead precipitate was treated with sulphuretted hydrogen and evaporated, whereby crystals were obtained consisting apparently of *resorcin;* they sublimed between watch-glasses, coloured ferric chloride violet, reduced silver nitrate on warming, gave a highly fluorescent product on treating with phthalic acid and sulphuric acid (Baeyer's test), and formed a body which, like *diazoresorcin*, was red, and became blue on adding ammonia, on treating the ethereal solution with nitric acid containing nitrous acid (Weselsky's test).

The liquid from which angelicin was disssolved out by ether as above described, contained the potash salt of a volatile acid, which appeared to be *angelic acid*. This was obtained by adding sulphuric acid and distilling; oily drops insoluble in water thus came over, and on collecting these and placing them in a freezing mixture, crystals separated, which were drained and pressed in filter paper, and these possessed all the properties of angelic acid. Valerianic and acetic acids come over, together with the angelic acid, on the first distillation.

THE ANALYSIS OF MINERAL COAL (ANTHRACITE, BITUMINOUS COAL, LIGNITE, ETC.) FOR PRACTICAL PURPOSES.*

BY PROFESSOR G. C. WITTSTEIN.

Having been for many years extensively engaged in the examination of mineral fuels of all kinds, I may perhaps be justified in believing that the continued practice and experience in this branch of analysis has secured for me some considerable skill, leading me at the same time to methods possessing some advantages over many now in use. With these hopes the following article was published.

The question whether a given specimen belongs to the class of pit coals or to the class of lignites, has only on rare instances been put to me; as practical men are either well informed on this subject previously or consider the question of but little importance. It may be well, however, in the present article to give this point some attention, mentioning at least several methods by which the question can be satisfactorily answered. About as much of the pulverized specimen as can be held on the end of a spatula is to be heated with about 5 gms. caustic potash (sp. gr. 1·12), for several minutes, and then allowed to cool. If, after cooling, the potash has remained colourless or become but slightly yellowish the specimen under examination belongs to the class of pit coals. Should the alkali however have become dark brown or opaque, the coal examined is a lignite. This process, though quite old, has never been surpassed by any of the more recent, and is especially superior to the method of subjecting coal to dry distillation, and examining the watery portion of the distillate for acetic acid. The latter process depends upon the fact that the distillate of brown coals contains considerable acetic acid, while that of pit coals is entirely destitute of it. A still more unsatisfactory method is that according to which a distinction can be made between lignites and pit coals by the quantity of sulphur they contain. It is indeed true that in general lignites contain more sulphur than pit coals; yet it is practically impossible to fix any limit sufficiently accurate to serve as a distinction between the two.

The total analysis of coal may be divided into four principal operations, for each of which a separate quantity of the sample is to be weighed out. These operations are:—

I. Determination of Sulphur.
II. Determination of water and the constituents of the ash.
III. Determination of Carbon and Hydrogen.
IV. Determination of Nitrogen.

It is of course necessary to make a quantitative analysis of the coal in the condition in which it was delivered. It is therefore advisable, since powdered coal on exposure to air always loses appreciably in weight, to pulverize the sample as soon as received, and then immediately to weigh out for each of the operations just mentioned the following quantities:—

For I.—1 gm.	For III.—5 gms.
For II.—10 gm.	For IV.—1 gm.

I. *Determination of Sulphur.*

This may be conveniently carried on in a crucible of silver or platinum, which must, however, be sufficiently large to hold at least 30 gms. of water. The 1 gm. of the

* From the *American Chemist* for April, 1876.

sample, previously well pulverized, is to be mixed with 4 gms. of nitrate of potash, and 2 gms. anhyd. sodic carbonate, in a glazed porcelain mortar. (The latter flux is added simply to diminish the violence of the reaction.) This mixture is then to be transferred in small quantities at a time to the crucible, the bottom of which has been heated to low redness. After each addition the lid of the crucible must be immediately put on. A gentle deflagration ensues, which must, however, have completely subsided before a fresh quantity is added. After the whole of the mixture has been introduced, the particles which during the operation have been hurled against the sides and lid of the crucible should be carefully scraped down into the interior. The lid is then to be replaced, and the crucible heated for at least ½ hour to a lively redness. Hereupon the flame is to be withdrawn and the crucible inclined and turned in such a manner that the fused mass may principally distribute itself on the sides. This is done to facilitate the subsequent solution.

The mass after fusion is usually yellowish, sometimes green or greenish, from the presence of manganese. As the latter constituent is estimated with iron in II., no further account need be taken of it here.

The contents of the crucible are next to be treated with water, and the more or less turbid solution supersaturated with HCl. After this it will have become much clearer, and at times perfectly so. To this solution, filtered if necessary, $BaCl_2$ is to be added, and the S estimated from the quantity of baric sulphate precipitated. In the lignites which I have examined, the S has in some specimens amounted to as high as 7 per cent.; whereas in pit coals I have found as little as ½ per cent. Coals absolutely free from S I have never as yet met with.

In precipitating the sulphuric acid obtained by the action of sodic nitrate of the coal, there is, however, one source of error, which if not carefully guarded against, may possibly give high results. As the liquid will still contain considerable nitric acid, it frequently happens, especially if great excess of baric chloride has been added, that baric nitrate is formed. This salt, it is known, will sometimes adhere to the baric sulphate so powerfully that it cannot be washed out with water alone. When such a precipitation has taken place, the baric sulphate will on ignition evolve nitrous fumes, and will, after cooling, give with test papers an essentially basic reaction. To free the precipitate from this impurity, it should be digested with HCl, whereby the free baryta, formed during ignition, together with the nitrate which may still be present, will be converted into chloride, in which form it may be easily washed out.

One objection may perhaps be raised against the above method of determining total S: namely, that it obviously will include the sulphuric acid which may have preexisted in the coal. For the purpose of satisfying myself on this point I have made numerous experiments on fossil fuels, by treating them, in the state of very fine powder, with warm water, and adding $BaCl_2$ to the filtrate. I indeed obtained, after a time, a turbidity; the precipitate, however, in almost all cases, was so slight as scarcely to admit of further determination. All the sulphates could not, of course, have been extracted in this manner as the dense texture of coal will prohibit water from completely saturating it, even when in the finest powder. The omission of this determination is, however, without importance in the estimation of the quality of coal. For all preexisting sulphuric acid will remain in the ash, and will therefore be, I may say, passive or indestructive. This quantity, after being deducted from the total S, gives the quantity of active or destructive S present. It is the latter part of the total sulphur, which, being evolved as SO_2, gives rise to all the objectionable consequences which attend the escape of the gas (corrosion of metals, bleaching, etc).

II. *Determination of Water and the Constituents of the Ash.*

The 10 gms. of pulverized coal weighed out for this part of the analysis, are introduced into a platinum crucible, capable of holding at least 30 gms. of water. This crucible is then to be placed in an air-bath and heated to about 120° C. It would have been possible to expel all water even at 100° C. The time, however, required in the latter case would be so much greater, that it is always advisable to elevate the temperature as much as possible, without, however, allowing it to become sufficiently intense to decompose the coal. In any case, at least one and a half to two hours should be allowed for the complete expulsion of all water. The end of the operation may be determinined by holding a plate of glass over the open tubulure of the air-bath. When a film of moisture is no longer formed, all the water has been expelled. The tubulure must then be closed, the gas turned off, and the crucible weighed immediately on cooling. The loss is water.

The quantity of water contained in some coals is truly astonishing; and yet in none of the specimens would we be likely to expect it from external appearances. Even after pulverization the coal remains perfectly dry. This peculiar fact immediately brings to our mind certain salts containing much water of crystallization, and we are strongly tempted to conclude, that the water in coal does not merely adhere mechanically, but is chemically bound, however weak this union may be. It is true that I have never as yet met with such high percentages of water in coals, as are contained, for instance in alum (45½), borax (47), Glauber salts (56), phosphate of soda (60), soda (63). Nevertheless 20 per cent. was not unfrequent. Specimens with 30 or even 35 per cent. sometimes occur; at other times, on the contrary I have found as little as 2 per cent.

The sample from which water has been expelled is next to be ignited for the purpose of determining the ash. If it is desirable to determine, at the same time, whether a given specimen belongs to the class of caking, cinder, or sand coals, the lid should be kept on the crucible until the escape of volatile matter is no longer apparent. At this point the flame is to be withdrawn and the contents of the crucible examined. The residue will have the appearance of a dense, porous, apparently molten mass (caking coal), or will be but slightly coherent (cinder coal), or finally will remain in the state of a powder (sand coal).

For the purpose of hastening the progress of ignition it is well to give the crucible an inclined position, and to stir the contents carefully from time to time with a platinum wire. The operation will be complete when the combustion within the mass has entirely ceased. The residue, when cold, is to be weighed as ash.

The quantity of ash in coal varies as widely as the moisture. I have found as high as 30 per cent. and as low as 1½ per cent. As the ash always contains iron, it is never quite white; and according to the quantity of this metal present, the ash will vary from a light buff to a dark brick-red.

The ash thus obtained is to be introduced into a small flask and digested with HCl. (1·12 sp. gr.) for one or two hours. It is then to be filtered from the undissolved SiO_2 and the sulphuric acid contained in the filtrate precipitated with $BaCl_2$. The sulphur herefrom determined is that which I have above called "indestructive;" by deducting it from the total sulphur previously obtained, the quantity of "destructive" sulphur may be found.

To the filtrate from the $BaSO_4$, sulphuric acid is to be added to precipitate the $BaCl_2$ employed. The filtrate herefrom should be tested with H_2S, for the purpose of determining whether copper (which I have found on several occasions) is present. When this is the case it may be precipitated completely with H_2S, which precipitate after ignition is weighed as cuprous sulphide, and the copper calculated therefrom. Copper when found in coals always exists as sulphuret.

Should the process for the separation of copper have been necessary, the iron in the liquid will have been reduced to a ferrous salt. It is therefore necessary to oxidize the liquid by ebullition with nitric acid, after which the ferric oxide, alumina, manganese, and phosphoric acid may be precipitated by ammonia.

From this precipitate (previously well washed) alumina and phosphoric acid may be separated by digestion with KHO. If to the alkaline filtrate acetic acid be then added, the phosphoric acid (necessarily present only in traces) will be precipitated as phosphate of alumina ($Al_2P_2O_8$); and from the menstruum we may obtain the remainder of the alumina by precipitation with ammonia.

The residue insoluble in KHO will consist of ferric oxide, and at times small traces of manganese. (The presence or absence of the latter metal will have been previously indicated during the fusion with KNO_3.) As, however, the determination of manganese is a matter of no importance, and since the two metals, manganese and iron, have very nearly the same combining weights, we may without sensible error estimate the whole as ferric oxide. Iron exists in coals principally in the state of pyrites. It may therefore be better to report it as Fe, and not as Fe_2O_3. Coals usually contain more sulphur than would be necessary to combine with the iron present. There are, however, some specimens in which the iron is in excess, in which case the difference will most probably exist as oxide.

In the filtrate from the iron, lime may be precipitated by oxalic acid, and thereafter the magnesia with phosphate of soda, and the quantities present estimated as usual.

I have frequently tested for alkalies, but with such unsatisfactory results that I now neglect the matter entirely. The estimation is made somewhat inconvenient from the invariable presence of magnesia. It would for instance be necessary to expel ammonia salts in the filtrate from calcic oxalate by ignition; then to precipitate the magnesia together with the H_2SO_4 present (due to the excess previously used in precipitating baryta, after the sulphuric acid estimation) with baryta water, and finally, after having precipitated the excess of baryta used, with ammonic carbonate, evaporated the filtrate to dryness and ignited, to look for alkalies in the residue. As such a process might give a positive result, it is perhaps better, in order to avoid as many sources of loss as possible, to weigh the residue of sulphate of magnesia and perhaps sulphates of potash and soda, freed from ammonia salts by ignition, determine the quantity of magnesia and sulphuric acid present, and then to estimate the alkalies by difference.

III. *Estimation of Carbon and Hydrogen.*

The 5 gms. of coal for this determination, after having been completely dried at 120° C. and again weighed, are to be ignited with CuO, finally in a current of oxygen, or with chromate of lead, as in ordinary organic analysis, and the C and H estimated from the CO_2 and H_2O obtained. It is fully as efficient and far more convenient to generate oxygen from potassic chlorate, instead of using a gasometer. This salt, in pieces about the size of peas, is to be placed in the back part of the tube, separated from the CuO by a layer of asbestos, and heated when the ignition has been nearly completed.

IV. *Estimation of Nitrogen.*

As no specimen of coal is free from N, and since up to the present time we have no direct method of estimating O, the necessity of estimating all the other constituents of coal, including N, for the purpose of making our analysis complete, becomes at once apparent. The estimation of N may be best effected by igniting the 1 gm. of pulverized coal (from which the water need not be previously expelled) with soda-lime. The N thus evolved in combination with H as ammonia, may be absorbed by acids. It was at first customary to employ HCl, convert the sal-ammoniac thus obtained into platinochloride of ammonium, determine the quality of Pt. contained by ignition, and estimate the N from this result. Afterwards dilute H_2SO_4 was recommended. The quantity of H_2SO_4 left free after the gas had passed through was determined by a standardized solution of NaHO, whence the quantity of ammonia absorbed, and consequently the quantity of N in the coal, was calculated. Notwithstanding the fact that the latter method has been much praised, I cannot recommend it in the present analysis, as in the case of a minimum of ammonia, the quantity of free acid remaining is so great as to prevent the volumetric estimation from being sufficiently accurate. Let us, for instance, suppose that the specimen contains 1 per cent. N (more will seldom be found, 2 per cent. would be beyond the maximum). In this case the 1 gm. operated upon will contain ·010 g. N, corresponding to ·012 of ammonia; these 12 m. g. would saturate 28 m. g. sulphuric anhydride. Now since the quantity of acid proposed seldom contains more than 1 gm. of SO_3, only the $\frac{1}{36}$ part of it would be neutralized by the ammonia. The remainder ($\frac{35}{36}$) is to be saturated by NaHO, so that even a few drops would cause appreciable error in the estimation. For this reason I have continued to use HCl as the absorbent, without, however, converting the sal-ammoniac obtained into platinochloride of ammonium. The method consists in evaporating the acid gradually (finally in a watch-glass) at a temperature not exceeding 100° C.

Herewith the actual analysis of coal would be completed. The only determination further desirable might be the quantity of thermal units evolved by the ignition of the specimen. By a thermal unit I here mean, the quantity of heat necessary to raise one kg. of water 1° C.

1 gm. carbon, on ignition evolves 8080 therm. units.
1 gm. hydrogen . . . . . 34464 „ „

The thermal units desired may be obtained:

I. By taking the percentage of 8080, which expresses the quantity of C present.

2. By taking the percentage of 34462, which expresses the quantity of free H present, and adding the results; as, for example:

In a specimen analysed were found:

$$\left.\begin{array}{r} 51{\cdot}70 - \mathrm{C} \\ 3{\cdot}49 - \mathrm{H} \\ 10{\cdot}32 - \mathrm{O} \end{array}\right\}$$

The 10·32 of O require 1·29 H, for the formation of H_2O; there therefore remain:

$$\left.\begin{array}{r} 51{\cdot}70 - \mathrm{C} \\ 2{\cdot}20 - \mathrm{H} \end{array}\right\}$$

Hence,

$$\begin{array}{ll} 1. & {\cdot}5170 \times 8080 = 4177{\cdot}3600 \\ 2. & {\cdot}0220 \times 34462 = 758{\cdot}1140 \\ \hline & \text{Sum} = 4953{\cdot}5240 \end{array}$$

which expresses the number of thermal units produced by ignition of 1 gm. of specimen.

ALCOHOLIC SOLUTION OF SHELLAC.*

BY A. PELTZ.

The production of a clear alcoholic solution of shellac has been the subject of numerous experiments, but hitherto none has turned out satisfactory except slow filtration. As is known, by digestion of one part of shellac with six or seven parts of 70 per cent. alcohol, a solution is obtained which when warm is almost clear, but upon cooling becomes turbid and is only partially clear after standing a week. The plan of pouring sufficient alcohol over coarsely powdered shellac to form a thin paste, yields upon the addition of more alcohol after the lapse of eight or ten hours a liquor that does not deposit any more, but which is not clear. Another method suggested, of boiling the alcoholic shellac solution with

* *Pharmaceutische Zeitschrift f. Russland.*

animal charcoal gives a clearer liquid, but there is always loss through absorption by the animal charcoal.

The object sought by the author was to obtain a clear alcoholic solution in a short time without much loss. Previous communications upon the substance occurring in shellac to the extent of five per cent., which renders its alcoholic solutions turbid, and is described by some authors as wax and by others as a fat acid, suggested an attempt to effect its removal before dissolving the shellac. The shellac therefore was boiled with water, from one to five per cent. of soda or ammonia being added, but without satisfactory result, a somewhat larger addition of the alkali caused the solution of the shellac.

The author next prepared a solution with one part of shellac and six parts of 90 per cent. alcohol at the ordinary temperature, which was effected with frequent shaking in ten or twelve hours. To this he added carbonate of magnesia to about half the weight of the shellac used and heated the mixture to 60° C. The solution so obtained cleared more rapidly than a solution to which magnesia had not been added and filtered in less time; but it did not supply what was sought. When powdered chalk was substituted for magnesia, the solution after standing some hours became three-fourths clear, whilst the lower turbid portion could be rapidly filtered. It only required a little alcohol to wash the filter, and a clear alcoholic solution of shellac was obtained. Further experiments, for instance, with sulphate of baryta, did not give a better result. When such a solution is made on a large scale it would be best filtered through felt.

Nothwithstanding that the object of the author had thus been attained, one or two other experiments were tried. To three parts of the above mentioned shellac solution one part of petroleum ether was added, and the mixture was vigorously shaken. After standing a few moments the liquid separated in two layers; the upper light coloured layer was the petroleum ether with the wax dissolved in it, the lower yellow brown layer was a clear solution of shellac with only a little petroleum ether adhering. Upon allowing the petroleum ether to evaporate spontaneously, the wax that had been dissolved out of the shellac was obtained as a white residue. By using a stronger alcohol (95 per cent.) to dissolve the shellac, and subsequently adding petroleum ether a perfectly clear solution was obtained that only separated into two layers after the addition of water. Consequently an alcohol weaker rather than stronger than 90 per cent. should be used.

The shellac solution obtained by means of petroleum ether, however, has the disadvantage that the shellac is left after the evaporation of the petroleum in a somewhat coarser form and easily separates; this may be obviated by the addition of one to three per cent. of Venice turpentine.

Further experiments showed that the petroleum ether could be replaced by the ordinary commercial benzine.

BLACK WRITING INKS.*

BY C. H. VIEDT.

The aqueous solution of the tannin of the gall-nuts undergoes the following change by fermentation, the ferment being present in the Aleppo galls:—

$$\underset{\text{Tannin.}}{C_{27}H_{22}O_{17}} + 4H_2O = 3(\underset{\text{Gallic Acid.}}{C_7H_6O_5}) + \underset{\text{Sugar.}}{C_6H_{12}O_6}.$$

On boiling the nuts with water, and exposing the solution to the air, this fermentation sets in. The Chinese galls do not contain this ferment, and, therefore, to bring about the above decomposition some yeast must be added. Concentrated solutions of ferrous salts give, with tannic acid, a white voluminous precipitate; in dilute solutions no change takes place. Ferric oxide solutions, with excess of tannic acid, give a blue-black precipitate of ferroso-ferric tannate, a part of the higher oxide being reduced to the lower one. This ferroso-ferric tannate is also formed when solutions of ferrous tannate are exposed to the air, partial oxidation taking place. With great excess of tannic acid even ferric salts give no precipitate, being thus reduced to ferrous salts. After a longer time the solution becomes blue-black; later on blue-black tannate is precipitated, the solution remaining of a dirty green colour. By boiling a mixture of a ferric salt with tannic acid, it becomes colourless, with liberation of carbonic acid, and thus it becomes evident that prepared gall-nut inks ought never to be heated to boiling.

The behaviour of gallic acid to iron salts is nearly analogous to that of tannic acid. Ferrous salts have no effect on gallic acid, but on exposure to air the solution becomes at first reddish, then violet, then dark blue, and at length an insoluble and blue-back ferroso-ferric gallate is precipitated. This insoluble gallate precipitates much more quickly than the corresponding tannate, but the supernatant solution of the gallate remains somewhat strongly coloured with gallate retained in solution. In choosing tannic acids for the manufacture of ink, it should be remembered that only those giving blue reactions with iron yield the best coloured inks; those which give a green colour, as sumach tannic acid, cannot be recommended. Many of the former variety also contain substances which damage the colour of the ink, as the tannic acid of the *Tormeutilla ereeta*, which contains an injurious red pigment besides tannic acid.

Gall-nuts are considered the best source of the tannic acid, and of these the Chinese galls with 72 per cent. of tannin are recommended as cheapest and best, because they also contain less extractive mucilaginous bodies than the Aleppo galls; they furnish an ink less liable to become mouldy.

To extract the tannic acid from the gall-nuts, they are coarsely pulverized, and mixed with an equal quantity of straw, cut small. This mixture is shaken in a high, narrow vessel of oak wood, furnished with a tap at the bottom, and close above a perforated false bottom. Here it is treated with lukewarm water, and the tannic acid extract is allowed to flow very slowly out, after which it is returned several times, still further to exhaust the powdered galls. The mixture of chopped straw is to obviate the difficulty caused by the swelling of the galls on lixiviation, and the yielding of a quantity of slimy mucilage, which would otherwise have rendered the mass impermeable. It is suggested that a row of small "diffusers," similar to those employed by the sugar-refiner, might be used with even greater advantage.

To preserve the prepared ink from mildew, three to five drops of pure *carbolic acid* should be added, or if the smell of this be objected to, *salicylic acid*. The presence of lime in the water used for ink-making is not injurious. The ferrous salt recommended is ferrous sulphate, "green vitriol;" the proportions will be 100 *parts of tannin* to 90 *parts of crystallized ferrous sulphate*. Of course, by the use of the pure ferrous salt the ink at first is very light coloured, though it afterwards darkens on exposure to air. To overcome the difficulty of this pale writing, the ink is coloured with logwood extract, or some soluble colouring matter. Logwood and cupric sulphate are used for ink-making besides gall-nuts and ferrous sulphate. Both yield beautiful blue-black precipitates; galls and cupric sulphate, however, give a slimy brown-black colour, which spoils the tint of the ink. It is better, therefore, not to use the copper salt at all.

LEECHES.

The following interesting note on a French leech farm appeared in 'Chambers's Journal' for July:—

The great demand which suddenly sprung up for leeches for surgical purposes at the end of last century, caused their natural haunts in the swamps and marshes to be invaded by armies of collectors, who soon denuded them of their ordinary stock. The French seem particularly partial to leeches, and their use in that country has always been more general than elsewhere. As a consequence of the drain upon her supplies, she was the first to suffer from a diminished yield; and in time the famine spread to Hungary, Turkey, Greece, and Germany, and even to Algeria and Syria, all of which countries were ransacked in the search for these bloodthirsty creatures. The scarcity and dearness of leeches at last attracted attention, and it was, we believe, about 1830 that the idea was conceived by a Frenchman that leeches might be kept in regular farms and bred, just like any other animal for which there is a steady market. The idea was soon carried into practice, and with such success that leech-breeding has come to be regarded as a distinct industry of no little importance, and is carried on to a considerable extent in different parts of the continent.

The success of such an establishment depends, of course, on the choice of a suitable locality, and as the spots best adapted for this purpose are generally tracts of marshy ground, which are either useless for any other purpose, or—worse than useless—a nuisance, the selection of such areas and turning them to account in this way, is a double benefit. As an instance of the advantages attending the establishment of the industry in such places, setting aside the actual and immediate profits of the trade, we may quote a French writer, who, twenty years ago, gave his experience of such an undertaking. Natural swamps previously neglected are cultivated and placed under control, their miasmatic effects are neutralized, and employment is given to many poor people, who would otherwise find it hard to get a living. In the department of La Gironde alone, about ten thousand acres of land have been devoted to this purpose; its value has risen six or eight fold; men's wages have risen from 1*s.* to 2*s.* 6*d.* and 3*s.* a day; women and children also find remunerative occupation; shops have sprung up where none previously existed; and the condition of the peasantry generally has been vastly improved.

Let us examine one of these farms which have been the means of doing such an amount of good. We will pay a visit to one of the first of many which were established by M. Laurens—namely, that at Parempuyre, about nine miles from Bordeaux. Here an area of about four hundred acres near the Garonne is devoted to this industry. The marsh is subdivided into compartments of five or six acres in extent, each of which can be inundated separately. It is surrounded by a ditch eight feet wide by five feet deep, outside which is a bank of earth which acts as an obstacle to the escape of the leeches, and which also enables the watchmen to go round the property at night without being seen; for there are some thieves who cannot resist the temptation of stealing even leeches when the opportunity presents itself. Outside the bank, is a second ditch, connected with the inner one by occasional breaches in the intervening bank. Each compartment is intersected with drains, and can be flooded or laid dry at will by opening the hatches with which the ditches are provided. In the case of draining the water off, the lower hatches are replaced by perforated metal ones, through which the water, but not the leeches, can escape. Besides these breeding-grounds there is a reservoir, similar to them in every respect, which is replenished at every opportunity with the larger leeches; so that, when the other beds are laid dry, there is always a stock on hand ready for the market. This reservoir is always kept covered with water to the depth of three to five inches, and holds from forty to fifty thousand leeches to the acre —a rate rather larger than that observed in the breeding-ponds, which are populated to the extent of thirty to forty thousand leeches per acre. During the cold season the leech remains quite underground; but the first rays of the spring sun bring him out, and then a troop of horses is made to enter the breeding-grounds, in the proportion of ten to the acre. The leeches attach themselves to the lower part of the legs of the animals, and then gorge themselves. The same troop of horses remain "on service" for five or six hours, when they are recalled and tended, and sent back to their pastures, where they are allowed to rest and regain strength. After eight or ten days' rest, the horses are again despatched on duty; the hitherto unfed leeches, and those that have digested their last repast come out again; and from about the 1st of March to the middle of June they are thus fed about eight or ten times each.

In June, the leeches all go underground, and the laying dry of the parks commences; the horses are kept out of them, the weeds and reeds are allowed to grow, and the soil becomes better knit together, as it were. In July and August the leeches come out to deposit their eggs in the tufts of herbage, and then the drains before mentioned are filled with water enough to keep the ground moist. The leeches having performed this duty, again burrow underground, and in a short time the young ones make their escape from the eggs.

The parks are inundated, and at the end of August the fishing commences. The fishers, protected by high boots, enter the pond arranged in lines, and beat the water with sticks, to arouse the dormant leeches, which soon appear in great numbers, ready, after their long fast, for another feast. The large ones are carefully lifted out and placed in bags, with which each person is provided; and the line of fishers gradually advances till the whole bed is thoroughly beaten. It is then left to be subjected, three or four days afterwards, to another careful search, a sufficient stock being always reserved in the shape of the young and small leeches, and those that, not having digested their food, do not put in an appearance on the unceremonious summons of the collectors.

An establishment such as that described above will produce several million leeches annually in a healthy condition. Serious losses are experienced in cold weather and in consequence of injudicious handling of the annelides; but the profits are nevertheless considerable, as the cost of maintenance and collection is not very great.

The method of feeding these interesting flocks is, as we have said, by sending a number of horses into the ponds periodically, for unless leeches are provided with an ample commissariat, they will take themselves off in search of forage elsewhere. The horses used for this purpose do not suffer to anything like the extent that might be imagined. They are closely watched during the operation, and carefully tended afterwards. In many cases, horses which have been bought for a trifle have, under the care bestowed upon them, improved so wonderfully as to have been sold afterwards at a profit, so little does the system injure them. Old horses, whose lives have hitherto been a succession of hard knocks and fastings, and a perpetual round of fatiguing journeys, here find a relief from their burdens; death is deferred for months, and even years, and the latter period of their life is passed in a paradise, compared with the experience they have gone through.

Paris alone "consumes" some twelve million leeches annually; and, prior to the establishment of the system of producing them in artificial reservoirs, the annual importation into France from abroad, exclusive of its own production, was nearly fifty millions. The enormous demand for these useful surgical attendants throughout the world may be estimated from the above figures.

THE PRESENT STATE OF THE BISULPHIDE OF CARBON INDUSTRY.*

BY O. BRAUN.

In 1872 the state of the bisulphide of carbon industry was the following:—

For the preparation of bisulphide of carbon, the only

* *Journal of the Chemical Society* for June. From *Chem. Centr.*, 1875, 810.

method used was that of Lampadius, depending on the passing of vapours of sulphur through red-hot coal. All the forms of apparatus described, except Galy-Cazalat's, are similar to each other, and consist of a retort, fixed vertically into a furnace, with a cover and two openings. Through one opening a tube open at both ends leads into the interior, and almost to the bottom of the retort; to the other opening a tube is attached, which forms a connection with the cooling apparatus. The latter is arranged so that it cannot be stopped up by the solidification of the sulphur, and thus prevent the outlet of the gases. After filling the retort to the brim with charcoal or coke, the cover is put on, the connection made between the tube and the cooler, and the fire lighted. Sulphur is now introduced into the retort through the tube, and passing from the bottom through the red-hot charcoal, combines with the carbon, and is condensed in the cooler to bisulphide of carbon. The process is continuous; the addition of sulphur takes place every 10 minutes, that of the coal every 12—24 hours. The great disadvantage in this mode of manufacture is the necessity of often completely emptying the retort, in order to remove the coal and sulphur residues, whereby the workmen are exposed to heat and vapours, and much loss of material and time is incurred, and these vapours cause great annoyance to the neighbourhood.

Galy-Cazalat and Huillard's patented apparatus consists of a retort, in which a portion of the coal is burnt, and then used for heating the remainder of the coke. This apparatus would doubtless answer very well if heat were liberated in the combination of sulphur with carbon. This, however, is not the case, and it therefore becomes necessary to renew the access of air; and although in so doing no violent explosions take place, since the bisulphide of carbon is ignited before forming a dangerous mixture of air and gas, still a considerable quantity of sulphur is lost, or at least only used as fuel. The author seems to doubt the use of this apparatus for the manufacture of animal charcoal, which was suggested by the inventor.

Clay retorts were probably used at first because the temperature necessary for the formation of the carbon bisulphide has been over-estimated. Cast-iron retorts are now used, the plates are about 50—70 mm. thick, and if well fixed last several months, so that with a retort weighing 1000—2000 kilos. 20,000 kilos. or more of bisulphide of carbon can be prepared. The mass of the retort is at the same time converted, with great increase of volume, into a sulphide of iron, difficultly soluble in dilute sulphuric acid. Vertical retorts ought to be used, the diameter not being more than 0·4 meter. It is also very advantageous to use elliptical retorts. Enamelled retorts might perhaps be durable. A considerable progress was made in the bisulphide of carbon industry when the sulphur was no longer put into the retort as a solid, but was passed into it in the form of vapour. Still the present method requires many alterations and improvements, especially with regard to the yield, the want of fuel, the wear and tear of the apparatus, and also the effect of the heat and the vapours on the workmen.

As charcoal and coke do not consist of pure carbon, but contain besides ash, also hydrogen and oxygen, other compounds are formed, such as sulpuretted hydrogen, which, as it contains sulphur, not only decreases the quantity of sulphide of carbon produced, but also escapes from the condenser, saturated with sulphide of carbon vapours. Besides this other gases are formed, which partly dissolve in the bisulphide of carbon, and give it a disagreeable odour. The quantity of gases increases with the amount of moisture (H and O) in the charcoal.

The crude bisulphide of carbon thus formed contains, besides about 10 per cent. of free sulphur, sulphuretted hydrogen and probably several other bodies, compounds of carbon, sulphur, and oxygen. Distillation alone does not give a pure product. Bonnière obtained a pure substance by arranging his rectifying apparatus in such a way that the vapours had to pass through solutions of potash, ferrous oxide, and salts of cupric oxide. Leyferth obtained a good product by precipitating the vapours with a stream of fresh cold water. Deiss recommends for the same purpose the use of soda, chlorine water, and chloride of lime. Sidot once rectifies his crude product, and then shakes it up with pure mercury. A very pure product is obtained by repeatedly distilling the bisulphide of carbon from pure oil; so long as the purification is not perfect, the oil has a very repulsive smell, and becomes sulphury.

The most important properties of bisulphide of carbon, with regard to its technical application, are its solvent power for oils, fat, resins, tars, sulphur, phosphorus, etc.; its insolubility in water; its specific gravity, which is greater than that of water; its low boiling point (46° C.); the high specific gravity of its vapour (38 compared with hydrogen); its low igniting point (170°C., but probably, under certain conditions, lower).

Several patents have been taken out describing details of the apparatus used for extracting with carbon sulphide, the principle being the same in all cases, viz., removing the oil with bisulphide of carbon until saturated, and recovering the same from the oil, as well as from the residue of the fatty raw material. From the exhausted residue the sulphide of carbon can be distilled with steam, hot air, or a mixture of both steam and air. Boiling water does not answer. From the oil the bisulphide of carbon is at first distilled with dry, and afterwards with wet steam.

In 1862 the author began to extract fatty wool residues, the difficulty consisting in recovering the bisulphide of carbon, after removing the oil, without spoiling the wool. A mixture of steam and air was passed into the wool, entering the vessel at the top, and thus causing the specifically heavier bisulphide of carbon to escape at the bottom. The apparatus was improved to such a degree that the escaping air was perfectly free from bisulphide of carbon, and that thus the consumption of the latter was but very slight (100 kilos. require 0·25 kilo. of CS_2).

In 1863 Bonnière patented an apparatus for extracting olive residues (Wagner's *Jahresbericht*, 1863, 562), and Moison's (*Annales du Conservatoire des Arts et Métiers*, iii, 55) apparatus was described by Payen.

Since 1868 the author has tried experiments on a large scale, for the purpose of extracting the press residues from oil factories where palm-nuts are worked up. These residues still contain about 25 per cent. of oil, and it is necessary to grind the fruits properly, in order to allow the bisulphide of carbon and steam to pass through them.

The author, in conclusion, describes an apparatus used by Braun Brothers, of Moabit, near Berlin, where 5000 kilos. of palm-nuts are exhausted in 12 hours, the apparatus consisting of a horizontal cylinder, holding about 10,000 kilos. of bisulphide of carbon, used for storing the same, four vessels holding smaller quantities of bisulphide of carbon, and used for measuring purposes; six extracting vessels, forming upright cylinders, 1·1 m. high, and 0·7 m. wide, holding 250 kilos. of pressed product, two distilling vessels with a worm and an air-pump.

Finally, the author states that petroleum cannot be profitably used for extracting purposes, as its solvent power is not so great as that of bisulphide of carbon, and as some residues, especially when wet, cannot be extracted by its use.

ON CHEMICAL NOTATION.*

BY M. M. PATTISON MUIR, F.R.S.E.,

Assistant Lecturer on Chemistry, The Owens College, Manchester.

1. In examining a chemical action we may pay attention to (1) the substances which take part in, and the final

* From the *Philosophical Magazine* for July, 1876.

products of, the action, or (2) to the force which is concerned in doing the work. Thus the action of sulphuric acid upon zinc is commonly represented by the equation

$$Zn + H_2SO_4 = ZnSO_4 + H_2,$$

which tells us that a given weight of zinc acts upon, or is acted upon by, a given weight of sulphuric acid, with the production of certain fixed weights of zinc sulphate and of hydrogen; and further, the equation implies that a certain amount of force is expended in the action. So again the equation

$$2H_2O = 2H_2 + O_2$$

not only states, in symbolic language, the fact that 36 parts by weight of water yield 4 parts by weight of hydrogen, and 32 parts by weight of oxygen, but it also implies the further fact that, in order to obtain the quantities of hydrogen and of oxygen from water, a certain amount of energy must be altered in form. The latter fact is not, it is true, stated in our ordinary chemical equations in the same prominent manner as the former, still it is, I think, unmistakably implied.

2. These two methods of regarding a chemical equation are not without close relationships to each other. In a paper published in this magazine by Dr. E. J. Mills, it is said that chemical substances are valued not for what they are conceived as being, but as doing—that the most important question with regard to a chemical substance is, how does it behave with this or that reagent? It appears to me that what a chemical substance *does* depends very much upon what it *is*, and that, although we are obliged to study these questions to a certain extent apart, we shall some day be able to express by one and the same formula the constitution and the various modes of action of all known chemical bodies.

3. In the following paper I shall endeavour to point out what appear to me to be some of the reasons for maintaining our ordinary formulæ, but at the same time, for supplementing them by investigations into, and symbolic representations of, the dynamical laws governing chemical transformations.

4. In the first place, all questions as to work done by different chemical substances imply the existence of these substances; change in the form of energy implies the existence of energy; but the existence of energy implies to our minds at any rate, a something which is the seat or vehicle of energy. This something is matter. Matter has been defined by two eminent naturalists as "that which is essential to the existence of the known forms of energy, without which therefore there could be no transformations of energy." The physical universe is often compared to a machine, the laws of the working of which are the laws of energy; but an investigation into these laws surely does not preclude, but rather prompts to an investigation into the structure of the machine itself. It may be urged that what we call matter has no existence outside of the mind of the observer; this objection, however, has been often refuted.*

5. One of the most well-founded generalizations concerning matter is to the effect that no particle of it can be destroyed, nor be produced by us. The mass of matter cannot be changed by us; its form may be changed, the forms of its energy may be altered, but its quantity remains the same. If this be so, surely it becomes of vital importance to every naturalist—and in the term naturalist we include the chemist—to have a symbolical language which shall express the weights of matter taking part in, or resulting from, any action between what we call different kinds of matter.

Now whatever theory we may hold concerning the constitution of matter, it can scarcely be denied that our ordinary formulæ do tell us the weights of those kinds of matter which take part in a given chemical reaction, or of those which result from that reaction. To the principle of the conversion of matter the writer already quoted appears to object. He would seemingly refuse his assent unless some one could experimentally prove to him that a given chemical compound has the same composition now that it had a hundred years ago.

Surely such a statement as this implies ignorance of the meanings of a scientific generalization. Elsewhere Dr. Mills speaks of the ideal reformer as one who "must have an infinite capability of doubting." Is the infinity of this capability to cause the ideal reformer to doubt every generalization which rests upon well known and most thoroughly trustworthy facts, because the special proof which *he* demands cannot, and that from the very nature of the case, be forthcoming?

6. A chemical equation expresses the weights of the different kinds of matter taking part in the reaction formulated; it therefore implies a dissimilarity of some sort between the *kinds* of matter. The equation $2H_2 + O_2 = 2H_2O$ implies that the kind of matter represented by the symbol $2H_2$ is different in its essential properties from that represented by either of the symbols O_2 or $2H_2O$,—and, further, that the kind of matter indicated by the last-mentioned symbol is in some way composed of the two other kinds of matter. To such an expression it has been objected that we do not know that the substance represented by the symbol $2H_2O$ is *composed* of the two substances $2H_2$ and O_2, that we have reasons for believing that each of these three substances is equally homogeneous. Now it appears to me that we may use such a chemical equation without commiting ourselves to any theory as to the manner in which the hydrogen and oxygen unite together to form water. When we say in chemical shorthand, 4 parts by weight of hydrogen, under certain conditions, so react with 32 parts by weight of oxygen as to produee 36 parts by weight of water, we state a fact. Here are three substances which exhibit to our senses different phenomena; with each of these substances certain definite phenomena are invariably associated; and we find that, under fixed conditions, for a mixture of certain weights of the two former a weight of the third equal to the sum of these two weights is invariably produced. In such a statement nothing is said of the homogeneity or non-homogeneity of the three substances; whatever views may be held on this subject, the fact of the production of the third substance by the mutual action of the other two is undeniable; and this fact is symbolically expressed in the equation we have been considering.

Of course chemists are generally in the habit of conceiving that water is *made up of* oxygen and hydrogen, that these substances exist in some way in the new substance formed by their action upon one another; and the equation will bear this meaning. On the other hand, it is at least possible, in the light of Mr. Lockyer's recent spectral researches, to imagine that hydrogen and oxygen may themselves be split up into simpler substances (just as water is split up into hydrogen and oxygen); but if this be the case the equation may remain unaltered; it expresses a truth, although probably not the whole truth. But we believe that chemical equations tell us much more about the composition of substances than the mere fact that certain weights of two bodies produce a certain weight of a third; this part of the subject, however, I shall defer to a later portion of the paper.

7. If we are to regard chemical substances chiefly in the light of what they *do*, it may, apparently, be urged

* 'Unseen Universe,' 1st edit. p. 71. "Some extreme thinkers write as if they would persuade us that a species of hallucination affects with similar impressions every individual mind, so that, for instance, one man may usefully warn another about a pitfall on a dark road, and so save him from a catastrophe which might otherwise be caused by something which exists, if at all, in the mentor's mind only—at all events not as yet in that of his pupil; though if the warning be unheeded, or not given, there will presently be another mind in which the pitfall will certainly exist with startling vividness. But this is altogether repugnant to every conviction which experience (our only guide in such matters) enables us to form, etc."

that our ordinary formulæ are of little use to us—that, inasmuch as these formulæ are based upon statical ideas, they are useless, or all but useless, when we come to deal with questions of kinetics.

If we investigate chemical formulæ, especially in their more recent outcome, I think we shall see that this is a mistaken idea.

8. Some chemists have affected to sneer at the "pictures," as they call them, which "deface" the pages of so many modern treatises. If they have convinced themselves that "Ignorance is bliss," then they are right in the conclusion "'Tis folly to be wise." That the use of structural or dissected formulæ may be carried to a pitch which does become ridiculous—especially in the case of compounds about which we know little or nothing, but whose graphic formulæ are, it would appear for that reason, to be continually sketched—can scarcely be denied. But why do chemists make use of such formulæ at all? is it not because they wish to express in the shortest possible manner the greatest amount of information about the *actions* of the substances formulated? Instead of putting down in words what this body will do under certain circumstances, how this body will react with other bodies, chemists seek to compress all they know of the *doings* of the substance into that shorthand expression by which they distinguish it from all other bodies. To say that structural formulæ do not tell us much about the actual, and even the possible, *actions* of the substances formulated, is simply to confess to ignorance of what these formulæ exhibit.

9. For proof of this statement I might refer to many researches; let one suffice.

In a remarkable paper published in the Philosophical Magazine,* Dr. C. R. A. Wright examined the relations between affinity and dissected or structural formulæ in the case of certain groups of compounds; and he showed that the dissected formula of a chemical compound may give us much information, not only with regard to the method of formation, and decomposition under the influence of various reagents, of that compound, but also with regard to the transformation of energy which take place during these actions. Thus, to take an example, it is shown that when an operation, "symbolically represented by the substitution of the group of symbols CH_3 for the symbol H in some constituent hydrocarbonous radical (CH_3, CH_2, or CH) in the dissected formula of the original substance," is performed upon a given vapour, then "heat is evolved during the performance of the operation," and the new and more dense vapour produced has a higher "affinity-value" than the original vapour. Here we have a most important generalization with regard to homologous series of compounds; as the series is ascended the 'affinity-value" increases; and these differences of affinity-values are "correlative with the differences between . . . dissected formulæ indicating substances chemically related together."

On the other hand, Dr. Wright shows that substitution of the group CH_3 for H in the OH group in the dissected formula of a vapour is attended with absorption of heat, and therefore with a decrease in affinity-value; thus the conversion of an acid into its methylic ether is attended with absorption of heat.

10. It may be urged that our formulæ do not express such relationships as those between transformation of energy and chemical action. At present they do not; but it would require only the addition of a symbolic expression of some kind, not the discarding of the formulæ and the invention of entirely new expression, to enable us to express such relationships. Dr. Wright's researches show (and this is the main point to be insisted upon) that there *is* a connexion between the commonly employed dissected or structural formulæ and changes in the energy of the substances formulated. This conclusion, might almost have been arrived at by a study of structural formulæ themselves. Such formulæ as

$$CH_4,\ CH_3(CH_3),\ CH_3(C_2H_5),\ CH_3(C_3H_7),\ CH_3(C_4H_9)$$

tell us that two volumes of each hydrocarbon vapour may be prepared from two volumes of the vapour of the hydrocarbon immediately preceding it by an operation symbolically represented by the replacement of H by a radical having the general formula C_nH_{2n+1}. Now there must be some change in the energy of these hydrocarbons before and after the performance of such operations; and inasmuch as we can ascend the series by a repetition of the same operation, we should expect that the change in energy, whatever it may be, would be regular, and would be related in some way to the regular change in chemical constitution.

11. Not only do the formulæ of compounds indicate the actions by which these substances are produced, and by which they may be transformed into other substances, but with the formulæ of the elementary bodies there is likewise associated information of a similar nature.

Mendelejeff* has pointed out that if the symbols of the elements be arranged in the order of their combining weights, beginning with the smallest, the elements may be divided into groups and series, the members of which are characterized by a gradation of properties, which gradation is closely related to the increase of the combining number. Each group possesses many properties in common, among these the power of forming oxides and other salts of similar type being very marked. We have here, then, a possible arrangement of chemical symbols such that, from its position in a regular series, each symbol shall tell us a great deal concerning the *power of doing* of the element which it symbolizes.

12. It appears to me, therefore, that our chemical formulæ do tell us very much about the *actions* of the substances formulated, about their methods of formation and of decomposition, and that as advances are made in a knowledge of the changes of energy, which are undoubtedly correlated with changes in chemical constitution these formulæ may be so modified as to express such knowledge. At present we know so little of chemical kinetics that it would be altogether premature to propose any method for giving symbolic expression to the few facts which have been brought to light.

13. In the symbolic expression of chemical actions such statements occur as these:—

$$K_2 + 2H_2SO_4 = 2KHSO_4 + H_2 \quad (1)$$
$$Ca_2 + 2H_2SO_4 = 2CaSO_4 + 2H_2 \quad (2)$$
$$Na_2 + 2HCl = 2NaCl + H_2 \quad (3)$$
$$Mg + 2HCl = MgCl_2 + H_2 \quad (4)$$

By comparing equations (1) and (2), it is evident that the quantity of potassium expressed by the symbol K has replaced, in sulphuric acid, a quantity of hydrogen represented by the symbol H, while twice this quantity of hydrogen has been replaced by the symbol Ca. The conclusion, therefore, to be deduced from these equations is, that, so far as the power of replacing hydrogen in sulphuric acid is concerned, the symbol Ca is equivalent to the symbol K taken twice. Similarly from a comparison of (3) and (4) it may be concluded that Mg is equivalent, in hydrogen-replacing power, to 2Na. From a consideration of such equations as these the idea of valency takes its origin. This idea has been largely developed; and chemists have been able to fix the valency of a large number of radicles, whether simple or compound. The valency of a chemical substance expresses a certain function which that substance is capable of performing; it tells us that the substance under consideration is capable of doing a certain amount of work; but inasmuch as the circumstances under which this work is done vary, the valency also will vary with the circumstances. Nevertheless we find that for each elementary radicle there is a

* December, 1874.

* *Ann. Chem. Pharm.* Suppl. vol. viii. p. 133.

fixed maximum valency; we have therefore a most useful means of classifying these radicals according to their power of doing a certain work. It is true that the unit of work done is not very strictly defined; it is only the unit weight of hydrogen displaced, or combined with. Yet this classification is in practice found to be most useful. Given the valency of a metallic radicle, and the basicity of an acid upon which that radicle exercises an action, it is possible to foretell what the composition of the resultant of that action will be. Hence those quantities of two or more radicles which are able to replace the same quantity of hydrogen may be truly said to be "equivalent" quantities.

14. Dr. Mills (*loc. cit.*) objects to this use of the word equivalent, and avers that "we might as well say that the values of the loads in a railway truck are always equivalent, whether the load consists of air, of hay, or bullion." They are equivalent in one respect, viz. in that they have displaced equal volumes of air. We have nothing to do with the general *value* of a radical when we speak of its valency in the commonly accepted meaning of the phrase. That amount of a given radical which will displace unit weight of hydrogen from an acid may not be that amount which will do some other kind of work, just as that amount of hay which will displace one cubic foot of air in the railway truck is *not* that amount which will do the work of an equal volume of bullion in so far as exchange is concerned, although it does accomplish the same amount of work when we define the unit of work as "replacing one cubic foot of air." Dr. Mills has introduced an unfortunate word by using the term *value.*

15. If we for a moment agree to view this matter of valency in the light of the molecular theory of matter, and of some recent researches of Michaelis and other chemists, the explanation given of the relation between valency and general chemical "value" would be something as follows. We may imagine the molecule of a chemical element performing a certain vibration in a definite period of time; during the performance of this vibration there are certain positions attained by the molecule, at each of which it is so situated as to be capable of exercising chemical action upon other molecules. The number of these positions is the valency of the molecule. But we can suppose that the total force exercised is not uniformly distributed, so that an unequal amount is capable of being exercised at each position; hence the valency may vary according to the reactions in which the molecule takes part. Again, it is clear that the total force exercised will not necessarily bear a simple relation to the number of positions in which the molecule may be capable of exercising this force; hence the general affinity (or chemical "value") of a molecule may be small, while its valency is large, or *vice versâ.*

16. Altogether, then, I think we have in valency a most useful means of classification, and that we are fully entitled to use the term "equivalent" in the acceptation generally assigned to it by chemists. This, however, does not prevent us from admiring Dr. Mill's proposal to determine the power of doing work, in terms of a fixed unit, of classes of chemical substances. Undoubtedly such investigations would be highly interesting, and would lead to most important results; but why we need do away with the advantages gained in order to gain further advantages I, for one, am at a loss to determine. Dr. Mill's has himself made some very careful and elegant experiments, by which he has determined the "dynamic equivalent" of various nitrates in terms of a fixed unit. It would be well that these researches should be extended.

But when we are in possession of a large amount of such information as this surely it will not be necessary to devise an entirely new system of notation, but only to modify the existing system so as to include the new knowledge. Our present notation is founded on facts; it does not necessarily involve any theory, only a generalization, as Dr. Wright has well pointed out; hence it is not to be thrown aside because at some future time it may not adequately express all our knowledge. Let us wait till that knowledge is gained, and then try to so modify our notation as to symbolize the knowledge.

But if we should not find it possible to do this, and it becomes necessary to have a new system of notation, it will be still a system which has been developed from, not a system which has overthrown, the old.

17. I have so far endeavoured to put forward reasons for believing that our existing system of notation symbolizes, to a certain extent, both the substances which take part in, and the final products of a chemical action, and also some of the relations existing between these substances and the changes of energy which accompany the action. In so far as the latter changes are concerned it must, however, be confessed that our ignorance is great, and that when more knowledge is gained it will be necessary for us to modify our notation so as to express this knowledge symbolically.

I have sought to show that our equations represent the initial and final distributions of matter during a reaction symbolized, that they imply changes of energy, that in the case of dissected or structural formulæ we can trace a close connexion between such changes of energy and the formulæ, and that in valency we have at any rate the rudiments of a method by which the power of doing work of different substances may be compared.

18. On looking at such an equation as

$$Zn + H_2SO_4 = ZnSO_4 + H_2,$$

one might imagine that the weight of zinc sulphate expressed by the symbols $ZnSO_4$ would be at once produced on the addition of that quantity of sulphuric acid represented by H_2SO_4 to Zn parts by weight of zinc, and that, were a somewhat larger quantity of acid to be added to the same quantity of zinc, the action would not be modified. The equation appears to convey this meaning; but the meaning is erroneous. Chemical action involves greater or less quantities of time; and it is certainly influenced by the total mass of the acting substances, as also by the mass of the resultants, and by the relation which these bear at any moment to the generating substances.

19. Hitherto we have not been able to express such facts as these symbolically. And at present it would be useless to attempt such a task; we are but on the threshold of such inquiries; we have been so long (perhaps too long) occupied with gathering facts concerning the substances produced by chemical action that we have had little time to devote to a closer study of the action itself in its various phases. Such study will form a part of the chemistry that is to be and will without doubt be rich in results of the highest importance. But granted that we cannot now express the process of a chemical change in our notation, this does not at all prove that the notation is founded on a false system. We know that one of the best-grounded generalizations of science is expressed by saying, that those substances which we call chemical elements, when they react together so as to form compounds (that is, bodies in which the characteristic properties of the reacting elements are merged), do so in simple multiples of a certain fixed number,—that the composition of the compounds may therefore be expressed by writing the names (or symbols) of the elements, with numbers attached to each expressive of the multiple of the certain fixed number which had before been assigned to each element.*

The Pharmaceutical Journal.

SATURDAY, JULY 29, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACEUTICAL EDUCATION IN BELGIUM.

A CORRESPONDENT in Ghent has favoured us with the following account of the state of pharmaceutical teaching in Belgium, and the modifications which have been made by the recent legislation on the subject.

Pharmacy in that country forms part of the scheme of University instruction; the students entered for the study of this subject form part of the faculty of medicine. They undergo examination before a combined board, of which half of the professors belong to a State University, whilst the other half are connected with an independent school. The student entered for an examination, therefore, knew beforehand who would have been his examiners. By this system there was a considerable control which could not but be favourable, as well to the teaching body as for the pupils; on the one hand, the professors found themselves stimulated, and were obliged to keep themselves *au courant* with science because they had before them, each year, other professors engaged in the same teaching, and belonging to another university; on the other hand, there was a greater guarantee for the public, because the certificated pupils had been examined by two kinds of professors, belonging to rival schools.

Education being free in Belgium, and the independent universities being equal in number to the state universities, it was necessary in reference to academical degrees to accord to the professors of the independent universities the same rights that were enjoyed by the professors of the state universities. The granting of this privilege had another advantage, that as a natural consequence the Government thus exercised an indirect power over the independent schools, while the professors of the State universities exercised, through the examinations, a control over the teaching in those institutions.

The new law of 1876 has put an end to this state of affairs, and, from the beginning of 1877, when it is to come into operation, every university, whether it be independent or whether it appertains to the State, will have the power of conferring diplomas. The State will retain the chief power in the government of its own universities, but will no longer exercise any control over the teaching in the independent universities. Time will show the value of this system of equalizing degrees in Belgium.

If, on the one hand, the new law of 1876 gives ground of fear that there may be an abuse of power, on the other hand, the teaching of pharmacy will be raised to a higher standard, and the examinations will become more difficult. Thus the curriculum for qualification in pharmacy is divided into two parts; the first, comprising the study of botany, physics, chemistry, mineralogy, and the elementary principles of zoology, will form the subject matter of a preliminary examination, the passing of which will confer upon those who shall have satisfied the examiners, a right to the title of *Candidat en Pharmacie.* With the exception of adding elementary zoology, the subject matter of this examination has not undergone any other modification. But it is not the same in respect to the second examination, which confers on him who is already a *Candidat en Pharmacie*, a right to the title of *Pharmacien.* Before the new law was passed the student had only to undergo an examination upon theoretical and practical pharmacy, as to his knowledge of the characters, properties, and preparations of drugs and medicines, as well as their adulterations and alterations together with the maximum doses of the more potent drugs and preparations, and to carry out satisfactorily two chemical operations, two pharmaceutical operations, and two toxicological researches.

The new law of 1876 has introduced a very great modification of this examination for obtaining the degree of *pharmacien*, and it will be divided into two parts: the first will comprise a theoretical examination on analytical and toxicological chemistry, on drugs and medicines as articles of merchandise, their alterations, adulterations and maximum doses, also on theoretical and practical pharmacy. The second part of the examination will be purely practical, and will consist of two chemical operations, two pharmaceutical operations, a complete analysis, a toxicological operation, an operation for discovering the adulteration of medicines, and a microscopical research.

The reform which pharmaceutical teaching is about to undergo is therefore considerable, and cannot but have the effect of raising the position of pharmacists in that country. No one will be able to establish himself in business as a pharmacien until he has given evidence by certificate, authenticated by a medical commission, that he has been practically engaged in the business for two years as an assistant in the open shop of a certificated pharmacien. The new law, consequently, requires from the candidate more profound knowledge at the commencement of his curriculum, and it also places him under the further necessity of continuing his studies afterwards in a still more thorough manner. The opinion held in Belgium with regard to the probable influence of the reform now about to be introduced is that the number of workers in the pharmaceutical domain will increase, and it is expected that it will induce many who are engaged in pharmaceutical pursuits to occupy themselves with researches of a similar character to those which are conducted with so much advantage by pharmacists in other countries, among which we may particularize Germany as being the most active in this respect.

We have on various occasions placed before our readers some accounts of the state of pharmacy in foreign countries and of the educational systems adopted there for the purpose of showing the relative advantages, or disadvantages, which obtain here and abroad. Some modifications of the educational system hitherto followed in Belgium have recently been introduced by the Government of that country, and as these are in certain respects analogous to those which have within the last few months been introduced in the examinations of the Pharmaceutical Society, it will be useful to compare what has been done in this direction in the two countries.

THE EFFECT OF AGE ON RHAMNUS FRANGULA BARK.

It is due to Mr. Baildon that the merit of the bark of the black alder tree (*Rhamnus Frangula*), as a valuable vegetable aperient, has during the past few years attracted some attention in this country. Considerable personal testimony has been given in its favour, but on the other hand the drug has not always produced the expected results. This may find an explanation in the fact recently pointed out by Dr. Lamm, of Stockholm, that there is a considerable difference between the action of old and fresh bark, and that the complaints as to the non-activity of the bark may have originated from useing it in a too recent state.

The bark was made officinal in the fourth edition of the Swedish Pharmacopœia (1790), but it was afterwards omitted until the seventh edition (1869), the reason for its omission from the intervening editions being probably the diminished confidence in its activity. The recommendation of German physicians about 1850, again gave rise to a demand for the bark, and good results were obtained with the old stocks then held by the apothecaries. The restored popularity, however, led to the introduction of a quantity of fresh bark, and it was soon noticed that to obtain the same effect the strength of the decoction and the dose had to be increased and that the new black alder bark was not half so strong as that formerly used. The result has been that the drug has again become almost obsolete. The last edition of the Norwegian Pharmacopœia recognizes this fact by ordering that the bark shall have been kept at least one year before using it. According to Fristedt, the fresh bark produces colic and vomiting, symptoms that have been observed to follow the administration of the bark without their having been previously attributed to its freshness.

THE SALE OF MEDICINES BY GROCERS IN FRANCE.

Some months since a grocer at Rouen was condemned by the correctional tribunal for selling a pectoral paste, which was a preparation of liquorice, the sale of medicines in France being, as is known, strictly limited to pharmaciens. Upon appeal, however, the conviction has been reversed, one of the grounds being that the law had not for its object the creation of a monopoly for the pharmaciens, but solely the protection of the public health; another was that liquorice, although included in the Codex, is an inert substance, or only an emollient. The pharmaciens of Rouen are much chagrined at this unexpected result; the grocers are proportionally elated, and have been encouraged to present a petition to the Chamber of Deputies praying for more liberal legislation on the subject, and that the monopoly of pharmacists may be restricted to products directly prepared by them and constituting real medicaments.

BRAZILIAN TAPIOCA.

The mandioca (*Manihot utilissima*), flourishes in intertropical and temperate regions, but most luxuriantly where the soil is loose and dry, especially if it be sandy. No less than thirty varieties are grown in Brazil, and of all the crops it is the one that gives the best return and the least trouble. The flour prepared from its root forms a staple food of the inhabitants. Mr. Acting-Consul Austin, of Rio, reports that he has been informed by a Campos planter that a square of 220 metres of land will grow 40,000 mandioca plants, which even in inferior soil will produce regularly 80,000 lbs. of farina. At the lowest valuation, 60 reis per lb., this would give a revenue of £520, a result superior to that derived from sugar or cotton. The preparation of tapioca from it is easy and inexpensive, and very profitable.

A PANIC AMONG SPONGE DIVERS.

Mr. Vice-Consul Jago, writing from Beyrout, says that the last crop of Turkey sponge was very deficient, and prices of ordinary and common sponges have greatly risen in consequence. The deficiency is attributed to a panic among the divers caused by the appearance in the neighbourhood of Batroun, Mount Lebanon, the chief sponge-fishing locality, of a sea monster, alleged to have been equal in size to a small boat. Its actual depredations among the divers appear at the present time to have been limited to one man, whom he is said to have swallowed whole.

ALEPPO SCAMMONY, ETC.

We learn from the consular returns just issued that scammony, opium, and other drugs, which have in past years held their places more or less advantageously in the Aleppo market, were all absent in the export trade of 1875. Opium, saffron, and cumin, which were formerly grown in the province, were not cultivated last year. Castor oil seed, too, was not sown to any great extent, and the crop was insignificant.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

A meeting for social and scientific purposes in continuance of the regular pharmaceutical meetings of this Society was held June 20th, 1876, Mr. James T. Shinn, in the chair.

A specimen was exhibited by Mr. J. U. Lloyd of a yellow neutral crystallized principle obtained from the root of *Eupatorium purpureum*. It is quite soluble in hot, slightly so in cold alcohol, and insoluble in water; it does not unite with dilute acids, is decomposed by strong sulphuric acid, is tasteless and as far as known has no medicinal value.

Professor Maisch read a note on—

Concentrated Solution of Salicylic Acid.

BY CHARLES L. MITCHELL.

A strong solution of salicylic acid, for convenience in both dispensing and prescribing, has long been a desideratum, and until recently no practical way of overcoming the difficulty has been known.

Salicylic acid itself is very sparingly soluble in cold water, and though readily dissolving by the aid of heat, nearly all separates on cooling. Its alcoholic solution is not adaptable to the purpose—for when diluted with water, the acid immediately separates.

Various methods have been recommended for rendering the acid more soluble, namely: the use of various salts, such as sodium orthophosphate, calcium chloride, ammonium acetate, etc.; and also by dissolving it in glycerin. None of these modes of procedure give a solution which contains more than ½ per cent. salicylic acid. The desideratum seems to be a concentrated solution which will bear dilution with water to any extent. Recently a writer in the *Druggists' Circular*, has recommended the use of sodium biborate and glycerin in the proportions of 1 part each of salicylic acid and of the biborate to 16 parts glycerin. This gives a solution containing about 6 per cent. salicylic acid, and one that is freely miscible with water in all proportions.

While recently experimenting with this formula, it occurred to the writer that probably a still stronger and more concentrated solution might be obtained by some slight modifications. After several experiments the following formula was adopted:—

Acid. Salicylic. pur.	ʒij
Sodii Biborat.	ʒj
Glycerinæ	q. s.

Mix the acid and borax with f℥iv glycerin, heat gently until dissolved, then add q. s. glycerin to make the measure f℥i This solution contains 25 per cent. salicylic acid, and can be diluted with either glycerin, alcohol or water to any degree desired.

The advantages of a concentrated solution of this description can scarcely be overestimated, as it affords a very convenient mode of both prescribing and dispensing salicylic acid.

Mr. J. T. Shinn observed when a solution was made with equal parts of borax and salicylic acid, the taste was very bitter, when, however, two parts of borax were used this was not the case.

Professor Maisch believed if the estimate of Professor Kolbe and others as to the virtues of salicylic acid are to be of value to physicians, they must use it in the free state as this is the only way in which it is effective; if salts are employed to effect a more ready solution, some chemical change is most probably the result.

Mr. E. M. Boring had, in common with many others, had trouble with prescriptions for this acid from physicians labouring under the error in regard to its solubility and the probable changes produced by the use of chemical solvents. Quite recently water of ammonia had been used to effect the solution of a large quantity of the acid in water. This was only another instance in which the elegant pharmacist gave the conscientious dispenser a great amount of trouble.

Mr. Boring exhibited honey which had been obtained by himself from the comb, and exposed to direct sunlight; it became candied in a short time, whereas a portion of the same lot exposed to diffused light had undergone no change. He said also that he had examined a sample of yellow wax which had the concave surface said to be characteristic of adulteration with paraffin, yet upon testing with sulphuric acid he failed to find any.

Professor Maisch exhibited a small branch of a plant from Oregon, probably a *Tetranthera*, natural order *Lauraceæ*, with a pellucid punctate leaf, having an aromatic ordour, and at first pleasant, but afterwards very pungent to the taste, which seems to indicate that it may possess medicinal properties.

Dr. Pile said that he had made dilute phosphoric acid by the second process of Professor Markoe, and succeeded very well, the summer temperature being favourable, and little attention being required. Other members had found it necessary to operate at a somewhat higher temperature than had been indicated by Professor Markoe. Dr. Pile also stated that he found written upon a prescription—"examined and found correct," and supposed this an additional method of indicating the correctness of an unusual dose.

SOCIÉTÉ DE PHARMACIE DE BORDEAUX.

The subject of preparations having for their base protochloride of iron having been selected by the Bordeaux Pharmaceutical Society as one it was desirable that the members should investigate, a note of which the following is an abstract was read at a recent meeting:—

Preparation of Protochloride of Iron.

BY M. DAMBIER.

The preparation of the protochloride of iron by direct combination, by a method analogous to that followed in the preparation of protoidide of iron for the corresponding syrup, is not convenient, as, instead of two solids, one gaseous and one solid body have to be dealt with. The best method of obviating this difficulty is the employment of hydrochloric acid instead of chlorine, and this is the plan usually described in chemical works, but without any information being given as to the exact quantities of iron and hydrochloric acid respectively required for the preparation. Having had occasion frequently to prepare syrup of protochloride of iron, the author was induced to pay some attention to this portion of the subject.

The formula $FeCl_2$ requiring 44·13 parts by weight of iron to 55·87 parts by weight of chlorine, it was necessary to calculate what quantity of hydrochloric acid of a certain density would be equal to this quantity of chlorine. Water saturated with gaseous hydrochloric acid at the ordinary temperature dissolves 38·38 per cent. of its weight; its density is then 1·19. In employing such an acid, therefore, 149·68 parts by weight would be required for 44·13 parts of iron.

In preparing the solution of protochloride, the author places in a tared vessel the proportion of hydrochloric acid above indicated with about double its weight of distilled water, and to this is added reduced iron rather in excess of the theoretical quantity—for a ten per cent. solution 14·968 of acid and about 5·000 of iron—the reduced iron of commerce never being in a state of absolute purity. The vessel is placed over the fire and the iron is added in small quantities at a time until the effervescence produced by the evolution of hydrogen ceases. The vessel is then removed from the fire, weighed, and sufficient distilled water added to bring the solution to the required strength.

The following table shows the quantities by weight of hydrochloric acid of different densities required to yield with 4·41 parts of iron, 10 parts of protochloride :—

Sp. gr. of Acid	Containing per cent. H Cl.	Quantity required	Containing real H Cl.
1·19	38·38	14·96	5·74
1·18	36·36	15·80	5·74
1·17	34·34	16·72	5·74
1·16	32·32	17·77	5·74
1·15	30·30	18·96	5·74
1·14	28·28	20·31	5·74
1·13	26·26	21·87	5·74
1·12	24·24	23·71	5·74
1·11	22·22	25·85	5·74
1·10	20·20	28·44	5·74
1·09	18·18	31·60	5·74

The author points out that the proportion of iron in the protochloride is nearly two and a half times greater than in the protoiodide, a point worthy of the notice of prescribers, the syrup of protochloride of iron having a much more decided styptic taste than the corresponding syrup of protoiodide.

The following table shows the proportion of iron to the other constituents in the ferruginous preparations usually employed :

	Iron	Other Constituents
Protocarbonate of Iron	48·28	51·72
Protoiodide of Iron	44·13	55·87
Protoxalate of Iron	38·88	61·12
Hypophosphite of Iron	37·34	62·66
Phosphate of Iron	36·84	63·16
Pyrophosphate of Iron	30·02	69·98
Bromide of Iron	25·93	74·07
Citrate of Iron	22·85	77·15
Tartrate of Potash and Iron	20·96	79·04
Lactate of Iron	19·45	80·55
Iodide of Iron	18·08	81·92
Antimoniate of Iron	13·65	86·35

It will thus be apparent that next to the protocarbonate, the protochloride contains the largest proportion of iron ; but the author finds that it presents the advantage over the protocarbonate of being much more easily preserved, and consequently more convenient for dispensing purposes, and also that its prolonged use does not induce constipation. The solution may be preserved unaltered for a long time by placing with it in the bottle several pieces of iron wire.

ROYAL SOCIETY.

Repulsion resulting from Radiation—Influence of the Residual Gas.*

BY WILLIAM CROOKES, F.R.S.

I have recently been engaged in experiments which are likely to throw much light on some obscure points in the theory of the repulsion resulting from radiation. In these I have been materially assisted by Professor Stokes, both in original suggestions and in the mathematical formulæ necessary for the reduction of the results. Being prevented by other work from completing the experiments sufficiently to bring them before the Royal Society prior to the close of the session, I have thought that it might be of interest were I to publish a short abstract of the principal results I have obtained, reserving the details until they are ready to be brought forward in a more complete form.

In the early days of this research, when it was found that no movement took place until the vacuum was so good as to be almost beyond the powers of an ordinary air-pump to produce, and that as the vacuum got more and more nearly absolute so the force increased in power, it was justifiable to assume that the action would still take place when the minute trace of residual gas which theoretical reasoning proved to be present was removed. The first and most obvious explanation, therefore, was that the repulsive force was directly due to radiation. Further consideration, however, showed that the very best vacuum which I had succeeded in producing might contain enough matter to offer considerable resistance to motion. I have already pointed out that in some experiments where the rarefaction was pushed to a very high point the torsion beam appeared to be swinging in a viscous fluid (194), and this at once led me to think that the repulsion caused by radiation was indirectly due to a difference of thermometric heat between the black and white surfaces of the moving body (195), and that it might be due to a secondary action on the residual gas.

On April 5, 1876, I exhibited at the *Soirée* of the Royal Society an instrument which proved the presence of residual gas in a radiometer which had been exhausted to a very high point of sensitiveness. A small piece of pith was suspended to one end of a cocoon fibre, the other end being attached to a fragment of steel. An external magnet held the steel to the inner side of the glass globe, the pith then hanging down like a pendulum, about a millimetre from the rotating vanes of the radiometer. By placing a candle at different distances off, any desired velocity up to several hundreds per minute could be imparted to the fly of the radiometer. Scarcely any movement of the pendulum was produced when the rotation was very rapid; but on removing the candle and letting the rotation die out at one particular velocity the pendulum set up a considerable movement. Professor Stokes suggested (and, in fact, tried the experiment at the time) that the distance of the candle should be so adjusted that the permanent rate of rotation should be the critical one for synchronism corresponding to the rate at which one arm of the fly passed for each complete oscillation. In this way the pendulum was kept for some time swinging with regularity through a large arc.

This instrument proved that, at a rarefaction so high that the residual gas was a non-conductor of an induction current, there was enough matter present to produce motion, and therefore to offer resistance to motion. That this residual gas was something more than an accidental accompaniment of the phenomena was rendered probable by the observations of Dr. Schuster, as well as by my own experiments on the movement of the floating glass case of a radiometer when the arms are fixed by a magnet.*

My first endeavour was to get some experimental means of discriminating between the viscosity of the minute quantity of residual gas and the other retarding forces, such as the friction of the needle-point on the glass cup when working with a radiometer, or the torsion of the glass fibre when a torsion-apparatus was used. A glass bulb is blown on the end of a glass tube, to the upper part of which a glass stopper is accurately fitted by grinding. To the lower part of the stopper a fine glass fibre is cemented, and to the end of this is attached a thin oblong plate of pith, which hangs suspended in the centre of the globe : a mirror is attached to the pith bar, which enables its movement to be observed on a graduated scale. The stopper is well lubricated with the burnt india-rubber which I have already found so useful in similar cases (207). The instrument is held upright by clamps, and is connected to the pump by a long spiral tube. The stopper is fixed rigidly in respect to space, and an arrangement is made by which the bulb can be rotated through a small angle. The pith plate, with mirror, being suspended from the stopper, the rotation of the bulb can only cause a motion of the pith through the intervention of the enclosed air. Were there no viscosity of the air, the pith would not move ; but if there be viscosity, the pith will turn in the same direction as the bulb, though not to the same extent, and, after stopping the vessel, it will oscillate backwards and

* From the *Chemical News*, July 21, 1876.

* *Proceedings of the Royal Society*, March 30, 1876.

forwards in decreasing arcs, presently setting in its old position relatively to space.

It was suggested by Professor Stokes that it would be desirable to register not merely the amplitude of the first swing, but the readings of the first five swings or so. This would afford a good value of the logarithmic decrement (the decrement per swing of the logarithm of the amplitude of the arcs), which is the constant most desirable to know. The logarithmic decrement will involve the viscosity of the glass fibre, but glass is so nearly perfectly elastic, and the fibre so very thin, that this will be practically insensible.

According to Professor Clerk Maxwell the viscosity of a gas should be independent of its density; and the experiments with this apparatus have shown that this is practically correct, as the logarithmic decrement of the arc of the oscillation (a c nstant which may be taken as defining the viscosity of the gas) only slightly diminishes up to as high an exhaustion as I can conveniently attain —higher, indeed, than is necessary to produce repulsion by radiation.

I next endeavoured to measure, simultaneously with the logarithmic decrement of the arc of oscillation, the repulsive force produced by a candle at high degrees of exhaustion. The motion produced by the rotation of the bulb alone has the advantage of exhibiting palpably to the eye that there *is* a viscosity between the suspended body and the vessel; but once having ascertained that, and admitting that the logarithmic decrement of the arc of oscillation (when no candle is shining on the plate) is a measure of the viscosity, there is no further necessity to complicate the apparatus by having the ground and lubricated stopper. A movement of the whole vessel bodily through a small arc is equally effective for getting this logarithmic decrement; and the absence of the stopper enables me to have the whole apparatus sealed up in glass, and I can therefore experiment at higher rarefactions than would be possible when a lubricated stopper is present.

The apparatus, which is too complicated to describe without a drawing, has attached to it—*a*, a Sprengel pump; *b*, an arrangement for producing a chemical vacuum; *c*, a lamp with scale, on which to observe the luminous index reflected from the mirror; *d*, a standard candle at a fixed distance; and *e*, a small vacuum-tube, with the internal ends of the platinum wires close together. I can therefore take observations of—

1. The logarithmic decrement of the arc of oscillation when under no influence of radiation.

2. The logarithmic decrement of the arc of oscillation when a candle shines on one end of the blackened bar.

3. The appearance of the induction-spark between the platinum wires.

1 measures the viscosity; 2 enables me to calculate the force of radiation of the candle; and 3 enables me to form an idea of the progress of the vacuum, according as the interior of the tube becomes uniformly luminous, striated, luminous at the poles only, or black and non-conducting.

The apparatus is also arranged so that I can try similar experiments with any vapour or gas.

The following are some of the most important results which this apparatus has as yet yielded:—

Up to an exhaustion at which the gauge and barometer are sensibly level there is not much variation in the viscosity of the internal gas (dry atmospheric air). Upon now continuing to exhaust, the force of radiation commences to be apparent, the viscosity remaining about the same. The viscosity next commences to diminish, the force of radiation increasing. After long-continued exhaustion the force of radiation approaches a maximum, but the viscosity measured by the logarithmic decrement begins to fall off, the decrease being rather sudden after it has once commenced.

Lastly, some time after the logarithmic decrement has commenced to fa lloff, and when it is about one-fourth of what it was at the commencement, the force of radiation diminishes. At the highest exhaustion I have yet been able to work at, the logarithmic decrement is about one-twentieth of its original amount, and the force of repulsion has sunk to a little less than one-half of the maximum. The attenuation has now become so excessive that we are no longer at liberty to treat the number of gaseous molecules present in the apparatus as practically infinite; and, according to Professor Clerk Maxwell's theory, the mean length of path of the molecules between their collisions is no longer very small compared with the dimensions of the apparatus.

The degree of exhaustion at which an induction-current will not pass is far below the extreme exhaustions at which the logarithmic decrement falls rapidly.

The force of radiation does not act suddenly, but takes an appreciable time to attain its maximum; thus proving, as Professor Stokes has pointed out, that the force is not due to radiation *directly*, but *indirectly*.

In a radiometer exhausted to a very high degree of sensitiveness, the viscosity of the residual gas is almost as great as if it were at the atmospheric pressure.

With other gases than air the phenomena are different in degree, although similar in kind. Aqueous vapour, for instance, retarding the force of repulsion to a great extent, and carbonic acid acting in a similar though less degree.

The evidence afforded by the experiments of which this is a brief abstract is to my mind so strong as almost to amount to conviction that the repulsion resulting from radiation is due to an action of thermometric heat between the surface of the moving body and the case of the instrument, through the intervention of the residual gas. This explanation of its action is in accordance with recent speculations as to the ultimate constitution of matter, and the dynamical theory of gases.

Parliamentary and Law Proceedings.

Alleged Poisoning by Antimony.

At the recent Waterford assizes, Bridget Reardon was indicted for having, on the 28th of November last, administered poison with intent to kill her husband. In a second count she was indicted for having administered a certain poison known as lunar caustic; and on a third count with having administered some poison unknown, with intent to kill and murder him. It appeared that the prisoner on one occasion gave her husband a cup of tea, and he gave his father another cup. In about three minutes afterwards both were attacked with violent vomiting and pains in the stomach. A doctor was sent for, and having administered appropriate treatment, carefully put into a jar the husband's egesta, and subsequently sent it to Dr. O'Keeffe, Professor of Medical Jurisprudence, Queen's College, Cork, who analysed it, and who found traces of antimony in it. Seven days after the man took the tea he died; and a *post-mortem* examination having been made, his stomach, a portion of his liver and the larger and smaller intestines were also forwarded to Dr. O'Keeffe, who, though he found no poison in them, still was of opinion that their appearance indicated that poison had passed through them. The jury, after a short deliberation, acquitted the prisoner.—*Medical Examiner*.

Prosecution by a Medical Association.

At the Wandsworth Police Court on Monday last, Mr. Sydney H. Witherington, a chemist, of 410, Wandsworth Road, was summoned by the East London Medical Defence Association, before Mr. Paget, for unlawfully pretending to be and using the titles of doctor of medicine and surgeon. It appeared that the defendant's name was outside his shop, and on a lamp in front the word "surgeon." In the window was placed a bill running as follows :—"Dr. Witherington may be seen by special arrangement." The defendant sold a box of pills to a constable bearing a label as follows :—"Antibilious pills. Dr. Witherington, surgeon, etc., Wandsworth Road, S.W." It also appeared that in March last, Dr. Carpenter, secretary of the association, called the defendant's attention to the titles outside his shop, and requested him to take them down. He said he did not put them up, and that he had not received any medical education.—Mr. Paget thought there had been an infraction of a very wholesome law, and fined the defendant £15 and £2 18*s.* 6*d.* costs, and, in default, ordered him to be imprisoned for twenty-one days.—*Standard.*

Compensation for Railway Accident to a Chemist and Druggist.

At the Manchester Summer Assizes, on Saturday the 22nd inst., the case of Eckersley *v.* the Manchester, Sheffield, and Lincolnshire Railway Company, came before Baron Bramwell and a special jury.

The plaintiff carried on business as a chemist and mill furnisher at Oldham. In this action he sought to recover damages from the Manchester, Sheffield, and Lincolnshire Railway Company for injuries he received in a collision on their line on the 27th of February, 1875.

On the day in question the plaintiff travelled by the 5·35 p.m. express train from Manchester to Oldham. On reaching Ardwick, the express came into collision with a goods engine, and the plaintiff received a severe shock to the brain, spinal cord, and nervous system. For a month he was obliged to keep his bed, and on getting up again he suffered a relapse, and all his nervous symptoms returned. Subsequently, by his doctor's advice he visited Whitchurch, in Monmouthshire, and also Blackpool. His recovery had up to the present time been very slow, and in the opinion of his medical advisers it would probably be a year before he would be completely well. His business as a chemist had fallen off owing to his absence from the shop.

The jury returned a verdict for the plaintiff—Damages, £600.—*Times.*

"Worcestershire Sauce" as a Trade Mark.

On Wednesday, July 26, in the High Court of Justice, Chancery Division, before the Master of the Rolls, a bill came on for hearing, filed by Messrs. Lea and Perrins, of Worcester, to restrain the defendant from using the name "Worcestershire" in connection with a sauce made and sold by himself under the style or firm of Richard Millar and Co., such name being claimed by the plaintiffs as exclusively belonging to the sauce manufactured by themselves from a recipe imparted to their predecessors in business by a nobleman of the county about the year 1835.

Mr. Fry, Q.C., Mr. Benjamin, Q.C., Mr. Davey, Q.C., and Mr. William Barber appeared for the plaintiffs; Mr. Chitty, Q.C., and Mr. C. P. Ilbert for the defendant.

The defence was that the name had become common property, having been openly and publicly used by the defendant and other persons in the trade for many years; and, on this being proved to be the fact, the plaintiffs' counsel declined to contest that part of the case any further, and addressed themselves to the subsidiary question, whether the defendant had infringed the plaintiffs' rights by imitating their wrappers and labels. In the result,

The Master of the Rolls said that he was of opinion that the plaintiffs' case wholly failed, and that Messrs. Lea and Perrins would have been better advised if they had not instituted the suit. Many years ago they might undoubtedly have succeeded in preventing other people from infringing their rights as the first makers of Worcestershire sauce, but they had allowed the maxim "*Vigilantibus non dormientibus subvenit lex*" to become applicable to their case. It appeared to his lordship to be established that Messrs. Lea and Perrins' predecessors in business either invented or obtained the recipe for an article to which they gave the name of Worcestershire sauce, and that they were the first persons to sell an article by that name. This was about the year 1836, and within a very few, probably not more than two, years afterwards other people, of whom one Batty seemed to be the first, began to sell an article under the same name. Indeed, the name, within a very few years after it was first used by Messrs. Lea and Perrins, appeared to have become a common name in the trade; and, as their own counsel had in the course of the argument abandoned their claim of an exclusive right to the word, he need say no more on that portion of the case. It remained for him to consider the question of infringement with regard to the label pasted on Messrs. Lea and Perrins' bottles prior to November, 1874. That label was printed in black, on a red ground, and contained the words, "Sole manufacturers, Lea and Perrins, Worcester," in bold black type. The defendant's label on his second quality of Worcestershire sauce differed only from the plaintiffs' label in the fact of the words, "Prepared and sold by Proprietors, London," being substituted for the words "Sole manufacturers, Lea and Perrins, Worcester." No doubt, this label was at some time or other copied from the plaintiffs', but it had been used by other persons as well as the defendant for over thirty years; and his lordship did not believe that any ordinary person could mistake the one for the other. At all events, it had not been shown or suggested that any person had been so misled. It had been argued that a person who could not read might be misled by the general resemblance between the two labels, but this could scarcely be the case, seeing that the plaintiff's sauce was sold at a shilling, and the defendant's at 6*d.* or 4½*d.* per bottle, according to the conscience of the retail dealer. The "proprietors'" label, as it had been termed in argument, appeared to have been in general use in the trade during very many years, and, in his Lordship's opinion, not a shadow of blame attached to the defendant for using a label which nearly everybody in the trade was in the habit of using, and which was kept in stock by at least three printers. Even if the label were an infringement, the Court was not in the habit of intervening unless damage was shown to have been sustained; and his Lordship did not believe that in this case the plaintiffs had sustained any real injury, seeing that the defendant's article was sold in an inferior class of shops and to a lower class of customers than those who were accustomed to buy Messrs. Lea and Perrins' more expensive compound. His Lordship was further of opinion that the plaintiffs had not shown due diligence in prosecuting infringers, and were out of Court on that ground. Besides, there was this conclusive answer to the suit, that the plaintiffs had in November, 1874, adopted a new label bearing their own signature as a distinctive mark, and had in the most public manner abandoned the old label, which they now sought to protect. His Lordship then dismissed the bill with costs.—*Times.*

Review.

Science Papers, chiefly Pharmacological and Botanical. By Daniel Hanbury, F.R.S., etc. Edited by Joseph Ince, F.L.S., F.C.S. 8vo, pp. 544, xii. London: Macmillan and Co. 1876.

Sixteen months have passed away since, on the authority of a brief telegram, we had to perform the painful duty of publishing that Daniel Hanbury was no more. Then it was generally felt that he had left no immediate successor to his preeminent position as a pharmacographist, *facile princeps*, at least in this country; nor has this feeling been diminished by anything that has happened up to the present time. No doubt this reputation was based largely upon the style of Hanbury's writings; so exact, terse, and thorough; as far removed on the one hand from the garrulous fulness of detail that sometimes passes muster for thoroughness of investigation as from superficiality on the other. Although, therefore, the most important results of his investigations were doubtless incorporated with his *magnum opus*, 'Pharmacographia,' we are glad, for the sake of students who desire to follow in his footsteps, that the masterly papers in which he first recorded many of his researches have not been allowed to lie buried in scattered graves of periodical literature. To such students, Hanbury, in these collected 'Science Papers,' "being dead, yet speaketh."

The volume before us contains no less than eighty-one papers from Daniel Hanbury's pen, sixty-seven of which appeared for the first time in the *Pharmaceutical Journal*, and the greater part of the remainder in the *Journal and Transactions* of the Linnean Society. They are not arranged chronologically, but more conveniently grouped, so that papers on the same subject, for instance those on storax, follow each other consecutively. A chronological list of the papers is however appended. It would be difficult to apportion to these papers degrees of merit, though of course the subjects are of varying importance. Notwithstanding the editor's opinion, however, we are inclined to think Mr. Hanbury's judgment was correct in giving the preeminence to those on Manna and Pareira Brava, which will probably leave their mark on the next British Pharmacopœia. But the spirit is alike in all, and is so well illustrated in the opening passage of the paper on Otto of Roses, that we quote it:—

"The importance of authentic specimens is well understood by naturalists. The botanist, who has had the opportunity of verifying the Linnean name of a plant by comparing it with Linnæus's own specimen, is sensible that no more satisfactory proof is wanting. The entomologist who can appeal to the specimens of Fabricius, or the zoologist who can point to those named by Cuvier as identical with his own, feels that he can rightfully adopt the names given by those authors. Nor is the student of Materia Medica much less in need of authentic or type specimens as standards of comparison. Yet how difficult it would be to point to a specimen of Sarsaparilla as indubitably the root of one particular species of *Smilax*, or to find in our museums a specimen of myrrh or olibanum, or gamboge, with indisputable data as to its botanical origin and place of production."

Another point, respecting which we venture to question the criticism of the author by the editor, is that relating to *Rheum officinale*. Mr. Hanbury looked upon this plant as "a true source" of rhubarb, but in the 'Pharmacographia' it is cautiously stated, "Whether the rhubarb of commerce is derived exclusively from this plant is not known." Mr. Ince, however, thinks that the Russian explorer, Prejevalsky, has ascertained beyond doubt that the true rhubarb of commerce is *Rheum palmatum*, and NOT *Rheum officinale*, and in a very prominently placed note states that "the passage, therefore, relating to the identification of the plant cannot stand good." Nevertheless, it is only recently that Professor Flückiger, also in possession of information respecting Prsevalsky's discovery, wrote, "In *Rheum officinale* we possess for the first time a plant, the root-stock of which agrees with the true rhubarb;" also, that "we require more exact information respecting *R. palmatum*, var. *Tanguticum*."

The papers are illustrated by the original lithographic plates and wood engravings, and the beautiful appearance that the skill of Messrs. Clay has given to the latter has made us regret that so much of their beauty had to be sacrificed to the necessities of journalism. A beautifully engraved portrait by Jeens fronts the volume, but it appears to have been taken from a left-handed photograph.

Mr. Hanbury did not write much upon strictly trade matters; but one passage at the close of his presidential address to the British Pharmaceutical Conference at Exeter is very pertinent to the present agitation respecting the sale of milk of sulphur:—

"Notwithstanding that attention has been repeatedly called to the desirableness of supplying this drug in a pure form, it appears that the calcareous *Milk of Sulphur*, consisting of about 34 per cent. of sulphur with 66 per cent. of sulphate of lime, is still very generally sold. In justification it is said that the public prefer the impure article as being whiter and more easily miscible with water, that it is the true *lac sulphuris* of the Pharmacopœia, *sulphur præcipitatum* being a distinct preparation;* to which I may add another consideration (too far fetched, let us hope, to be real), that the first is but half the price of the second. It is hard to combat popular prejudice, and sometimes impossible for a druggist to convince his customer that one article is less adapted to his requirements than another. I have heard a person require the rankest and most offensive cod-liver oil in preference to what was sweet and new; and have even known an ointment that was old and rancid habitually preferred to that which was freshly made. Yet in proportion to the amount of confidence reposed in the knowledge, skill and fidelity of the druggist, so will the public accept his judgment in matters pertaining to his own art; and even a druggist's dictum that pure sulphur is better than sulphur and plaster of Paris will come to be admitted as reasonable."

It is not our intention here to enter upon the biography of Mr. Hanbury; after all, little can be added to what was said within a few days of his death. The present book contains two memoirs, one by Mr. Ince at the commencement, and the other written by Professor Flückiger, and translated from the German by Miss Katherine A. Hanbury, at the end. We make no secret of our preference for the latter. Mr. Ince quotes from a note where Mr. Hanbury says, "It is as hard as iron for me to compose a decent piece of English—in fact, quite impossible, unless it is written out two or three times." What he who judged himself so unsparingly would have said respecting some of his editor's syntax we can only conjecture. Such sentences as—"and that the crowning honour was bestowed also in 1867, when he was elected a Fellow of the Royal Society, and placed on its Council in 1873" (p. 17); "The point at issue in the PAREIRA PAPER was that its botanical source was not *Cissampelos Pareira*" (p. 11); and others of which these are typical are not what we expect from so skilful and practised a writer as Mr. Ince. Neither were we prepared to read, after the statement (p. 9), that Mr. Hanbury undertook Spanish for the sake of the Peruvian balsam sketches, that he learned Spanish for the sake of reading the epistles of Senor Joaquim Correa de Méllo, of Campinas, Brazil (p. 19).

One statement we would venture to supplement, the imperfectness of which probably was due to the form of the entry in the Society's Calendar. It is true that Mr. Hanbury first became a Member of the Pharmaceutical Society in 1857, but he was elected an Associate as early as 1842.

In another article we intend to refer more particularly to some of the results of Hanbury's researches, as disclosed in these 'Science Papers.'

* It was true that the *sulphur præcipitatum* of the Pharmacopœia of 1746 was ordered to be made with sulphur, lime and sulphuric acid; and the *lac sulphuris* of that of 1721, with sulphur, lime *or salt of tartar*, and sulphuric acid. But it is questionable if the chemists of that period were aware of the essential difference of the products obtained, according to whether a lime or a potash-salt were decomposed with sulphuric acid, for Pemberton, in his 'Dispensatory,' 1746, calls the preparations "*similar*," but says that the one "*will not look so white*" as the other.—[D. H.]

Notes and Queries.

[518.] COCKROACHES.—Can any one give me an idea of the best thing to keep cockroaches out of a bedroom which is infested with them?—CHAS. M. FOOTTIT.

[519.] LIQ. AMMON. FORTISS. ODORIF.—BETA asks for a formula for an odorif. liq. ammon. fortiss. for pungent salts.

[520.] JAPANNING.—Will any gentleman be kind enough to publish a receipt how to polish japanned boxes?—COULTHARD.

[521.] GLYCERINÆ PHOSPHAS.—Could you kindly oblige me with the formula for preparing glycerinæ phosphas? I cannot find it in any work in hand.—EDWIN B. VIZER.

[522.] GUM.—Has any one noticed a mixture of what I take to be some foreign gum, with the gum arabic now in the market? Portions of several lots that have come under my notice lately, dissolve with difficulty and then in a most unsatisfactory manner, appearing more like white of egg, and only mixing when well beaten up.—SALED.

Obituary.

Notice has been received of the death of the following:—

On the 1st of July, 1876, Mr. John Bailey, Chemist, and Druggist, Tynemouth. Aged seventy-two years.

On the 13th of July, 1876, Mr. James Fowler, Chemist and Druggist, Warwick. Aged twenty-eight years.

On the 17th of July, 1876, Mr. William Henry Holt, Pharmaceutical Chemist, Altrincham. Aged thirty-five years. Mr. Holt had been a member of the Pharmaceutical Society since 1865.

On the 18th of July, Mr. James Charles Cruse, Chemist and Druggist, Bristol. Aged thirty-three years.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

MUSEUM OF PHARMACEUTICAL APPARATUS.

Sir,—Mr. Schacht's scheme for the establishment of a Museum of Pharmaceutical Apparatus at Bloomsbury Square has been discussed and temporarily (I trust not permanently) abandoned. I do not therefore desire to open up a fresh discussion on the subject, but the present seems a suitable time for pointing out the fallacious nature of one of the most prominent arguments brought to bear against it.

The statements that the Society could not afford the expense or find sufficient room for such a collection were feasible enough in their way; but there were those who asked, If accomplished, what useful purpose would be served? and they seemed, with considerable satisfaction, to find a negative reply in the question itself.

But, sir, the Committee of the Science Loan Collection at South Kensington have deemed a similar but more extended scheme worthy the expenditure of some £25,000 and no end of trouble to accomplish even a temporary purpose. And the result is now sufficiently satisfactory that a memorial has been recently handed in to the Duke of Richmond and Gordon for the establishment of a permanent museum of pure and applied science. Do our pharmaceutical objectors see no moral here? May we not look forward to the time when their minds will have expanded sufficiently to grasp the utility of Mr. Schacht's scheme, and when the increased or better manipulated finances of the Society will enable them to carry it into effect? Meantime, would it not be better to return to the former custom of an annual exhibition at Bloomsbury Square, at the Conversazione, of matters interesting to pharmacists rather than the present useless promenade? I am told it cost considerably less, and the amount so saved would not be despised by the promoters of the Museum of Pharmaceutical Apparatus to form the nucleus of such a collection as I am persuaded will one day become a leading feature of the Society's establishment.

CHARLES SYMES.

Liverpool, July 22, 1876.

W. Roberts.—(a) *Vicia Cracca*; (b) *Equisetum arvense*; (c) *Polypodium vulgare*. It is impossible to name grasses without flowers, or to correctly name such fragments as d, e, and f.

H. S.—(1) *Rhus Catinus* (exotic); (2) *Centranthus ruber*; (3) *Cornus sanguinea*; (4) *Inula species* (exotic); (5) *Marrubium vulgare*; (6) *Clematis vitalba*; (7) *Ligustrum vulgare*; (8) An exotic plant, probably *Solidago Canadensis*. We must request correspondents not to send garden plants for identification.

M. P. S.—Try Pulv. Fol. Hyoscyami.

F. Bullock.—The formula for Ung. Boracis (Lister) is—

Boracic Acid in fine powder . . .	1 part.
White Wax	1 part.
Paraffin	2 parts.
Almond Oil	2 parts.

The ingredients, after being mixed by melting the wax and paraffin, are stirred in a warm mortar till the mass thickens, and then set aside to cool, after which the firm substance is reduced in a cold mortar in successive portions, to an uniform soft ointment.

"*Liverpool.*"—Colenso's 'Arithmetic,' published by Longmans, would probably answer your purpose.

"*Inquisitor.*"—*Aqua Lactucae.* Probably the *Eau Distillée de Laitue* of the Codex is meant. Lettuces, deprived of their lower leaves, 10 parts. Water, 10 parts. Distil over a moderate fire until the product amounts to 10 parts.

J. B. (who should have sent his name and address).—Your former communication has not been received. Dynamite is a mixture of nitro-glycerine and siliceous earth.

W. Strongitharm.—You are recommended to lay your views before the Council.

ON THE POWER OF ETHER TO EXTRACT QUININE IN THE PRESENCE OF AMMONIA CITRATE.

BY A. J. COWNLEY.

In last week's number of the Journal (No. 318) Mr. A. N. Palmer has been at some pains to explain his views on the capability of ether to extract quinine from solutions containing certain other substances and especially ammonic citrate. The conclusion arrived at by Mr. Palmer, viz., that ether does not extract the whole of the quinine in the presence of ammonic citrate, is one quite at variance with my own experience, and I am disposed to think that deficiencies so great as those particularized by Mr. Palmer, varying from 6·5 per cent. to one-half of the actual quantity of quinine, must be referred to some other cause than the impossibility of extracting quinine by ether even from solutions containing ammonic citrate.

It is beside the question at issue to consider whether the Pharmacopœia method of testing citrate of iron and quinine be good or bad as a means of determining the amount of quinine, and there is no doubt much to be said with Mr. Palmer on the discrepancies which are liable to occur by following that method; but parenthically it may be said that washing the alkaloid is only one of the sources of error; in addition to the possibility of quinine being dissolved by water, there is the further possibility that even a slight excess of ammonia may increase the quantity of quinine removed in solution, for, as is well known, the solubility of quinine in weak ammonia is so considerable that Kerner has proposed to estimate the other alkaloids in quinine sulphate by a method based on the relative solubility of quinine and other alkaloids in ammonia. But these facts are generally allowed, and it is with the statement that ether fails to extract quinine in presence of ammonic citrate that I wish particularly to deal.

When the liquid containing quinine has been shaken with ether and ammonia, there is always some ether retained in solution by the lower layer, and consequently some alkaloid is dissolved in it, so that unless this liquid be again shaken with a fresh quantity of ether there will be some loss, and incorrect results will be obtained. I am disposed to believe that this was really the cause of the discrepancies observed by Mr. Palmer, not only from my own experience of the use of ether, but also from the fact that in the case in point, the substratum was said to be very bitter besides having a strongly ethereal smell. If the plan I have indicated be followed there will be no bitter taste whatever in the aqueous liquid.

In repeating Mr. Palmer's experiments the following results were obtained from one and the same sample of Ferri et Quiniæ Citras. One gramme was taken in each case, and dissolved in 30 c.c. of water, the solution was then shaken in an ordinary separating funnel, with 10 c.c. of the solvent employed, and with ammonia in sufficient quantity to precipitate the whole of the alkaloid. The alkaline liquids in both cases were again shaken with the respective solvents. The total ethereal or chloroform liquid was then evoporated to dryness and the residue weighed.

	P. Cent.
(1) Residue from Ether . . .	12·9
(2) „ „ Chloroform .	13·35

As the citrate of iron and quinine operated upon had been kept for some time, the results are possibly abnormal as regards the amount of quinine. The sample when dried gave 8·97 per cent. of water, and this gives an expression to the results of—

	P. Cent.
(1) Residue from Ether . . .	14·17
(2) „ „ Chloroform .	14·66

In any case it appears that the difference between the results obtained with ether and with chloroform is very small.

These two experiments though not made with extreme care are sufficient to show the fallacy of the views put forward in the paper referred to, and they lead to the conclusion that even in the presence of ammonic citrate, ether will extract the whole of the quinine. As that was the only point intended to be elucidated, I have not dealt with the unadvisability of weighing the residue left by ether or chloroform and regarding that as pure quinine, but will reserve the consideration of this point for a future communication.

By the kindness of Dr. Paul these experiments were made in his laboratory.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 4.)

ACACIA CATECHU.—*Local name*, KHEIR.

Impure catechuic acid or keersal obtained from cavities in the wood, occurs in small irregular fragments like little bits of very pale catechu mixed with chips of reddish wood, the fragments often adhering closely to the wood. This drug is collected by men who split firewood and fetches a high price as it is only occasionally met with; it has a sweetish very feeble astringent taste, and under the miscroscope is seen to be composed of minute needle-shaped crystals. When placed in water the colouring matter of the particles of wood mixed with the drug communicate a red colour to it. Keersal is soluble in boiling water, but is thrown down in conglomerate masses of small needle-shaped crystals upon the water cooling; it is also soluble in rectified spirit and is deposited in the same form on the spirit evaporating. In native practice it is valued as a remedy in chest affections, and is thought to promote expectoration.

STRYCHNOS NUX VOMICA.—*Local name*, KAJRA.

The wood Goagurree or Kajra che lakor. Nux vomica wood is too well known to require description; it is commonly met with in the Bombay shops in sticks about 14 inches long, and from 1 to 1½ inches in diameter with the bark on. It is quite a domestic medicine among the Bunnias. When a tonic is required a small portion is brayed upon a stone and administered; its efficacy is supposed to be much increased by the addition of a piece of the kernel of the coco-de-mer (Lodoicea). There is no doubt that the preparations of nux vomica are particularly valuable in the atonic complaints so common in a hot climate.

FAGONIA MYSORENSIS.—*Local name*, DUMASO.

The whole plant is commonly kept in the shops, it is suffrutescent, much branched, with opposite, two stipuled leaves; the stipules are often thorny, leaflets linear cuspidate; the wood of the stem is white and very hard, covered by a ragged light brown bark, which becomes slimy and mucilaginous when moistened. Dumaso has no particular taste; it is used to prepare a cooling wash for the mouth.

CUSCUTA REFLEXA.—*Local name*, AKASWAIL.

A common parasite on bushes; it consists of a tangled mass of tough dark green stems, branched, marked longitudinally with delicate pale green lines; the largest are the size of a crow quill; the branches are provided with small round suckers like those of the common dodder. Sections of the stem show a strong fibro-vascular layer and loose central pith. The fruit is globular, of the size of a pea, and surmounted by the remains of the sepals; on removing the outer envelope of the fruit, which is leathery, an inner envelope is exposed which consists of two layers, the outer cartilaginous, the inner fleshy and lined with white hairs, each containing a delicate spiral filament; within this central cavity is a third delicate membranous envelope covered with hairs of a similar description and containing the seeds, it is not in contact with the second envelope except at the base and apex. Akaswail is used in native practice as an alterative in bilious affections and for piles.

CALOPHYLLUM INOPHYLLUM.—*Local name*, WOONDY.

The oil of the seed Woondy che tel; the resin Woondy cha gond. This tree grows in the neighbourhood of Bombay; the fruit is ovoid and green; it varies in size; on old trees it is often as large as a bantam's egg; the pulp surrounding the nut dries up when the seed is mature, and the previously smooth skin covering it becomes brown and much wrinkled; the endocarp is hard, woody, and white, as thick as the shell of a filbert; within it is an inner endocarp, soft and corky, of a red colour, thicker than the woody shell towards the apex of the fruit, but gradually becoming very thin towards the base; the inner surface of this layer is highly polished. The seed is of the same shape as the nut; it is very oily and has somewhat the taste of a rancid filbert; it consists of two cotyledons very closely united; under the microscope a stroma of small ovoid cells is seen through which numerous large vessels loaded with green oil run in a longitudinal direction. The green oil is valued as an application in rheumatism; it is also used for burning. The resin of *C. inophyllum* is translucent, of a greenish yellow colour, softening and becoming sticky when handled. It has an odour like parsley. I have not been able to ascertain that the resin is ever collected for sale in Bombay, or that any use is made of it by the country people.

IPOMÆA PES-CAPRÆ.—*Local name*, MURJA DEVI.

A perennial plant with a tough woody root as thick as the finger and many feet in length; it abounds in the sand on the sea shore; from the enlarged crown of the root grow a number of creeping stems, fleshy and purplish when young, but becoming woody as they mature; the shape of the leaf is indicated by the name of the plant; a section of the root shows in the central portion five wedge-shaped bundles of fibro-vascular tissue; external to these is a row of laticiferous vessels full of a viscid yellow latex, then again come a number of irregularly placed fibro-vascular bundles, and external to them another zone of laticiferous vessels. The cellular structure of the root contains starch and large conglomerate raphides. The whole plant is mucilaginous and is used externally in rheumatism in the form of decoction and internally in colic.

ALSTONIA SCHOLARIS.—*Local name*, SATWEEN.

The bark Satween che sal described in the 'Pharmacographia.' It is sufficiently remarkable from its large stony cells and wavy medullary rays. The tree abounds in the hilly districts at a short distance from the coast. The bark is much esteemed by the natives as a bitter tonic, but I have not seen it used in European practice. The discovery of Ditain will probably lead to its value being properly tested.

TERMINALIA BELLERICA.—*Local name*, YELLA.

The gum Yella cha gond. In vermicular pieces about the thickness of the finger, of the colour of inferior gum arabic. Hardly at all soluble in water, in which it swells up and forms a bulky gelatinous mass; its taste is insipid. I make no mention of the fruit of this tree, as it is well known.

HYMENODICTYON OBOVATUM.—*Local name*, SUFED KURWAH; and H. EXCELSUM.—*Local name*, KALA KURWAH.

Both of these trees grow in this neighbourhood, and both yield a bitter bark in common use among the natives as a tonic. The bark of *H. excelsum* is much the most bitter and may be distinguished from that of *H. obovatum* by its red colour; it is probably the most valuable, but I am not aware of either of the barks having been properly tested in European practice. The minute structure of these barks resembles that of the cinchonas, but the bundles of liber cells are larger, especially in *H. obovatum;* the spiral and laticiferous vessels also are more numerous, the latter being very large in *H. obovatum*, and exuding when cut a waxy latex. In *H. excelsum* many of the cells are filled with a red colouring matter as in cinchona bark, and there is a continuous ring of liber cells near the junction of the bark with the wood; the liber cells in both varieties exhibit a large central cavity. The bark examined was from a branch about one inch in diameter.

(To be continued.)

FURTHER NOTES ON OLIVE OILS.

BY W. GILMOUR.

In my last communication on the spectra of olive oils (*Pharmaceutical Journal*, 8th July), it may be remembered I confined my observations entirely to the variations to be found in ordinary commercial oils. Out of eighteen different samples (the number which I have examined altogether is very much greater) specified in the table,* no two may be said entirely to coincide, although several very closely approximate. Without attempting in the meantime to account for all the phenomena embraced in this diversity, there are still several features in this oil capable, under certain circumstances, of being developed, not without some general interest, apart altogether from any direct bearing which they may have on the points hitherto considered.

Olive oil, it need scarcely be mentioned, unlike most oils derived from the vegetable kingdom, is principally obtained from the pericarp. The ripe fruit is collected into heaps and allowed to stand for a few days until thoroughly softened, and the oil is then removed by gentle pressure. When thus obtained it is called virgin oil, cream oil, etc., and has a pale greenish yellow colour, with a peculiar sweetish nutty smell and flavour. It requires to undergo no process of clarification, with the exception of allowing it to settle gradually on the lees in the cisterns or jars into which it has been conveyed from the press.

So far as the finest oil is concerned there are several circumstances which doubtless very materially affect its nature as well as its quality (whether considered chemically or optically), and they must be given effect to in any attempt at creating a standard of comparison. The district in which the olives are produced, the season, whether in early autumn or later during the rains, in which the fruit is collected; the length of time that it is exposed previous to pressure, and the amount of heating and fermentation which it has in consequence undergone; the direct application of heat in the process of extraction, and above all probably the general care bestowed upon the whole operation, whether of pressing the fruit or storing the oils, are all modifying influences more or less directly affecting the oil produced. But apart from this, there are also inferior oils to be met with, obtained by other processes from the refuse of the finer oils. The cake or marc for example from which the finest oil has already been extracted is treated with hot water, from the surface of which a second and inferior oil is ultimately skimmed, or the marc is allowed thoroughly to ferment and is then treated several times with hot water and subsequent pressure, etc. These oils are frequently refined by agitating with a saturated solution of caustic soda, which converts them into a soapy mass from which a kind of saponaceous deposit is ultimately precipitated, the oil then floating on the surface clear and pure. Oils, it will thus be seen, may be genuine olive oils in respect that they have undergone no direct sophistication, and yet exhibit an almost endless variety of qualities. Are there, then, any limits within which good oil may be circumscribed, or any distinctive feature whereby an inferior oil may be readily recognized?

In answer to this, and without wishing to dogmatize on a matter which is to a considerable extent in the meantime beyond proof, I can only, after still further experiments, re-affirm of olive oils, what I have already said of fixed oils in general, namely, that I think it more than probable that the spectroscope will yet be able to afford very great assistance in disclosing something of their nature and history. An oil, for example, which showed no absorption bands I might have no hesitation in altogether rejecting, whilst on the other hand, one that had all the bands very distinct and dark I might look upon with considerable suspicion. Here we have, as it were the two extremes, and yet it must be confessed that two such oils as I have just imagined, might both, at the time of examination, be commercially good and genuine oils, according to the construction which we have already put upon the term, whilst a third, which showed the bands in what I consider their characteristic form, might altogether be an inferior or even an adulterated oil. The whole subject is fraught with difficulties similar to this, and in such circumstances the error consists in assuming that the spectroscope is *the* means and *the only means* for their detection, and ignoring it altogether on finding it is only a help, when from its very nature and the nature of the subject it probably can never be more.

The two cases however, which I have here, put of an oil with no bands, and one with bands very decided, are not altogether imaginary. I would look with considerable suspicion on the one with all its bands very dark, even when otherwise assured of its genuine nature, from the fact that I have found such oil, on further examination and testing generally, to be of inferior quality; and I would reject the other with no bands, even when assured of its being the finest virgin oil, from the fact that I have ascertained this to be the first stage of a chemical change in the nature of the oil. If now on the other hand, I had no assurance as to the original quality of the oil, I have in this case a double cause of suspicion or rejection, as it may happen, for now I would have in addition to my original doubts (I purposely refrain from putting it stronger) all the uncertainty of adulteration. In these circumstances, it is not, I think, unreasonable to say that we have surely here the limits within which a good oil may be recognized, or an inferior one altogether rejected.

(1) *Oils with bands very dark and of some considerable breadth.*—Chlorophyll, the substance to which these bands owe their existence, is the green colouring matter present in the leaves and other parts of plants. According to Lommel (*Pogg. Ann.*, cxl. iii. 568) the spectrum of even a dilute solution exhibits—1, a broad dark absorption band close behind B; 2, another band in the orange between C and D; 3, a third band a little behind D; and 4, another in the green close before E. In the case of all the oils which I have examined, only three of the bands at the most have been visible, and of these 1 is by far the darkest and most persistent, 3* being next in order, whilst 2 has been in most cases exceedingly delicate, and in several quite wanting. These bands are permanent so far as regards their position, but they vary very considerably, both as regards intensity and breadth, with the strength of the solution. Chlorophyll being soluble in most oils its presence in olive oil is readily accounted for, and the intensity and breadth of the resulting bands will of course depend upon the amount held in solution by the oil. This amount may probably vary according to the time at which the fruit is collected, the process of extracting the oil, or the amount of pressure applied in its extrac-

* See *ante*, p. 22.

* Through some obscurity in the original manuscript I placed the band in the diagram of the first paper before F. This is corrected in the second.—W.G.

tion. The last two conditions, judging from the intensities of the bands in all Gallipoli and other inferior oils which I have examined, and on which I could depend to any degree, are those most likely to affect the amount of chlorophyll in any given sample. At least, I have seldom failed to find that in most inferior oils, in their natural state, its presence was generally very marked so far as all the three bands were concerned. There are undoubtedly many inferior oils to be found with bands varying in degree down to ultimate disappearance, but such oils are not in what I have here called their natural state. They have either inherently or artificially undergone some change, and it is so far fortunate (avoiding, as it does, any complication) that the change is altogether, as we shall immediately see, in the direction of attenuation. The bands may be reduced in intensity and breadth, they may be modified in character, or even in certain cases so far changed in nature as to become split into two, but no extraneous agency has yet been found able to act in the opposite direction, and therefore, though an inferior oil may optically take the place of a superior one, the process cannot, so far as is yet known, by any possibility be reversed.

(2) *Oils with no bands.*—But if the process cannot be reversed, it must be confessed there seems practically little difficulty in the elevation, optically, of a very inferior oil to the position of a superior one. Caustic soda, which I have already indicated as being used extensively as a refining agent, together with caustic potash and heat, all exert a decidedly softening and refining action on the oil itself, whilst on the bands they have also a peculiar modifying influence. According to Chautard an alcoholic solution of chlorophyll mixed with a few drops of solution of caustic potash or ammonia is very little changed, but by boiling with solution of caustic potass the characteristic absorption band in the red is divided into two, whilst the rest of the bands disappear almost entirely. In the case of olive oils, however, I have invariably found that on being thoroughly incorporated with any of the caustic alkalies, even for a short time the bands thin very considerably, and if the action is continued the more delicate of the bands very quickly disappear altogether, and ultimately, though much more slowly, band 1 itself. I have little doubt from all my experiments that this action is accompanied and very probably hastened by some change in the constituents of the oil, but whether it is caused entirely by the action of the alkalies, or by the alkalies with atmospheric influence and exposure combined I have not been altogether able to determine. I am, however, inclined to think from the very powerful influence exerted by the latter on olive oils that they have as much to do with it as the former.

Six hours' exposure in direct sunshine, for example, in a bottle hermetically sealed, I found removed permanently every trace of a band, and otherways altered very materially the spectrum of what I have reason to believe was a pure virgin oil. This experiment was repeated with a second and third "cream" oil with the same results, and in none but the last only, which had assumed a slight cloudiness, was there to be detected, on even a minute examination (I refer to an ordinary examination), the least apparent change in colour, smell or taste. With an inferior oil, such as I have already described, under the same conditions the two more delicate bands had disappeared but the first was very broad and dark, while the oil itself had faded perceptibly in colour. Next, exposing the finer oils in an open vessel the action was found to be essentially the same only much quicker, and at the end of six hours the oils had paled somewhat in colour, and in addition had acquired a peculiar biting flavour, the first external indication of a somewhat important change in their nature and constitution. L. Moschini ('Gayzetta Chimica Italiana,' i. 580) refers to this change. He remarks, that, "Olive oil in its natural state contains in solution a yellowish substance which, when the oil is treated with acids or with caustic soda gives rise to the well known greenish colouration. By exposure to sunshine this colouring matter is essentially altered, the oil being thereby decolorized and no longer exhibiting a greenish colour when treated with the reagents above mentioned. Moreover, other changes take place at the same time in the constituents of the oil, the olein in particular being greatly altered, and acquiring the fundamental property of *elaïdin*, namely, that of not solidifying in contact with nitrate of mercury mixed with nitrous products. At the same time free acids are formed and the oil acquires a rancid taste and odour. From these results it appears that the method suggested by some authors of distinguishing olive oil from other oils by means of sulphuric acid, caustic soda, and nitrate of mercury, can be depended upon only when the oil is in its natural state, not altered by exposure to sunshine." The importance of the spectroscope as a means of detecting this change in the oil need not be commented upon.

When the oil is continued under exposure for several days the spectrum at the violet end undergoes a most peculiar modification. It is not only considerably elongated, but immediately behind F there also appears a dark shading—it can scarcely be called a band—extending over a considerable space and most intense towards the violet end. Whether this is only one of the characteristics of a chlorophyll solution mentioned by Lourmel when he says "that just before G the absorption is somewhat weaker, increasing again behind G," or one of the many peculiarities of it when modified or decolorized I can scarcely yet say. I have, however, only met with it in those oils which from exposure have undergone some considerable change and which have in consequence exhibited the somewhat high smell and flavour accompanying it.

There are several other features not without interest which might have been here referred to, but as these would have necessitated to a certain extent retracing ground already gone over in previous papers, I have purposely avoided them, and rather confined my observations within the limits originally intended. I cannot, however, avoid again noticing the very important assistance which it is quite apparent from all the foregoing, the spectroscope can yield us in determining the quality of an olive oil. These experiments have brought out amongst other things the close relationship there is existing in this oil optically and chemically, and probably no test will be found so delicate, so certain, or so simple, as the spectroscope in detecting even the primary stages of a decomposition, somewhat extensive, as well as interesting in its nature, and which has hitherto it must be confessed, frequently tried both the skill and the patience of the chemist.

ON CHEMICAL NOTATION.*

BY M. M. PATTISON MUIR, F.R.S.E.,

Assistant Lecturer on Chemistry, The Owens College, Manchester.

(*Continued from page* 100.)

This statement merely generalizes a vast number of observed facts. Unless we are to take the results of each individual experiment as expressive of the exact truth as regards the composition of the substance under examination, in which case a science of chemistry would be impossible, we must accept such a statement as this. As our chemical notation is founded on this generalization from facts as one of its main supports, it follows that the results of future experiments in the direction of tracing the exact steps of chemical action, and of measuring the various forces which there come into play, whatever the results may be, cannot overthrow our present system of notation; they may cause us to modify it greatly, perhaps so greatly that one who had been accustomed to the old would hardly recognize the new notation as in any way connected with it. Nevertheless we may be certain that the process will involve no breach of continuity.

20. But I must now pass on to consider chemical notation in the light of that theory which appears to me to explain the best-known facts of material science in a more thorough and satisfactory manner than any which has yet been proposed: I mean the Molecular Theory of Matter.

21. And in the first place I would insist upon the truth of Dr. Wright's remark (*loc. cit.*), that neither this theory nor the atomic theory, generally so called, is taken for granted in the formation of chemical equations, or in the general methods of chemical research. The meaning of the words "atomic theory,"and the distinction between the generalization and convention upon which our chemical notation is really based, and the hypothesis upon which it is so often *said* to be based, are so ably pointed out by Dr. Wright in the paper referred to,† and in a previous paper, that I need do no more than refer any one who wishes for clear ideas on the subject to those papers.

22. Premising, then, that chemical notation does not assume the existence of "atoms," but admitting that if the atomic hypothesis were granted the existing chemical notation would readily adapt itself to the necessities of an atomic notation, let me pass on to consider some of the reasons which appear to me to favour the adoption of the molecular theory of matter. "A molecule may be defined as a small mass of matter, the parts of which do not part company during the excursions which the molecule makes when the body to which it belongs is hot." This quotation from Professor Clerk Maxwell's 'Treatise on the Theory of Heat,' gives a clear definition of what is meant by the term molecule. The theory in question supposes that any given piece of matter consists of a definite number of molecules, that all the molecules of the same substance contain the same quantity of matter, that a molecule may consist of "several distinct portions of matter held together by chemical bonds," and, finally, that "the molecules of all bodies are in a state of continual agitation."

23. The molecular theory of matter is to be distinguished from a theory which would assert that there is an absolute limit to the divisibility of matter. What the theory asserts is, to use Professor Maxwell's words, "that after we have divided a body into a certain finite number of constituent parts called molecules, then any further division of these molecules will deprive them of the properties which give rise to the phenomena observed in the substance."

24. The "Daltonian atomic theory" cannot of course be regarded as identical with that which I have just sketched. It appears to me, however, that the atomic theory of the chemist is based upon and is an outcome of the molecular theory of the physicist, and that we can only rightly understand the former when we have gained a knowledge of the latter,—in fact that the atomic theory, so called, is implied in the molecular theory of matter, and stands or falls with it.

25. One of the objections raised by Dr. Mills* against the atomic (and therefore, it appears to me, against the molecular) theory of matter is, that this theory is not a result of inductive reasoning. An objection, in principle the same, is stated in his papers already referred to (*Phil. Mag.*, Jan. 1876), in these words (he is speaking of the examination of natural phenomena) :—"Instead of demanding a theory, it would be better to ask how we could dispense with one. It is juster and wiser to adhere to facts than attempt to transcend them."

In making such statements as these, it appears to me that Dr. Mills has misapprehended the method by which science gains her finest results. That method, I would make bold to say, is not entirely an inductive one; it makes use likewise of deductive reasoning. Science begins with facts; by observation and experiments she accumulates facts; by a proper use of imagination she frames hypotheses to account for the facts; and by subsequent appeal to facts she proves or disproves the truth of her hypotheses. Had science dealt with facts by strictly inductive methods only, she would never have been able to rise to those general expressions which we call laws. Hypotheses must be framed if science is to make any advances. Given a large number of facts, it might be possible, by arranging these in all possible combinations, to arrive at last at a proper classification; but this method is utterly impracticable, because of the vast number of data to be dealt with. It may be affirmed with a considerable amount of certainty that every great advance in science has been made by the use of hypotheses. Newton professed not to deal with hypotheses; but what is the 'Principia' but the record of wonderful discoveries which became possible only by the greatest freedom in theorizing? Kepler theorized; Hooke asserted that the natural philosopher must be ready to guess the solution of many phenomena; Sir Humphry Davy did not despise hypotheses; and who made freer use of his imagination than Faraday?—the greatest of all experimental philosophers. In framing hypotheses we must see that they agree with facts; in other respects they may be as inconceivable (not self-contradictory) as any fairy tale. The suppositions involved in the theory of gravitation, and in the undulatory theory of light are seemingly sufficiently absurd; in the latter theory we are compelled to imagine the existence throughout space of a so-called æther, possessed of the highest elasticity, and at the same time more solid than steel! Dr. Thomas Young even imagined (and it would appear that we cannot deny the possibility of his imaginings being true) "that there may be independent worlds . . . . pervading each other, unseen and unknown, in the same space" (I quote from Professor Jevons' work on the 'Principles of Science).' Provided that a theory does not go against the primary laws of thought and of Nature, we must accept it, however absurd it may appear, if it be in accordance with facts. But in applying the deductive method of scientific reasoning, we are apt to forget that a theory, however perfect and satisfactory it may appear, is to be put to the severest test; it is only by showing that the known facts are explained by the theory, by foretelling facts which must be facts if the theory be true, and again by showing that these are indeed true, that a scientific theory can pass successfully into the number of accepted hypotheses. Newton's method of treating the theory of gravitation, and Faraday's method throughout his magnificent series of 'Experimental Re-

* From the *Philosophical Magazine* for July, 1876.

† *Phil. Mag.* [IV.], vol. xliii. p. 503.

* 'Laboratory,' 1867, p. 6.

searches,' are typical examples of the true positions of Theory and Fact in scientific investigation. If it can be shown, therefore, that the molecular theory is not in accordance with facts, or is self-contradictory, it must be discarded; but to refuse to accept it because it has not been gained by purely inductive reasonings is simply, it appears to me, to show an ignorance of the true method of scientific investigation.

26. In examining the position of the molecular theory of matter as a scientific hypothesis, I would inquire —Is it in accord with known facts? does it enable us to explain what would else appear to be disconnected phenomena? and we are able by its aid to predict phenomena which are afterwards proved to be true? In the following statement concerning the physical proofs of the molecular theory, I have drawn largely from Professor Clerk Maxwell's 'Treatise on Heat.'

27. The molecular theory is in accord with known facts concerning the condition of hot bodies.

A hot body possesses a certain amount of energy. This energy is capable of being changed from potential into kinetic energy; but such a change involves motion of some kind. When a hot body loses heat by radiation, this radiation must be effected either by the motion of material particles from the hot body to the body which receives the heat, or by the motion of some medium which fills the space between the body giving out and the body receiving heat; hence the particles on the outer surface of a body radiating heat must be in a state of motion. But hot bodies are continually radiating heat; therefore their outer particles must be in a state of continual motion; hence part, at least, of the energy of a hot body exists in the form of kinetic energy. But the motion of the particles of a hot body cannot be the motion of the body as a whole; otherwise the motion would be visible to us; it must be the motion of exceedingly small parts: hence arises the conception of molecules, *i.e.*, of small parts which remain intact during the movements which each part makes when the mass of the body to which it belongs is hot.

28. Again, the molecular theory is in accord with known facts concerning diffusion. If two gases be arranged in distinct strata, it is found that in a short time the presence of that gas which was at first confined entirely to the lower stratum is perceptible in the upper stratum, and *vice versa*; further, it is found that if a stratum of gas be issuing through another gas which is at rest, the movement of the former tends to communicate itself to the latter, which, in its turn, reacts upon the moving gas, tending to bring it to rest. Again, if the upper stratum of a gas be heated, it is found that the heat is communicated to the lower stratum. We have here, then, three kinds of diffusion—diffusion of matter, diffusion of momentum, and diffusion of energy. As we have learned to think of small parts of a body in a state of motion, we may extend the idea to the phenomena of diffusion, and imagine the little parts of the two diffusing gases becoming mingled together in the diffusion of matter; we may imagine the particles of the moving stratum of gas passing upwards and downwards into the surrounding strata of gas at rest, and hence having their motion partly checked, while they in turn communicate somewhat of their motion to the particles of the surrounding gas; and we may imagine, finally, the communication of heat from one part of a heated gas to another by the diffusion of the heated particles of the gas. But the rates of these diffusions are slower in liquids than in gases, especially the rate of the diffusion of matter, which is slowest of all (if, indeed, it takes place) in solids. Why is this? Because these little particles of molecules (their existence being granted) have not in solids the same freedom of motion which they have in liquids, in which, again, they have less freedom of motion than in gases. Although the particles of solids are not possessed of the same freedom of motion as is granted to those of liquids, yet we can easily see how there may be a rapid diffusion of energy from particle to particle, and hence can understand the fact that rapid diffusion of heat through solids is so often noticed.

29. Again, the molecular theory is in accord with known facts concerning evaporation and condensation.

If we grant that a gas consists of a number of molecules in a state of motion, we must believe that these molecules will from time to time come into collision; hence, even if their initial velocity be the same, an inequality of velocity will be produced. In a liquid the average velocity of the molecules must be smaller than the average velocity of the molecules in a gas; nevertheless this does not prevent us from believing that the velocity of individual liquid molecules may be greater than that of individual gaseous molecules. Supposing that liquid molecules of such great velocities are moving at the surface of the liquid *from* the liquid, they will tend to escape from the liquid into the surrounding vapour. Supposing that a gaseous molecule of great velocity strikes the surface of the liquid, it will tend to become entangled in the liquid. Hence we shall have evaporation of the liquid and condensation of the vapour going on continuously.

30. So also I might go on to show that many of the facts of spectroscopy are in keeping with the molecular theory—that the vibration of each molecule may well be supposed to communicate itself to the ether in a regular manner, that an increase in density of a gas will cause the introduction of irregular motion among the molecules, and hence the appearance of a more or less continuous spectrum; but, for a consideration of the bearings of the molecular theory of matter upon the explanation of spectroscopic phenomena, I must refer to a lecture by Mr. J. Norman Lockyer, reported in *Nature*, vol. x. p. 69.

31. In those points which I have briefly touched on, the molecular theory is, it appears to me, not only in accord with known facts, but it also enables us to group together and so to explain what had appeared to be isolated phenomena. But this theory does more than this: we can deduce from it certain conclusions which may then be proved true by experiments. Thus the law of Boyle, the law of Charles, and the law of Gay-Lussac may be deduced from a consideration of the dynamical conditions which must prevail among a group of particles supposed to constitute the mass of a gas, the pressure and temperature of which vary from time to time.

32. It has been possible to predict certain results from a consideration of phenomena viewed in the light of the molecular theory, which results have afterwards been verified. Thus the rate at which diffusion of energy must take place through air when one portion is heated was predicted from data derived from experiments on viscosity. The actual measurement of the diffusion-rate, made by Professor Stefan, of Vienna, has proved to be in close agreement with the predicted rate.

33. If we interpret chemical notation in the light of the molecular theory, we assume that the symbol of each chemical substance represents a molecule of that substance, and that chemical equations represent the results of the mutual actions of molecules. The relative weights of molecules are therefore assumed to be represented by our chemical symbols. In order to deduce such weights with accuracy, we are obliged to determine the relative densities of the substances in the form of gas, and to assume the truth of the law of Gay-Lussac or of Avogadro. But this law can be deduced from the molecular theory of matter; hence, when we speak of "molecular weights," we assume the truth of the molecular theory; and I therefore think that it behoves us to know what this theory really is, and on what physical grounds it can be upheld.

34. I have already stated that the ordinary chemical notation does not appear to me to necessitate the assumption of the existence of molecules; but, granting that matter has a molecular structure, this notation will readily lend itself to the needs of such a theory. Can we, however, with equal facility explain the general pheno-

mena of chemical action in terms of the molecular theory of matter?

35. The definition of a "molecule" quoted from Professor Clerk Maxwell's work does not prevent one from imagining an inner structure for such molecules. We may think of one of these little parts which holds together while the body to which it belongs is hot as made up of a greater or less number of still smaller parts, parts either of the same or of different kinds of matter. In the conception of such smaller parts we have the idea of chemical atoms. Now it may legitimately be supposed that during the excursions which molecules are ever making, some of them will be so knocked about as to have their atomic structure disarranged; under ordinary circumstances this disarrangement will quickly be restored; but if a new force be called into play which shall act by increasing the tendency to molecular disaggregation, we shall have a more or less complete decomposition of the original molecules, attended, of course, with the production of new molecules. The electrolysis of liquids may be regarded as a directive action exercised by electromotive force upon those molecules which have undergone disaggregation by clashing together; whereby one component part of the disaggregated molecule is directed in one direction and another in another direction.

36. So also the phenomenon of dissociation meets with an explanation in terms of the molecular theory by supposing that at high temperatures the clashing of molecules is carried on so violently that more molecules suffer decomposition in a unit of time than are able to regain their original structure. Dissociation is then explained as a "change in the configuration and motion of a material system."

37. If this view of intramolecular action be adopted, we must regard chemical action as constantly taking place. To use Dr. Mill's words (*Phil. Mag.*, Jan. 1876), "Chemical action can begin, because it never has ceased."

38. Suppose, however, that the molecules of a given substance A come into contact with those of another substance B, and that these substances are capable of exercising chemical action upon each other, we shall have an interchange of "atoms" between the molecules A and B; at any moment, therefore, we shall have four kinds of molecules present—A and B, the generating substances, and A′ and B′, the products. We shall have an exchange of atoms taking place between A and B, an exchange of atoms taking place between A′ and B′ (and possibly an exchange of atoms taking place between A and A′, and between B and B′, etc.). Now the final condition of atomic distribution among the reacting molecules will depend chiefly upon the rate of atomic interchange; if more changes take place between the atoms constituting the molecules A and B than between the atoms constituting the molecules A′ and B′ in equal times, it is clear that an increase in the number of the molecules A′ and B′ will take place; and conversely, if more atomic changes take place between A′ and B′ than between A and B in equal times, the number of A and B molecules will increase; in other words, the decomposition of A and B will cease. Again, if by any means it is possible to remove the newly formed molecules A′ and B′ from the sphere of action, then the atomic interchange represented by the equation $A+B=A'+B'$ will proceed until A and B have entirely disappeared, and the sum of the weights of A′ and B′ is equal to the original sum of the weights of A and B. Such an action as this very generally takes place in ordinary chemical reactions. For instance, the equation

$$BaCl_2+Na_2SO_4=2NaCl+BaSO_4$$

represents the final atomic arrangement of the molecules taking part in the reaction; but we must imagine that a secondary reaction, symbolized thus,

$$2NaCl+BaSO_4=Na_2SO_4+BaCl_2$$

also takes place, but only to a very limited extent, because the molecule $BaSO_4$ is removed from the sphere of action almost as quickly as it is produced. It is true, as has been urged, that the equation $Zn+H_2SO_4=ZnSO_4+H_2$ has never been rigorously realized in practice. Why? Because, before the atomic interchanges symbolized are completed, so many molecules having the composition $ZnSO_4$ have been formed, and have *not* been removed, that the completion of the change becomes impossible. Remove the products of the action, however (as is actually done in general practice), and the equation represents the final atomic distribution. Yet, although the equation does not express everything that occurs when zinc and sulphuric acid are mixed together, it does express the great fact that a definite quantity of zinc is invariably associated with definite quantities of sulphur and of oxygen in the production of the substance called sulphate of zinc. (For a further discussion of this subject see the address of the President, Dr. Williamson, to the British Association at Bradford, 1873.)

39. Further, such atomic interchanges will involve changes in the form of the energy of the reacting molecules: potential will be converted into kinetic energy, or *vice versâ*. Such changes will be marked by absorption or by evolution of heat. These energy-changes will certainly bear a close relation to the general character of the products of the reaction. Thus evolution of heat (stoppage of molecular motion of some kind) is accompanied with the production of a substance whose "affinity-value" and whose boiling-point are higher than those of the generating substance (Wright, *Phil. Mag.*, Dec., 1874).

40. Now this change in the form of energy will be dependent upon a change in the relative position of the parts of the material system, the energy of which is changed; hence the mere fact of "heat-disturbances" taking place in chemical reactions is in perfect keeping with a molecular theory of matter.

41. But certain special cases of heat-disturbance have been cited as being apparently inexplicable in terms of the molecular theory. Thus Dr. Wright* brings forward the fact that there is a change in the form of energy of the material system accompanying the exchange of matter symbolized by the equation $H_2+Cl_2=HCl+HCl$ as opposed to, or at least as being probably incapable of satisfactory explanation by the molecular theory. He holds that, "granting that the substitution of chlorine for hydrogen is attended by a given change of motion, the inverse substitution must be accompanied by the opposite change." He supposes that in the reaction under notice an atom of chlorine in the chlorine molecule is replaced by an atom of hydrogen, while an atom of hydrogen in the hydrogen molecule is replaced by an atom of chlorine, and that "those complementary changes should cause, on the whole, no difference as to the ultimate amount of motion in the two original and the two resulting molecules." It appears to me that Dr. Wright has here assumed that two equal and opposite actions, called by him "substitution" and "inverse substitution," are taking place. It would, I think, be more in accord with the molecular theory to suppose that there is taking place so rapid an atomic interchange among the molecules both of hydrogen and of chlorine, that when these two substances are brought together, under suitable conditions, it is easy for the momentarily dissociated atoms to combine together so as to form the new molecules of hydrochloric acid, and that when these are formed there is not so rapid an atomic exchange taking place among them as there is among the molecules of the generating substances. The general result of such an action, so far as change of energy is concerned, would therefore be an evolution of heat. Indeed, the fact that it is possible to completely carry out the reaction symbolized above, appears to me to be in perfect keeping with the fact of the evolution of heat which is noticed during the reac-

* *Phil. Mag.* [IV.] vol. xliii. p. 511.

tion; for if the number of atomic exchanges between the products HCl HCl were as great as those between the generating molecules H_2 Cl_2 in equal times, the decomposition would cease before the equation was completely realized. But the actual result points to the conclusion (on the assumption that the molecular theory is true) that there are less rapid intramolecular movements occurring in the case of the molecules HCl HCl than in the case of the molecules H_2 Cl_2—in other words, that some portion of the initial molecular motion has disappeared. But inasmuch as the total energy of the system is supposed the same, the energy which has disappeared in one form must have reappeared in another; it *has* reappeared as heat.

42. Lastly, as to isomerism. So called isomeric bodies undergo different reactions; they are produced by different reactions, etc.; these facts may be expressed irrespective of any theory as to their cause, by means of structural or dissected formulæ. It has been supposed that isomerism is to be explained by imagining that the atoms are differently arranged in isomeric molecules. Again, it has been supposed that isomerism is to be explained by granting that isomeric bodies are endowed with varying amounts of energy, that in the formation of these bodies different quantities of energy change form, and that, conversely, the various reactions noticed with isomeric substances are to be traced to different degrees of conversion of one form of energy into another. Dr. Mills (*loc. cit.*) says, "to measure, both in quality and in quantity, the energy associated with each isomeric substance, is to give a complete account of the phenomenon of isomerism." Not, it seems to me, to give a complete *dynamical* account of the phenomenon of isomerism; for it is only when we explain a phenomenon as a "change in the configuration and motion of a material system," that we give a complete dynamical explanation of that phenomenon. If isomerism depends on changes of potential energy, we must remember, to quote Professor Clerk Maxwell ('Treatise on Heat,' p. 283, 1st ed.), "that potential energy depends essentially on the relative positions of the parts of the system in which it exists, and that potential energy cannot be transformed in any way without some change of the relative position of those parts."

Hence I think that the energy theory of isomerism is not altogether inconsistent with the position theory, and that both meet with their fullest development in terms of the molecular theory of matter.

43. I have thus attempted to show that our ordinary chemical notation is founded on facts, that it gathers together and symbolizes a great many phenomena, that it does not necessarily imply the acceptance of any theory as to the constitution of matter, but that it receives its fullest meaning when viewed in the light of the molecular theory. I have further briefly endeavoured to point out some of the deficiencies of chemical notation, but have expressed a belief that when the present system is superseded by a better, the new will be the legitimate outcome of, and will not be in any fundamental point opposed to the old.

LACTIC ACID, ITS USES AND ITS PREPARATION.

Lactic acid was recommended ten years ago in France, by Bricheteau and Adrian, for inhalation in the atomized state in order to dissolve croup-membranes of the larynx, so that they might be moved by coughing. The use of such inhalations after tracheotomy in croup by continental surgeons is said to have been attended with very favourable results. French observers have found that the false membranes were quickest dissolved in a solution of lactic acid, less quickly in lime-water, and even more slowly and incompletely in solutions of chlorate of potash or soda; other salts of alkali in solutions fit for use with the living subject proved entirely ineffectual.

Lately the pure acid or its soda salt has been made use of for internal application as a narcotic by German physicians, and it has been recommended for insomnia after hæmorrhage or exhausting disease, for quieting persons of anxious and diseased mind and in other mental derangements, though it acts less powerfully than opium. The most reliable mode of administration seems to be an enema, and it is recommended to give from 5 to 20 grammes in a solution with about an equal weight of carbonate of soda. Dr. Foster, of Birmingham, who has used this acid in cases of diabetes mellitus, noticed acute inflammation of joints after large doses in two patients suffering from that disease.*

The chemical preparation for pharmaceutical purposes is, of course, obtained by fermentation of lactic sugar solution, or may be formed by synthesis from aldehyd, hydrocyanic acid and hydrochloric acid. We take the following directions for its preparation from the well-known work of Professor Hoppe-Seyler, of Strassburg University:† A solution of cane sugar is to be mixed with sour milk and oxide of zinc and exposed with frequent stirring for some time in a warm atmosphere. The crusts of lactate of zinc which form are to be dissolved in hot water, then filtered, and from the still hot solution the metal is to be precipitated by sulphuretted hydrogen. Filter again, evaporate over a water-bath, and shake the syrupy remnant with ether which will absorb the lactic acid. Upon distillation the latter is obtained in a pure state. It is the aethylid lactic acid (aethylidenmilchsaure). The paralactic acid which forms an important constituent of Liebig's Extract of Meat, has been found also in many pathological secretions, as, for instance, in the urine after phosphorus-poisoning. The ethylen lactic acid which has been found in meat extract and in pathological liquids by Wislicenus (*Annalen der Chemisch. Pharmacie*, vol. 166 and 167) is always combined with the paralactic and is separated from it by dissolving its zinc-salt in alcohol and letting the paralactate of zinc crystallize, the salt then remaining in solution is aethylen lactate of zinc. The fourth lactic acid of the formula $C_2H_4(OH)\ CO_2H$, called hydracrylic acid has been produced artificially only from betaiodic propionic acid (beta-jod propionsaure).

THE DETERMINATION OF THE SOLIDIFYING-TEMPERATURE OF LIQUIDS, AND IN PARTICULAR OF SULPHUR.‡

BY D. GERNEZ

The determination of the temperature at which the passage of a body from the solid to the liquid state is effected, or inversely, presents, notwithstanding its apparent simplicity, uncertainties which have only been dissipated for a relatively restricted number of substances, even when the change of state takes place abruptly—that is to say, when the solid becomes suddenly liquid through an infinitesimal change of temperature. The slowness with which the fusion of a body is produced in a bath at a constant temperature but little above the fusing-point, and the imperfect conductivity of the substances (which permits certain parts of the liquid to attain temperatures above that of the part not melted), have led physicists to substitute for the determination of the fusing-point that, *supposed* identical, of the point of solidification: only it often happens in this case that the measurements are found to be falsified in consequence of the phenomena of surfusion. As I will show, these phenomena can be utilized to determine the solidifying-temperature of liquids with a precision only limited by the patience of the experimenter.

* *British Medical Journal*, December 23, 1871.

† 'Handbuch der Physiologisch und Pathologisch Chemischen Analyse,' 1875, p. 95.

‡ From the *Philosophical Magazine*, July, 1876.

For this purpose, into a glass tube 3 centims. in diameter, closed at one end, such a quantity of the solid is put that in the liquid state it forms a column 5 or 6 centims. in height; along the axis of the tube a thermometer, held by a cork, is arranged, the bulb of which, sufficiently small to have only a negligible effect on the temperature of the surrounding liquid, descends to within a few millims. of the bottom, without touching the tube. The fusion of the body is then determined by putting it into a bath of water or paraffin at a temperature a few degrees higher than the presumed point of solidification. When the body is entirely melted the tube is brought into a bath at a constant temperature lower than the temperature sought; and we wait until the indications of two thermometers (one internal, the other external) differ only very little. The result is accelerated by turning the tube on its axis—which does not provoke solidification unless in the movement the thermometer rubs against the sides of the tube bathed by the liquid. The body being thus in the state of surfusion, a fine glass needle with its extremity covered with a small quantity of the material in the pulverulent state is introduced through a second aperture in the cork, and this extremity brought into the liquid, the solidification of which is immediately determined. To urge on the phenomenon the cork is rotated about its axis, which moves the stem and carries the crystalline germs cylindrically round the thermometer, the indications of which are then followed, it soon attaining a maximum certainly not higher than the solidifying-point, but possibly lower. The experiment is then recommenced, the preceding maximum being chosen for the temperature of the surrounding bath; and by operating in the same manner the solidification of the liquid is determined: it is found that the thermometer rises to a maximum higher than the previous one. After two or three trials of this sort temperatures are arrived at which differ from one another by only a negligible fraction of a degree: the highest of them is taken for the solidification-temperature of the substance, applying to it the correction arising from the circumstance that the whole of the stem of the thermometer is not bathed by the liquid.

I have turned to account the precision which this process permits, especially to elucidate the various peculiarities presented by the change of state of sulphur; and the following are the chief results at which I have arrived:—

The most simple results is that which relates to sulphur insoluble in sulphide of carbon, obtained by exhaustion from flowers of sulphur. The solidification of this variety takes place at 114°·3 C., whatever may be the temperature at which it was melted: thus, in all the experiments, I have not found more than $\frac{1}{10}$th of a degree difference between the temperature of solidification of the sulphur which had been brought to ebullition and that at which the same substance solidifies after being heated to 170° only, or even 121°.

This constancy of the solidifying-point is not found in the other varieties. For octahedral sulphur the temperature of solidification is higher when it has been fused at the lowest possible temperature—for instance, at 121°; in this case it reached 117°·4. If the liquid has been heated to 144°, it is only 113°·4; it descends to 112°·2 for the sulphur kept five minutes at 170° (which renders it very viscous, and, according to M. Berthelot's experiments, produces the maximum of insoluble sulphur). Starting from this value, the temperature of solidification rises rapidly to 114°·4, the solidifying-point of the sulphur which has been heated to various temperatures between 200° and 447°. This last value is sensibly the same as that which corresponds to the solidification of the insoluble sulphur.

In regard to prismatic sulphur, its temperature of solidification depends on its previous state. If it comes from insoluble sulphur it behaves likes this; nevertheless, when it is submitted to several successive fusions and solidifications, not much exceeding the fusing-temperature, the solidifying-point may risé more than one degree. In like manner, if it comes from octahedral sulphur, its solidifying-temperature depends on the temperature to which it has been brought. Thus, if it comes from sulphur heated to 170° (the solidifying-point of which is 112°·2), and has been liquefied at about 120° or 123°, the temperature of solidification rises gradually each time, and after a sufficient number of fusions and crystallizations it becomes equal to 117°·4.

Soft sulphur, flowers of sulphur, and roll sulphur conduct, as might have been expected, to results intermediate to those which I have noted for insoluble and octahedral sulphur, both of which enter into their constitution.

These peculiarities account for the diversity of the numbers given for the temperature of change of state of sulphur by observers whose skill there is no reason for calling in question. They also show how tenacious are the modifications resulting from the tempering of sulphur, since, in order to cause their disappearance, a considerable number of successive fusions and crystallizations are necessary.

THE SUNFLOWER AND ITS USES.*

The cultivation of the sunflower (*Helianthus annuus*) is carried on extensively in some countries, as central Russia and Hungary, chiefly for obtaining the oil of the seeds, which forms an excellent salad-oil, while the residuary cakes find employment as food for cattle. The yield is so large and the labour connected with its cultivation so trifling, that it deserves the attention of agriculturists. Each acre of land may easily contain 16,000 plants without at all interfering with each other. Numerous trials have shown that each fresh plant weighs on an average 10½ pounds including the seeds, which amount to about ½ pound. The yield of one acre may be stated as 80,000 lbs. of stems, 80,000 lbs. of leaves, flowers (excluding seeds), and roots, and 8000 lbs. of seeds. The stems and leaves contain a considerable amount of potassium nitrate, and are therefore easily reduced to ash, which will yield to water about 2300 lbs. of potash. There are two varieties of the plant, one containing white and the other black and white seeds. The former contain from 25 to 28 per cent. of oil, the latter from 16·25 to 26 per cent.; but the amount of kernel varies in the two sorts. The average yield from 100 parts of kernel is about 44·6 per cent. of oil. But it must be understood that this percentage is the actual amount existing in the seeds, and extracted with ether. In practice, especially when pressure alone is resorted to, the actual yield will be somewhat less. Analysis of the ash of the plant (excepting the seeds) yielded the following results; the corresponding figures obtained from an analysis of the ash of the seeds are added after each constituent in brackets; potash, 47·687 [14·475]; soda, 1·092 [6·119]; lime, 9·851 [6·811]; magnesia, 5·291 [1·0960]; alumina, 0·280 [0.227]; ferric oxide, 0·170 [1·427]; chlorine, 5·004 [2·162]; sulphuric acid, 1·344 [2·036]; phosphoric acid, 6·968 [31·848]; silica, 0·687 [10·811]; carbonic acid, 21·626 [13·074].

PRESERVATION OF GRAIN, ETC., BY MEANS OF BAR-IRON OR METALLIC MERCURY.†

Mr. Massie has made a number of experiments on a novel method of preserving certain organic substances, the results of which are given below in a condensed form.

He has been in the habit for several years of using an iron bar of about 3 lb. weight as a means of preserving barley, rice, and bran in wooden boxes, well closed and of

* *New Remedies*, From *Arch. d. Pharm.*, 1876.

† From *New Remedies*, June 15, 1876.

a capacity of about 40 gallons. In order to thoroughly test the efficacy of this method, he filled thirteen sets of litre-flasks with various substances, there being three flasks in each set, one of which (*a*) was filled with the substance without any addition, the second (*b*) containing the substance and a bar of iron weighing 80 gm. (1234·6 grs.), and the third (*c*) containing the same substance, together with 5 gm. (77·2 grs.) of mercury.

Barley, rice, bran, and various grades of corn, some of which was badly worm-eaten and partly alive with corn-moths before its being placed into the flasks, were found to be entirely altered or destroyed in *a*; in *b* and *c*, however, they were perfectly preserved, and where alteration had already commenced before the addition of the protecting substances, the latter were found to have arrested the change. The same was found to be the case with ergot, in which case two different sets of flasks were used, one being left open and the other closed; the latter was found to have undergone less change in *a* (unmixed in closed flask); but in *b* and *c* both sets were equally well preserved. Whole Spanish flies were similarly treated, and also found completely protected from change. But the most remarkable case was an experiment with the government biscuits ("hard tack"); the unprotected biscuits (in *a*) were entirely destroyed; the mass resembled a collection of small sieves; in *b* only a few perforations could be seen; and in *c*, which contained the mercury, the biscuits were completely preserved, without a trace of perforation by weevils. Each set was allowed to stand for the space of seven months.

FERRIC AND ALUMINIC PHOSPHATES.*

BY M. MILLOT.

Ferric phosphate. $2P_2O_5.Fe_2O_3.8H_2O=Fe_2P_4O_{13}.8H_2O$.—This phosphate is obtained when ferric hydrate or oxide is dissolved in hydrated phosphoric acid, either cold or hot. If an insufficient quantity of phosphoric acid is employed, the mass hardens and more phosphoric acie must be added till it remains pasty. Water is added and the liquid is filtered. On addition of water to the washings, the phosphate, $3P_2O_5,2Fe_2O_3,8H_2O$, is deposited. The mass left on the filter, after purification, has the formula, $2P_2O_5.Fe_2O_3.8H_2O$.

The anhydrous salt is prepared by fusing ferric oxide with an excess of phosphoric acid, and removing the excess by washing: If a high temperature be employed, part of the product becomes insoluble in acids, but does not vary in composition from the portion which dissolves. The hydrated phosphate dissolves in ammoniacal ammonium citrate, and in alkalies and their carbonates, but is insoluble in acetic acid.

The precipitate obtained on adding water to the filtrate from the preparation of the above mentioned phosphate is white and crystalline. Its formula is $3P_2O_5.2Fe_2O_3.8H_2O=Fe_4P_6O_{21}.8H_2O$. It is more easily prepared by heating a solution of ferric sulphate with dihydric ammonic orthophosphate, thus:—

$$3(NH_4)H_2PO_4+2Fe_2(SO_4)_3= Fe_4P_6O_{21}.H_2O+6(NH_4)HSO_4.$$

The liquid is filtered while boiling, and the precipitate is washed with boiling water. When ignited it turns to a greyish-blue mass, which dissolves easily in acids. Its properties are similar to the preceding one.

Aluminic Phosphate. $2P_2O_5.Al_2O_3.8H_2O=Al_2P_4O_{13}.8H_2O$.—This salt cannot be prepared in the same manner as the corresponding iron salt, owing to the solubility of alumina. It may be obtained by treating the phosphate, $Al_4P_6O_{21}.16H_2O$, with two equivalents of phosphoric acid; it is dried, washed, and the treatment repeated. It may be obtained in the anhydrous state by igniting a salt of alumina with excess of phosphoric acid and washing out the metaphosphoric acid formed, with water. The product is partially insoluble in acids.

$$3P_2O_5.2Al_2O_3.16H_2O=Al_4P_6O_{21}.16H_2O.$$

This phosphate is obtained when two equivalents of aluminium sulphate and three equivalents of dihydro-ammonic orthophosphate are boiled together, thus:—

$$2Al_2(SO_4)_3+3H_2(NH_4)PO_4= Al_4P_6O_{21}.H_2O+3(NH_4)HSO_4.$$

The precipitate is filtered and washed with boiling water, for it is soluble in cold water. Free sulphuric acid must be present during its preparation, or it will contain excess of alumina. This salt is formed when commercial superphosphates are washed with water. When ignited it becomes partially insoluble in acids:

$$2P_2O_5 3Al_2O_3.8H_2O=Al_6P_4O_{19}.8H_2O.$$

If an acid solution of one of the previously described phosphates is precipitated with ammonia, taking care not to add sufficient to dissolve it, this phosphate is produced. When ignited it dissolves in acids.

All these phosphates are hygroscopic; they are all insoluble in acetic acid, but dissolve in ammoniacal ammonium citrate, ammonium oxalate, alkaline carbonates, and ammonia; those of alumina dissolve much more easily than the corresponding iron salts.

* From the *Journal of the Chemical Society*, for June. (*Compt. Rend.*, lxxxii., 89—92.)

AN ALKALOID OCCURRING IN THE BRAIN AND THE LIVER, AND IN THE WILD POPPY.*

BY F. SELMI.

In examining the brain or liver for poisonous alkaloids, if after treatment with ether, it is extracted with amylic alcohol to ascertain if morphine is present, and the solution is evaporated, a yellowish residue is obtained partially soluble in dilute acetic acid. On adding a drop of iodized hydriodic acid to this solution after it has been concentrated at a gentle heat, and *immediately* examining it under the microscope (650 diameters), brown crystalline plates will be observed, sometimes solitary, sometimes united to form a cross, and rapidly disappearing, being transformed into brown oily drops. The same phenomena are observed even when the acetic solution has been evaporated to dryness and heated for some time to 120°, if the residue is again dissolved in water and tested with the iodized hydriodic acid. As these crystals closely resemble those produced with morphine by the action of the same reagent, it is always necessary in toxicological researches to apply the iodic acid test. On agitating the amylic extract with water several times, the alkaloid is dissolved out, yielding an alkaline solution which after being acidulated with acetic acid, gives the above mentioned reaction even more definitely. The quantity contained in the brain and liver is, however, very small.

When examining the green heads of the wild poppy for morphine, by exhausting them with alcohol, mixing the extract with baryta, and finally treating it first with ether and then with amylic alcohol, the author observed that the amylic solution behaved in a manner precisely similar to that obtained from the brain and liver; the acidified aqueous extract giving fugitive crystals identical in form and colour with those previously mentioned; no morphine, however, could be detected, neither did the dried capsules contain any alkaloid giving these reactions. On keeping the alkaline solution obtained by agitating the amylic extract with water, it lost its alkaline reaction after a week and no longer gave the same kind of crystals with the iodized hydriodic acid. The solution, saturated with acetic acid, may, on the contrary, be preserved unaltered if mixed with an equal volume of alcohol. The alcoholic extract of the brain should be made with absolute alcohol, then precipitated by basic acetate of lead, filtered, and mixed with ether; this produces a second precipitate which is to be removed, and the clear solution evaporated after the lead has been separated by means of ammonium sulphide. The second lead precipitate produced by the ether, when decomposed in a similar manner, yields a substance differing from the new alkaloid, in that it does not give any precipitate either with the iodide of potassium and cadmium, or with Meyer's reagent.

The Pharmaceutical Journal.

SATURDAY, AUGUST 5, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE USE OF METHYLATED SPIRIT.

WITHIN the last few days a general order has been issued by the Board of Inland Revenue concerning the use of methylated spirit and, as our readers will observe, the subject was brought under the notice of the Council at its meeting last Wednesday with the result that a deputation was requested to wait upon the Commissioners of Inland Revenue.

The object of the order now referred to is that of preventing the use of methylated spirit in the preparation of medicine for internal use, and we are entirely in accord with the Inland Revenue authorities as to the impropriety of such use of methylated spirit, inasmuch as it would be no less a breach of the Pharmacy Act than of the law which relates to protection of the Revenue.

But while the order just issued directs Excise officers immediately to remind all wholesale or manufacturing chemists in their respective stations, that the use of methylated spirit in preparing medicines for internal use is strictly prohibited by the Act, 28 and 29 Vict., c. 64, s. 8, it also directs them to make known that the Board does not consider the use of methylated spirit legal in any medicinal preparations except soap liniment and compound camphor liniment.

This specific limitation of the use of methylated spirit to these two preparations is, we believe, likely to involve chemists and druggists in some difficulty, for it is at variance with the practice which very generally prevails of preparing both the liniment of aconite and the liniment of belladonna with methylated spirit, not for sale or use as Pharmacopœia preparations, but in order to meet special requirements. In the general order it is directed that any infringement of the Act is to be at once reported to the Board by the Supervisors; and a sample of the medicine sent to the laboratory at the chief office. Until, therefore, some settlement of the question at issue is arrived at, as a result of the communication between the Council and the Board of Inland Revenue, it will be advisable to avoid the risk that might attend the sale of these preparations.

Meanwhile it may be useful if we indicate briefly what are the general facts of the case, and at the same time point out a circumstance which may to some extent account for the opinion evidently held by the Board of Inland Revenue.

The object of the Act of 1866, regulating the sale and use of methylated spirit, was exclusively the protection of the Revenue from fraud, and though the restrictions placed upon the use of methylated spirit comprised its use in the preparations of articles capable of being used internally as medicine, it may be assumed that this restriction was mainly intended to prevent this spirit from being used internally as a beverage. At any rate it is certain that in regard to medicinal preparations the prohibitory clauses of the Act apply specifically and only to those which are capable of being used internally.

It would, indeed, be inconsistent with the principle upon which the use of duty free methylated spirit was originally permitted by the Government, to suppose that there could have been at any time a disposition to impose upon any particular class vexatious regulations, interfering with the full enjoyment of that privilege, and in the general order issued shortly after the date of the Act now referred to, there was evidence of the utmost desire to be considerate in allowing the use of duty-free spirit. It was stated that, notwithstanding the provisions of the Act, the Commissioners had still power to authorize the use of methylated spirit in any branch of art and manufacture approved of by them, and chemists desirous of using methylated spirit for such purposes were directed to make application to the Commissioners for the purpose of obtaining the requisite permission.

The fact that copies of this general order were furnished to all chemists and druggists in the country was perhaps the cause of greater attention being given to it than to the Act itself, and owing to what may have been a clerical error, the omission of a single word seems to have given rise to the idea that it was not lawful to sell or to be possessed of any article in the manufacture of which methylated spirit had been used, unless by special permission.

In the Act itself it is stated that no person shall use methylated spirit in the preparation of any article capable of being used either wholly or partially as a beverage, or internally as a medicine; and it provides that if any person shall sell or have in his possession any *such* article, etc., he shall forfeit the sum of one hundred pounds, and such article shall be forfeited, together with the vessels or packets containing the same. This is clearly to be understood as not applying to preparations incapable of being used as a beverage or internally as medicine. But the word "such" which we have italicized is omitted in the General Order of 1866, and from that document it appears to be illegal to sell or possess *any* article in the preparation of which methylated spirit shall have been used.

It is therefore intelligible that, guided by this document and also by the direction to apply to the Board for special permission to use methylated spirit in particular cases, certain persons desiring to prepare liniment of aconite and of belladonna with methylated spirit should have actually applied for permission to do so, and have received it. Probably the fact that further applications have been made with the same object may have caused the Board to feel some difficulty in the matter which has led to the course taken in the recent general order, but as the subject is under consideration we abstain from entering upon that view of it and confine ourselves to such matters of fact as are within our cognizance.

In the first place we may instance the exception made in favour of soap liniment and compound camphor liniment as an indication that the Board does not contemplate enforcing upon pharmacists any greater restrictions in the use of methylated spirit than are requisite for protecting the Revenue from fraud, and that it has no intention in this respect of placing them at a disadvantage as compared with other classes of manufacturers.

In a recent article on this subject we expressed a doubt whether the permission of the Inland Revenue Commissioners to use methylated spirit would justify the application of it even for making Pharmacopœia preparations that are not intended for internal use—such as the liniments of aconite or of belladonna—since the Pharmacopœia orders rectified spirit to be used. But this is not a question affecting the Revenue, and it is provided for by other enactments specially relating to such matters.

The Pharmacy Act, however, while imposing a penalty on any one who should compound medicines of the British Pharmacopœia except according to the formularies of the said Pharmacopœia does not by any means preclude pharmacists from making and selling other preparations than those of the British Pharmacopœia. This is likewise the case with the Sale of Food and Drugs Act, with which the Pharmacy Act is incorporated, for while the sixth section of this Act provides that no person shall sell to the prejudice of the purchaser any drug which is not of the nature, substance, and quality of the article demanded and it may reasonably be held that this provision would apply to the use of any other than Pharmacopœia preparations in the dispensing of physicians' prescriptions, it does not interfere with the sale of preparations made by other formulæ so long as the articles are what the purchaser desires to have, and provided they are sold with labels so distinctly indicating their nature that they are not liable to be mistaken for the preparations of the Pharmacopœia.

It is to two articles of this description that the recent General Order of the Board of Inland Revenue more particularly applies, viz., the liniments of aconite and of belladonna, which it is well known are largely used in hospitals, dispensaries and other charitable institutions where cost is an important consideration. In such cases, no less with medical practitioners in country districts, it is a great advantage to be able to save the additional cost which the use of duty paid spirit would entail, possibly with the effect of preventing many from enjoying the benefits to be derived from the use of these preparations.

THE ROYAL GARDENS AT KEW.

THE annual reports on the Royal Gardens at Kew are always the records of interesting facts in botanical science, and the one just issued is no less interesting than its predecessors. Before now the reports have told us of the successful acclimatization in India of the Cinchonas or the Ipecacuanha, but this year there is no special reference to any medicinal plant. Nevertheless, considering the valuable services Kew has rendered to pharmaceutical science a few notices of the work done at that well known botanical establishment, as illustrated in this last report, will, we believe, prove interesting to our readers.

Dr. HOOKER states at the commencement that there has been a considerable falling off in the number of visitors during the past year as compared with the preceding. To this we do not attach much importance, as we think the value of the gardens lies in its scientific position and not as a popular place of resort. Every year, however, Kew is more frequented by scientific men, a record of whose names would show the real value of the establishment.

The erection of two new buildings, one for the herbarium and library and the other as a laboratory, will make the gardens still more valued by scientific men. The ground for the former, however, has only recently been cleared, while the building for the latter is already finished with the exception of the fittings and apparatus. In the laboratory will be conducted investigations in chemical physiological and microscopic work.

Much has been done at Kew of late years in collecting together in shrubberies or distinct beds plants belonging to the same natural orders, and during the past year collections have been thus brought together of species of *Clematis*, *Magnolia*, *Berberis*, *Cistus*, *Helianthemum*, *Hypericum*, *Hibiscus*, and allied genera; as well as of *Vitis*, *Rhamnus*, *Euonymus*, *Celastrus*, etc. Many of the genera here mentioned are well known to the pharmaceutical student and the fact of the species being found together will be a boon to all those in any way interested in plants.

To the museums contributions continue to flow in to such an extent that to an ordinary observer there seems but little room for fresh additions But by judicious selection, new and better specimens are being frequently substituted for those that have become changed by time and exposure. The issue of the sixth edition of the 'Museum Guide,' to which we have before had occasion to allude, abundantly testifies to the utility and popularity of these museums.

Altogether, the year 1875 at Kew was one that resulted in a good store both of scientific and practical work.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, August 2nd, 1876.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Cracknell, Greenish, Hampson, Hanbury, Hills, Mackay, Owen, Shaw and Stacey.

The minutes of the previous meeting were read and confirmed.

ELECTION OF AUDITOR.

Mr. HENRY AYSCOUGH THOMPSON was unanimously elected an Auditor of the Society in the room of Mr. Stacey, who vacated his office on being elected a Member of the Council.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the Seal of the Society:—

Allen, Charles Bowen.
Amoore, Lewis Perigoe.
Baikie, Peter.
Bennett, Charles.
Bessant, Frederick Railton.
Best, John William.
Bowen, John William.
Dimmock, Augustus Frederick.
Dymott, Frank.
Glegg, John.
Haworth, Benjamin Henry.
Hicks, William Thomas.
Hunt, Arthur.
Jones, James Parry.
Lewis, David.
Milton, Thomas Clement.
Newbury, Samuel.
Newton, Alfred Henry.
Severs, Samuel Thomas.
Weddell, Arthur.
Wright, Thomas David.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists

Allen, Charles Bowen ....London.
Bessant, Frederick Railton ......Oxford.
Best, John William ....Darlington.
Bowen, John William ....Southwark.
Dymott, Frank ....Southampton.
Glegg, John ....Lochhead.
Haworth, Benjamin Henry......Ramsey, Isle of Man.
Hunt, Arthur ....London.
Milton, Thomas Clement.........Exeter.
Newton, Alfred Henry ....Kenilworth.
Severs, Samuel Thomas ....Ripon.
Weddell, Arthur... ....Winchester.
Wright, Thomas David ....Lancaster.

ASSOCIATES IN BUSINESS.

The following having passed the Minor examination, and being in business on their own account, and having tendered their subscriptions for their current year, were elected "Associates in Business" of the Society:—

Ellison, John Clement ....Brisbane, Queensland
Griffin, Alfred William ....Bath.
Pittuck, Frederick William ...Hebburn-on-Tyne.
Spilsbury, James ....Leamington.

ASSOCIATES.

The following having passed their respective examinations, and having severally paid (as apprentices or students) or tendered the subscription for the current year, were elected "Associates" of the Society:—

Minor.

Abraham, Alfred Clay............Liverpool.
Babb, James ....Taunton.
Carr, John Allen ....Lancaster.
Clayton, Thomas ....Malton.
Elkington, Thomas Valentine...Spalding.
Fargher, Henry Spencer ....Warrington.
Foggan, George.....................Newcastle-on-Tyne.
Frank, John ....Whitby.
Goodall, William Anthony ......Clifton.
Hart, James Connorton ....Horselydown.
Hatch, James Oliver ....London.
Hollick, Richard ....Birmingham.
Johnson, William Henry.........Nuneaton.
Jones, Richard Edward ....London.
Jones, William Henry............Landport.
Kiddle, Richard Neller ....Lambeth.
Laurie, John.........................Ipswich.
Madden, Ronald George ....London.
Nichols, Frederic Bulstrode ...Chelsea.
Owen, Griffith Charles Roose...Carnarvon.
Place, Frederick William ......Betley.
Roberts, Joseph ....Liverpool.
Robertson, Andrew ....Markinch.
Rumsay, James Window.........Crickhowell.
Silverwood, Joseph ....Manchester.
Stacey, Peter.........................London.
Trevaskis, George Marrack......London.
Treweeks, Richard Harwood ...Pembroke.
Truman, Henry Vernon ....Nottingham.
Veitch, Andrew ....Shildon.
Walker, George ....Liverpool.
Wallas, Thomas Irwin............Carlisle.
Wardle, William Stephens ......London.
Widdowson, Reuben ....Nottingham.
Wilkinson-Newsholme, G. T. ...Huddersfield.

Modified.

Goucher, Levi Tom ....Manchester.
Thorburn, Henry William ......Bishop Auckland.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination, and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Bolton, Frederic William ......London.
Brown, Richard, jun...............Rochester.
Cliff, James ....Wakefield.
Emerson, Henry Wall............West Hartlepool.
Field, William ....Shoreham.
Flintan, Francis Robert ....Weybridge.
Frost, John Henry ....London.
Fulcher, Herbert Ashton.........Beckford.
Gifford, Richard Lord ....Blackburn.
Halton, George Richard ....Douglas.
Hardy, James Hammond ......Filey.
Hart, Herbert Wheatley.........Wimbledon.
Hemmons, John ....Kingsdown.
Holme, William A. ....Northampton.
Holmes, James Henry............Kendal.
Layng, Henry ....Brandon.
Lockyer, Eden Henry............Bristol.
Mallen, James Edward ....Llantrissant.
Norman, William Haswell ......Wellingborough.

Ombler, William Henry ....Windsor.
Paul, Ernest ....Windsor.
Pheasant, William ....Clapham.
Pike, Frank Horton ....Reading.
Roughton, William ....Loughborough.
Smith, Robert Frazer ....Glasgow.
Smith, Tom Henry ....Howden.
Stonham, William Burne ......Maidstone.
Talbot, Wm. John Campbell ...Howden.
Whiffin, Henry......................Market Harborough.
Woodward, Harry Joshua W...Sheffield.
Yeates, Alfred ....Kington.

Reports of Committees.

Finance.

The report of this Committee was read, and sundry accounts ordered to be paid.

Benevolent Fund.

Previous to the report of this Committee being read, the Secretary announced that he had received a donation of 100 guineas to the fund from Mr. Thomas Buck, late of Kingsland Road. A resolution was passed conveying the thanks of the Council to Mr. Buck for his liberal donation.

The report of the Committee contained recommendations of the following grants:—

£20 to the widow of a member, in great distress owing to the death of her husband who had for some time previously been in very straitened circumstances.

£5 to an associate, suffering from illness, and at present dependent on his friends.

£5 to an associate out of employment, having recently failed in business.

Two other cases were ordered to stand over, one for further information and the other because the applicant had had four previous grants, one very recently.

The report and recommendations of the Committee were received and adopted.

Library, Museum, and Laboratory.

This Committee had held two meetings, at the first of which the name of Mr. Stacey was added to the Committee.

Professor Attfield had reported that he had 57 students working in the laboratory, making 122 entries since the commencement of the session.

The Librarian had reported that the average attendance in the Library during the day had been 26; in the evening 11; the circulation of books had been 141 in town; country 28, to 17 places.

The Committee recommended the purchase of the following books from the general fund:—

Alcock's 'Botanical Names for English Readers.'
'British Homœopathic Pharmacopœia,' second edition.
Tilden's 'Chemical Philosophy.'

The question of obtaining the foreign periodicals before referred to was again discussed, and it was recommended that Messrs. Friedländer and Sohn, of Berlin, be commissioned to obtain the volumes or numbers required to complete the sets of the following:—*Repertorium für die Pharmacie und Neues Repertorium; Annalen der Chemie und Pharmacie; Archiv der Pharmacie; Jahrbuch für Praktische Pharmacie und Neues Jahrbuch für Pharmacie.*

The Curator had reported the progress he was making in preparing the sets of lecture specimens for the Professors; and that the materia medica portion of the catalogue had been carefully revised by Messrs. Betty and Greenish. It was recommended that this portion be printed forthwith. The average attendance in the Museum had been during the day 20; in the evening 5. The Committee considered what arrangements would be necessary to provide for the Hanbury collection, and the Secretary and Curator were requested to wait on Mr. Hanbury and arrange for the removal of the collection as soon as possible. An interview had been held with the printer of the Journal with reference to an improvement in the folding and cutting the Journal, and it was promised this should be attended to. The Committee recommended that the Library and Museum should be closed in the evening during August and September. At the second meeting of the Committee it was reported that the materia medica portion of the Hanbury collection was now on the Society's premises, and it was recommended that it be placed in the Museum in the portion at present devoted to Animal Materia Medica.

The report and recommendations of the Committee were received and adopted.

House.

This Committee had held two meetings, the principal business being the consideration of the water supply which had been found defective. At the second meeting it was reported that the turncock had been communicated with, and that since then the supply had been adequate.

Mr. Hampson thought the Council ought not to rely only on a turncock, but that the water company ought to be called upon to provide for an adequate supply of water for which so much money was paid.

Some discussion ensued upon the matter and ultimately it was decided to leave the matter still in the hands of the Committee, with the understanding that it should receive continuous attention.

The arrangements of the gas in the Laboratory had also been considered, and the cleaning, etc., in the house, necessary to be attended to during the recess, were recommended.

The report and recommendations of the Committee were received and adopted.

The Pharmaceutical Conference.

Mr. Mackay asked if it were not possible to make any exceptional arrangement for the next Council Meeting, so that members of Council might be able to attend the Conference in Glasgow, which would take place at the same time.

Mr. Bottle said if there were not a *quorum* present no business could take place; so that if they agreed amongst themselves not to come the business would simply be suspended.

The President said under such circumstances it would be better not to summon the Committees for the Tuesday preceding the Council.

Law and Parliamentary.

The report of this Committee included a report from the Society's solicitor as to various cases which had been in his charge. In one case proceedings had been commenced, and in others further information was being sought. The name of Henry Jackson, of Hartlepool, was recommended to be removed from the register, and prosecutions in other cases were ordered.

The report and recommendations of the Committee were received and adopted.

Methylated Spirits.

Mr. Hampson drew attention to an order recently issued by the Board of Inland Revenue concerning the preparation and sale of methylated preparations for external use. It was to the effect that it was only legal to use this spirit in the making of soap liniment and compound camphor liniments, thus excluding aconite, and also belladonna liniments. Now, this order seemed most arbitrary and uncalled for; and the Council knew that in hospitals, etc., large quantities of these liniments prepared with methylated spirits were used. It seemed quite absurd to allow soap and compound camphor liniments to be made and to exclude the stronger and more dangerous compounds. The only object of the authorities, he should imagine, would be to prevent the use of duty free spirit for drinking purposes, but the step they had now taken, amounted to a confiscation of large stocks of these useful liniments, and seemed to be very oppressive, in fact it amounted to preventing poor persons using these articles, since they could not afford the more expensive preparations made with pure spirit. He suggested that the President and Vice-President should have some communication with the Inland Revenue authorities on this matter.

The VICE-PRESIDENT said this was not a new subject.

Mr. GREENISH said it was a new phase of it.

The VICE-PRESIDENT having read the clause bearing on the question,

Mr. STACEY said if he had known this question was coming up he would have brought with him a letter he had received from the Inland Revenue Office on the previous Friday. In 1869 he applied with reference to the making of several preparations and after a good deal of correspondence obtained permission to make aconite and belladonna liniments, as well as soap and compound camphor liniments, with methylated spirit. A few months ago some one called at his premises and put one or two questions with regard to the manufacture and sale of these preparations. He did not happen to be at home at the time, but the person was shown his premises, and he did not think any more of it until last Friday, when he received a letter, signed "Adam Young," stating that the Commissioners saw reason to withdraw the permission granted in 1869 for the use of methylated spirit for aconite and belladonna liniments. The person who called to make inquiries stated that only one other house, he believed it was, but certainly not more than two others, had asked for permission for such use of the spirit. He inferred that the authorities were annoyed at finding that large quantities of these preparations were being made without leave having been asked.

Mr. MACKAY said it was well known that large quantities of these liniments were made with methylated spirit.

Mr. HAMPSON said the matter was very important, and if something were not done about it, any of their brethren might be liable to a fine of £100. He thought it would be well if some notice of it were taken in the Journal, and if the President and Secretary would kindly undertake to see the Inland Revenue authorities they would be doing good service to the Trade.

Mr. SHAW had always understood that methylated spirit might be used for external applications.

The PRESIDENT remarked that belladonna liniment contained camphor and he doubted therefore if a magistrate would convict for selling it as it might be looked upon as a camphor liniment.

Mr. ATKINS said this was a very important matter, and it would be a most serious thing with regard to parochial practice in the country if the regulations were insisted on. He knew a medical man who used large quantities of these liniments, which he could not afford to do if he were obliged to employ pure spirit. It seemed to him that if the only object was to prevent fraud on the revenue, these two potent poisons of all others might be safely permitted to be sold.

After some further conversation it was resolved on the motion of Mr. Hills, seconded by Mr. Mackay, that the President, Mr. Stacey, and the Secretary should wait upon the Commissioners of Inland Revenue and represent to them the hardship which was inflicted by this new regulation.

Mr. MACKAY suggested that in the meanwhile it would be well for chemists to abstain from dealing in these articles until the result of the interview was known.

General Purposes.

The reports of the Professors as to the examinations for the sessional prizes had been presented to this Committee.

Professor Redwood had reported very satisfactorily of the attendance, progress, and general conduct of the students in the chemistry and pharmacy class. There were nine competitors for the silver medal, and seven for the bronze medal at the termination of the second course.

Professor Bentley had reported with regard to the botany and materia medica class that the competition was a very good one, fifteen candidates having presented themselves. The number of students during the session showed a marked increase over last year, the total number being about 120. He was also able to report most satisfactorily of the general good conduct, diligence, and progress of the students.

Professor Attfield had presented an exhaustive report respecting the practical work in the laboratory, from which it appeared that 123 pupils had attended during the session, the highest number by ten that had ever worked in the laboratory since the establishment of the school. He was able to testify as usual to diligence and gentlemanlike behaviour of the students. Fourteen competed for the Council prizes at the close of the session, the result of which will be found below. Professor Attfield added some remarks on the importance of attending to manipulation as well as results in awarding the marks, and expressed his opinion that the results of the weekly examinations throughout the session should be taken into account by the Professors, in addition to the terminal examination now held, in determining the position of candidates for the Council prizes.

The Committee had also received the report of the two Examiners appointed by the Council as to the result of the competition for the Council Examination Prizes, also the report of the President and Vice-President, and the two Examiners appointed by the Board, as to the result of the competition for the Jacob Bell Memorial Scholarships.

Professor Bentley had reported with regard to the Herbarium Prize that only two collections had been sent in, viz., from Mr. C. B. Buck, Sandgate, and from Mr. N. Cooper, Bradford-on-Avon. The first contained 510 specimens, and the second 446, and though in both cases the drying was somewhat deficient, they were both so well arranged and named that he recommended that the silver and bronze medals should be respectively awarded.

Mr. SHAW said it was considered very desirable some time ago, by some gentlemen, that the Pereira Medal should be competed for in the country under the same conditions as the Bell Scholarships. There were eight competitors here, and one in Edinburgh, but it was not stated whether they belonged to London or came from the country.

The SECRETARY said most of the men were from the country; but strangely enough, hardly any one who had passed his examination in the earlier part of the session had put in an appearance.

Mr. SHAW was very pleased to find that the examination being restricted to London and Edinburgh, did not prevent a number of men from the country coming up to it.

Mr. ATKINS, having congratulated Mr. Greenish on the success of his son in the competition, said he was very much gratified at hearing the reports of the Professors, in particular that of Professor Attfield, who had analysed with great care the whole work of the session. He was especially pleased to find that 75 per cent. of the students came from the country.

Mr. GREENISH said the Pereira Medal was the highest honour which the Council had to bestow, and yet out of sixty-two who had passed their Major examination, and were eligible to compete, only nine had presented themselves. This was much to be regretted, and he could not help expressing a hope that at no very distant period some other system would be adopted, and that this medal should be awarded not merely for success in an examination, but that some proof of capacity for original research should also be required of the candidates.

The SECRETARY thought the competition was rather restricted by the examinations being confined to London and Edinburgh. Many who passed their Major examination in the early part of the session got drafted off into different parts of the country and would not undergo the trouble and expense of a long journey for the chance of obtaining the medal.

The PRESIDENT thought a more potent reason for not competing was a feeling on the part of the young men who had passed some little time before, that their knowledge was not quite so fresh, and that they would probably be surpassed by those who had only just finished their studies.

The SECRETARY said he thought the feeling should be the other way, and that those who had passed their examination earlier should rather be inclined to read up and study in order to compete.

Mr. SHAW also thought it would be well if the conditions of the Pereira Medal competition were assimilated to those of the Bell Scholarship.

Mr. HILLS said they had had so many changes lately that he hoped no further alteration would be made at present. Before very long they would have to settle the conditions for the Hanbury Memorial Medal, and they could then consider the matter.

The report and recommendations of the Committee were then passed unanimously.

PRIZE AWARDS.

The following awards were made on the recommendation of the General Purposes Committee.

Jacob Bell Memorial Scholarships.

George William Bullen.
George Frederick Gutheridge.

Chemistry and Pharmacy.

(Five months course.)

Bronze Medal ....Alfred Clay Abraham.

(Ten months course.)

Silver Medal ....Henry George Greenish.

Certificates of Honour... Arthur William Wheatly. Samuel Newbury.

Certificates of Merit ... Thomas Ridgley. William Champley Kidd. Frederick William Place.

Botany and Materia Medica.

(Five months course).

Bronze Medal ....Charles Edward Palmer.

(Ten months course).

Silver Medal ... .Henry George Greenish.

Certificates of Honour... Arthur William Wheatly. Thomas David Wright. Samuel Newbury.

Certificates of Merit ... Augustus Frederick Dimmock. Charles Edward Stuart. Thomas Ridgley. James Hart.

Practical Chemistry.

Silver Medal ....Henry George Greenish.

Bronze Medals .... William Champley Kidd. Samuel Newbury.

Certificates of Honour Frederick E. Pollard. Henry Campbell. Samuel Thomas Severs. Arthur William Wheatly.

Certificates of Merit ... Thomas David Wright. William Gardner. Augustus Frederick Dimmock.

Botanical Prize.

Silver Medal ....Charles Burton Buck.
Bronze Medal........ .....Albert Henry Cooper.

Council Examination Prizes.

Pereira Medal (Silver) and books value £5.
Arthur William Wheatly.

Pharmaceutical Society's Medal (Silver) and books value £3.
Harry Alma Thomas.

Pharmaceutical Society's Medal (Bronze) and books value £2.
Samuel Newbury.

Two certificates received in lieu of the Society's Examination :—

1 University of Oxford.
1 Royal College of Surgeons in Ireland.

Mr. GREENISH suggested that it would be well if the Examiners presented a report once a year or once in six months giving some idea of the general efficiency of the young men, and also stating what subjects they were found chiefly deficient in. This would enable the Council in some degree to judge how far the lectures given by the Professors were adequate to the requirements of the students.

Mr. MACKAY said this plan might be adopted with regard to the Preliminary examination, but he did not see how it could be applicable to the other examinations, since a man who was found hopelessly deficient in one branch of knowledge was sent back without examining him in all the others; and the Examiners had not the materials for furnishing such a report.

The SECRETARY said that the Examiners did not know where the candidates came from, or where they obtained their knowledge. Some years ago he used to ask the young men where they had studied, but that was objected to as being rather inquisitorial, and it had therefore been discontinued.

Mr. GREENISH said it was not a question of where a man came from, but what was the average weakness of his knowledge.

Mr. BETTY considered that to require such a report would be impolitic, and would be an abuse of their power by raising a question between the Examiners and the Professors.

The VICE-PRESIDENT said his experience had taught him that the greatest credit was due to the Examiners for the very kind way in which they treated the candidates; but it was certainly the case that when a man failed in one or two subjects he was at once told that there was no chance of his success, and that he had better retire, consequently they could not say how far he would fail in other subjects.

Mr. HAMPSON did not think Mr. Greenish wished to get any information in the manner Mr. Betty suggested, but rather to elicit information for the guidance of the Council, and if it could be obtained it would certainly be useful. It seemed, however, very doubtful whether the plan was feasible.

The PRESIDENT said the information certainly could not be obtained through the Board of Examiners. They were there to examine not those who passed through the Society's school, but all comers, and they had no right to inquire where a man had been educated.

THE BIRMINGHAM CONFERENCE.

The SECRETARY read a letter from the Secretary of the Birmingham Conference enclosing a copy of a resolution to the following effect:—

> "That this Conference urges upon the Pharmaceutical Society the necessity of testing the legality of co-operative societies selling and dispensing poisons."

There was also a letter from a chemists' association at Bridgwater to the effect that it is desirable that the Pharmaceutical Society should endeavour by all means in its power to protect the interests of the trade throughout the country.

Mr. ATKINS said he was very glad the Council decided at the previous meeting to obtain a full report of the proceedings at the Conference, but with regard to the immediate request before them he thought the best way would be to refer it to the Parliamentary Committee. He desired, however, to say that he was not yet convinced that the Society was not both able and willing to undertake the work which he saw certain speakers at the Conference seemed rather to suggest that they were unwilling or unable to carry out. He very much wished that members of the pharmaceutical body throughout Great Britain should understand that a very large amount of important business in the way of protection of every just and legitimate interest was being constantly conducted at the Council Board. All matters were not reported, and wisely so in some cases, but the information was available for those who wished to have it. He had learnt that morning that some of the more important questions which they were charged by some men—who could not be perfectly informed—with neglecting, did receive the most careful attention they could bestow; and, therefore, while he did not stand up to deprecate the gathering of that assembly, but hoped and believed that it would be fraught with good results, yet he should personally deprecate the existence of an association outside their own as a permanent institution. The gathering of that body for the purpose of debate might act as a useful stimulus, but to have two institutions, so to speak, existing side by side, necessarily with some degree of antagonism, and certainly with an alienation of part of those funds which many could but ill afford to spare, would not be desirable. With regard to the immediate question before them he thought it was a point for very careful consideration in committee, and consultation with the aid of those legal opinions which the Society had at its command. There certainly existed outside the Pharmaceutical Council, and to a large extent outside the Society, an impression that they did not sufficiently care for the practical trading interests of the body, but he felt before he entered the Council, and he wished to say as the result of his very brief experience in the Council Room, that they did, and were prepared to, give due consideration to every question and every grievance that came before them. If he found that there was not the ability or the disposition to deal with such matters he should certainly protest against it, but he respectfully declined to attend that great and important gathering at Birmingham, because he considered that Council possessed the means of rectifying, so far as possible, every fair grievance that came before them.

The VICE-PRESIDENT said, whilst the Society was always ready to take up cases laid before it, yet it would often happen, to take an illustration, that a local secretary communicated to the Registrar that some one in his neighbourhood was infringing the law, the Registrar then wrote suggesting that the local secretary should obtain the necessary evidence for prosecution, but the reply to this generally was that the local secretary could not do so without making himself a marked man. That was the position the Council was constantly placed in. If the trade Association could do anything to meet that difficulty by employing some one to go round and get up evidence for prosecutions there might be a good result, but unless it did something of that kind he did not see how it could be of much assistance.

Mr. HAMPSON thought they were not called upon to discuss the suitableness of a trade organization being formed, but simply the resolutions which had been sent to them. He also suggested that they were out of order in entering upon the discussion unless some resolution was before them.

Mr. BETTY thought they had a right to discuss the letter which had been received, even without a formal resolution.

The PRESIDENT said it was necessary to have some discussion before deciding on the course to be taken, but he presumed a resolution would be proposed to carry out the wishes of the Council.

Mr. ATKINS said he should be prepared to move a resolution that the correspondence be referred to the Law and Parliamentary Committee.

Mr. BETTY could see no disadvantage to any one in treating of the correspondence now before the Council as a whole. He then proceeded to comment on a suggestion in Mr. Hampson's speech at Birmingham as to the incompatibility of a seat on the Council and the performance of a public duty, which led to a remonstrance from that gentleman. Mr. Betty continued that there was no one present for whom he had a greater personal regard than for Mr. Hampson, and he felt assured his friend would not less esteem him for the freedom of speech which had not overstepped the bounds of debate. There was no doubt that the Council was placed in a somewhat difficult and unenvious position by that part of the Birmingham Conference proceedings which urged the Pharmaceutical Council, by a formal requisition, to involve the Society in a costly legal process which the Council had been advised could not but be abortive. He would much have preferred that this subject should have been dealt with by what he would beg to term a more constitutional mode of procedure—that is, by one that would have brought together for the consideration of it the Council and its constituents in the form and manner provided for the conduct of the Society's affairs; at least this would have been fair play, for at any annual or special general meeting of the Society both sides would have been heard. It appeared to him that the remarks of Mr. Hampson in introducing the resolution at the Conference had tended to throw down the apple of discord between the Council and their constituents; he was fully convinced that no ground for disagreement existed, and he should be prepared to second a resolution that the communication from Birmingham be referred to the Parliamentary Committee to report the form of reply for the Council's sanction, a reply which would prove that frequently and earnestly the subject of co-operative dispensing had been considered by the Council, and that in their resolutions they had acted for the best interests of the Society.

Mr. Hampson said no apology was needed from him as a member of the Council for having taken part in the meeting at Birmingham, and he should not, therefore, offer any. He did feel, and had felt for some time, that the Council had not done its duty in reference to the question of co-operative societies, and if he were permitted to have a seat at the Board two or three months longer he should endeavour to take an opportunity of bringing the question again before the Council for reconsideration. That would perhaps be the most straightforward course to adopt, though he should have preferred some other gentleman holding similar views to himself doing so. He felt that he had a duty to fulfil there, but he had also a duty to fulfil with reference to the well-being of the trade. He had more than once been told at that Board that it was unwise for them to meddle in almost any trade matter, in fact, he had been told by an old member of the Board that it was unwise to refer to any profit derived from their calling. When such remarks were made there was no justification required for members of the trade supposing that the Council did not take a really genuine interest in trade questions. He did not think it was desirable to prolong the discussion at this time, and would only add that nothing but a sense of duty would have led him to attend the Conference, and if such circumstances arose that he felt the two things were incompatible—his seat at the Board and his action as an independent member of the Society—he should be prepared to resign his seat rather than give up his independence.

Mr. Atkins wished it to be mostly distinctly understood that he did not deprecate the meeting being held at Birmingham, and personally he was very glad that not only Mr. Hampson, but another member of the Council had attended it. He might be wrong in his judgment, but he desired to record his feeling that it would not be desirable to have a permanent institution of that kind existing. As an occasional meeting to express the opinions of the trade, and to give a stimulus to themselves, it might serve a useful end, but with his present views he should deprecate the existence of two institutions collaterally. He moved that the matter be referred to the Law and Parliamentary Committee for two reasons—first, because anything coming from that Conference deserved careful consideration; and, secondly, because the Committee might have had this very point before them already, and in fact carefully considered it. They had a large number of earnest struggling men in the trade doing their best to pay their way—men who were members of a trade rather than of a profession—and who thought that the Council did not sufficiently sympathize with them. These men deserved their deepest sympathy, and ought to be assured that the Council would entertain every fair and just representation which came before them. It was out of the question to think they could snuff out or extinguish an important meeting such as that at Birmingham, and it was from no desire to make light of the resolution that he proposed its being referred to the Committee. On the other hand he was sure they would give it the most cautious and calm consideration, and he believed great good would result.

Mr. Betty seconded the resolution.

Mr. Shaw could not agree that the organization set on foot at Birmingham was to be looked upon as antagonistic in any way. Some months ago they started a similar association in Liverpool, but their objects were in the first place to bind the whole of the trade together and to protect themselves, and in the second place to support the action of the Pharmaceutical Society. Another object was to promote the exemption of registered chemists and druggists from serving on juries, and another to take cognizance of any proposed legislation having special reference to the trade. They had an organization with president, vice-president, secretary, treasurer, and funds in hand, and therefore if occasion required, they could at once put themselves in action and assist the Secretary and Registrar in carrying out what was desired. Another object was to assist the Registrar in preventing illegal trading, because there was a difficulty which had often been alluded to with regard to persons engaged in the business taking a active part in getting up evidence, being required to go into court and submit to cross examination. If some public functionary were appointed to perform this duty, it would relieve those engaged in the trade from a very unpleasant duty, and he understood that this organization proposed to have an officer of this description. He had taken an active interest in the question of Civil Service Trading in Liverpool, and formed one of a deputation to their members of Parliament asking them to use their influence with the Government to prevent Civil Servants in the receipt of large salaries from engaging in trade, and he thought that was a principle which could not be objected to. He therefore suggested as an amendment that a reply should be sent to the latter to the effect that the question had been repeatedly before the Council, and would continue to receive its earnest attention.

Mr. Bottle thought it would be rather unwise to adopt Mr. Shaw's suggestion. It was much better to refer the matter to the Parliamentary Committee. It was within his knowledge, as an old member of the Committee, that this particular question had been before it and before the Council over and over again. They had taken opinions and advice, and had acted, as they considered, in the best interest of the Society. Some of their friends at Birmingham seemed to think that they had not done quite as much as they ought to have done, and as there were gentlemen now on the Council who were not present when these discussions took place, and the opinions were taken, he thought it would be well to afford an opportunity for them to understand the question in all its bearings, by having the matter thoroughly rediscussed in Committee. He would ask, therefore, that full time be allowed the Committee to consider the matter, and that all the information and opinions previously obtained should be laid before them.

Mr. Hanbury said it so happened that he was a member of the Council some years ago when this matter came before it. The Council then felt that it was necessary to proceed with extreme caution, and legal opinions were obtained which it was not thought desirable to publish, but an immense amount of time was devoted to the subject in which, naturally, they all felt deeply interested.

Mr. Mackay also bore witness to the great anxiety the Council had already shown with reference to this matter, and he was quite sure there was not a member of it who had not been actuated by the strongest desire to put down what they considered to be illegal trading, but when they were advised by their solicitor, backed by the highest legal opinion in the country, that they had better not meddle in the matter, he considered they had acted wisely in following the advice so given them. Therefore he quite agreed with the proposal to remit the matter again to the Committee, since it was really very much for the purpose of allowing their friends who had not been behind the scenes an opportunity of knowing what had been done. They must send a reply to their friends at Birmingham, and he was sure it would be so framed that it would convince them that they had been acting in the dark in passing the resolution they did, which was, he believed, considered by many as somewhat in the nature of a vote of censure.

The PRESIDENT, before putting the resolution, said he must express his opinion that it was a great pity that these gentlemen who were so eloquent at Birmingham did not come to the annual meeting of the Society and give them the benefit of their suggestions. The fact was that at the annual meetings, as a rule, there was a very limited attendance, hardly any one came up from the country, and they had the greatest difficulty in keeping up a discussion for half an hour on the last occasion. Why were not all these gentlemen present at the annual meeting? It would be a great advantage to the Council if they could meet their constituents once a year and take counsel with them, and he did hope that the result of this Birmingham conference and of the discussion it would create, would be to make their friends in the country take more interest in their proceedings, come to the annual meetings and give them the benefit of their criticisms if they thought fit.

Mr. OWEN said if they gave notice that this subject was to be discussed they would have a crowded meeting.

The PRESIDENT said the annual meeting was for the purpose of discussing any matters of the kind which were brought forward.

Mr. STACEY had been somewhat surprised at this resolution from Birmingham, because it appeared to him in some degree to be a vote of censure on the Council. He had been but a very short time a member of the Council, but as a member of the Law and Parliamentary Committee he should like to express how thoroughly convinced he was that the Council was probing to the very bottom the grievance which the Birmingham Conference, to a greater or less degree, had censured them for disregarding.

The resolution was then put and carried unanimously.

A communication was received from the Secretary of the Students' Association, thanking the Council for the use of rooms, gas, etc., for the purpose of holding the meetings of the Association during the past session.

DETERMINATION OF QUININE.—SUPPLEMENTARY NOTE.

Sir,—Mr. A. H. Allen, of Sheffield, referring to my paper on the Determination of Quinine (*Pharmaceutical Journal*, July 29), has done me the honour to inquire whether an alkalized solution of "Ferri et Quiniæ Citras" which (after having been shaken up once with ether in the way I described), is found to retain still a considerable quantity of the alkaloid, does not yield the greater part of the latter, at any rate when shaken up with a second quantity of ether. I shall be glad if you will permit me to say that this is in fact the case. An alkalized solution of 50 grains of "Ferri et Quiniæ Citras" in an ounce of water, after having been twice shaken with ether (of which in all 7 fluid drachms were used) and the aqueous layer carefully drawn off from the ethereal one, was found to retain only ·2 per cent. quinine; when 8 drachms of ether were used only ·14 per cent. were retained, and when 12 drachms, less than ·1 per cent.

But I by no means wished to intimate that "Ferri et Quiniæ Citras" could not be accurately estimated at all when ether was used as solvent, but only to show that it could not be accurately estimated by ether in a certain case, the circumstances of which case had been minutely described. I wished to point out that a mode of estimation by ether, which was found quite accurate when applied to simple solutions of quinine, was inapplicable to preparations of quinine containing much citrate of ammonium. When quinine is precipitated in a simple solution, ether takes up on the very first shaking all, or all but a trace of the quinine present. When precipitated in a solution of citrate of ammonium, however, ether does not at the first shaking remove nearly all the quinine, the agitation with ether, having, as we now see, to be sometimes twice repeated before this result is achieved. Chloroform, on the other hand, applied in the way described, can be absolutely relied on in presence not merely of citrate of ammonium, but of sugar and glycerine, for extracting the whole of the quinine contained in the sample under examination. There are two or three practical reasons which seem to make chloroform preferable to ether for estimating most quinine containing preparations, but especially "Ferri et Quiniæ

Citras." To these, or rather to some of these (for I do not wish unduly to extend this note), I will briefly refer. Ether, especially in hot weather, is a troublesome substance to work with: it is very volatile and very inflammable; it creeps up the sides of the vessel, and there are occasional mishaps which (if I may judge from my own experience) one is liable to in using it. Now I have had during the last twelve months or so a great number of determinations of quinine to make in all sorts of pharmaceutical preparations, and when I have effected these by chloroform, using the separating-vessel in the way described in my paper, I have got nearly always such constant and evidently accurate results, and got them so readily and unfailingly, that I can hardly conceive it possible, following this method, when ordinary care is taken, to have a mishap or to get results that cannot be depended upon. It is another case of course when the fluid under examination contains non-volatile substances, as colouring matter, etc., that are soluble in chloroform; but into this I cannot enter now.

ALFRED N. PALMER.

69, *Market Street, Manchester.*

BUTTER ANALYSIS

Sir,—We have read with much interest Mr. Bell's valuable paper on Butter Analysis, which was presented to Parliament, and subsequently published in your Journal, July 22, 1876.

As every chemist and food analyst is aware, and as Mr. Bell states in his paper, we have for some years past been much occupied in working on the same subject, and we were the first who succeeded in placing butter analysis, once considered a problem incapable of solution by chemical means, on an equal footing with other branches of food analysis, by giving a simple chemical method not only for the qualitative detection, but also for the quantitative determination of foreign fats in factitious butters. We should therefore, be much obliged, if you would grant us a little space in your valuable columns to discuss some of the points raised by Mr. Bell in the paper above referred to.

We demur to his statement that our method "met with little acceptance from analysts, so that the test for a time practically fell into abeyance." On the contrary it was eagerly taken up by a great number of the leading public analysts, and was discussed in every journal which had any pretension to deal with scientific subjects. We could name not a few of such analysts, who, from the very publication of our pamphlet in 1874, after having carefully and critically tested the method proposed by us, expressed their entire assent to the principle and to its practical value. The method has never for one moment fallen into "abeyance." The many prosecutions of dealers for selling adulterated butters which commenced to be instituted soon after the appearance of our pamphlet show clearly that the new way opened was actively pursued by many fellow labourers. To day we believe there is hardly one single public analyst's laboratory wherein the determination of the amount of insoluble fatty acids is not constantly used and relied upon to detect admixtures of foreign fats in butters.

There have been many modifications and important improvements made upon our method, but still the process itself was not altered. Our standard was soon recognized as somewhat too low, and was generally raised for about a percentage and a-half. We, however, even now again have reason to believe that that original standard was very near the truth and that still the many hundreds of figures subsequently obtained are too high. Experiments recently made by Dr. Turner and by Dr. Dupré, F.R.S., clearly point to such a conclusion.

Furthermore, this original standard was not, as Mr. Bell conceives it to have been, founded upon the analyses of samples obtained from "one part of the country only," for our list includes most kinds of butter to be procured in commerce coming from places widely distant, from the Isle of Wight, Sussex, Normandy, Jersey, Surrey, and Hertfordshire.

The specific gravity of the melted butter fat seems to Mr. Bell to fulfil every requirement of an easy and certain test to discover and determine adulteration of butter with foreign fats, but on the authority of Dr. Dupré, F.R.S, who more than any other food analyst has inquired into this subject, we may state that this test has only a limited application, and although valuable in many cases as corroborative evidence must not be relied upon when taken alone,—in many instances it seems to fail altogether. For further information upon this matter we must refer your readers to a paper by Dr. Dupré in the *Analyst* for July.

The sp. gr. test is doubtless easier and more quickly obtained than an estimation of the insoluble fatty acids, which indeed requires care and some manipulative skill, but we beg leave strongly to doubt, whether any chemist would prefer a specific gravity test to a tangible gravimetrical estimation; what we stand in need of in all analytical processes, is not a slight physical, but a real chemical difference. This desideratum cannot in all cases be obtained, but in butter analysis we contend that it has been.

Arguing from a general standpoint we urge that specific gravity tests are as a rule less reliable and more easily baffled than are chemical methods, and we suggest that if any analyst desire to certify upon one test only he will be safer with the chemical than with the specific gravity method, but that it is preferable to test the sample microscopically, chemically, and physically.

One impression which Mr. Bell's figures, if left without comment, would be sure to produce would be, that pure butter may sometimes yield, as in No. 115, "County Galway" 89·90 per cent. fixed fatty acids. We have personal reasons for perfect faith in Mr. Bell's skill and bona fides; at the same time we must take exception to the want of proof of the genuineness of his samples. No doubt, but that the officers deputed to collect would, in the main, do their duty with care, but in such a number it is not unlikely that some did not exercise the extreme pains needed to ascertain beyond any doubt the freedom of the sample from any kind of sophistication.

During the quarter ending Midsummer of this year we analysed eighty-four samples of salt or "tubbed" butter officially collected in the county of Hants; 25 per cent. of these were found to be adulterated in most cases with foreign fats. Forty-four samples of home-made fresh farm butter were also analysed, and all found to be pure. This tends to show that the admixture of foreign fats is done upon a large scale, and not by those who are small producers. If natural butter ever yields so high a percentage of insoluble fatty acids as 89·90, it is strange that in no instance out of forty-four samples did it reach anything like such high figures. If we take Mr. Bell's conception that there can be no question whatever as to the genuineness of the 117 samples of butter in Table II., then we admit that pure butter can often contain 20 per cent. of water or 15 per cent. of salt. We fail to perceive any difference between adding and intentionally leaving in large percentages of water, and the fact that large quantities of water are often found in the highest priced butter is easily understood when we reflect that such skilful manipulation of valuable products must yield great profits to the manufacturers. That No. 15, obtained from the dairy of a private gentleman, contained 16·99 per cent. of water proves at most that that gentleman had very careless servants, and as a matter of fact we know that in the private dairies of Hampshire no such quantity of water or butter milk would be left in. On the other hand we found in one or two instances tubbed butter containing abnormal quantities of water.

In conclusion we beg to state that we have the greatest possible regard for Mr. Bell's sincerity of intention, but although he speaks of our discovery in terms of acknowledgment, we have thought it necessary to trouble you with this communication in order to anticipate and correct erroneous impressions which Mr. Bell's paper would be likely to produce.

ARTHUR ANGELL and OTTO HEHNER,

Analysts for the County of Hants.

NOTES ON THE DRUGS COLLECTED BY THE PRINCE OF WALES IN INDIA.

BY JOHN R. JACKSON, A.L.S.,

Curator of the Museums, Royal Gardens, Kew.

It was recently announced in the *Pharmaceutical Journal* that the Kew Museums had become possessed of the collection of vegetable products brought home by H.R.H. the Prince of Wales from India. This collection consists of about 180 specimens of seeds, fruits, barks, gums, etc., besides a fair collection of woods of more or less interest. The best portion of the collections are the produce of Southern India and were arranged and catalogued in Madras, the specimens being classified under distinct heads. The catalogues, however, though well printed, and the names for the most part accurate, are mere lists, no information being given as to the nature of the plants furnishing each product, or even of its uses.

Amongst spices and condiments several seeds occur that are equally as much used in medicine. The drugs are placed under a distinct head, foremost amongst which is the star anise (*Illicium anisatum*, Lour.). This tree which grows to a height of about twenty feet, is originally a native of South Western China, from whence European commerce is supplied, the well known stellate arrangement of the carpels giving the name star anise to the fruit. Besides the quantity sent to England, France, Germany, and Italy, for flavouring liqueurs or spirits and for the expression of an oil, the fruits form a large article of trade between various Asiatic nations. In India, China, and Japan, they are commonly used for flavouring food, and they are frequently chewed after meals with the double view of imparting a fragrance to the breath and of assisting digestion. They are also commonly used by the native practitioners as a stomachic and carminative. The form or variety which has been described as a distinct species under the name of *I. religiosum* is held sacred by the Japanese, who decorate their tombs with wreaths made from it and burn the bark as incense in their religious rites. It is said to burn slowly and evenly, and on this account is powdered and put into tubes, graduated on the outside, which being burnt during the night mark the time.

Under the name of tree turmeric are specimens of the young wood of *Coscinium fenestratum*, Colebr. This wood is of a bright greenish-yellow colour and has a bitter taste. Upon cutting a piece of the stem across it is seen to be very open in structure, without concentric rings, and the medullary rays very prominent. It is usually known under the name of false calumba, and though not officinal in India it is often used as a tonic; indeed it is reported that after extensive trials made at the Trevandrum Charity Hospital, this wood was recommended as a pure bitter tonic where calumba was not available, and as being "well worthy the attention of practitioners in the east as a cheap and efficient tonic." The form in which it is usually given is as a tincture or infusion. The specimens in the Prince's collection are small, not more than an inch in diameter, the specimens previously existing in the Museum being from 2 to 2½ inches across.

In *Toddalia aculeata*, Pers., a prickly, climbing rutaceous plant, we have also a stimulating tonic medicine, which has a place in the Indian Pharmacopœia. The part used is the bark of the root, which is of a yellowish corky nature, with a pungent aromatic taste. In a dry state it becomes of a yellowish brown colour but retains its pungency for a long time. It has been shown by Guibourt and confirmed by Hanbury in the 'Pharmacographia' that the root of this plant, together perhaps with other species of *Toddalia* and also of *Zanthoxylum*, furnished a drug which at one time had considerable reputation in Europe as a remedy in diarrhœa under the name of Lopez root. In India the root bark of *Toddalia aculeata* is administered either in the form of infusion or tincture. The plant is plentiful in jungles and hedge-rows in Malabar, Mysore, Coromandel, and other parts of the Madras Peninsula.

Cassia Absus, L., called the Black Gram, occurs not only in India but in Northern Africa. The seeds are small, black and shining, and are used both in India and in Egypt in ophthalmic cases, being reduced to a fine powder and introduced in minute quantities beneath the eyelid. They have a bitter aromatic taste, and are commonly seen in the Indian bazaars. The seeds also of *Cassia auriculata*, L., are sometimes used in diseases of the eye. The bark, however, of this species is alone represented in the collection just received at Kew; this is in small pieces of a reddish brown colour, and has a somewhat astringent taste. It has been employed in India for gargles instead of oak bark. In some parts the bark is bruised, mixed with molasses, and the whole allowed to ferment and a spirituous liquor prepared from it. On account of its astringency it is used by the native tanners for tanning leather, and also for dyeing a buff colour. Neither of these species of *Cassia* are officinal in India, though both are favourably spoken of by European practitioners.

Vernonia anthelmintica, Will., a composite plant, common in waste places throughout the East Indies, has small black seeds, which are commonly to be seen in most of the bazaars. They are used, as the specific name indicates, as an anthelmintic. A notice, however, of their uses appeared in the *Pharmaceutical Journal* for December 12, 1875, vol. vi., 3rd series, p. 463.

The specimen belonging to the Prince of Wales's collection is called Purple Fleabane. In the natural order Scrophulariaceæ is another non-officinal substance, namely the roots of *Picrorrdiza Kurroa*, Royle, a plant growing in Kumaon and other parts of the Himalaya. These roots, which are found in the bazaars in short, irregular pieces about as thick as a quill, somewhat tapering and partly covered with rootlets, are of a dark colour and have a strong bitter taste. It is extensively used by the natives as a tonic.*

In the Graminaceæ, *Bambusa arundinacea* claims the first attention, more, perhaps, on account of the multitudinous uses to which the bamboo is put generally than of any real medicinal properties contained in any part of the plant; nevertheless, it has a reputation amongst the natives for the cure of various diseases. Thus, for instance, the leaves are considered emmenagogue and anthelmintic, the bark as a specific in eruptions and the root as a diluent. It is, however, for the peculiar siliceous concretion called *Tabasheer*, that the bamboo is most valued in native medicine. This is found in the hollow stems near the joints or

* See *Pharm. Journ.*, vol. iv., 3rd series, p. 1034.]

articulations; it is considered by the natives a certain cure for paralysis, flatulence, etc., but from careful researches it would seem that as a medicine it has no power whatever. The plant is not officinal in India. The specimen received at Kew consists of the seeds or grains which are called bamboo rice. Why they are included under the head of drugs we cannot say. The other products under the head are so well known that we merely give their names, *Strychnos Nux vomica* and *S. potatorum* seeds, *Hyoscyamus niger* seeds, *Cubeba officinalis* fruits, and others of a similar nature. There are also the young miniature fruits just formed of *Eriodendron anfractuosum*, D C., but we do not know to what use these are put in India. The uses of the gum yielded by the tree, as well as of the cotton which fills the ripe fruit, are of course well known, but these young fruits are new to the museum and their uses are quite unknown to us.

Amongst gums and resins there are none that call for special remark. They are of the usual character such as those from *Feronia elephantum*, Corr., *Garcinia pictoria*, Roxb., *Azadirachta indica*, Juss., *Styrax Benzoin*, etc.

THE OIL OF ORRIS ROOT.*

BY PROFESSOR F. A. FLUCKIGER.

Orris root owes its use during more than two thousand years chiefly to its fragrance, which curiously enough, does not belong to the living root. Its slight and by no means aromatic smell is first developed into the agreeable perfume after drying, without doubt in consequence of changes of a chemical nature, concerning which at present our knowledge is deficient. When the dried root stock is submitted to distillation with water eventually there appears upon the water a crystalline odorous matter which is justly prized in perfumery and is specially prepared by some of the larger distillers. But the yield is very small, only about 1 part per 1000 of the orris root used. The product is of a yellowish-brown colour, of the consistency of a firm ointment, and possesses the characteristic odour of orris root.

H. A. Vogel was probably the first chemist who occupied himself with oil of orris or orris stearoptene, though the details given by him are quite unimportant. In 1835, Dumas made the following communication to the French Academy:—

"Orris root of Florence, submitted to distillation with water gives a nacreous crystalline lamellar product, insoluble in water and capable of being collected by filtering the distilled water. The product contains—

$$\left.\begin{array}{lr} \text{Carbon} \ldots & 67{\cdot}2 \\ \text{Hydrogen} \ldots & 11{\cdot}5 \\ \text{Oxygen} \ldots & 21{\cdot}3 \end{array}\right\} \text{Formula } C_8H_8O.$$

"The formula of this body is very remarkable. It will be remembered that in essence of roses there exists a crystalline product, the formula of which is that of bicarbonated hydrogen. It may be that the substance from the Florentine iris is an oxide of the substance from essence of roses; but the small quantity I have had at my disposal has not allowed any experiment for the verification of this conjecture."

By repeated recrystallizations from alcohol of a specimen of oil of orris prepared by Messrs. Herring and Co., the author obtained it, with the help of animal charcoal, in colourless crystalline scales, the form of which could not be decided. By this purification of the oil, or presumed stearoptene, the odour was concentrated in the mother-liquor, the crystals becoming more and more odourless, until finally they perfectly lost all aroma. An alcoholic solution of the crystals possessed no rotatory power, and energetically reddened litmus paper moistened with alcohol. After repeated recrystallizations the melting point reached 52° C.; a less pure preparation melted at some degrees lower temperature. Carbon bisulphide appears to be be unsuitable for the removal of the perfume from orris root; the quantity of essential oil is exceedingly small, and this solvent removes with it a very soft resin, tannin, and probably also fatty matter.

Elementary analysis of the crystals gave—

	I.	II.	III.
C	75·54	73·29	74·05
H	12·31	12·78	11·69

These figures taken in conjunction with the previous observations leave no doubt as to the nature of the presumed orris stearoptene; it is myristic acid, $C_{14}H_{28}O_2$. This formula requires—

			Mean of the Analyses.
14 C	168	73·69	73·96
28 H	28	12·28	12·26
2 O	32	14·03	

After this point had been established it was easy to remove the fat acid from the crude product by digesting the alcoholic solution with anhydrous sodium carbonate or bicarbonate, to obtain a soap solution from which the myristic acid is precipitated upon addition of a stronger acid and dilution with water. Upon heating the liquid to 60° C. it rises as an oily layer, which solidifies in a crystalline form at a temperature some degrees below 50° C. By repetition of this treatment the product may be easily brought to approximate and finally to attain the melting point of pure myristic acid, 54° C. The effect of the presence of the smallest quantity of the obstinately adhering volatile oil, or of a trace of lauric acid ($C_{12}H_{24}O_2$), melting at about 44° C., which may easily accompany the myristic acid, must be to lower the melting point.

The above observations upon the London oil were so far repeated with a sample of oil from Messrs. Schimmel and Co., of Leipzig, as was necessary to show the identity of the perfumes.

After these experiments upon the perfectly odourless myristic acid the preparation remains saturated with a somewhat volatile oil. Upon digesting the crude product in a closed flask with lead oxide, the oil separates as a rather thick brownish fluid, which remains fluid at −10° C.

As the oil containing myristic acid is only obtained by the most careful distillation, in the proportion of about 1 in 1000, the quantity occurring in the root itself may be estimated as being much smaller still, possibly not amounting to 1 in 10,000. It may probably be included in the as yet uninvestigated class of so-called ferment oils, in that so far as is indicated by the smell it does not occur in the living root.

The question arises, how the myristic acid, which can only with difficulty be distilled without decomposition, passes over with the oil. The explanation

* Abstract of paper in the *Archiv der Pharmacie*, for June, 1876.

of this is to be sought in the phenomenon of diffusion. Rose oil is similarly accompanied by a stearoptene that it is difficult to volatilize by itself.

The occurrence of myristic acid in oil of orris is probably to be attributed to a fat which is present in the root and is split up by the vapour of water. The quantity of this fat must be very small, since 300 grams of orris root powder exhausted with carbon bisulphide gave a soft perfumed resin, but neither free myristic acid nor neutral fat could be detected. The author also sought to ascertain whether free myristic acid was already present in the root. The carbon bisulphide extract was digested with sodium carbonate and alcohol in order to obtain a solution of sodium resinate and myristate, from which the acid sought could be precipitated by acetic acid. If myristic acid were present it would on prolonged digestion of the turbid acid liquid, gradually rise to the top as an oily layer. This, however, did not take place even after several days; the brown resinate slowly sank to the bottom as a pulverulent mass, and the liquid became clear without yielding any oily layer.

THE COMPOSITION AND ANALYSIS OF BUTTER FAT.*

BY A. DUPRÉ, PH.D., F.R.S.,

Lecturer on Chemistry at the Westminster Hospital.

Up to the year 1874 butter fat was regarded as consisting, like other fats, of a mixture of tri-stearate, palmitate, oleate, etc., etc., and with only a trace, 2 per cent. at most, of butyrine. On the strength of this assumption no attempts were made to distinguish butter fat chemically from other fats, as it was felt that a maximum difference of 2 per cent. gave far too small a margin for safe conclusions to be drawn.

In July, 1874, however, Messrs. Hehner and Angell published a small pamphlet in which they showed that butter fat yielded only about 86 per cent. of fatty acids insoluble in water, whereas, on the above assumption, it should yield, like most other animal fats, about 95 per cent. Here, then, was a difference, apparently, at once constant and of sufficient magnitude, to be available for the detection of adulteration of butter fat with at least such fats as are more commonly used for this purpose. The value of this alleged fact, for the purpose of detecting adulteration, depends chiefly on the constancy of the alleged proportion of insoluble fatty acids; and is independent of the nature of the substance making up the remainder. Nevertheless, it is of advantage to know the nature of this remainder, if for no other reason than to demonstrate why the insoluble acids should be as low as alleged. Messrs. Hehner and Angell accordingly made some attempts to supply this deficiency, and came to the conclusion that it consisted, besides, of course, the necessary glycerine residue, of fatty acids soluble in water, butyric acid chiefly The method by means of which they endeavoured to show this was, however, open to objection and their explanation was therefore not generally accepted.

In the summer of 1875, I in consequence undertook a series of experiments, in order, if possible, to clear up this point, which seemed to me of considerable interest. The work was frequently interrupted and therefore progressed but slowly. At our meeting in January, 1876, I gave, however, a short description of some of these experiments, which seemed to me to demonstrate that butter fat really did contain a considerable proportion of fatty acids soluble in water, as Messrs. Hehner and Angell had alleged. The experiments, it may be recollected, consisting in heating butter fat either with water alone, or with water and a known amount of alkali in closed tubes to a temperature of 500° F. In the first case the fat splits up into soluble and insoluble fatty acids and into glycerine, in the second case the soap produced may be decomposed by means of a known amount of acid, the insoluble fatty acids collected as usual, while the soluble fatty acids are estimated in the filtrate by standard alkali. None of the experiments then recorded were, however, quite satisfactory, as owing to constant leakage of the tubes, some loss had taken place in each case. Since then I have overcome this difficulty and now beg to lay the results of these later experiments before you.

Heating with water only.—About five grammes of the dry filtered butter fat were enclosed in a silver tube, with about 80 cub. cent. of water, and heated to a temperature of from 500 to 550° F. for a period of four to five hours. After cooling, the tube was opened and the contents washed into a beaker, or latterly a flask, as recommended by Dr. Muter, and the insoluble fatty acids thoroughly washed, dried, and weighed without removing them from the flask or beaker. The silver tube was washed out with ether, and the amount of fatty acids thus obtained, added to that found as above. The aqueous filtrate containing the soluble fatty acids and glycerine was neutralized with barium carbonate, boiled, filtered and evaporated, at first on a water-bath, finally in vacuo over oil of vitriol. The residue obtained was then weighed and the glycerine present extracted with alcohol, or expelled by prolonged heating to a temperature of 130° C., and the rest again weighed, the loss being taken as glycerine. Finally the residual barium salt was converted into sulphate, from which the amount of soluble acids present could be calculated. Neither of these processes is, however, quite satisfactory; in the first some barium salt is dissolved by the alcohol, in the second the glycerine cannot be all expelled without danger of decomposing some of the barium salt. (Owing to this I have not as yet been able to estimate the exact equivalent of the soluble acids present, but I believe that it is very near to that of pure butyric acid. I am now engaged in some experiments to settle this point more conclusively.) In some of the experiments I therefore weighed the mixed residue of glycerine and barium salts, added sulphuric acid, evaporated, ignited, and weighed again. On the assumption that the soluble acid present is butyric acid, we are then able to calculate both the acid and the glycerine contained in the residue. The general results of the experiments I have already stated, viz.:—that they show the presence of a notable proportion of soluble fatty acids. I may, however, give one experiment in full.—

Dry filtered butter fat taken .	4·800	grammes.
Insoluble fatty acids obtained .	4·202	"
Mixed glycerine and barium salt	1·059	"
Sulphate of barium	0·3395	"

This gives the composition of the fat as follows:—

Insoluble fatty acids	87·54	grammes.
Soluble " "	5·33	"
Glycerine	12·62	"

This still leaves a deficiency, due in part, I have no doubt, to an under estimation of the insoluble fatty acids, owing to difficulties of manipulation, in part to the fact that the soluble acid is not, as assumed, pure butyric acid. In three other experiments, each made with a different sample of butter, I obtained soluble fatty acids, 5·3, 6·4, and 5·8 per cent., mean of the four 5·70 per cent., and glycerine 10·86, 11·5, and 11·8 per cent., mean of the four experiments 11·69 per cent.

Heating with standard aqueous alkali.—The same amount of butter fat as previously given was heated with 25 cub. cent. of normal soda solution, generally with the addition of some water, in the closed tube as before, to a temperature of 500° F. for four hours. The resulting soap wa

* Read before the Society of Public Analysts, June 14, 1876.

decomposed by 25 cub. cent. standard acid, slightly stronger than the alkali used, and the insoluble fatty acids washed, dried and weighed as usual. In the filtrate the acidity was estimated by a decinormal soda solution, and after subtracting the excess of acid added the rest was calculated as butyric acid. Some of the results obtained were very good, but as I found that unless the soda solution used for saponification was very much stronger than that given above, which, of course, is very objectionable on other grounds, nothing was gained by substituting soda solution for pure water, except, perhaps, that the experiments could now be performed in an iron instead of in a silver tube. In either case I had to heat to at least 500° F. for not less than four hours to ensure decomposition. I therefore abandoned this method also, but will give two experiments performed in this manner.

Twenty-five cub. cent. of the standard acid added to 25 cub. cent. of the standard soda required 3·8 cub. cent. decinormal soda to produce exact regularity.

	1st Exp. Grammes.	2nd Exp.* Grammes.
Butter fat taken	4·041	3·599
Insoluble acids obtained . .	3·519	3·166
Cubic cent. decinormal soda used	28·5	25·8

From this we have—

Insoluble fatty acids . . .	87·08	87·96
Soluble „ „ . . .	5·37	5·38

Finally, I have adopted the following method, which, I believe, leaves nothing to be desired on the score, either of facility of execution or of accuracy. Abou 5 grammes of the dry filtered butter fat are weighed into a small strong flask (I always use one of the small assay flasks), 25 cub. cent. of a normal alcoholic soda solution are added; the flask is closed by means of a well fitting caoutchouc stopper, firmly secured by a piece of canvass and string, and heated in a water-bath for about one hour. I think a much shorter time would be sufficient, but hitherto I have always heated for one hour. When cool the flask is opened, the contents—which are semi-solid—carefully liquefied by heat and washed into a flask with hot water. This flask is now heated for some time on a water-bath to expel the alcohol, some more hot water is added and 25 cub. cent. of diluted sulphuric acid, somewhat stronger than the alkali used, are run in. The contents are now allowed to cool and the acid aqueous solution below the cake of fatty acids is passed through a filter. The fatty acids in the flask are washed by hot water in the manner recommended by Dr. Muter—*i.e.*, each time allowed to cool; all the washings are passed through a filter. I use no cambric, but pass everything through paper. With care scarcely any of the fatty acid will find its way into the filter. At first I used to dry the fatty acids in the flask and on the filter paper separately, making use of a counterpoised filter. I found, however, that the fatty acids evaporate from the filter paper even at a temperature of 105°C., and I now, after the washing with water is completed and the flask drained, wash any fatty acid that may be on the filter into the flask by means of a mixture of alcohol and ether, boil off the alcohol and ether on a water-bath, and finally dry the fatty acids in the flask at a temperature of 105°C. The drying can be done readily if the melted fat is now and then shaken briskly, so as to subdivide the water as much as possible. In this way the acids, when once in the flask, are not taken out until their weight has been taken, thus reducing the risk of loss to a minimum. Meanwhile the acidity of the aqueous filtrate and washings is estimated by decinormal soda solution. Subtracting from the amount required the proportion necessary to neutralize the excess of acid added in decomposing the soap, the rest represents the soluble fatty acids contained in the butter taken, and on the assumption of its being butyric acid, we can, of course, calculate the amount of this acid present. When once the equivalent of the soluble acids present in butter is fairly determined, this, of course, will have to be substituted for that of butyric acid. The results thus obtained are, I believe, very accurate, and the process is very simple in execution. I have satisfied myself by repeated experiments that the alkalinity of the alcoholic soda solution by itself is not altered by the process. At one time I had hoped that the process might be conducted in open flasks, but the following experiments will show that a loss of soluble acid is thus occasioned, which renders it necessary to use a closed flask. When once the decomposition of the fat is complete the alcohol may be boiled off without loss. This boiling off of the alcohol is not, I believe, absolutely necessary, for, if we add a sufficient amount of water before adding the sulphuric acid, the fatty acids separated are practically insoluble in the very diluted spirit. As, however, the boiling off is, as far as I can see at present, no disadvantage, it may be as well to do it.

Five portions of the same sample of dry filtered butter fat were treated each with 25 cub. cent. alcoholic soda solution; the first three, contained in open flasks, were heated on a water-bath for a quarter of an hour, half an hour, and one hour respectively, the last two were heated in closed flasks for one hour in a water-bath. In one of the latter experiments, No. 4, the alcohol was allowed to remain; in the other, No. 5, the alcohol was boiled off previous to the addition of the acid. The following are the results:—

	Per Cent.
Exp. 1—¼ hours' heating, soluble acid found .	5·38
„ 2—½ „ „ „ „ „ .	4·90
„ 3—1 „ „ „ „ „ .	4·86
„ 4—1 „ „ „ „ „ .	5·49
„ 5—1 „ „ „ „ „ .	5·50

The series clearly shows that prolonged heating in an open flask occasions a serious loss of soluble acid. It may perhaps be useful to give one of the above experiments in full. I will give No. 5.

Twenty-five cub. cent. of the acid added to 25 cub. cent. of the alcoholic soda required 29·1 per cent. decinormal soda solution to produce perfect neutrality.

Dry butter fat taken . . .	4·380 grammes.
Insoluble acids obtained . .	3·885 „
Decinormal soda required .	56·5 cub. cent.

56·5 – 29·1 leave 3 27·4 decinormal soda neutralized by the soluble fatty acids present. From this we obtain:—

Insoluble acids	88·69 per cent.
Soluble acids	5·50 „

The same butter fat had previously been examined in the usual manner for insoluble fatty acids only, when 88·56 per cent. had been found.

As a further illustration of the process I will give the analysis of the butter used in the above experiments, and those of the last six samples of butter received in my district, and will add for comparison the specific gravity of the melted fat taken at a temperature of 100° F. compared to water at the same temperature.

	Sp. Gr. at 100° F.	Insoluble Fatty Acids.	Soluble Fatty Acids.
My own butter . .	912·4	88·69	5·50
District butter, No. 1	912·3	87·83	5·40
„ „ „ 2	912·6	87·61	5·73
„ „ „ 3	913·1	87·31	5·66
„ „ „ 4	913·0	87·40	5·51
„ „ „ 5	912·3	88·10	5·25
„ „ „ 6	912·3	88·03	4·92

Calculating the amount of glycerine residue in each of the above cases, and adding it to the sum of acids found,

* This was a different sample of butter.

we do not in any case come up to 100. This is, as before observed, no doubt due in part to the fact that the soluble fatty acid is calculated as butyric acid, whereas some higher acids are also present, in part, however, also to the fact that butter fat, as obtained by simple drying and filtering, does not consist of pure glycerides.

The results given in the foregoing show, I think conclusively, that butter fat really does contain from 5 to 6 per cent. of soluble fatty acids. It will be seen that the fat, whether decomposed with water only at a temperature of 500° F., or with diluted alkali at the same temperature, or with alcoholic soda in an open flask at a temperature not exceeding 176° F., or finally, with alcoholic soda, in a closed flask at a temperature of 212° F., yields substantially the same products. The amount of glycerine found also agrees with this assumption, although but little stress can be laid upon that, as the glycerine cannot be estimated with sufficient accuracy. I am inclined to put more stress on the fact that the amount of glycerine residue calculated, added to the amount of acid found, falls short of 100. In what exact state of combination this soluble acid is contained in butter fat must be decided by future experiments.

In conclusion, a few words in regard to a process (the spec. gr. of the fat taken at 100°F.) first employed by Mr. Bell, and since then strongly recommended by Dr. Muter, who even thinks, going in this somewhat beyond Mr. Bell, that a reputed sample of butter may safely be passed over as good if it shows a spec. gr. above 911. Now, I am sorry to say, I cannot endorse this last statement. I believe that the spec. gr. of the fat is, as one of several factors, of great value in judging of the genuineness of a given sample of butter, but it cannot safely be taken as the sole guide. Within the last week or so, I took the spec. gr. of a sample of mutton dripping, obtained about nine months ago out of my own kitchen, and since kept in my laboratory, and found it to be 917·3. The spec. gr. was taken several times, and otherwise checked, and there can be no doubt of its correctness. On my mentioning this fact to Mr. Bell, he suggested to me that the dripping had probably been strongly heated. I accordingly procured a fresh sample of mutton dripping from my kitchen, and this time found the spec. gr. to be 904·8, when, however, this same sample was heated in a flat porcelain dish, for some time to a temperature of about 300°C., the spec. gr. was raised to 914·4, thus confirming Mr. Bell's suspicion so far. I think it very probable that prolonged exposure to the action of the air, even at ordinary temperature, may have a similar effect. This clearly shows that taken by itself, spec. gr. cannot be absolutely relied on as showing the genuineness of a sample of reputed butter. On the other hand, I think it will be found that whenever a sample of reputed butter shows a spec. gr. below 911 it may safely be pronounced adulterated. I must express my strong conviction that, as far as I can see at present, no single property of butter fat, taken by itself, is of absolute value as a guide for judging of the genuineness of a given sample of butter, and I would, therefore, advise every one to submit each sample that comes before him to as many tests as possible before he pronounces an opinion.

Addendum. Since the foregoing paper was written, I have effected the saponification, decomposition of the soap, and the washing and drying of the fatty acids, at ordinary temperature, thus still further reducing the risk of breaking up the higher into lower acids. The saponification is readily effected by using a sufficiency of alcoholic soda. Between four and five grammes of the dry butter fat were shaken up, for several minutes, with 100 cub. cent. of normal alcoholic soda. The butter soon dissolves, but after a time the solution gelatinizes to a clear transparent jelly. (The temperature of the laboratory at the time of these experiments ranged between 22° and 25°.) This jelly is now allowed to stand over night, during which time the smell of butyric ether, very strong at first, entirely disappears. In one of the experiments the alcohol was allowed to evaporate spontaneously, before the acid was added; in the other (made with a different sample of butter), the soap was dissolved in about half-litre of water, and at once decomposed by the addition of hydrochloric acid. The fatty acids, which separated in white curdy masses, were thoroughly washed on a filter, with cold water, about four litres, dried in vacuo over oil of vitriol and weighed. The following are the results :—

1st Exp. Butter fat taken 4,545 gaammes, insoluble fatty acids obtained 3,888 grammes.

2nd Exp. Butter fat taken 4,982 grammes, insoluble fatty acids obtained 4,299 grammes.

Percentage of insoluble fatty acids found 1st Exp. 85·5 per cent.

Percentage of insoluble fatty acids found 2nd Exp. 86·3 per cent.

Butter fat, therefore, yields the same proportion of insoluble fatty acids, whether saponified with or without the aid of heat.

For the sake of completeness, I give the analyses of the samples of mutton dripping referred to in the paper

	Spec. Gr. at 100° F.	Insoluble Fatty Acids.	Soluble Fatty Acids.
1st Sample	917·3	92·43	1·69
2nd Sample, before heating	904·8	95·44	0·09
2nd Sample, after heating	914·4	93·64	0·78

It has been suggested, that the addition of alcohol or ether to the fatty acids, and the subsequent drying, might give either too high a result by the formation of non-volatile ethers, or too low a result by the production of volatile ethers. I find, however, that such is not the case. The fatty acids, when alcohol or ether have been added, certainly require a longer time of heating before the weight becomes constant than is necessary when no such addition has been made, the ultimate amount found is, however, the same in either case.

A report on "Butter Analysis," by Mr. J. Bell, dated May 31, 1876, has just been presented to the House of Commons, which contains some useful details, and I hope to return to it at some future time. Meanwhile, I would take this earliest opportunity to refer to two points in this report. Firstly, Mr. Bell is under a great misapprehension in supposing that Messrs. Hehner and Angell s process ever fell practically into abeyance. On the contrary, it was at once taken up by a number of public analysts, and at the time of the report was, I believe, adopted by every public analyst, who had at all worked on the subject of butter. As evidence of the interest taken in this question, I need only refer to Dr. Muter's paper, published with the discussion in the *Analyst* for March; and my short note read at the meeting of public analysts, in January. Secondly, I should like to ask Mr. Bell, if the percentages of fixed fatty acids given in Table III., and from which it is inferred that this percentage increases with the age of the butter, are in each case the results of two or more concordant analyses, or represent a single analysis only? If the latter is the case, the table is I fear of little or no practical value, since the results are then, in four at least out of the six cases given, within the limits of experimental error.

DR. SIEVEKING ON MEDICAL TEACHING IN ENGLAND.

At the meeting of the British Medical Association, which was held at Sheffield on the first four days of the present month, the address in Medicine was delivered by Dr. E. H. Sieveking. Amongst the topics referred to was the increase in the facilities for obtaining a medical education which has come into existence in this country during the present century This subject was discussed in the following passage:—

"At the commencement of the nineteenth century, the medical profession was still in a chaotic state in Great Britain and Ireland. Its detractors denied that it occupied a scientific status; and in spite of the eminence of some of the heroes of our calling, we could scarcely ignore the trade mark which was conspicuous on its documents. In vain have I sought for any evidence of corporate professional feeling in the earlier history of British medicine. Great names—aye, and greater than Italy, Germany, or France can boast of—illumine our roll of distinguished citizens; but how many of them had to lay the foundation of their medical knowledge in foreign schools, because the means were wanting at home to acquire the alphabet of their profession?

"Linacre, the founder of the Royal College of Physicians, studied at Bologna and Padua, where he took his degree of Doctor of Medicine; Caius studied physic under Montanus, and dissected with Vesalius, at Padua, where he graduated; Harvey, to whom the whole world bows in reverent admiration, learned his profession under Fabricius ab Aquapendente, Minadous, and Casserius, and took his degree at the same university. Leyden, Heidelberg, Avignon, Paris, Montpelier, are some of the many foreign universities, which, as we learn from Dr. Monk's erudite 'Roll of the College of Physicians,' claim as their alumni most of the eminent medical men belonging to the sixteenth, seventeenth, and even far into the eighteenth centuries. These men did not, as is well and wisely done by physicians and surgeons of the present day, go abroad to compare foreign with home experiences, and to perfect a professional education of which the foundation had been laid in their own schools and universities, but they undertook the risk and fatigue of travel, which in their days was no slight matter, to acquire knowledge which was unattainable in their own country.

"I have in vain sought for early evidences of medical teaching in England, or especially in the English universities, before the beginning of the sixteenth century. Nicolas of Farnham, and John of Gaddesden, who treated Edward III., when he had the small-pox, by wrapping him up in a scarlet cloth, and discovered the method of distilling fresh from salt water, appear to have been the first exceptions to the rule that our princes brought over their medical attendants from abroad. Nicolas de Farnham (as we are told by Matthew of Paris),* who was elected in 1241 to the see of Durham, had been rector in arts at Paris, and afterwards practised medicine at Bologna. He became pre-eminently distinguished in, and obtained great favour by his skill. The king and queen, Henry III. and his consort, by the advice of some learned men, and expressly at the instance of Otto, the legate, the Bishop of Carlisle, and some other of the king's secret advisers, summoned Nicolas to take charge of their souls and bodies, and to be their familiar counsellor; in which office he conducted himself well and prudently till he was elected to the said episcopal dignity.

"The first medical lectures of which I can find any record were delivered in Oxford by a foreigner of the name of Andrew Alazard,† who had graduated at Montpelier, and was appointed by the chancellor and proctors to lecture on medicine, and to explain, from tables of his own, *Avicenna de Pulsibus*.

"So little, however, was the science of medicine appreciated in Oxford during the sixteenth century, that the university admitted, about 1550, Simon Ludford, originally a Franciscan Friar, and subsequently an apothecary in London; and afterwards David Langston, a coppersmith, two ignorant, unlettered, and incompetent persons, to the honours of a baccalaureate in medicine. The visitors of the university, on being applied to by the College of Physicians (*Caio Præsidente*), interdicted the university from a repetition of their licence, and provided that a certain course of study should be followed by each

candidate previously to his incorporation.* The utter neglect of medicine by the highest educational bodies in the realm was not redeemed by any supplementary efforts on the part of others. The barber-surgeons, who were incorporated by letters patent from Edward IV., in 1461,† and whose functions were of the most limited nature, were the only representatives of the general practitioner of the present day, until the corporation of barber-surgeons was dissolved in the 18th of George II. At this date, the surgeons, who seceded from the barbers, were incorporated, but they were not endowed with a charter till the beginning of the present century. The apothecaries, as a mere trading company, were founded in 1606, by James I., but they exercised no influence on the profession of medicine till Parliament, in 1815, conferred upon them powers which they have since wisely exercised and developed."

A DOMINANT LANGUAGE FOR SCIENCE.

BY ALPHONSE DE CANDOLLE.‡

At the period of the Renaissance, Latin was the language employed by all the learned men of Europe. It had been carefully preserved by the Romish Church; and not one of the modern languages presented, at that time, a sufficiently rich literature to become its rival. But at a later period the Reformation disturbed the unity of the Romish influence. Italian, Spanish, French, and English gained successively regular idioms, and became rich in literary productions of every kind; and at last, eighty or one hundred years ago at most, the progress of science caused the inconvenience of the use of Latin to be felt. It was a dead language, and, in addition to that, was wanting in clearness, owing to its inversions, to its abbreviated words, and to the absence of articles. There existed at that time a general desire to describe the numerous discoveries that were being made, and to explain and discuss them without the necessity of seeking for words. The almost universal pressure of these causes was the reason for the adoption of modern languages in most sciences, natural history being the only exception. For this, Latin is still employed, but only in descriptions—a special and technical part, where the number of words is limited and the construction very regular. Speaking truly, what naturalists have preserved is the Latin of Linnæus, a language in which every word is precise in meaning, every sentence arranged logically, clearly, and in a way employed by no Roman author. Linnæus was not a linguist. He knew but little even of modern languages, and it is evident that he struggled against many difficulties when he wrote in Latin. With a very limited vocabulary and a turn of mind which revolted equally from the periods of Cicero and the reticence of Tacitus, he knew how to create a language precise in its terms, appropriate to the description of forms, and intelligible to students. He never made use of a term without first defining it. To renounce this special language of the learned Swede would be to render descriptions less clear and less accessible to the *savants* of all nations. If we attempt to translate into the Latin of Linnæus certain sentences in modern floras, written in English or German, we quickly perceive a want of clearness. In English the word *smooth* applies equally to *glaber* and *lævis*.§ In Germany, the

† Maitland's 'History of London,' 1775.

‡ The fifth chapter of the 'Histoire des sciences et des savants depuis deux siècles,' 8vo., Genève, 1873. London, Dulau. Translated by Miss Miers, by permission of the Author. 'Ann. and Mag. N. Hist.,' ser. 4, vol. xi. From the 'Smithsonian Report for 1875.'

§ The word *glaber*, in botany, means bald or not hairy, which is applied to other parts as well as the head; and *lævis*, smooth, not rough; but I know they have both been carelessly translated "smooth," as M. de Candolle implies.—J. E. G.

construction of sentences indicating generic or other characters is sometimes so obscure that I have found it impossible, in certain cases, to have them put into Latin by a German, a good botanist, who was better acquainted than myself with both languages. It would be still worse if authors had not introduced many words purely Latin into their language. But, exclusive of paragraphs relative to characters, and wherever successive phenomena or theories are in question, the superiority of modern languages is unquestionable. It is on this account that, even in natural history, Latin is every day less employed.

The loss, however, of the link formerly established between scientific men of all countries has made itself felt. From this has arisen a very chimerical proposal to form some artificial language which should be to all nations what writing is to the Chinese. It was to be based on ideas—not words. The problem has remained quite devoid of solution; and even were it possible, it would be so complicated an affair—so impracticable and inflexible—that it would quickly drop into disuse.

The wants and the circumstances of each epoch have brought about a preference for one or other of the principal European languages as a means of communication between enlightened men of all countries. French rendered this service during two centuries. At present various causes have modified the use of this language in other countries and the habit has been almost everywhere introduced that each nation should employ its own tongue. We have, therefore, entered upon a period of confusion. What is thought to be new in one country is not so to those who read books in other languages. It is vain to study living languages more and more; you are always behindhand in the complete knowledge of what is being published in other countries Few persons are acquainted with more than two languages; and if we try to pass beyond a certain limit in this respect, we rob ourselves of time for other things; for there is a point at which the study of the means of knowledge hinders our learning. Polyglot discussions and conversations do not answer the intentions of those who attempt them. I am persuaded that the inconvenience of such a state of things will be more and more felt. I also believe, judging by the example of Greek as used by the Romans and French in modern times, that the need of a prevailing language is almost always recognized; it is returned to from necessity after each period of anarchy. To understand this we must consider the causes which make a language preferable, and those which spread its employment in spite of any defects it may possess.

Thus, in the seventeenth and eighteenth centuries, motives existed for the employment of French in preference to Latin throughout Europe. It was a language spoken by the greater part of the educated men of the period—a language tolerably simple and very clear. It had an advantage in its resemblance to Latin, which was then widely known. An Englishman, a German, was already half acquainted with French through his knowledge of Latin; a Spaniard, an Italian, was three parts advanced in his study of the language. If a discussion were sustained in French, if books were written or trans lation made in this language, all the world understood.

In the present century, civilization has much extended north of France, and population has increased there more than to the south. The use of the English tongue has been doubled by its extension into America. The sciences are more and more cultivated in Germany, in England, in the Scandinavian countries, and Russia. The scientific centre of gravity has advanced from the south towards the north.

Under the influence of these new conditions, a language can only become predominant by presenting two characters: first, it must possess sufficient German and Latin words or forms to be within reach at once of the Germans and of the people who make use of Latin tongues; secondly, it must be spoken by a considerable majority of civilized people. In addition to these two essential conditions, it would be well for the definitive success of a language that it should also possess the qualities of grammatical simplicity, of conciseness, and clearness.

English is the only language which may, in fifty or a hundred years, offer all these conditions united.

The language is half German and half Latin. It possesses German words, German forms, and also French words, and a French method of constructing sentences. It is a transition between the principal languages used at present in science, as French was formerly between Latin and several of the modern languages.

The future extension of the Anglo-American tongue is evident. It will be rendered inevitable by the movement of the population in the two hemispheres. Here is a proof, which it is easy to give in a few words and a few figures.

At the present time the population stands thus ('Almanach de Gotha,' 1871):*

English-speaking peoples in England, 31,000,000; in the United States, 40,000,000; in Canada, etc., 4,000,000; in Australia and New Zealand, 2,000,000; total, 77,000,000.

German-speaking peoples in Germany and a portion of Austria, 60,000,000; in Switzerland (German cantons), 2,000,000; total, 62,000,000.

French-speaking peoples in France, 36,500,000; in Belgium (French portion), 2,500,000; in Switzerland (French cantons), 500,000; in Algeria and the colonies, 1,000,000; total, 40,500,000.

New, judging by the increase that has taken place in the present century, we may estimate the probable growth of population as follows:†

In England it doubles in fifty years; therefore, in a century (in 1970) it will be 124,000,000. In the United States, in Canada, in Australia, it doubles in twenty-five; therefore it will be 736,000,000. Probable total of the English-speaking race in 1970, 860,000,000.

In Germany the northern population doubles in fifty-six to sixty years; that of the south in one hundred and sixty-seven years. Let us suppose one hundred years for the average. It will probably be, in 1970, for the countries of German speech, about 124,000,000.

In the French-speaking countries the population doubles in about one hundred and forty years. In 1970, therefore, it will probably amount to 69,500,000.

Thus the three principal languages spoken at the present time will be spoken a century hence with the following progression:

The English tongue will have increased from 77 to 860 millions.

The German tongue will have increased from 62 to 124 millions.

The French tongue will have increased from 40½ to 60½ millions.

The individuals speaking German will form a seventh part, and those speaking French a twelfth or thirteenth part of those of English tongue; and both together will not form a quarter of the individuals speaking English. The German or French countries will then stand toward those of English speech as Holland or Sweden do at present with regard to themselves. I am far from having exaggerated the growth of the Anglo-Australian-American populations. Judging by the surface of the countries they occupy, they will long continue to multiply in large proportion. The English language is, besides, more diffused than any other throughout Africa and Southern Asia.

America and Australia are not, I confess, countries in which the culture of letters and sciences is so much advanced as in Europe; and it is probable that, for a length of time, agriculture, commerce, and industry will absorb all the most active energies. I acknowledge this. But it is no less a fact that so considerable a mass of intelligent

* No notice is here taken of the English-speaking people in India and the East.—J. E. G.

† 'Almanach de Gotha,' 1870, p. 1039.

and educated men will weigh decisively on the world in general. These new peoples, English in origin, are mingled with a German element, which, with regard to intellectual inclinations, counterbalances the Irish. They have generally a great eagerness for learning and for the application of discoveries. They read much. Works written in English or translated into that tongue would, in a vast population, have a very large sale. This would be an encouragement for authors and translators that is offered by neither the French nor the German language. We know in Europe to what degree difficulties exist in the publication of books on serious subjects; but open an immense mart to publishers, and works on the most special subjects will have a sale. When translations are read by ten times as many people as at present, it is evident that a greater number of books will be translated; and this will contribute in no small degree toward the preponderance of the English language. Many French people already buy English translations of German books, just as Italians buy translations in French. If English or American publishers would adopt the idea of having translations made into their language of the best works that appear in Russian, Swedish, Danish, Dutch, etc., they would satisfy a public dispersed over the whole world, and particularly the numerous Germans who understand English. Yet we are but at the beginning of the numerical preponderance of the English-speaking populations.

The nature of a language does not, at first sight, appear to have very great influence on its diffusion. French was preferred for two centuries; and yet Italian was quite as clear, more elegant, more harmonious, had more affinity with Latin, and, for a length of time, had possessed a remarkable literature. The number, the activity of the French, and the geographical position of their country were the causes of their preponderance. Yet the qualities of a language, especially those preferred by the moderns, are not without their influence. At the present time briefness, clearness, grammatical simplicity are admired. Nations, at least those of our Indo-European race, began by speaking in an obscure, complicated manner; in advancing they have simplified and made their language more precise. Sanscrit and Basque, two very ancient languages, are exceedingly complicated. Greek and Latin are so in less degree. The languages derived from Latin are clothed in clearer and simpler forms. I do not know how philosophers explain the phenomenon of the complication of language at an ancient period; but it is unquestionable. It is more easy to understand the subsequent simplifications. When a more easy and convenient method of acting or speaking has been arrived at, it is naturally preferred. Besides, civilization encourages individual activity; and this necessitates short words and short sentences. The progress of the sciences, the frequent contact of persons speaking different languages, and who find a difficulty in understanding each other, lead to a more and more imperious need for clearness. You must have received a classical education to avoid the perception of absurdity in the construction of an ode of Horace. Translate it literally to an uneducated workman, keeping each word in its place, and it will have to him the effect of a building the entrance-door of which is on the third story. It is no longer a possible language, even in poetry.

Modern languages have not all, to the same degree, the advantages now demanded, of clearness, simplicity, and briefness.

The French language has shorter words and less complicated verbs than the Italian; this in all probability has contributed to its success. The German has not undergone the modern revolution by which each sentence or portion of a sentence begins with the principal word. Words are also cut in two, and the fragments dispersed. It has three genders, whereas French and Italian have but two. The conjugations of many verbs are rather complicated. Nevertheless, modern tendencies weigh with the Germans, and it is evident that their language is becoming a little modified. Scientific authors especially exert themselves to attempt the direct modes of expression and the short phrases of other countries in the same way that they have abandoned the Gothic printed letters. Should they correspond with strangers, they often have the politeness to write in Latin characters. They willingly introduce in their publications terms taken from foreign languages, modifications sometimes merely of form, occasionally fundamental. These attest the modern spirit and the enlightened judgment of the learned men so numerous in Germany. Unhappily, the modifications of form have no great importance, and the fundamental changes take place very slowly.

The more practical English language shortens sentences and words. It willingly takes possession of foreign words, as German does; but of *cabriolet* it makes *cab*; of *memorandum* it makes *mem.* It makes use only of indispensable and natural tenses—the present, the past, the future, and the conditional. There is no arbitrary distinction of genders; animated objects are masculine or feminine; the others are neuter. The ordinary construction is so sure to begin with the principal idea, that in conversation you may often dispense with the necessity of finishing your sentences.

The chief fault of the English language, its inferiority in comparison with German or Italian, consists in an orthography absolutely irregular, and so absurd that children take a whole year in learning to read.* The pronunciation is not well articulated, not well defined. I shall not go as far as Madame Sand in her amusing imprecations on this point; but there is truth in what she says. The vowels are not distinct enough. But, in spite of these faults, English, according to the same clever writer, is a well-expressed language, quite as clear as any other, at least when English people choose to revise their MSS., which they will not always do, they are in such a hurry!

English terms are adapted to modern wants. Do you wish to hail a vessel, to cry "stop" to a train, to explain a machine, to demonstrate an experiment in physics, to speak in few words to busy and practical people, it is the language *par excellence.* In comparison with Italian, with French, and, above all, with German, English has the effect, to those who speak several languages, of offering the shortest cut from one point to another. I have observed this in families where two languages are equally well known, which often occurs in Switzerland. When the two languages are German and French, the latter almost always carries the day. "Why?" I asked of a German-Swiss established in Geneva. "I can scarcely tell you," he replied; "at home we speak German to exercise my son in the languages, but he always falls back into the French of his comrades. French is shorter—more convenient." Before the events of 1870, a great Alsatian manufacturer sent his son to study at Zurich. I was curious to know the reason why. "We cannot," he said, "induce our children to speak German, with which they are quite as familiar as with French. I have sent my son to a town where nothing but German is spoken, in order that he may be forced to speak it." In such preferences you must not look for the causes in sentiment or fancy. When a man has choice of two roads—one straight and open, the other crooked and difficult to find—he is sure to take, almost without reflection, the shorter and more convenient one. I have also observed families where the two languages known in the same degree were English and French. In this case the English maintained supremacy, even in a French-speaking land. It is handed down from one generation to another. It is employed by those who are in haste, or who want to say something in as few words as possible. The tenacity of

* Surprised, on one occasion, by the slowness with which intelligent English children learned reading, I inquired the reason. Each letter has several sounds, or you may say that each sound is written in several ways. It is therefore necessary to learn reading word for word. It is an affair of memory.

French or English families established in Germany in speaking their own language, and the rapid disappearance of German in the German families established in French or English countries, may be explained by the nature of the languages rather than by the influence of fashion or education.

The general rule is this: In the conflict of two languages, everything else being equal, it is the most concise and the most simple that conquers. French beats Italian and German. English beats the other languages. In short, it need only be said that the more simple the language is, the more easy it is to be learned, and the more quickly can it be made available for profitable employment.

The English language has another advantage in family use—its literature is the one most suitable to feminine tastes; and every one knows how great is the influence of mothers on the language of children. Not only do they teach what is called "the mother tongue," but often, when well educated, they feel pleasure in speaking a foreign language to their children. They do so gaily, gracefully. The young lad who finds his language-master heavy, his grammar tiresome, thinks very differently when his mother, his sister, or his sister's friend addresses herself to him in some foreign tongue. This will often be English, and for the best of reasons: there is no language so rich in works (written in a spirit of true morality) upon subjects which are interesting to women—religion, education, fiction, biography, poetry, etc.

The future preponderance of the language spoken by English, Australians and Americans thus appears to me assured. The force of circumstances leads to this result; and the nature of the language itself must accelerate the movement.

The nations who speak the English tongue are thus burdened with a responsibility which it is well they should recognize at once. It is a moral responsibility toward the civilized world of the coming centuries. Their duty, as it is also their interest, is to maintain the present unity of the language, at the same time admitting the necessary or convenient modifications which may arise under the influence of eminent writers, or be arranged by common consent. The danger to be feared is that the English language may, before another century has passed, be broken up into three languages, which would be in the same relation to each other as are Italian, Spanish, and Portuguese, or as Swedish and Danish.

Some English authors have a mania for making new words. Dickens has invented several. Yet the English language already possesses many more words than the French, and the history of its literature shows that there is greater need to suppress than to add to the vocabulary. No writer for three centuries past has employed nearly so many different words as Shakspere; therefore there must have been many unnecessary ones. Probably every idea and every object had formerly a term of Saxon origin, and one of Latin or French origin, without counting Celtic or Danish words. The very logical operation of time has been to suppress the double or triple words. Why re-establish them? A people so economical in its use of words does not require more than one term for each thing.*

The Americans, on the other hand, make innovations of accent or orthography (they almost always spell *labour* "labor," and *harbour* "harbor"). The Australians will do the same if they do not take care. Why should not all possess the noble ambition of giving to the world one uniform concise language, supported by an immense literature, and spoken in the next century by eight hundred or one thousand million of civilized men? To other languages it would be as a vast mirror, in which each would become reflected, thanks to newspapers and translations, and all the friends of intellectual culture would have a convenient medium for the interchange of ideas. It would be rendering an immense service to future races, and at the same time the authors and men of science of English-speaking race would give a strong impulsion to their own ideas. The Americans, above all, are interested in this stability, since their country is to be the most important of those of English tongue. How can they acquire a greater influence over Old England than by speaking her language with exactness?

The liberty of action permitted among people of English race adds to the danger of a division in the language. Happily, however, certain causes which broke up the Latin language do not exist for English nations. The Romans conquered nations the idioms of which were maintained or re-appeared here and there in spite of administrative unity. The Americans and Australians, on the contrary, have before them only savages, who disappear without leaving any trace. The Romans were conquered and dismembered in their turn by the barbarians. Of their ancient civilization no evidence of unity remained, unless it was in the Church, which has itself felt the influence of the universal decline. The Americans and Australians possess many flourishing schools; they have the literature of England as well as their own. If they choose, they can wield their influence by means of maintaining the unity of the language. Certain circumstances make it possible for them to do so; thus the teachers and professors mostly come from the States of New England. If these influential men truly comprehend the destiny of their country, they will use every effort to transmit the language in its purity; they will follow classic authors, and discard local innovations and expressions. In this question of language, real patriotism (or, if you will, the patriotism of Americans really ambitious for their country) ought to be, to speak the English of Old England, to imitate the pronunciation of the English, and to follow their whimsical orthography until changed by themselves. Should they obtain this of their countrymen, they would render to all nations and to their own an unquestionable benefit for futurity.

The example of England proves the influence of education upon the unity of a language. It is the habitual contact of educated people and the perusal of the same books which, little by little, is causing the disappearance of Scotch words and accent. A few years more, and the language will be uniform throughout Great Britain. The principal newspapers, edited by able men, also exercise a happly influence in preserving unity. Whole columns of the *Times* are written in the language of Macaulay and Bulwer, and are read by millions of people. The result is an impression which maintains the public mind in a proper literary attitude.

In America the newspaper articles are not so well written; but the schools are accessible to all classes, and the universities count among their professors men especially accomplished in their use of the English tongue. If ever there should arise a doubt in the opinions of the two countries as to the advisability of modifying the orthography, or even making changes in the language, it would be an excellent plan to organize a meeting of delegates from the principal universities of the Three Kingdoms, of America, and Australia, to propose and discuss such changes. Doubtless they would have the good sense to make as few innovations as possible; and, thanks to common consent, the advice would probably be followed. A few modifications in the orthography alone would render the English language more easy to strangers, and would contribute toward the maintenance of unity in pronunciation throughout Anglo-American countries.

* A clever English writer has just published a volume on the institutions of the people called *Swiss* in English. He names them *Switzers*. For what reason? Will there soon be *Deutschers?*

MEDIÆVAL ENGLISH GARDENS.*

The fickle tide of fashion may soon demand the native and early plants of England in place of the exotics now imported, lovely though they are; and in the practice of gardening the plants of our own land may surely claim a passing notice, even amid the press and hurry of rapid progress. The date, too, of the introduction of many plants to England is often the topic of discussion, so that a brief review of English gardening from early times may not be wholly unacceptable.

The Rose, our English emblem, finds a first place in the "noble garden" described by Alexander Necham, the invaluable authority on early horticultural matters. His garden should be arrayed with roses, lilies, sunflowers, violets and poppies, and narcissus (?). Roses and lilies were among the plants bought for the royal garden at Westminster in 1276, and a wreath of these flowers was sent by King John to his lady at Ditton, so that the rose tree can boast of a very early introduction to this country. In the fourteenth and sixteenth centuries several varieties both of red and white roses are enumerated by Lawson. The Provence rose was probably first imported in the fifteenth century, at the time of the marriage of Margaret of Anjou with Henry VI. A common reserve or quit-rent was the yearly tender of a rose or bunch of roses. The part the rose has subsequently played is familiar to the most casual reader of English history.

The commonest flower was the gillyflower, or clove pink (*Dianthus Caryophyllus*), the *Clove de Giroflée* of the Normans. Loudon states that the cruelties of the Duke of Alba in 1567 were the occasion of our receiving through the Flemish weavers who flocked to our shores gillyflowers, carnations, and Provence roses, but, as recently pointed out by an eminent writer, the gillyflower had been known and prized in England centuries before. The flower frequently served the same purpose with the rose as a tender for land. This has been frequently mistaken for the clove of commerce, the similar use of the peppercorn and the term peppercorn rent favouring the theory; but in old documents the term *unius clavi gariofili* is obviously the clove pink; cloves also were not introduced in the twelfth and thirteenth centuries, when this kind of reserved rent was most common.

The periwinkle or pervinke was also a common flower. As it flourishes in shady situations, its bright, fresh green appearance made it a favourite in the sombre convent grounds. Chaucer, whose eye for beauty was not likely to pass the least "flowre" by, does not forget it:—

"There sprang fresh Violet all newe,
And fresh Pervinke rich of hue;
And flouris yellow, white and rede,
Such plente grew there nor in the mede."

The number of bees which were kept, and the frequent mention of the various uses of honey at an early date, also render it extremely probable that the list of flowers was more varied than we can find actual mention of. In the days of the Plantagenets flowers were a passion with our forefathers. They were on festal occasions strewn with the rushes, which formed the simple but beautiful carpet of those days. When "Merrie June" arrived—

"Maydens gin strewe their boweres
With the red Rose and Lily flowers."

Froissart relates that the Count de St. Foix went to his "chamber, which he found ready strewed with rushes, green leaves, and the walls hung with boughs newly cut for perfume." Sir Thomas More (1483) describes Elizabeth, the widowed Queen of Edward IV., when in the sanctuary at Westminster, as "sitting alone amongst the rushes in her grief and distress." Bradshaw, in St. Werburg (1500), writes—

"All herbes and floures fragrant, fayre, and sweete,
Were strewed in halls and layed under their feete."

In the laying out of gardens little art appears to have been shown before the fifteenth century. No resemblance to modern flower beds is traced earlier than the fourteenth century. When they are occasionally seen the beds appear surrounded with a wattled fence. In the 'Romaunt de la Rose' occurs a representation of a garden of the fourteenth century, which shows the "erbour" and the construction of the seats and banks of "camamile" and other flowers. This trellis-arbour might almost be a construction of to-day, so nearly does it approach to the common design now in use, and so faithfully has the old penman depicted it. Later, we have an introduction of Flemish origin, the mound or "mount," no doubt borrowed from the mound, thrown up within the bailey of a Norman fortalice to enable the archers to see over. This still later was more elaborately constructed of stone or wood, "curiously wrought within and without, or of earth," covered with fruit trees, and were ascended by "stares of precious workmanship." Hampton Court in the time of Henry VIII. had much of the "anticke" work, and many decorated mounts therein. The greensward of the garden was doubtless the scene of many a pleasant diversion in mediæval days; bowling alleys and butts for the practice of archery were commonly erected in them, and we can imagine the maiden while occupied with her distaff or needle looking out from the flower-decked window of her bower at the rough sports of the men.

The simples of the kitchen garden are now despised, but they were in their turn the safest and most effectual medicines known in England. The garden of the fifteenth century was the storehouse of the medicines of the good village dame or lady, to be by her dispensed for the cure of all the ailments of her neighbours. Tusser tells of forty-two herbs for the kitchen, fourteen for salads, eleven to boil, a number for windows and pots, seventeen to still in summer, and twenty-five necessary herbs to grow in the garden for physic. We have passed thus abruptly into a comparatively late period in our mention of the kitchen garden, for little can be said with certainty respecting the culinary vegetables grown in England previous to the fifteenth century. The cabbage tribe was, no doubt, early introduced and generally cultivated in the middle ages. The pea and bean were grown in the thirteenth century. Necham mentions beet, which was probably the chief esculent root. Of salads, the lettuce, rocket, mustard, water-cress, and hop were known. Onions, garlic, and leeks were in use before the year 1400. The kitchen garden was evidently the delight and care of the dame, and furnished the many herbs related in the rather doggrel rhyme of Tusser, with

"Conserves of Barberry, Quinces, and such,
With syrups that easeth the sickly so much."

Burton in the 'Anatomy of Melancholy' alludes to the medical skill of the country ladies—"Laurel and asarabecca," which every gentlewoman in the country knows how to give. A knowledge of the mysteries of stilling was one of the qualifications of the good housewife—

"The knowledge of stilling is one pretty feat,
The waters are wholesome, the charges not great."

The preparations of the dame famous in this art rendered her a welcome guest at every manor house around, and from distant parishes many would come to partake of the cordial waters. The still-room was an institution, the name of which only lingers amongst us. The practice of stilling now is in the hands of trade and commerce, and but here and there can be found one with leisure and patience enough to practise the difficult art of extracting the essence of the "vertuous herbe."

The Pharmaceutical Journal.

SATURDAY, AUGUST 12, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CONFERENCE MEETING.

WITHIN a month from the present time many of the pharmaceutical brotherhood will be travelling northwards from all parts of the country to the Conference in Glasgow, and in conformity with our usual custom we now place before our readers some details of the attractions which the city and its neighbourhood present to tourists, as well as the arrangements made in reference to the Conference Meeting and the simultaneous meeting of the British Association.

Though it is only five years ago that the British Pharmaceutical Conference, following the path chosen by the British Association, held a meeting in North Britain, we do not doubt but that the recollections of the time passed either in Edinburgh itself, or in excursions to other parts of Scotland, will be sufficiently pleasant to induce many to take advantage of the present opportunity to visit Glasgow.

The arrangements for the Pharmaceutical Conference meetings and for the accommodation of visitors will this year be unusually convenient, for not only has the Local Committee succeeded in securing the reserve of a considerable number of rooms in one hotel, so that those who apply for rooms soon enough can be located together in the same house, instead of being distributed through the city, but the hotel where this accommodation has been secured is the place where the general meetings of the Conference will be held. The Royal Hotel in George Square, the very centre of Glasgow, will, therefore, be not only the head quarters where visitors may enjoy the society of their friends, but also the place of transacting the business which gathers them together. It is to be hoped that this convenient arrangement secured by the exertions of the Local Committee will be largely taken advantage of, and those who desire to take this course should at once communicate their intention to Mr. KINNINMONT, the Local Secretary, and request him to secure rooms for them.

As a further inducement for doing so we are glad to state that the disgraceful system of extortion practised on some occasions will not be followed this year, but the charges at the hotels will be the same as on ordinary occasions—bedrooms ranging from *3s.* to *5s.* a night. There will also be a *table d'hôte* each day in a separate room for members of the Conference.

The General Conference meetings will as usual be held on two days, and the proceedings will commence at ten o'clock on Tuesday, the 5th of September, and be continued during the Wednesday following. On the Thursday it is intended that there shall be an excursion to the western coast, for which the Local Committee and their friends have engaged a special steamer known as one of the best and swiftest on the river Clyde. It is intended to to visit the Gareloch, Loch Long, Loch Goil, Holy Loch, Loch Striven, to sail through the Kyles of Bute to Loch Ridden, thence round the Isle of Bute, passing the entrance to Loch Fyne, and getting a near view of the Island of Arran with its lofty peaks; returning in ample time to allow of the Members being present at either of the Conversaziones to be held on the same evening by the British Association in the Crystal Palace, and by the Philosophical Society in the Corporation Galleries. All desiring to accept the invitation to join this excursion are requested to intimate their intention to Mr. KINNINMONT

The special attractions of Glasgow and its immediate vicinity are sufficiently distinct from those of Edinburgh to admit of any fear that on account of the last meeting in Scotland having been only five years ago there will be any falling off in the number of visitors to the western city. In place of the more exclusively historical associations connected with Edinburgh, we have the fact that Glasgow is the seat of some of the most important branches of trade and manufacturing industry; that it is the birthplace of several chemical arts, as well as the place where the invention of JAMES WATT was practically worked out, and where BLACK laid the foundation of our modern chemistry.

The manufacture of iron and cotton, of paraffin and hydrocarbon oil, chemical preparations, paper, etc., as well as dyeing, sugar refining, and the construction of machinery, shipbuilding, etc., are carried on upon a vast scale, either in Glasgow or its neighbourhood, and the attention given to these and other industrial pursuits has led to the increase of the population to upwards of half a million, or nearly double what it was when the British Association last held its meeting there twenty-one years ago, under the presidency of the Duke of ARGYLL.

For those who can spare time for excursions, Glasgow is a point offering unusual facilities of access to some of the most beautiful scenery in the world. Loch Lomond, the Queen of the Scottish Lakes, Loch Katrine and the Trossachs, and the classic land of BURNS, can be reached in two or three hours. The mouth of the Clyde and the Western Islands can be visited by means of steamers which are superior in accommodation to those in any part of the Kingdom, and these islands offer a wide field of attraction to the botanist, geologist, or antiquarian, in addition to the peculiar charm of their scenery.

In the city itself is an ancient cathedral and one of the oldest universities of the country, located in modern buildings of great elegance and convenience, besides a number of other features of interest to the most varied tastes. A new Guide Book to Glasgow and its neighbourhood is to be ready before the time of meetings, which will include full information respecting the industrial, educational, and historical objects of interest.

Altogether the attractions of the locality as well as the preparations and arrangements made for the reception of visitors are such that we may anticipate the meetings both of the British Association and of the Pharmaceutical Conference will be very largely attended, and those who have had any experience of Glasgow hospitality will know that there will be no lack of effort on the part of its inhabitants to accord a hearty welcome to all comers.

CONCENTRATED MEDICINES.

The practice of prescribing concentrated medicines is one involving such great risks that no excuse is needed for giving extra publicity to a fresh illustration of its dangers. Mr. Charles Gross, of Guy's Hospital, writing to the *Lancet*, states that on several occasions he had given a personal friend an ounce bottle containing six drachms of tincture of perchloride of iron and two drachms of solution of strychnia, with instructions to put the mixture into an ordinary quart wine-bottle, fill this up with water, and take half a wineglassful two or three times a day. This his friend had been in the habit of doing; on one occasion, however, he put the concentrated mixture into the quart bottle, but having no water at hand did not fill it up. Two days after, forgetting this omission, and apparently forgetful also of the dose, he went after a hearty breakfast and drank the whole of the mixture at a gulp. He experienced a sense of burning and constriction of the throat, but even then it did not occur to him that the medicine was undiluted. About an hour after he was seized with a tetanic convulsion, a very natural result from swallowing a grain of strychnia, and was conveyed to Guy's Hospital, where, being treated with belladonna and iodine he recovered. Mr. Gross speculates upon the probability that if the case had terminated fatally he would have been charged with poisoning his friend with an overdose of strychnia, as no one would imagine that an intelligent man would drink off such a dose of a strong medicine without remembering that he had omitted to dilute it. Mr. Gross has come to the very sensible determination that he will not prescribe concentrated medicine again in a hurry.

TARTAR EMETIC.

Even poisons may have their seasons of popularity, and just now the very name of tartar emetic is sure to attract the public eye. A statement in the *Pall Mall Gazette* that a grocer, living at Ballina, County Mayo, has been remanded on a charge of selling tartar emetic for cream of tartar, evokes from *Mr. Punch* the question, Is it lawful for a grocer to sell tartar emetic at all? We reply that in Great Britain it is not; but as to Ireland, we recommend him to address his question to Sir Michael Hicks Beach,—it might have the effect of dispersing some doubts that appear to exist on the subject. Our contemporary suggests that, if it is lawful, the sooner it ceases to be so the better, unless the grocer shows his qualification by submitting to a proper examination. Even then, he suggests an extended inscription should go over the grocer's shop door, describing him as being "Licensed to deal in tea, coffee, snuff, arsenic, corrosive sublimate, prussic acid, oil of vitriol, tartar emetic, vinegar, pepper, and poisons generally."

A correspondent writing to the *Times*, relates that going to a cupboard where medicines were kept, for the purpose of taking a seidlitz draught, the ingredients of which were kept in two bottles, he took down the tartar emetic instead of the tartaric acid bottle, stirred in a spoonful, and drank without noticing the absence of effervescence or difference in taste. In five minutes he vomited violently, and in ten or fifteen minutes was violently purged. The quantity taken was estimated at sixty grains, and the doctors attributed his escape from death to the largeness of the dose.

A NEW POISONS BILL THREATENED.

On Monday last, in the House of Commons, Sir W. Frazer gave notice that he would, early in next session, move for leave to bring in a Bill to amend the law relating to the sale of poisons and poisonous drugs. The *Globe* is of opinion that it is a question of growing importance whether the sale of poisons has not been granted too much freedom. It considers that in some cases the regulation providing for the inscription of purchasers' names in a book is quite inoperative as a public safeguard.

POISONING BY PELLITORY.

In the *Practitioner* for the present month, Mr. H. Langley Brown reports the case of a child, three and a half years old, who swallowed about fifty minims of tinctura pyrethri, left in a bottle that had been in use for toothache. No emetic was administered by the parent, who is a chemist, the drug being looked upon as harmless. Profuse perspiration and restlessness ensued, followed by an exhausting and painful diarrhœa, then by stupor, rapid and weak pulse, and twitchings of the limbs. Fourteen hours after the poison was swallowed the twitchings increased to violent convulsions lasting for an hour and leaving the child apparently moribund, after which he gradually improved, but for some time there were occasional convulsive movements. The irritation of the bowels and twitching subsided after about thirty-six hours, but the pulse continued rapid (120 to 130) during four days. The treatment consisted in enemata of starch with five drops of tincture of opium, port wine and coffee, with ice to the forehead and spine. A farinaceous diet was continued during three deys.

Proceedings of Scientific Societies.

ROYAL SOCIETY.

The Polarization of Light by Crystals of Iodine.*

BY SIR JOHN CONROY, BART., M.A.

On examining by means of a Nicol prism the light reflected from the surface of a layer of iodine, obtained by heating a fragment of that substance and then squeezing it between two plates of glass, I found that the film did not appear of uniform brightness, and that when the Nicol was rotated the relative brilliancy of different parts of the film changed—a portion that had appeared dark when the principal section of the Nicol was vertical, became bright when it was horizontal, and *vice versâ*; and, also if instead of altering the position of the Nicol, the film of iodine was rotated horizontally, the Nicol remaining at rest, the same changes in brilliancy occurred.

Removing the upper glass made no difference, except that the surface of the film of iodine tarnished rapidly, and then the amount of light reflected by it became considerably less.

The light incident upon the surface of the iodine was either ordinary diffused daylight or the light of a paraffin lamp; and in neither case did it show more than the merest trace of polarization, and generally not even that, when examined by means of a double-image prism and a plate of selenite.

It therefore appears that the light reflected from the surface of a layer of iodine is polarized, and that the position of the plane of polarization is not, of necessity, either parallel or perpendicular to the plane of incidence, but bears a definite relation to some direction within the crystals composing the film.

I also found that when these films were sufficiently thin to be transparent the light they transmitted was polarized, and that the plane of polarization of the transmitted light was perpendicular to the plane of the light which was polarized by reflection from the same portion of the film.

After making these observations I ascertained that W. Haidinger had announced, upwards of twenty years ago (Pogg. Ann. clxxi. p. 321, 1847), that the surface-colours which certain substances show by reflected light, in the case of some of the platino-cyanides, namely, those of potassium, barium, and magnesium, consist partially of light polarized in a plane which bears a definite relation to the axis of the crystal; and in a subsequent paper (Sitzungsberichte der kaiserlichen Akademie der Wissenschaften, viii. p. 97, 1852) he states that certain other substances have the same property. He mentions iodine in this latter paper as showing these "surface-colours," but does not appear to have noticed that the plane of polarization of the light reflected from its surface bore any relation to some fixed direction within the substance.

I arranged a form of polariscope by means of which these observations could be repeated with a greater degree of accuracy. The instrument used consisted of a divided brass circle fixed vertically to a firm support; a Nicol furnished with a graduated circle was carried by an arm moving round the centre of the circle, and the slip of glass with the layer of iodine rested horizontally on a stage at the top of a tube, the height of which could be adjusted so that the surface of the iodine was level with the centre of the graduated brass circle. Both the stage and the tube revolved horizontally, and could be rotated independently of each other; and the latter had an index moving over a divided circle attached to it, and a diaphragm with an opening about 6 mm. wide fixed in it. By altering the position of the arm moving over the vertical circle the light reflected from the surface of the iodine at different angles could be examined; and by reflecting light along the axis of the tube, by a mirror placed below it, and clamping the arm in such a position that the axis of the tube and Nicol were in the same straight line, the polarization of the light transmitted by the iodine could also be observed. A second or polarizing Nicol was so arranged that it could either be brought below the tube or placed between the surface of the iodine and the source of light, so that the behaviour of the film, when the incident light was polarized, could be studied.

On repeating the before-mentioned observations with reflected light, I found that occasionally portions of the film of iodine appeared quite black in certain positions of the film and Nicol, and that these same portions, when examined by transmitted light, did not merely alter in colour as the film or Nicol was rotated, as the remainder did, but in certain positions transmitted no light at all—or, in other words, that they behaved in a similar manner to what a plate of tourmaline would have done; and when seen by ordinary light and the naked eye, although they appeared to be of the same thickness as the remainder of the film, by which they were wholly or partially surrounded, they were of a much paler colour; usually, moreover, they reflected rather less light than the rest.

The change in the appearance of these portions of the film when seen through a Nicol was very striking in the case of some of the larger ones, as in certain positions they appeared perfectly transparent and of a pale yellow colour, and objects situated behind them could be clearly seen; but on turning either the film or the Nicol they became perfectly opaque, and resembled highly polished metallic surfaces.

On examining one of these films of iodine with a microscope with a ⅔ object-glass I found that those portions of the film which polarized light most strongly differed considerably in appearance from the remainder, and that they appeared to consist of long crystals about ·003 inch wide adhering together side by side, whilst the rest of the film seemed to consist of thin plates of iodine overlaying one another, these also being long in proportion to their width.

A Nicol prism was placed over the eyepiece, and I then found that when the principal section of the Nicol was perpendicular to the long axes of the crystals, the maximum amount of light was transmitted, and when the principal section was parallel with the long axes of the crystals, they either appeared perfectly opaque or transmitted the minimum amount of light, according as the crystals in the field of view belonged to one or other class.

Other specimens of iodine showed this crystalline arrangement with different degrees of distinctness; but in all, or nearly all, some trace of it could be seen. In some cases, however, the minimum amount of light was transmitted when the principal section of the Nicol was not parallel with what appeared at first sight to be the long axes of the crystals; but a more careful examination usually showed some traces of crystalline structure in a direction parallel with the principal section of the Nicol.

I shall refer to these two forms of iodine as iodine α and iodine β, calling those portions of the film α which are of a darker colour and polarize the light imperfectly, and the light-coloured strongly polarizing parts β.

From the appearance of the film, when seen under the microscope, it appears probable that this difference depends merely on the arrangement of the crystals, and that when they are regularly disposed in a single layer the film is one of those which I have called iodine β; whilst iodine α consists of several layers of thin crystals lying in various directions, or it may be due to different faces of the crystals of iodine being in contact with the glass, and to the light passing through the crystals in a different direction.

The difference between the action of the crystalline

* Paper read before the Royal Society.

film on the transmitted light is one of degree only; for I obtained two specimens of iodine β in which the film was of unequal thickness; and in this case, when the principal section of the Nicol was parallel with the long axes of these crystals, the thick portion of them appeared opaque. but a considerable amount of light was transmitted by the thinner portions of the very same crystals. Moreover several specimens of iodine β which appeared perfectly opaque in certain positions of the Nicol when seen by ordinary daylight, were of a deep red colour when examined by direct sunlight; and I have recently succeeded in preparing several films of iodine β so thin that they were only opaque when seen through a Nicol, whose principal section was parallel with the length of the crystals, with very weak light; by ordinary daylight they appeared of a deep red colour under these circumstances.

Iodine α.—Films of iodine α between two slips of glass were laid on the stage of the polariscope, and the light they transmitted examined with the analysing Nicol; on turning either the stage or the Nicol, the colours of the film varied, according to their thickness and the relative positions of the film of iodine and the Nicol, from a kind of brownish yellow to a deep red, the colours being similar to those of solutions of iodine in alcohol of various strengths.

When the incident light was polarized, and the film of iodine placed so as to transmit the minimum amount of light, or at right angles to this position, the field was dark when the Nicols were crossed and light when they were parallel. When, however, the film of iodine was in an intermediate position, the field was no longer dark in any position of the analyser, the colour and intensity of the light varying slightly as it was turned.

Iodine β.—A film of iodine β of a yellowish brown colour was examined by transmitted light; the field appeared perfectly dark in two positions of the film and Nicol. With polarized light, when the film was placed at right angles to the position in which it transmitted no light, the field was dark when the Nicols were crossed and light when they were parallel. When, however, the iodine film was placed in an intermediate position, the field was no longer dark when the Nicols were crossed, though it was so in two positions of the analyser 180° apart.

In order to simplify the description of the experiments, I shall speak of the direction in the film which, when placed parallel with the principal section of the Nicol, caused the field to appear dark, or in the case of iodine α to be least bright, as the axis of the crystal.

Very thin films of iodine β, as I have mentioned before, are not opaque when the principal section of the Nicol is parallel with the length of the crystals, and, when examined with the polariscope, appear of a deep red colour, when, under similar circumstances, a thicker film would transmit no light at all.

Hence it would appear that iodine belongs to the class of double refracting substances in which the coefficient of absorption differs according to the direction in which the light passes through the crystal, and, further, that the ray whose plane of polarization is perpendicular to the axis of the crystal is most energetically absorbed.

This is the case with both forms of the crystalline layer of iodine; but the two rays are much more unequally absorbed by iodine β than by iodine α—so much so that whilst the latter only appears absolutely opaque when the principal section of the Nicol and the axis of the crystal are parallel, when the film is so thick that but little light can pass through under any circumstances, the former absorb the one ray so energetically that a layer which appears light yellow when the Nicol is in one position is absolutely opaque when it is turned through an angle of 90°.

When a thin film of iodine β is seen through a Nicol whose principal section is so placed that the minimum amount of light is transmitted, the light usually appears of the same colour and brightness as that which has passed through the adjacent portions of the film consisting of iodine β; and it is impossible to see where one form of the film ends and the other begins. From this it would appear as if both forms of the crystalline layer absorbed light polarized in a plane perpendicular to the axis of the crystals with equal intensity, but that they differ greatly in their absorptive powers for light polarized in a plane at right angles to this.

I have shown, in the preceding paper, that solutions of iodine in alcohol, when seen by transmitted light, vary in colour, from a pale yellow to a deep red, according to the strength of the solution and the thickness of the layer through which the light has to pass. In a similar manner, in proportion as the thickness of the films of iodine increases, the light becomes more and more red; and four films of iodine β, which when seen separately were of a pale yellow, appeared of a deep red when superimposed, and so placed with respect to each other that they transmitted the maximum amount of light.

The light of a paraffin lamp reflected from the surface of a film, consisting partly of iodine α and partly of iodine β between two slips of glass, was examined by means of the Nicol, the angle of incidence being about 60°.

When the principal section of the Nicol was in the plane of incidence, and when consequently but little of the light reflected from the surface of the glass was transmitted, portions of the film of iodine appeared of different degrees of brightness; and on rotating either the Nicol or the stand, the relative brilliancy of different portions of the film changed, those portions which consisted of iodine β appearing perfectly black in certain relative positions of the film and Nicol, whilst the remainder of the film merely became more or less bright.

The film of iodine was then placed so that the portion consisting of iodine β appeared perfectly black when the principal section of the Nicol was in the plane of incidence. On rotating the stand, light reflected from the surface of the iodine was transmitted by the Nicol, and increased in quantity till the stand had been turned through 90°, when the surface of the iodine had a brilliant metallic lustre. On continuing the rotation, the surface gradually lost its brilliancy, and when the stage had been turned through 180° appeared perfectly black again.

On rotating the Nicol the same changes took place; but the light reflected from the surface of the glass marked the effect to a considerable extent when the principal section of the Nicol was no longer in the plane of incidence.

The light incident upon the surface of the glass showed no signs of polarization when examined by a double-image prism and plate of selenite, and only the faintest trace of it after passing through, at an angle of about 60°, a slip of glass similar to those used for covering the layers of iodine; consequently the polarization of the light must be due to the film of iodine.

From this it appears that the light reflected from the surface of a film of iodine β is polarized; and by examining the light transmitted by the same portion of the film, it was ascertained that the plane of polarization of the reflected light is perpendicular to that of the ray which is most freely transmitted, and consequently that the reflected light is polarized in a plane at right angles to the axis of the crystals.

When the incident light was polarized, it was found that it was reflected from the surface of the iodine when the plane of polarization of the light was perpendicular to the axis of the crystals, and extinguished when parallel.

As has been stated before, when a film of iodine α is seen through a Nicol, it does not appear black in any position; but the brilliancy of the surface alters as the Nicol or iodine is rotated.

Experiments similar to those just described show that when a ray of plane polarized light is incident upon such a surface of iodine, it is never completely extinguished, as is the case with iodine β; but the intensity of the reflected light depends on the relative position of the plane of polarization and the axis of the crystals, being least when they are parallel.

When the slips of glass between which the iodine has been melted are carefully separated, the film usually remains attached to one of them in a sufficiently perfect condition to be examined. At first it is extremely brilliant, and shows exactly the same appearances as have already been described as occurring with film of iodine under glass. The surface, however, not only tarnishes rapidly, but even at a low temperature (10°) the film quickly evaporates, and consequently the uncovered films are somewhat difficult to examine.

They, however, permit some additional facts to be observed, which either are seen with difficulty or not seen at all when the iodine is covered with a plate of glass; and chief amongst these is the "surface-colour" which iodine shows when light is incident upon it at a high angle.

When a film of either iodine α or β is placed on the stage of the polariscope with its axis parallel with the plane of incidence and the principal section of the Nicol in the same plane, the surface of the iodine appears bright and metallic when light is incident on it at an angle of about 60°. As the angle of incidence increases, the colour of the reflected light changes; at about 70° the surface appears blue, and is still bright, but has lost its metallic appearance to a considerable extent, and at about 72° the colour is most intense; but as, in addition to the difficulties which are inseparable from determinations of this kind, the instrument which I have used for these experiments does not allow of any very accurate measurements being made with it, the value of these angles can only be regarded as approximate.

On rotating the stand the amount of reflected light diminishes rapidly, and the iodine appears dark or nearly so when the axes of the crystals are perpendicular to the plane of incidence.

On rotating the Nicol, the axes of the crystals of iodine remaining parallel with the plane of incidence, the surface of the iodine becomes bright and metallic, the maximum amount of light being transmitted when the principal section of the Nicol is perpendicular to the plane of incidence.

When the incident light is polarized in the plane of incidence the surface of the iodine appears brilliant and metallic in all positions, and when seen through the analyser the amount of light reflected by the film alters as the former is rotated, but there is no trace of colour.

When, however, the light is polarized perpendicularly to the plane of incidence the reflection from the surface of the iodine is a coloured one when the axes of the crystals are parallel with the plane of incidence; consequently the appearance of the film is exactly the same when unpolarized light falls on its surface and it is seen through a Nicol whose principal section is vertical, and when the incident light is polarized perpendicularly to the plane of incidence and it is seen directly.

These experiments show that when light falls upon the surface of a film of iodine at an angle of about 72° a portion of the light is polarized by reflection in the plane of incidence, and this independently of the position of the crystals composing the film, and that another portion of the light, which is coloured by reflection, and to which the surface-colour is due, is polarized in a plane whose direction depends on that of the crystals composing the film, and, further, that this light is polarized perpendicularly to the axis of the crystals.

The surface-colour can only be seen when the angle of incidence which the light makes with the surface of the iodine is a large one; and the reason that, in the case of iodine covered with glass, it is not visible, apparently is, that with a large angle of incidence nearly the whole of the light is reflected from the surface of the glass. I succeeded in seeing the blue colour in the case of a fragment of iodine which had been melted between a slip of glass and one of the sides of a small crown-glass prism of an equilateral section, and also when such a prism was placed on the surface of one of the glass slips covering the iodine, a drop of carbon tetrachloride (the index of refraction of this liquid being nearly the same as that of the glass) being placed between the slip and the prism, as under these circumstances light can reach the surface of the iodine at a greater angle than is possible when it is covered by a flat piece of glass; but in neither case was the surface-colour so well seen as when the iodine was uncovered.

Haidinger has remarked (Sitzungsberichte der kaiserlichen Akademie der Wissenschaften, Band viii. p. 97) that the surface-colours are complementary to the colour of the light transmitted by the same substance; and this also appears to be the case with iodine, as in the solid and liquid condition, and also when dissolved in certain liquids, it absorbs most readily the blue rays; but at the same time, as Professor Stokes has pointed out, the surface-colour and the colour of the transmitted light can only be said to be complementary within very narrow limits, as the colour of the transmitted light varies with the thickness of the layer of substance through which it passes.

Films of iodine α and β, when the light was incident on their surface at a considerable angle, were found to polarize the light elliptically in certain positions of the film, as was shown by the black cross being distorted when a plate of Iceland spar, cut perpendicularly to the axis of the crystal, and a plano-convex lens of about 40 mm. focal length were placed between the surface of the iodine and the analysing Nicol. The amount of distortion, which was never very considerable, increased with the angle of incidence, and appeared to attain its maximum when the angle was about 72°.

When a film of either iodine α or β is placed on the stage with its axis perpendicular to the plane of incidence and the principal section of the analyser parallel with the latter plane, the black cross is perfect; but on turning the film till its axis is parallel with the plane of incidence, the cross becomes slightly distorted, and the centre appears bluish. When the light falling on the surface of the film is polarized in a plane forming an angle of 45° with the plane of incidence, the principal section of the analysing Nicol still remaining in that plane, the black cross is perfect as long as the axis of the iodine is perpendicular to the plane of incidence, and distorted when it is parallel.

Iodine β only shows the black cross very faintly with unpolarized light when its axis is perpendicular to the plane of incidence.

The distortion when the incident light is polarized is far greater than that produced by the reflection of a ray of light, polarized at an angle of 45° with the plane of incidence, from the surface of a piece of glass, and quite comparable in amount with the effect produced when the light falls on a metallic surface.

I selected from a large quantity of freshly sublimed iodine a few pieces bearing a more regular crystalline form than the rest, and amongst these there were two nearly triangular plates, about 10 mm. long and 8 mm. broad.

One of these was arranged on the stage of the polariscope, and the light reflected from the surface observed in the way that has already been described in the case of the films of iodine.

The light was most completely polarized when the angle of incidence was about 72°; when the length of the crystal was perpendicular to the principal section of the analyzer it appeared darkest, and when parallel with it lightest.

The surface-colour and the distortion of the black cross were as clearly seen as with the film of iodine.

After several unsuccessful attempts I succeeded in preparing some well-defined crystals of iodine by carefully heating on a sand bath a small quantity of that substance in a wide-mouth stoppered bottle, when some perfect rhomboidal plates of iodine about 1 mm. long were deposited on the cool part of the bottle. When these were examined with the polariscope, the principal section of the Nicol being in the plane of incidence, they appeared brightest when their long axis was parallel with, and darkest when it was perpendicular to, the plane of incidence.

Hence it appears that when the long axes of these crystals are parallel with or perpendicular to the plane of incidence, part of the light reflected from their surface is polarized in the plane of incidence, and part in a plane at right angles to their long axes, and consequently that the long axes of these rhomboidal plates correspond with that direction within the film of iodine which has been spoken of as the axis of the crystal: and as iodine belongs to the trimetic system, this may be considered the principal axis, as being the one in the direction of which the crystals are prismatically developed to the greatest extent; and it also appears that when a ray of light passes normally through such a crystal it is divided into two rays polarized respectively parallel with and perpendicular to the same axis; and the one whose plane of polarization is parallel with the principal axis suffers the least absorption.

ANN ARBOR SCIENTIFIC ASSOCIATION.*

The Aromatic Group in the Chemistry of Plants.

BY PROFESSOR PRESCOTT.

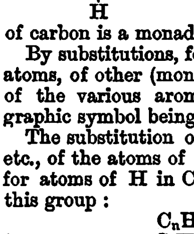
The term Aromatic Group was first given to the benzoic series of compounds, as classified around the common nucleus benzoyl, by Leibig and Wöhler in 1833. Benzoyl, C_7H_5O, was the first compound radical recognized in complex vegetable products, and its discovery at once opened new ways of investigation in the field of organic chemistry. From time to time other chemical nuclei have been defined, in the construction of other groups of carbon compounds, until, now, it may be said, there are as many series of these bodies as most persons care to number among their scientific acquaintances. But there has been no greater activity or keener enthusiasm or richer reward, in all the labours of the forty years of organic chemistry, than in the work devoted to the aromatic group. The place which this group holds in organic chemistry is similar, in certain respects, to the position which organic chemistry itself occupies in general chemical science.

Among the valuable results of the labour devoted to this group we must accept, first, a clearer insight into the constitution of molecules, throwing better light upon the chemistry of all bodies. That phase of "the new chemistry" which finds expression in graphic formulæ—the theorizing as to the relations of atoms to each other within the molecule, with whatever of well-grounded philosophy or of fallacious hypothesis appertains—has, in no small share, been due to work which has been sceptically designated as that of "those German chemists running crazy with what they call their aromatic group." It is not to be supposed that the expenditure of this labour, or of any pioneer labour in science, has been without waste. But the evidence of its substantial success is before the chemical world in the long list of well-defined aromatic bodies now as truly under the control of the chemist, in analysis and synthesis, as are the metallic salts. And this evidence is not addressed to the chemical world alone. The world of factories and ships, the world seeking a sign as to the truth and use of all and any science, has received from the chemistry of the aromatic group a good number of palpable demonstrations of the power of chemical knowledge. There have been produced, under chemical direction, from the waste of coal-gas manufacture alone, aromatic substances as follows: since 1856, anilin dyes, now sold at ten millions of dollars yearly, to colour stuffs in the tints of the rainbow for every household; since 1870, madder dye, amounting in 1873 to 1000 tons, valued at over four millions of dollars; and, this year, the acid of wintergreen oil, promising to be the most useful of the antiseptics, being applicable to foods and drinks,—beside a considerable number of other products, in themselves of no slight importance in commerce and the arts. Assuredly, the aromatic bodies have been found valuable material both in physical science and in industrial economy.

As regards their significance in biological science, the question will arise: how far may an insight into the constitution of molecules formed in plants help the chemist toward an understanding of the *formative steps* in plant chemistry? Before we can reach this final question in our subject, we must consider, first, what the aromatic group is, and where in the vegetable kingdom it extends, and, next, by what steps the molecules of this group are formed outside of living bodies, under conditions arranged by the chemist.

The aromatic group, when this term was first adopted, consisted of benzoic acid, bitter almond oil, amygdalin, cinnamic acid, cinnamon oil, cuminic acid and cummin oil, with a considerable number of artificial derivatives from these bodies,—nearly all having penetrating aromatic odours. The possession of aromatic odours, however, is not especially characteristic of the very great number of bodies now classified in this group. The present definition of the aromatic group, is, in briefest terms, *the series of bodies built upon benzene.*

Benzene (also termed benzole), containing $\frac{72}{78}$ carbon and $\frac{6}{78}$ hydrogen, may be formulated as C_6H_6: being in vapour 39 times heavier than its volume of hydrogen, its molecular weight is 78 and it must be formulated as C_6H_6. Carbon, here as almost everywhere, is a tetrad, and the six tetrad atoms of carbon have twenty-four bonds of chemical union. As only six of these are occupied by the six monad atoms of hydrogen, eighteen bonds must (it is believed) connect carbon with carbon,—forming nine lines (or movements?*) of union between carbon atoms. As it is found in certain compounds that each one of the six carbon atoms behaves alike, it appears that each must hold the same relations to its fellows, and they must be disposed in a ring, as first proposed by Kekule, in 1865.



The nine lines of union between the six atoms of carbon (if not connecting alternate or opposite atoms, *i.e.*, if disposed in the ring) require the alternate unions to be made by double lines. Then each atom of carbon in the ring has one bond of union free to be held by atoms (or semi-molecules) outside of the carbon ring: so that as regards other elements each atom of carbon is a monad.

By substitutions, for one or more of the six hydrogen atoms, of other (monad) atoms or radicals, the formulæ of the various aromatic compounds are obtained: the graphic symbol being always a hexagon.

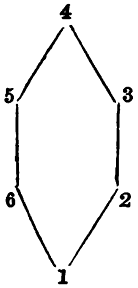
The substitution of methyl, CH_3, for one, two, three, etc., of the atoms of H (around the hexagon)—and also for atoms of H in CH_3—constructs *the hydrocarbons* of this group:

	C_nH_{2n-6}	*Number of possible Isomers.*
1.	C_6H_6	Benzene.
2.	$C_6H_5(CH_3)=C_7H_8$	Toluene.

* Reprinted from the 'Proceedings' for 1875-6.

* Kekule, *Ann Chem. u. Pharm.*, clxii, 77. Ladenburg, *Deut. Chem. Ges. Ber.*, v., 322. 'Watts' Dictionary of Chem.' 2nd Supplement, 132.

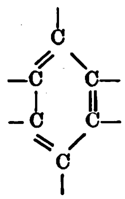
3. $C_6H_4(CH_3)_2 = C_8H_{10}$ Xylene. Three (1, 2: 1, 3: 1, 4).
4. $C_6H_3(CH_3)_3 = C_9H_{12}$ Cumene. Three (1, 2, 3 : 1, 2, 4 : 1, 3, 5).
5. $C_6H_2(CH_3)_4 = C_{10}H_{14}$ Cymene. Three (1, 2, 3, 4 : 1, 2, 4, 5 : 1, 3, 4, 5).
6. $C_6H(CH_3)_5 = C_{11}H_{16}$ Amylbenzene. One (1, 2, 3, 4, 5).
7. $C_6\ (CH_3)_6 = C_{12}H_{18}$ Amylmethylbezene, etc.



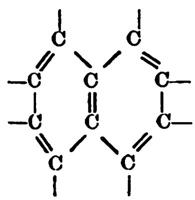
The hydrocarbon having two of the original hydrogen atoms displaced (No. 3) may evidently have contiguous or alternate or opposite atoms displaced, thus presenting three different kinds of molecules,—and the number of variations mathematically possible is given above as a theoretical number of possible isomers. The full number of possible isomers, on this theory, has been actually produced in most instances, though not in all, and perhaps has not been exceeded in any instance. Thus, there are known three compounds having the ultimate composition and molecular weight of xylene, differing in certain properties: orthoxylene (having parts 1 and 2 of the hexagon occupied by methyl), isoxylene (having 1 and 3) and metaxylene (having 1 and 4 occupied by methyl). This correspondence between fact and theory in the number of isomers strengthens the evidence that the hexagonal figure represents the *actual relations* of the atoms in the molecule. But it must be borne in mind that, while figures are placed upon paper to represent certain ascertained *relations* of atoms to each other, nothing has been ascertained as to the *places* of atoms in molecules. Other relations than those of place may be represented geometrically, with advantage.

The aromatic hydrocarbons, together, are known as the benzoles—the chief liquid distillates from coal tar—coal tar naphtha. Among the distillates from coal tar are two other hydrocarbons, which are solid, and are of unusual importance in industry, namely: naphthalene and anthracene. These are not homologous with benzene, as members of the same series (C_nH_{2n-6}), but belong each in another series related progressively to the benzene series, with mathematical harmony, as follows:

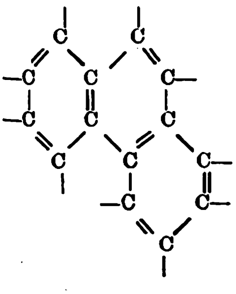
Benzene——C_6H_6 or C_nH_{2n-6}——Single Hexagon——



Naphthalene—$C_{10}H_8$ or $C_nH_{2n-2\times6}$ —— Double Hexagon—



Anthracene—$C_{14}H_{10}$ or $C_n\,H_{2n-3\times6}$—Triple Hexagon—



From these hydrocarbons (*i.e.*, from the hexagon, single, double or triple) all the aromatic bodies are extended. *Displacing* (one or more atoms of)

H by OH, phenols are formed (as in carbolic acid).

H by $C\left\{\begin{matrix}O\\OH,\end{matrix}\right.$ acids „ „ (as benzoic acid).

$\left.\begin{matrix}H\\H\end{matrix}\right\}$ by $\left\{\begin{matrix}OH\\C\left\{\begin{matrix}O\\OH\end{matrix}\right.\end{matrix}\right.$, acids „ „ (as salicylic acid).

H by $N\left\{\begin{matrix}H\\H,\end{matrix}\right.$ amines „ „ (as anilin).

$\left.\begin{matrix}H\\H\end{matrix}\right\}$ by $\left\{\begin{matrix}O\\|\\O,\end{matrix}\right.$ quinones „ „ (as anthraquinone).

The aromatic hydrocarbons have been looked upon as bodies of too simple chemical construction to exist in plants, and this is certainly true of the lighter portion of them. The first three members of the benzene series are not found in the vegetable kingdom, and the fourth, cumene, or trimethylbenzene, has been reported found only in Roman cummin oil. But the fifth member of the series, cymene, or tetramethylbenzene—a body having the molecular weight 134 and hence in vapour 67 times heavier than its bulk of hydrogen—a liquid closely approaching both in composition and in properties to turpentine oil—is, in its various isomers, distributed among plants to an extent not fully understood. It has generally been put down as more especially an educt of three plants, *Cuminium cyminium* (cummin) and *Cicuta virosa* (water hemlock), of the umbelliferæ, and *Thymus vulgaris**, of the mint family; also sometimes of a fourth, *Ammi Copticum*. But a large number of the volatile oils of plants contain hydrocarbons of the composition $C_{10}H_{14}$, more and more of which are found by chemical treatment to yield aromatic products and almost certainly to be built upon the benzene nucleus and to fulfil the character of "cymenes." *Eucalyptus globulus*, the Australian fever tree, which has received much attention of late years, contains a cymene as well as a terpene.

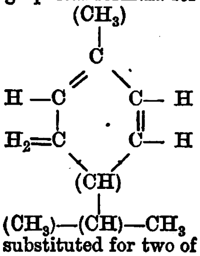
Now there appears to be only a short step in composition between cymene $C_{10}H_{14}$, and *oil of turpentine*, $C_{10}H_{16}$, which is found in the coniferous trees, but this short step suffices to throw oil of turpentine out of the homologous series of aromatic hydrocarbons. Now isomeric with turpentine oil proper are "the terpenes" generally, including the essential oils of apricot, bergamot, birch, camomile, caraway, cloves, cubeb, elemi, hop, juniper, lavender, lemon, orange, parsley, pepper, savin, spike, tolu, thyme, and an indefinite number not named or not brought to notice. In fact, a large proportion, probably a majority, of essential oils contain terpenes, generally with other essential oil constituents. To present some approximate indication of the extent of distribution of the volatile oils altogether, a count has been made of the number of plants reported to contain volatile oils in the tabular summary of plant constituents given as the Second Part of Wittstein's 'Chemischen Analyse von Pflanzen und Pflanzentheilen' (1867). This summary includes 576 plants in 114 natural orders. Among these, essential oils are reported in 156 or 27 per cent. of the plants, and in 45 or 39 per cent. of the families.†

Oil of turpentine and its numerous isomers have mostly been placed, unclassified, among "the vegetable substances little known," but there is a beginning that promises to draw them into the aromatic group and assign them

* C. R. A. Wright, *Jour. Chem. Soc.*, 1873, 686.

† Of the natural orders, the Labiatæ had the largest number of plants containing volatile oils (13 p.c. of all); the Umbelliferæ the next largest number; the Synantheriæ next, and the Myristiceæ next (6 p.c. of all).

Rolls, however, in his judgment, expressly declares 'that graphical formulæ of the hexagonal type. In 1872, A. Oppenheim reported to the German Chemical Society an investigation at the Berlin Laboratory* on the production of a cymene from oil of turpentine by abstraction of hydrogen (cymene dibromide being heated with anilin). As a result of his research the investigator gives this graphical formula for turpentine oil:



Here one of the carbon atoms of the ring has been loosened and displaced by the triad CH, giving the adjacent carbon atom only one line of connection in the ring and two outside bonds, so that four carbon atoms carry five of hydrogen. The remaining two points of the hexagon have taken methyl (CH_3) instead of hydrogen and one of these methyl molecules has methyl again substituted for two of its hydrogen atoms. Later, Oppenheim reports the formation of cymene from the terpene of cummin oil† and offers other confirmations. Kekule has since traced relations between cymene and camphor (the immediate oxidate of a terpene), $C_{10}H_{16}O$, from which he presents a graphical formula. Kekule confirms the relationship between cymene and the terpenes, using iodine instead of bromine, and accepts Oppenheim's conclusions.‡

Graebe has dissented from the view that turpentine oil is of the aromatic type, although he finds a relation between the terpene in wormseed oil and cymene. § The conclusions of Oppenheim are mostly confirmed and extended by the labours of C. R. A. Wright with oils of lemon, orange and nutmeg, reported to the London Chemical Society, in 1873. ‖ It seems, then, strongly probable, if not yet fully established, that the terpenes, extending as they do widely through the vegetable kingdom, are all built upon the benzene nucleus, being, however, somewhat complex extensions of that nucleus.

From this standpoint, too recent to be secure, no small share of the most simple carbon compounds which plants contain—those destitute of oxygen and nitrogen—belong to the aromatic group. It has long been well known that plants contain *oxidized* aromatic compounds very closely related to hydrocarbons, so that the latter are easily *obtained from plant constituents*. Benzene itself took its name from the abundant educt benzoic acid, from which Mitscherlich first obtained it in 1834, by heating with lime or by stronger heat with iron. It is obtained by dry distillation or by more gentle treatment from the most of the aromatic compounds, and by harsher methods from bodies not built upon it; having been discovered by Faraday in 1825 among the vapours distilled at a high temperature from fats. Toluene was obtained by Deville, who first examined it and named it, by distilling Tolu balsam; and it is obtained with especial ease by the moderate action of heat upon a large number of resins—this being one of the many indications that most resins contain the aromatic nucleus. Xylene is also easily obtained from resins. The reverse of these transformations, the constant production of resins from terpenes by atmospheric oxidation in balsams and turpentines, will require mention further on. And the manufacture of aromatic hydrocarbons, on the large scale, from coal, will be noticed with the methods of production from inorganic sources.

Parliamentary and Law Proceedings.

IMPORTANT DECISIONS UNDER THE REGISTRATION OF TRADE MARKS ACT,

In the Chancery Division of the High Court of Justice, on Friday, July 28, an application *ex parte Stephens* was made before the Master of the Rolls, which was of some importance under the Trade Marks Registration Act, 1875.

The applicant, Henry Charles Stephens, recently applied to the Registrar under the Act to be registered as the proprietor of a trade mark, and sent in a statement stating that the trade mark was composed of certain letters in the following distinctive combination:—AEILYTON, which he alleged that he used as a distinctive device for certain inks manufactured by him, and upon his invoices, cards, etc., to describe and distinguish the said inks. The Registrar having refused to register the trade mark in question, on the ground that it was a mere word, and therefore, not within the Act, as it had not been used as a trade mark before the passing of the Act, Mr. Stephens now applied that the register might be rectified by inserting his name as proprietor of this trade mark.

Mr. Chitty, Q.C., and Mr. W. C. Fooks, in support of the motion, contended that the word was a "device" within the meaning of section 10, and, as such, capable of registration, quoting, amid some laughter the authority of Longfellow for the word "Excelsior" being "a strange device;" but

The Master of the Rolls said that the Registrar was quite right. The Act defined a trade mark, for the purposes of the Act, to be either the name of an individual or firm printed, impressed or woven in some particular and distinctive manner, or a written signature or copy of a written signature of an individual or firm, or a distinctive device, mark, heading, label, or ticket. And there was a proviso that there might be added to any one or more of these particulars any letters, words, or figures, or combination of letters, words, or figures. It was his Lordship's opinion that the Act did not enable a mere word to be registered unless it had been used as a trade mark before the passing of the Act, which this word had not been. He therefore refused the motion, with costs.

Respecting this decision Mr. Stephens, has written to the *Times* as follows:—"The decision on the 28th of July of the Master of the Rolls (the first judicial decision under the above Act) upon my right to have the word 'Aeilyton,' as applied to a new discovery of mine registered under such Act, is of wide commercial importance. Until the Act was passed the Courts of Law and Equity recognized a right of trade mark in a distinctive word or name as applied to any particular manufacture, and protected the owner of such trade mark in its exclusive user as applied to such manufacture. Without multiplying instances I may mention the well known words 'Eureka,' as applied to shirts; 'Excelsior,' as applied to soap; 'Anatolia,' as applied to balm; and 'Glenfield,' as applied to starch. The commercial world will learn with surprise that the law, according to the Master of the Rolls, will not for the future recognize a right of trade mark in any distinctive word unless such word was in use before the passing of the Act. I, in common with a large proportion of my manufacturing and commercial brethren, never imagined, and do not now believe, that it was the intention of the Legislature in defining a trade mark to consist, among other things, 'of a distinctive device, mark, heading, label, or ticket,' to reverse the previous law on the subject and to exclude from right to registration any new and distinctive word specially devised for employment as a title, heading, or label for any particular class of manufacture. The Master of the

the power to register as a trade mark a distinctive word used before the passing of the Act clearly negatives the conclusion that a distinctive word can be used as a trade mark after the passing of the Act.' Now, Sir, can it be supposed that it was the intention of the legislature by an enactment purporting to further the interests of commerce to reverse the previous law on the subject by implication merely? Surely the Legislature would have expressed any such intention by direct and positive enactment; and if the law be such as from the decision of the Master of the Rolls, it would seem to be, the attention of the commercial world cannot be too earnestly directed to the matter with a view of procuring another amendment of the Act."

In the High Court of Justice, Chancery Division, on Monday last, before Vice-Chancellor Sir C. Hall, an application was made by Mr. James Meikle, a tea merchant, to have his name inserted on the register of trade marks, as the proprietor of a device used by him in his business. The device bore the word "registered," and the question was whether under the recent Trade Marks Registration Act, 1875, this word could be retained. In March, 1874, Mr. Meikle had had his device registered under the Copyright of Designs Act, 1862, and thenceforward adopted the word "registered" on his wrappers; but, in consequence of the new Act, he applied to the Commissioners of Patents for registration under such Act. It appeared, however, that the Registrar, acting under the direction of the Commissioners, refused to entertain the application unless the word "registered" was struck out, and Mr. Meikle now applied by summons under Section 5 of the Act of 1875, to have the register "rectified" by having the design registered in its integrity. Under the Act and the rules of the Commissioners a design must be published or advertised in the *Official Trade Marks Journal* for three months prior to registration; but in Mr. Meikle's case, this had not been done in consequence of the Registrar's direction that the word "registered" should not appear in the journal. By the Act, the Commissioners have power to frame rules and give directions for the direction of the Registrar.

The Vice-Chancellor said he was unable to make the order asked for. In the first place, no advertisement of the design had been made as required by the Act. The object of the Act in requiring advertisements was to give any member of the public an opportunity of objecting to the intended registration. In the next place, the Registrar was the officer of the Commissioners, and was bound to act in accordance with their directions, and they had directed him not to place the word "registered" on the register. If his Lordship were now to give directions that this should be done he would be directing the Registrar to act in complete opposition to the orders of the Commissioners, and such a direction he could not give to a subordinate officer, and the Registrar could not act upon such a direction. He was, therefore, of opinion that although the Court had jurisdiction in a proper case to rectify the register, yet, looking at the position of this officer, he could not control and direct him by making the order asked for. The applicant must, therefore, take such other course as he should think fit.

Leave was then asked to amend the summons by giving directions for the insertion of the proper advertisements of the design, with a view to registration, and

His Lordship gave leave accordingly.—*Times.*

Poisoning by Cyanide of Potassium.

At an inquest held in Cork, respecting the death of Henry Hunter, it appeared that the deceased, who had been for some time mentally affected, had died from the effects of swallowing about 20 grains of cyanide of potassium.

Obituary.

Notice has been received of the death of the following:—

On the 9th of July, 1876, Mr. James Graham, Chemist and Druggist, of Glasgow.

On the 14th of July, 1876, Mr. Walter Fisher, Chemist and Druggist, Horwich. Aged 33 years.

On the 25th of July, 1876, Mr. Joseph D. Blacklock, Pharmaceutical Chemist, Old Steine, Brighton. Aged 63 years. Mr. Blacklock had been a Member of the Pharmaceutical Society since 1841.

On the 25th of July, 1876, Mr. George John Atterbury, Chemist and Druggist, Sutton-on-Trent. Aged 70 years.

On the 29th of July, 1876, Mr. Michael Henry Ainlie, Chemist and Druggist, Peckham. Aged 50 years.

On the 25th of July, 1876, Mr. Robert Durno Mitchell, Pharmaceutical Chemist, Berkeley. Aged 33 years. Mr. Mitchell had been a Member of the Pharmaceutical Society since 1867.

Correspondence.

The Birmingham Trade Conference.

Sir,—Just a word on the effect which the Birmingham Trade Conference had upon the equanimity of some of our representatives at the late Council meeting.

When the President expressed his regrets "that these gentlemen who were so eloquent at Birmingham did not come to the Annual Meeting of the Society," he must have forgotten that the Pharmaceutical Society only includes 20 per cent. of the registered members of the trade, and if his invitation should be accepted he may be requested to defray the return travelling expenses of those whom he could not admit to the annual meeting. Surely, the trade may meet in Birmingham, if they wish it, without first asking permission from Bloomsbury Square. Let me remark that the meeting was directly representative of 1200 chemists, a number larger than that of the voters who have conferred his office upon Mr. Williams. On the charge of eloquence made against our speakers, please extenuate this fault of my friends, Mr. Editor. I do not feel that it would be right to retort *tu quoque.*

That the Conference has already had a rousing effect at Bloomsbury Square is thoroughly satisfactory. It is the perpetual cry of "all's well" that we want to get rid of. I will give one fact that should upset a great many of the optimist assertions about the Pharmaceutical Society doing all that it possibly can for the trade. About a year since, a chemist at Leeds was prosecuted for the sale of Milk of Sulphur, and, as is well known to your readers, after an adjourned hearing, the stipendiary dismissed the case. In this interval, in my capacity of local secretary, I applied to the Secretary of the Pharmaceutical Society that if the decision should be against the chemist, we should be authorized to apply for a case for a higher court. I received a refusal, with some compliments upon our powers of self-preservation. Fortunately, the necessity for appeal did not occur.

But, as remarked before, the effect of the Conference has been excellent, and it will probably be but a few years, when the Council in omitting its September meeting will bracket the gathering of the Chemists and Druggists' Trade Association with that of the British Pharmaceutical Conference as the reason.

Richard Reynolds.

13, Briggate, Leeds,
August, 8, 1876.

SULPHUR PRÆCIPITATUM.

Sir,—At the June meeting of the Society of Public Analysts, the President, Professor Redwood, in the course of his remarks on Dr. Hill's paper, is reported to have said —"It would be found, if the two preparations were properly examined, that the sulphur existed in milk of sulphur in a more pure and less nauseous state than that in which it existed in precipitated sulphur. The method usually adopted in examining these preparations afforded a very imperfect insight into their respective natures. By the application of heat one was volatilized entirely, and the other left a residue of sulphate of lime; from which it was inferred that the one was pure sulphur and the other was not. If examined in another way, however, a different conclusion might be arrived at. Let each powder be treated with bisulphide of carbon, by which the sulphur would be dissolved, leaving in one case a dark-coloured oily residue of persulphide of hydrogen, and in the other case pure silky crystals of hydrated calcic sulphate."

This statement seemed to me so remarkable, that I was induced to test its truth by experiment; and a short account of the results may not be without interest. A good sample of precipitated sulphur was treated with carbon disulphide, and there remained a dark coloured residue—not oily, however, but pulverulent. This was placed on a small filter, and washed with carbon disulphide, and as soon as it had become dry, a minute portion was put on a glass slide with a drop of water, and viewed under the microscope, when it appeared as a fine amorphous powder. The remainder was examined chemically, and found to consist chiefly of calcium, iron, chlorine, and sulphur.

Several other commercial samples were examined in the same way, and with similar results. All contained a little iron, and all gave dark brown residues.

A small quantity of precipitated sulphur was made in accordance with the directions of the British Pharmacopœia. This specimen was of a pale yellow colour, without any tinge of grey, and on treatment with carbon disulphide left a light yellow residuum of insoluble sulphur.

I next prepared some hydrogen persulphide by pouring a solution of calcium disulphide into an excess of hydrochloric acid. When the yellow oily liquid was dropped into carbon disulphide, it quickly dissolved.

It is evident, then, that the method employed by Professor Redwood to prove the presence of hydrogen persulphide in precipitated sulphur is based on "scientific use of the imagination."

JOHN T. MILLER.

Sheffield, August 7, 1876.

THE EFFECT OF AGE ON RHAMNUS FRANGULA BARK.

Since my first introduction of this bark at the Pharmaceutical Conference held in Edinburgh, in 1871, I have probably had more pass through my hands and sent out more of the concentrated decoction than any other person, and fortunately the bark that I have made use of has always been of considerable age. The first supply which I received from Holland was certainly one or two years old before it was used, and as I have always taken care to have a good supply on hand, the bark must in all cases have been kept a year or two. This must be held to account for the fact that in no one instance have I known or heard of the action of this drug to be other than a pure mild aperient, or as Mr. Giles put it, perhaps the only true aperient that we have. It is, therefore, very desirable that no new bark should be used, and as I hope to see it introduced into the next edition of the British Pharmacopœia, stress should be laid upon its being old. The experience of the last five years has added to my conviction that Rhamnus Frangula is a most valuable medicine, and Dr. De Vrij's testimony to the estimation in which it is held in Holland should induce medical men in this country to make trial of it to a still greater extent than they have yet done—especially in hospital practice.

H. C. BAILDON.

CAMPHOR AND IODINE.

Sir,—While reading over the paper on the liquefaction occurring in the admixture of camphor and chloral hydrate, contributed by Mr. Saunders (of Canada), it struck me that he or some other investigator might be able to explain the cause of an apparently similar phenomenon which takes place on rubbing together camphor and iodine with iodide of potassium.

I do not know whether any of your readers have observed the effect, but I first noticed it some time ago while preparing linimentum iodi, some of which I required, but it had run out of stock. Accordingly I proceeded to make the quantity ordered in the official formula, so having triturated the dry ingredients in a wedgwood mortar for a few minutes and continued the same while I reviewed the proportions I had used of the requisite constituents previous to adding the spirit, I observed the mixture had become quite moist and pasty. I, therefore, carried on the rubbing a little further when the mass assumed the form of a thick blackish looking semifluid of a tarry consistence, ultimately being converted into a dark reddish coloured mobile liquid (not unlike bromine in appearance), which occupied a bulk of six fluid drachms, and on dilution with ℥vj of S.V.R., it measured exactly ℥iss.

On that occasion I had not time for contemplation but simply attributed the cause of these physical changes to some unaccountable property, probably akin to the remarkable union of chloral and camphor—owing (as I considered) to the analogy of chlorine with iodine. However, I thought no more of the subject until the article alluded to published in the issue of July 29, brought the circumstance to my recollection and led me to think this time a suitable opportunity of eliciting (through the medium of the Journal) the opinion of some competent authority, which is always more satisfactory than mere speculation.

Since writing the above I repeated the process by way of experiment, excluding the potassic iodide, when the result attained was quite different, so that my rashly formed conclusions were erroneous. The questions which now present themselves to my mind are:—Has the iodide anything to do in the matter? Is it the sole cause of the change? Would any other salt exercise the some influence? Is it a chemical combination or merely a mechanical mixture? But I am not in a position to answer these problems. Possibly the effect produced may depend on the humidity of the atmosphere, the moisture being attracted by the mineral salt. Still I scarcely imagine that the absorption of water from the air could have been so rapid, and I doubt whether the deliquescent property of the iodide of potassium be great enough to justify the acceptance of that assumption as a sufficient explanation, so I wait until the difficulty be solved by some one capable of handling the subject.

JAMES B. L. MACKAY.

Newcastle-on-Tyne, August 8, 1876.

C. Crook.—*Arnica Cerate.*—The formula is as follows—

"Spermaceti	. . . . .	3 ozs,
White Wax	. . . .	6 „
Olive Oil	. . . . .	14 „

"Add 1 drachm of medicated tincture to every 9 drachms of cerate, and stir briskly until cold."

"*Nostrum.*"—Wittstein's 'Pocket Book of Nostrums' could probably be obtained through Messrs. Williams and Norgate, or any foreign bookseller. It is written in German.

"*An Old Student.*"—You are recommended to address your question to the Secretary.

"*Aqua.*"—(1) It probably would do so. (2) You will find an account of the mode of procedure in any elementary work on analysis.

A. C.—The substance is bitartrate of soda.

F. S. T.—See an article on the Preservation of Plants for Herbaria, in vol. iv. (1874), p. 754.

W. R. Fowler.—The Act may be obtained from Her Majesty's printers, Messrs. Eyre and Spottiswoode.

In reply to several correspondents who have sent specimens of plants, we regret being unable at present to furnish the information they require, since our Botanist is "over the hills and far away."

F. J. Barrett.—(1) We know of nothing of the kind. If you refer to Watts's 'Dictionary' you will find the coefficient of expansion from which you can calculate what you want to know. (2) Bolley and Paul's 'Handbook of Technical Analysis' (Bohn's Scientific Series).

R. J. Atkinson.—The crystals are selenite, or hydrated calcium sulphate.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Peters, Mr. Annacker. Mr. Edward, Mr. Lewis, Mr. Fowler, S. W.

AVA, OR KAVA-KAVA.

The root known under the name of Kavà-Kava has lately attracted some attention in France as a remedy for gonorrhœa, and will probably be tried in this country.

Although the plant which yields it (*Piper methysticum*, Miq.) has been known since the time of Captain Cook, and although papers have more than once appeared in the *Pharmaceutical Journal* concerning it, yet a full description of the root and leaf for the purposes of pharmacognosy does not appear to have been given in either of the papers alluded to. A figure of the plant and of portions of the root were supplied with Mr. Morson's paper in

Fig. 1.—*Piper methysticum*, Miq.

1844,* but since many of our readers may have some difficulty in referring so far back, Mr. Morson's figure of the plant is here reproduced, and a fresh figure of the root structure is added. We are led to believe that these wood-cuts, together with a description of the root and leaf, will be useful to some of our readers, from the fact that we have lately received from Paris, under the name of Kava-Kava, some leaves and fruit, which consist of matico leaves mixed with the fruit of the arnatto plant!

The Kava-Kava plant is known by different names in different islands: thus in Viti it is known as "Yaquona," in Tahiti as "Ava-Ava," in Hawaii as "Kawa,"* and in the Marquesas Islands as Kava, or Kava-Kava.†

In New Zealand a species of pepper (*Piper excelsum*, Forst.) very similar in appearance to *Piper methysticum*, Miq., is known under the name of Kawa-Kawa. This plant, however, does not appear to possess the intoxicating properties generally ascribed to the root of *Piper methysticum*, but is only used as a tea and for toothache.‡ Its leaves, are generally only about half the size of those of *Piper methysticum*, and have only 5—7 veins radiating from the top of the leaf-stalk.

The Ava, or Kava-Kava plant, is cultivated in Viti, Tahiti, Hawaii, the Society and Tongan islands. Several varieties of the plant are distinguished by the natives. Those which grow on dry soil are said to produce the most active roots.

The *Piper methysticum* is a shrub about six feet high, with stems varying from 1 to 1½ inch in thickness. The leaves are rather large, varying in size from 4—8 inches in length, and being nearly as broad as they are long. In shape they are cordate, tapering above somewhat suddenly into a very short acute apex. The leaves are stalked, the petiole being usually from 1 to 1½ inch long, and dilated towards its base. To the naked eye the leaves appear smooth, although with the aid of a lens they are seen to have the veins covered with minute hairs, while the rest of the leaf has short hairs thinly scattered over it. The principal veins of the leaf, of which there are usually ten to twelve, radiate from the top of the petiole, the three central veins being very close together for about half-an-inch upwards from the base of the leaf.

The root is large and fibrous, but rather light and spongy in texture. When fresh it is said to weigh usually from 2 to 4 lbs., although it sometimes attains as much as 20 lbs. in weight, or even more. In drying, however, it loses rather more than half its weight. Externally the root is of a greyish-brown colour, and has a very thin bark, which when sliced off shows a complete network of woody tissue (Fig. 2), some of the interstices of which are filled with soft yellowish-white cellular matter, whilst others are quite empty. Internally the root is of a yellowish-white colour (In a variety of the plant known as "Marea" it is citron-yellow internally, and in another variety known under the name of "Avini-Ute" it is of a pinkish colour.) A transverse section (Fig. 3) shows a number of narrow lines (woody

* *Pharm. Journ.* [1], vol. iii., p. 474.

* Seemann, 'Fl. Vitiensis,' p. 260.

† *Pharm. Journ.* [2], vol. iv., p. 85.

‡ Hooker, 'Flora of New Zealand,' Part I., p. 228.

bundles) radiating from near the centre to the circumference, the portions of the soft cellular tissue by which

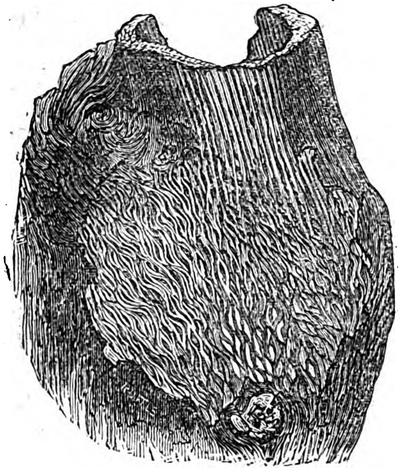

Fig. 2.—Section exposing the network of woody tissue below the thin root bark.

the lines are separated from each other being much wider than the lines themselves. The central portion of the root is soft and cellular, with a few woody bundles anastomosing with each other and proceeding at right angles to the radiating bundles, so

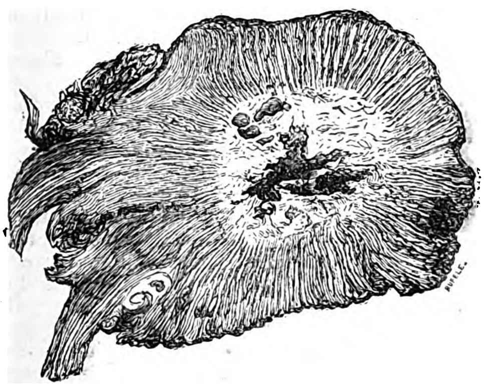

Fig. 3.—Transverse section of the root.

that they form a network in the centre of the transverse section. The root has a pleasant odour, recalling that of the lilac (*Syringa vulgaris*, L.), or meadowsweet (*Spiræa Ulmaria*, L.). It has a slightly pungent taste, and causes an increase in the flow of saliva, with a slightly astringent sensation in the mouth; and a scarcely perceptible bitterness.

The root and extreme base of the stem are the parts generally used.

The form in which it has been used for medicinal purposes is an infusion made by macerating about one drachm of the scraped root in a quart of water for five minutes. Unlike most other remedies for gonorrhœa, the taste of the infusion is pleasant, while its bitterness improves the appetite and does not produce nausea. The root contains, according to M. Cuzent, an essential oil of a pale yellow colour, 2 per cent. of an acrid resin, and about 1 per cent. of a neutral crystalline principle called Kavahin or Methysticin, which is obtained in acicular crystals by crystallization from a concentrated tincture. Kavahin differs from piperine and cubebin in being coloured red by hydrochloric acid, the red colour fading on exposure to air into a bright yellow, and in being coloured by strong sulphuric acid a purplish violet colour, which passes into green. The root contains also nearly half its weight of starch.

The action of Kava root appears to vary with the amount taken. In small doses it is generally stated to act as a stimulant and tonic, but when taken in large doses it produces an intoxication which differs from that caused by alcohol in being of a silent and drowsy nature, accompanied by incoherent dreams, the drinker not being quarrelsome or excited.

The roots grown in damp soil, however, produce a slightly different effect, the drunken person becoming irritated by the least noise. For an interesting account of the way in which the intoxicating beverage is made the reader is referred to former papers in this Journal.*

It appears probable that the medicinal properties of the plant are due neither to Kavahin nor to the resin, since a watery infusion produces the characteristic effects of the drug, and neither Kavahin nor the resin are soluble in water. The therapeutical properties of the different chemical constituents of the root, therefore, still require more accurate investigation.

The root is stated to have been used with success in erysipelatous eruptions,† which is rather remarkable since when taken in excess as an intoxicating beverage it produces a peculiar kind of skin disease, called in Tahiti "arevarea." In old drinkers the vision becomes obscure, and the skin, especially in parts where it is thick, becomes dry, scaly, cracked and ulcerated. In Nukahivi the natives use Kava for phthisis and in bronchitis, a small dose being taken at bedtime. It has also been recommended to be used internally and locally for gout.‡

It was first recommended for gonorrhœa in 1857.§

COMPARATIVE ANALYSES OF RADIX FILICIS MARIS.‖

BY PROVISOR KRUSE.

In the Baltic provinces and many other districts in Russia the rhizome of the male fern collected at Wolmar is preferred as a remedy against tapeworm before all others. The author therefore thought it would be useful to undertake an analysis of this drug and especially to note the variations in composition which the rhizome might undergo at different seasons of the year.

In the neighbourhood of Wolmar the male fern is dug up in forests; but that collected in the dry forests of broad-leaved trees (*Laubwäldern*) is preferred, because it is less decayed and yields a rhizome that can be more easily cleaned. The rhizome having been freed from the frond and the decayed portions of the root is washed and quickly dried with a moderate heat. After drying the rhizomes

§ *Annal. de Therap.*, 1857, p. 61.
‖ Abstract of a communication from the Pharmaceutical Institute in the University of Dorpat (*Archiv der Pharmacie* for July, p. 24.)

they are examined separately, and perforated pieces and those that have become somewhat brown in drying are thrown away. Admixture of the rhizome of *Filix mas* with that of *Filix fœmina* can seldom occur, as the latter but seldom occurs in this district. But the area in which the true male fern grows is year by year taken up by the destruction of the forests, so that probably it will not be collected much longer in the neighbourhood of Wolmar.

The author used for his experiments a sifted powder prepared from picked rhizomes possessing the peculiar beautiful green colour and strong smell. The rhizomes collected in April and October possessed greater intensity of colour than those collected in July of the same year (1874). In order to see how great the variation might be in different years, the author also analysed some rhizomes dug up in the autumn of the following year (1875).

Percentage estimation of the Moisture, Hygroscopicity, and amount of Ash.

	April.	July.	Oct.
Air-dried rhizome further dried at 110° C. gave off moisture	15·7	13·4	13·5
Powder kept two days in air saturated with steam at 15°C. gave off in moisture when dried at 110°C.	24·5	23·7	28·1
Amount of ash from the air-dried rhizome	1·9	2·2	2·1
Amount of ash from the rhizome dried at 110°C.	2·2	2·5	2·5

The ash consisted of—

	1874			1875
	April.	July.	Oct.	Sept.
Manganese (MnO)	5·0	5·5	3·2	3·0
Ferric Oxide (F_2O_3)	—	—	1·8	1·75
Magnesia (MgO)	?	?	19·3	19·4
Lime (CaO)	15·3	12·8	16·4	16·5
Potash (K_2O)	17·7	16·1	17·6	17·3
Soda (Na_2O)	1·9	2·3	1·9	2·1
Carbonic Acid	2·6	3·7	3·9	3·5
Silicic Acid (SiO_2) and Sand	10·8	11·0	10·3	10·0
Phosphoric Acid (P_2O_5)	20·2	20·1	19·0	19·6
Sulphuric Acid (SO_3)	5·4	5·3	5·6	5·8
Chlorine	0·59	0·69	0·61	0·61

The quantitative examination of the ash was made with two portions. With one the carbonic acid was estimated in a Geissler's apparatus by means of nitric acid, and the chlorine by titrating the neutral solution with silver nitrate, using neutral chromate of potash as an indicator. The second portion was heated to dryness with concentrated hydrochloric acid, redissolved by the aid of dilute hydrochloric acid and the undissolved silicic acid filtered off. The filtrate was divided into two parts. In one (A) the sulphuric acid was estimated with chloride of barium, the phosphoric acid was separated with sesquichloride of iron and acetate of ammonia, the manganese was precipitated as sulphide; after the removal of the alkaline earths the potash and soda were estimated together as chlorides and then the potash alone as platino-chloride. B was neutralized with ammonia, redissolved in acetic acid, acetate of ammonia added and the iron precipitated by boiling as ferric phosphate. The filtrate was again divided into two parts: in one (A) the phosphoric acid was estimated volumetrically with acetate of uranium; in B, after removal of the phosphoric acid with ferric chloride, etc., the lime was estimated by means of oxalate of ammonia and ammonia in the presence of ammonium chloride, as oxalate and afterwards converted into caustic lime by incineration. Finally the magnesia was precipitated with ammonia and phosphate of soda.

Extraction with Water, Alcohol, Ether, Petroleum Spirit, etc.

A. The rhizome was exhausted with water at the ordinary temperature after macerating 24 hours, the product filtered under atmospheric pressure, and the filtrate at once evaporated to dryness. The extract was dried until two succeeding weighings gave the same result. The remaining powder was then exhausted with 85 per cent. alcohol.

	1874			1875
	April p. cent.	July p. cent.	Oct. p. cent.	Sept. p. cent.
The dried aqueous extract amounted to	36·4	25·4	35·1 36·6	35·5
The alcoholic extract amounted to	21·6	22·8	8·5 8·7	8·5

The rhizome after exhaustion with water and alcohol yielded to ether only a small quantity of fat, the greater part of the fat and the filicin must have already been taken up by the alcohol.

B. A fresh portion of the root was now extracted first with alcohol, and the extract was evaporated to dryness as above. The root was then treated with water. As the results obtained in these experiments showed a great difference from those obtained in the previous set, a controlling experiment was made, but with almost exactly the same results:—

	1874			1875
	April p. cent.	July p. cent.	Oct. p. cent.	Sept. p. cent.
The dried alcoholic residue amounted to	27·3	26·1	39·5	39·0
The aqueous extract to	14·7	17·0	10·7	10·1

In comparing the results of these two series of experiments a difference is observable, which at first is difficult to explain. We find that the sum of the constituents soluble in water and alcohol differs with the order in which the solvents are used, and that the yield from the April and July rhizomes is greater, and from the October rhizomes smaller, when treated first with water and then with alcohol. The different result with the April and July rhizomes can be explained by the assumption that previous to and during the period of vegetation, the rhizomes contain albumen coagulable by alcohol. It can also be accepted that certain bodies insoluble in water are carried into solution by the tannin then present. But these circumstances are probably insufficient perfectly to explain the difference.

C. A portion was next exhausted with ether, and the extract dried at 100° to 110° C. The portion insoluble in ether was then extracted with alcohol, and the extract dried. The portion soluble in alcohol was soluble in water also. The residue insoluble in ether and alcohol still yielded a further quantity of extract to water.

	April p. cent.	July p. cent.	October p. cent.
1. Ethereal extract	10·3	12·4	11·5
2. Alcoholic extract	17·8	16·7	24·5
3. Aqueous extract	12·8	6·9	14·8

Ether dissolves fat, chlorophyll and filicin, of which, as shown by experiment A, the greater part is taken up by alcohol also. Accordingly the total quantity soluble in ether and alcohol in C should be precisely equal to the quantity of substance soluble in alcohol in B. With the April and July rhizomes this proved to be nearly the case, but not with the October. The portion in C insoluble in ether and soluble in alcohol must be referred for the greater part to tannic acid and sugar. The portion in C insoluble in ether and alcohol and soluble in water consists of mucus, salts, and substances of unknown composition.

D. A fresh quantity of the rhizome was extracted with a petroleum spirit having a low boiling point, and the extract dried at 100° to 110° C. It was afterwards exhausted with alcohol and gave an extract that was soluble in water also.

	April p. cent.	July p. cent.	October p. cent.
1 Petroleum ether extract	9·3	8·4	9·1
2. Alcoholic extract, soluble also in water . . .	16·9	15·2	19·4

The October rhizome, after treatment with petroleum spirit gave with alcohol a beautifully green coloured extract (probably chlorophyll which had retreated to the rhizome in the autumn), whilst the extracts from the April and July rhizomes were yellow.

The petroleum spirit extract is free from resinous substances and chlorophyll, and so far may be taken as a more exact expression of the quantity of fat than the ether extract in C. It is possible that it does not contain the whole of the filicin, but the greater part is certainly present in the extract.

E. Another quantity of the rhizome was treated with doubly rectified petroleum, and yielded a thick fluid dark green extract. The remaining powder was then treated with acetic ether.

	April. p. cent.	July p. cent.	October. p. cent.
1. Petroleum extract . . .	14·0	11·4	17·2
2. Acetic ether extract . .	4·9	5·1	4·9

A portion of the fat of the rhizome is insoluble in petroleum as well as in the less volatile portion of the petroleum spirit.

Estimation of the Starch.—In order to estimate quantitatively the amount of starch the rhizome was digested 48 hours in a steam bath with a 4 per cent. alcoholic potash solution, and then washed with alcohol and water until it showed no alkaline reaction. The impure starch remaining upon the filter was boiled with dilute sulphuric acid until no more dextrine was precipitated by alcohol, and the liquid was filtered, neutralized, and titrated with Fehling's solution. The starch in the April rhizome amounted to 28·2 per cent., in the July to 22·7 per cent., and in the October to 15·4.

Estimation of Sugar.—The rhizome was extracted with equal parts of alcohol and water, the product filtered, the alcohol distilled off, and the tannic acid precipitated with acetate of lead. The precipitate was filtered off, excess of lead removed from the filtrate by sulphuric acid, the liquor filtered, then neutralized with soda solution, and titrated with Fehling's liquor. The sugar amounted in the April rhizome to 1 per cent., in the July to 1·4 per cent., and in the October to 2·8 per cent.

Estimation of Tannic Acid.—The rhizome was exhausted with hot water and the product filtered under pressure. The filtrate was decomposed with acetate of copper and the precipitate of tannate of copper washed, dried at 110° C. and weighed. It was then decomposed by moistening with fuming nitric acid and the oxide of copper thus obtained subtracted from the tannate of copper gave the amount of tannic acid precipitable by copper. This amounted in the April rhizome to 4·6 per cent., in the July to 6·9 per cent., and in the October to 5·9 per cent.

A second quantity was treated similarly with acetate of lead. This gave, however, for the April rhizome 9·2 per cent. of tannic acid, July 9·8 per cent., and October 11·7 per cent.

The tannic acid of the fern blackened solutions of ferroso-ferric oxide, and precipitated gelatine solution but not solution of tartarated antimony.

Estimation of Filix Red.—The ammoniacal aqueous extract of the root exhausted with water was evaporated with dilute sulphuric acid to dryness, the residue dissolved in water, the filix red collected upon a filter and washed with water until it showed only a weakly acid reaction. The filix red from the April rhizome amounted to 5·2 per cent., the July to 6·9 per cent., and the October to 7·8 per cent.

Estimation of Mucus and Albumen.—Two portions of each of the three samples were exhausted with water, the aqueous extract evaporated to a syrupy consistence, and alcohol added. The precipitate was separated by filtration, washed, dried at 110° C., and weighed. From the weight found the weight of ash was deducted and the difference was taken as the amount of mucus and albumen. It amounted in the April rhizome to 5·1 and 5·4 per cent., in the July rhizome to 2·2 and 2·5 per cent., and in the October rhizome to 2·1 and 2·15.

The Estimation of Filicic Acid was unfortunately without result. The fat oil was removed from the rhizome by means of twice rectified petroleum, and an attempt was made but unsuccessfully to obtain the filicic acid by means of acetic ether. The petroleum could not be driven off from the root without a very strong heat, by which the filicic acid was decomposed. Further, a portion of the tannic acid always dissolved in the acetic ether. An experiment was also made by boiling the rhizome with carbonate of soda, dissolving with alcohol the compounds of soda with the fatty acid and filicic acid, and separating by addition of an acid. But the precipitated filicic acid dissolved in the fat oil. An attempt to separate the filicic acid from the fat oils by dissolving in acetone also failed, the filicic acid and the fatty oils always dissolving together. Neither could the methods given by Dr. Luck for the preparation of filicic acid be used for its quantitative estimation as the yield was much too small and the fatty oil separated always carried with it a part of the filicic acid.

METHODS OF CHEMICAL DECOMPOSITION AS ILLUSTRATED BY WATER.*

BY PROFESSOR J. H. GLADSTONE, PH.D., F.R.S.

Among the most venerable of the Chinese classics is the 'Shoo King,' a collection of ancient historical records; and one of these records, the fourth book of Chow, contains a still more ancient document, 'The Great Plan with its Nine Divisions,' which purports to date from the early part of the Han dynasty—according to Dr. Legge, about 2000 B.C. This remarkable treatise bears

* A lecture delivered at the Royal Institution of Great Britain, Friday, May 5, 1876. From the *Chemical News*, August 4, 1876.

on physical as well as ethical philosophy, and commences with an account of the five elements, viz., water, fire, wood, metal, and earth. The first element, water, is said to "soak and descend," and also to "become salt."

This seems to be the earliest known record of that doctrine of elements which spread widely over the ancient world. In the 'Institutes of Manu,' we read of the elements also as five, but they are earth, fire, water, air, and ether; and according to the cosmogony of the Hindoo legislator, light or fire produced water, and water produced earth. There was, however, at least as late as two centuries ago, a sect in India who held it as a religious tenet that water was the prime and original element.

Similar opinions found their way to Europe. Thus Thales, of Miletus, who flourished in the sixth century B.C., taught that water was the origin of all things. The Greek philosophers generally adopted the theory of several elements, but reduced the number to four—fire, air, earth, and water.

It is hard to say what was the precise meaning attached by the ancients to the term "element." It no doubt did not always convey the same idea. Water also, at least in the Aristotelian philosophy, was a generic expression for many bodies in a fluid condition, and signified not so much a special material substance as an inherent quality of things. Thus it was said to be cold and moist, and the opposite of fire which was hot and dry. In the philosophy of the middle ages we find the same views prevailing, and the early chemists still looked upon water in the same light. Thus Becker enumerated five elements—air, water, and inflammable, mercurial, and infusible earth; while Stahl adopted four—water, acid, earth, and phlogiston. The ancient theory maintained its hold till the experimental philosophers at the latter part of the eighteenth century gave a definite meaning to the term element, and showed that water, air, and earth are compound bodies. Yet the idea of the elementary character of water was not easily abandoned.

In 1781 Cavendish found that when a mixture of what were then called "inflammable air" and "dephlogisticated air" is exploded by a spark in such proportions that the burnt air is almost entirely phlogisticated, pure water condenses on the sides of the vessel, and is equal in weight to the weight of the two airs. His theory was that water consists of "dephlogisticated air united to phlogiston," and that "inflammable air is water united to phlogiston." At the time of explosion, according to him, the excess of phlogiston was transferred from the inflammable to the phlogisticated air, and thus both airs "turned into water." Cavendish also explained Priestley's production of inflammable air on heating iron filings strongly, by contending that the phlogiston of iron united with the moisture from which they had not been freed. Lavoisier gave a different explanation of these phenomena. He held that "dephlogisticated air" is an elementary substance—oxygen—united with imponderable caloric, and that "inflammable" air, or hydrogen, is capable of taking the oxygen from the caloric, thus producing water and heat. "Water is not a simple substance, but is composed, weight for weight, of inflammable and vital air." Thus water was at length deposed from its rank as an element.

In the first year of this century, when the news of Volta's great discovery of the pile was made known in England, Messrs. Nicholson and Carlisle made various experiments with a series of half-crowns, zinc plates, and pasteboard soaked in salt. Knowing that water conducted electricity, they inserted brass wires through corks at the two ends of a tube filled with water, which they are careful to tell us came from the New River. They were surprised to see a stream of minute bubbles rising from one pole while the other was corroded, and that this decomposition took place at each pole, though they were nearly 2 inches apart. They enlarged the distance, and found that 36 inches of water was too much for their force to traverse. Substituting flattened platinum for their brass wires, they found that the water was decomposed with the production of hydrogen at one end and oxygen at the other.

The old notion that water, by continuous boiling, was turned into stone had been previously dispelled by Lavoisier, but Davy found that some salts and earths remained behind when water was electrolysed, and that when the experiment was conducted in two cells communicating with one another, the liquid in the one cell became acid and the other alkaline. He traced the origin of this in a masterly research, which formed the Bakerian lecture for 1806.* He found that the earthy substances were original impurities in the water, or came from the vessels employed; and using gold cones filled with distilled water and united together by asbestos, he convinced himself that nitric acid was produced at the positive pole and ammonia at the negative. Suspecting that these were produced from the small quantities of nitrogen dissolved in the water combining with the liberated oxygen and hydrogen respectively, he took extraordinary precautions. Making use of water which he had carefully distilled in a silver still at 140° F., and performing the experiment *in vacuo*, or rather in a space which he had twice filled with hydrogen and exhausted as thoroughly as the means at his disposal would permit, he then found that the water was decomposed without the least production of either acid or alkali. "It seems evident then," wrote Davy, "that water, chemically pure, is decomposed by electricity into gaseous matter alone, into oxygene and hydrogene."

In the following year Davy discovered the metals of the alkaline earths, potassium and sodium, and found that when these bodies are thrown upon water they decompose it, appropriating its oxygen and setting free its hydrogen. This is due to the superior chemical power or "affinity" of the alkaline metals.

In 1846, Mr., now Sir William, Grove observed that when steam was subjected to something like a white heat, small quantities of mixed oxygen and hydrogen gas were always produced.† It has since been shown that the gases are actually dissociated in one part of the flame of the oxy-hydrogen blowpipe, after their first combination.

It thus appears that there are three distinct ways in which water may be decomposed:—By an electric current;‡ by some substance which has a superior attraction for one of its elements; or by heat alone.

It will readily be understood that the power of any one of these agents will be augmented by the co-operation of either of the others. Thus, the action of chemical affinity is usually augmented by heat; for instance, if a pellet of sodium be thrown upon cold water it melts, on account of the chemical action at once set up, but if upon boiling water it not only melts but bursts into flame through the greater violence of the action. This is the reason why, in Priestley's experiment, iron at a red heat decomposed steam, though it will not do so at ordinary temperatures.

Similarly the electrolysis of water is much facilitated if there is some chemical affinity between the oxygen and the metallic conductors. It is generally said that it requires two cells to decompose water electrolytically. Now, it is true that if platinum poles are employed there is no visible disengagement of gas when one cell only is used; but with zinc poles a single cell of Bunsen or Grove is amply sufficient. Zinc alone without the voltaic current is incapable of displacing the hydrogen in water; but it must be borne in mind that the tendency to com-

* *Phil. Trans.*, 1807, p. 1.

† *Ibid*, 1847, p. 1.

‡ Though volatile electricity alone is referred to in this discourse, it is well known that other forms of the same agent will effect chemical decompositions. Thus Professor Andrews has resolved pure water into its constituent gases by frictional electricity, and by that derived from the atmosphere.

bine with oxygen is a constant property of this metal and is easily brought into activity by the co-operation of the feeble voltaic current. The increased effect upon electrolysis which is due to the nature of the poles is in proportion to the electromotive force of the different metals. For pure water the order is — zinc, lead, iron, copper, silver, platinum, as tested by a galvanometer. This difference of result according to the nature of the metals employed in the electrolytic cell appears generally to have been overlooked, and it is the feeblest metal—platinum—which is usually employed for experimental purposes, doubtless because it is incapable of oxidation—the very reason of its feebleness.

When the other metals of the above list are used, not only does the positive pole oxidize, but the oxide, or rather hydrate, dissolves more or less in the pure water, and becomes itself an electrolyte. The consequence of this is that the positive electrode gradually wears away, while the metal is transferred to the negative electrode, and is deposited upon it in crystalline fringes or filaments. With silver these are particularly beautiful, as they assume arborescent forms, especially when able to spread over the surface of the containing vessel.

The temperature also of the liquid subjected to electrolysis has a great influence upon the result. Thus in an experiment where zinc poles and pure water were employed, the deflection of a galvanometer was found to increase about fourfold between 5° C. and 80° C., and the action augmented nearly *pari passu* with the temperature.

A similar result occurs, as might be expected, when two dissimilar metals, such as zinc and copper, are placed in cold water in connection with one another, and the water is heated. The deflection was found to double between about 30° and 80° C., but the difference for every 5° at the higher temperatures was several times greater than at the lower ones.

Another very important point in the electrolysis of water is to reduce to a minimum the very great resistance offered by the water itself. This is effected by bringing the electrodes as near to one another as possible; and for the same reason, if the force be generated by the action of two dissimilar metals upon water, they should be brought into the closest proximity.

A still more powerful means of decomposing water would evidently be a combination, not of two, but of all three agents, chemical affinity, heat, and voltaic force acting at an insensible distance. Thus zinc has a strong affinity for oxygen, but is unable of itself to displace the hydrogen of water; when united, however, with a more negative metal, such as copper, its power is enhanced to such a degree that a separation of the constituents does take place; but in the ordinary arrangement of a voltaic cell the action is so slight that no evolution of gas is perceptible. To produce a visible effect, the metals must not only be close together, but ought to touch one another at a myriad of points. This may be brought about by depositing the copper upon the zinc in a spongy condition; then the zinc will be oxidized, and bubbles of hydrogen will appear among the branches of the copper, even at the ordinary temperature, but the effect is greatly increased by the application of heat.

The arrangement just described is the "copper zinc couple," which has been employed by Mr. Tribe and the speaker, and more recently by others, to effect a variety of chemical decompositions. Zinc foil is immersed in a solution of sulphate of copper until a black velvety deposit of the metal is produced; the soluble salts are then washed away, and the couple after being dried is ready to be placed in any liquid it is desired to decompose. Water was the first body experimented upon, and it was found that the action would go on as long as there was any metallic zinc left in union with the copper, the amount of hydrogen evolved gradually diminishing, though varying somewhat with the temperature of the day. The great influence exerted by heat is, however, better shown in the subjoined table, which gives the results of an experiment reduced to the unit of an hour's work.

At 2·2° C.	1·1 c.c. of hydrogen produced.	
22·2	5·5	„
34·4	13·9	„
55·0	62·0	„
74·4	174·6	„
93·0	528·0	„

These figures strikingly exhibit the rapid acceleration of the action at the higher temperatures.

A greater effect may be produced by substituting for the copper a still more negative metal. Thus a zinc platinum couple acts with much greater energy upon water. Gold zinc couples, and many others also, have been tried, but gold has the practical disadvantage that the precipitated metal does not adhere well to the zinc. Aluminium alone does not decompose water, not even according to Deville, at a red heat; but an aluminium copper couple decomposes it slowly, and an aluminium platinum couple more rapidly, even in the cold. One of the most recent discoveries is that aluminium when amalgamated with mercury is converted into hydrate, even by the moisture of the air. The most powerful combination, however, might be expected to be that of the most positive and the most negative metal which can be conveniently brought together. These are magnesium and platinum; and in fact, if strips of magnesium foil be coated with finely-divided platinum by immersing them in platinic chloride, and the resulting salts be washed away, a couple may be obtained which produces a most vigorous evolution of hydrogen when it is placed even in cold water.*

The decomposition of water by the copper zinc couple was of course a matter of little practical importance; it does, however, yield hydrogen in a state of purity, even though the zinc be largely contaminated with such a substance as arsenic—a fact which may prove of great consequence in medico-legal inquiries. These observations on water led to a long series of experiments on other bodies, especially organic compounds. The action of the two metals in conjunction frequently effects not only the splitting up of a compound, but a re-distribution of its elements; and this has resulted not only in the discovery of a simple means of producing various substances previously known, but the formation of several others hitherto unknown. Thus the first trials were made on iodide of ethyl in the hope that Professor Frankland's beautiful process for making zinc ethyl might be simplified; and not only was a better result obtained in a shorter time, but when the experiment was performed in the presence of alcohol it was found that pure hydride of ethyl was given off, and a new substance, the iodoethylate of zinc, remained in the flask.

Among the bodies which may be prepared more easily or in greater purity by the copper zinc couple are the following:—

Hydrogen.	Olefiant gas.	Diallyl.
Methyl hydride.	Acetylen.	Zinc ethiodide.
Ethyl hydride.	Propylen.	Zinc ethyl.
Propyl hydride.	Diamyl.	Zinc-amyl.
Amyl hydride.		

The substances that have been discovered by this agency are the following:—

Zinc propiodide	$Zn(C_3H_7)I$.
„ propyl	$Zn(C_3H_7)_2$.
„ isopropyl	$Zn(C_3H_7)_2$.
„ ethylobromide	$Zn(C_2H_5)Br$.
„ iodoethylate	$Zn(C_2H_5O)I$.
„ bromethylate	$Zn(C_2H_5O)Br$.
„ chlorethylate	$Zn(C_2H_5O)Cl$.

* Phenomena resulting from different metals in combination have frequently been observed by several experimenters, and some of them are described by Mr. W. N. Hartley in the *Chemical News* (vol. xiv., p. 73); but it does not appear that the metals have ever been freed from concomitant salts, or their action understood or appreciated.

Zinc propyl is a volatile liquid body, of sp. gr. 1·098, which takes fire spontaneously in the air, burning with a bluish white flame. The haloid ethylates are a new class of bodies which have been prepared from both ethyl iodide and iodoform, and their corresponding bromine and chlorine compounds.

The couple has also thrown some light upon the chemical structure of some of these organic bodies—as, for instance, by its different behaviour with the two isomeric bodies, chloride of ethylen and chloride of ethylidin. This is a direction in which future investigation is likely to be rewarded.*

This method of quietly bringing about a chemical change has found a practical application in the hands of Professor Thorpe for determining the amount of nitrates in samples of water—a question of great importance, which has hitherto been also one of great difficulty. The nitric acid is reduced by the couple to the condition of ammonia. In a similar way chlorates are reduced to chlorides.†

The progress of research by means of the copper zinc couple was interrupted by the discovery of a curious reaction, by which also water and other substances may be decomposed. Metallic aluminium does not attack water by itself, neither does iodine; but if the three are brought into contact, oxide of aluminium is formed and hydrogen gas is evolved; and not only this, but the solution so produced will cause the oxidation of any excess of aluminium with the formation of an equivalent amount of hydrogen. It is not even necessary that free iodine should be employed, for iodide of aluminium itself will determine the oxidation of any amount of metal. This action is greatly quickened by coupling platinum with the aluminium. By employing alcohol instead of water a similar action is set up, and this has led to the discovery of aluminium ethylate, $Al_2(C_2H_5O)_6$, alcohol in which the replaceable hydrogen is substituted by aluminium. It is a solid body at the ordinary temperature, but easily melts, and is capable of being sublimed unchanged, its vapour burning with a luminous flame and white smoke of the oxide of metal. Other compounds prepared by this singular reaction, and the nature of the chemical changes which occur, are at present the subject of study.‡

THE THERAPEUTIC VALUE OF THE CRYSTALLINE PRINCIPLES OF ALOES.§

BY NELSON C. DOBSON, F.R.C.S., AND WILLIAM A. TILDEN, D.SC. LOND., F.C.S.

Medical practice in this country recognizes commonly only two kinds of aloes—the one obtained from Socrotra, the other from Barbadoes,—both of which are directed to be employed in the preparations of the British Pharmacopœia. As is well known, all varieties of the drug consist of the dried inspissated juice, which, after cutting, exudes from peculiar vessels resident in the leaf of the plant.

Socotrine aloes is obtained from a plant (*Aloë Socotrina*) which grows or is cultivated in the island of Socotra in the Indian Ocean. The drug as it appears in commerce varies somewhat in character. It is imported chiefly in boxes from Bombay, and generally exhibits a reddish-brown colour. It is translucent when in thin fragments, and possesses an odour peculiar but not altogether disagreeable. When moistened with spirit of wine it exhibits under the microscope many small prismatic crystals. It is sometimes opaque and liver-coloured (hepatic), probably from the presence of feculent matter.

From certain highly crystalline varieties of Socotrine aloes imported into this country by way of Zanzibar, and first examined by the late Daniel Hanbury, F.R.S., it has been found possible to extract the crystalline constituent in a state of purity. The aloin obtained from this source is not identical with the aloin of Barbadoes and other varieties of aloes. It crystallizes in small pale-yellow prisms. which are soluble in water and in spirit of wine, and contain about 14 per cent. of water of crystallization. For sake of distinction it is called *zanaloin* or *socaloin*.

Barbadoes aloes is brought in gourds or boxes. It is obtained from the leaves of *Aloë vulgaris*, which is cultivated in Barbadoes. It occurs in masses of dark-brown colour, having a conchoidal fracture, which exhibits a peculiar dull, waxy surface, and emits, especially when breathed upon, a disagreeable alliaceous odour. Moistened with spirit, it displays abundance of crystals, and its crystalline constituent is easily obtained in large quantity from good samples. This crystalline constituent has long been known as "aloin," but now that there is abundant proof that each kind of aloes contains a crystalline principle peculiar to itself, it is desirable to distinguish this substance from the rest by the name *barbaloin*. It forms yellow prismatic crystals, soluble both in water and in spirit of wine. These crystals contain about five per cent. of water of crystallization.

Since 1869 a considerable quantity of a new variety of aloes has been imported into this country from Natal. The plant from which it is prepared has not yet been identified. It is of a character quite peculiar and distinct from both Socotrine and Barbadoes aloes, as well as from ordinary Cape aloes. Natal aloes is dull-yellow, very opaque, and possesses but little odour. It contains a large quantity of a crystalline substance (*nataloin*), which is altogether different from the corresponding substances obtained from other kinds of aloes. It forms thin, rectangular, pale-yellow scales, which are but slightly soluble in water, and far less soluble in rectified spirit than barbaloin or socaloin. These crystals contain no water.

Socaloin has the formula $C_{16}H_{18}O_7.3H_2O$. It yields substitution-compounds with chlorine and bromine, having the formulæ $C_{16}H_{15}Cl_3O_7$ and $C_{16}H_{15}Br_3O_7$ respectively. When boiled with nitric acid, chrysammic acid is the characteristic product.

Crystallized barbaloin has the formula $C_{16}H_{18}O_7H_2O$. It yields bromo- and chloro- derivatives corresponding with those of socaloin, and it also yields chrysammic acid under the influence of nitric acid.

Nataloin is believed to have the formula $C_{16}H_{18}O_7$. It is distinguished by inferior solubility, by its peculiar crystalline form by yielding no substitution-compounds like those of barbaloin and socaloin, and, lastly, by giving no chrysammic acid, but only oxalic and picric acids, when boiled with nitric acid.

It will be observed, upon examination of these formulæ, that in the anhydrous state these three crystalline substances, albeit exhibiting well-marked differences of properties, and possessing, it must be supposed, different chemical constitution, have the same composition. They are, in short, isomeric.

An easy test by which the three substances are detected and distinguished from one another is as follows:—Cold nitric acid dropped upon socaloin produces very little

---

* Further particulars respecting the decomposition of water by this special kind of electrolysis may be found in *Proc. Royal Soc.*, 1872, p. 218; 'Report Brit. Assoc.,' 1872, Abstracts, p. 75; *Journal Chem. Soc.*, 1873, p. 452; *Phil. Mag.*, 1875, pp. 284, 285. The account of 'Researches on the Action of the Copper Zinc Couple on Organic Bodies' is given in the *Journ. Chem. Soc.*, 1873, pp. 445, 678, 961; 1874, pp. 208, 406, 410, 615; 1875, p. 508. See also vol. vii. of *Proc. Royal Inst. of Great Britain*, p. 521.

† *Journ. Chem. Soc.*, 1873, p. 541.

‡ Since this discourse was delivered, this peculiar reaction has been elucidated in a paper read before the Chemical Society, on "The Simultaneous Action of Iodine and Aluminium on Ether and Compound Ethers." An intermediate body, the aluminium iodoethylate, $Al_2(C_2H_5O)_3I_3$, is there described.

§ From the *Medical Times and Gazette*, August 12, 1876.

change of colour; with barbaloin an intense, but quickly fading, crimson coloration is produced; and with nataloin a blood-red coloration, which does not fade unless heat be applied.

Barbaloin has long been an article of commerce, and has been represented as possessing great activity as a purgative. Some difference of opinion upon this question has, however, existed, and it seemed to us desirable to determine the question of its activity by systematic experiment. It also seemed to us worth inquiry whether the crystalline principles of Socotrine and Barbadoes aloes which are constantly prescribed indiscriminately, were possessed of equal purgative power, or whether any marked difference in this respect could be observed between them. To the results obtained we have added a number of similar observations upon the purgative action of nataloin.

The crystalline principle of Barbadoes aloes has had numerous trials as to its efficacy, and especially as regards its purgative action; and the most widely different results have been obtained by various observers. We shall not attempt to account for this difference of opinion, but content ourselves with the record of our own conclusions based upon the observations we have made in fifty cases. But that this question is not already finally and satisfactorily settled would appear from the following extract taken from one of the most recent works on Therapeutics (Wood's):—"Aloin was formerly believed to be the active principle of aloes, but at present evidence is decidedly against this view. According to Messrs. T. and H. Smith, in doses of one or two grains it is almost a drastic purge; on the other hand, Robinquet took fifteen grains of it without effect, and affirms that it is a simple bitter." Dr. Craig, in the *Edinburgh Medical Journal*, says aloin is the only active principle found in aloes, and he says further that its "uniformity of strength, the smallness of its dose, and the certainty of its action, should commend it to the favourable consideration of all medical practitioners." So far as our observations go, they do not fully agree with the experience of Robinquet or Dr. Craig, We have generally found that when either barbaloin. zanaloin, or nataloin has been administered in doses of two grains or upwards there has been, in the majority of cases, some action of the bowels; but most certainly we have never once found doses of one or two grains to be "almost a drastic purge," as asserted by Messrs. Smith.

The before-named crystalline principles were prepared by Dr. Tilden, who assumes the responsibility of their chemical purity. The dose was given in the form of a pill, made by mixing the crystals with conserve of roses (except in twelve cases, in which barbaloin was mixed with hard soap). The observations made had reference only to the aperient action, or otherwise, of the substances under consideration. The persons to whom they were administered were, in most cases, adult males.

The general conclusions at which we arrived were that neither zanaloin, nataloin or barbaloin were altogether inert, but that each of them, when given in doses of two grains or upwards, produced more or less action on the bowels. Barbaloin in doses under two grains frequently produced some slight laxative action; but with none of the substances, even when large doses were given, did the effect produced approach anything like a drastic purge. Barbaloin appeared to be rather more active than either of the other two. In our observations we did not give more than two-grain doses of this substance. Between the zanaloin and the nataloin there was not much difference in purgative action; the former was frequently given in doses of four grains without producing more than two slight motions. Nataloin in similar doses sometimes produced two, three, and even four motions; and sometimes there was no action following the dose. In one case four grains, given to a convalescent nigger produced no result; and six grains, given three days afterwards, also failed to act. In another case, a delicate girl took two grains with no effect; and six grains given the next day acted three times.

To summarize the general result of our observations: It appears that barbaloin, zanaloin, and nataloin, in doses of two grains, are each of them more or less aperient; barbaloin, apparently, rather more active in combination with hard soap than with conserve of roses. They are each of them decidedly uncertain and variable in their action. In those cases in which we have a record, the time which elapsed after the administration before there was any perceptible action varied from two and a half to fifteen hours. It did not appear to us that the crystalline principle was more potent than a similar dose of aloes; nor did we discover any advantages it possesses over an equal dose of aloes—except, perhaps, that griping was rather less common than when aloes alone was given.

HELENIN AND INULA CAMPHOR.*

BY J. KALLEN.

A previous paper by the author on this subject appeared in abstract in the *Journal of the Chemical Society* (1874, 352). Further research has shown that when elecampane root is exhausted with alcohol, and the extract is precipitated with water, the crystals thereby obtained contain, besides helenin, two other bodies. One of these has not yet been obtained pure, but it is without doubt isomeric with laurel-camphor. This the author calls *inulol*. The other, which exists in much larger quantity, is the anhydride of an acid termed *inulic acid*.

Inulol.—Elecampane root yields by distillation with steam a white crystalline mass, which is a mixture of inulol and inulic acid. On pressing the mass between blotting-paper, the inulol is absorbed, and may afterwards be obtained tolerably pure by distilling the paper with steam. Inulol is a slightly yellow liquid, of aromatic taste and peppermint-like odour, boiling at 200°. Its composition agrees with the formula $C_{10}H_{16}O$. When distilled with phosphorus pentasulphide, it yields hydrocarbon, $C_{10}H_{14}$, which boils at 175°, and is converted into terephthalic acid by oxilation with chromic acid.

Inulic Anhydride.—When the crystals obtained by distilling elecampane root are recrystallized from alcohol, inulic anhydride is obtained in colourless prismatic needles of faint smell and taste, melting at 66°. It dissolves sparingly in water, freely in alcohol, ether, etc., boils at 275° with partial decomposition, and sublimes when gently heated. Analysis leads to the formula $C_{15}H_{20}O_2$.

Inulic acid, obtained by heating inulic anhydride with weak potash, and decomposing the salt thus formed with hydrochloric acid, is sparingly soluble in water, but dissolves easily in alcohol, and crystallizes therefrom in delicate needles melting at 90°—91°. When melted it gives off water, and is converted into the anhydride. The numbers found by analysis agree with the formula $C_{15}H_{22}O_3$. The acid is diatomic and monobasic. The potassium salt is freely soluble in water and alcohol, and is obtained with difficulty in small needles. It is decomposed by carbon dioxide, with separation of inulic anhydride. The ammonium salt, formed by dissolving the acid in aqueous ammonia, decomposes on evaporating the solution, leaving the pure acid. The silver salt, $C_{15}H_{21}AgO_3$, crystallizes in small brilliant scales. The barium salt is moderately soluble in water, and separates in warty mases on evaporation.

A solution of inulic acid in absolute alcohol, into which dry hydrochloric acid gas is passed, yields large, colourless, rhombic tables, which melt at 140°, decomposing, and giving off hydrochloric acid. This substance forms

* From the *Journal of the Chemical Society* [*Deut. Chem. Ges. Ber.*, ix, 154–147].

salts, which however decompose easily, yielding chlorides. Its formula is $C_{15}H_{21}O_2Cl$. By the action of excess of potash upon it, a new acid, *di-inulic acid*, is formed. This acid—a white amorphous powder—forms two series of salts, of which only one (the neutral) has yet been obtained pure. The potassium salt crystallizes in delicate pearly laminæ, moderately soluble in water: its solution is decomposed by much water. The silver salt, $C_{30}H_{40}O_5Ag_2$, obtained by precipitating silver nitrate, is a white flocculent precipitate, slightly soluble in water.

Inulamide, $C_{14}H_{20}(OH)CO,NH_2$, obtained by passing ammonia into an alcoholic solution of inulic anhydride, forms small feathery crystals, feebly basic, and sparingly soluble in alcohol. It melts at about 210°, undergoing decomposition. It is decomposed by potash, the products being ammonia and potassium inulate. Inulamide forms with hydrochloric acid the compound $2(C_{15}H_{23}NO_2) + HCl$, which gives with platinum chloride a double salt insoluble in water and very sparingly soluble in alcohol.

FENUGREEK.*

BY J. R. JACKSON, A.L.S.

Trigonella, the genus to which the fenugreek belongs, is a group of herbaceous plants belonging to the Papilionaceæ, natural order Leguminosæ, rather widely distributed in Southern Europe, Northern, Central, and Southern Africa, Western and Central Asia, and one species (*T. suavissima*) in Australia. All the plants possess a strong, clinging, aromatic odour, which is particularly the case with *T. Fœnumgræcum*, the most important plant in the genus. It is a native of the region of the Mediterranean, where it has been cultivated for a very long time, and is an erect annual from one to two feet high, with obovate cuneate leaflets and yellow papilionaceous flowers borne in the axils of the leaves. The pods are from two to four inches long, pointed or beaked, and contain from ten to twenty small, rough, brown seeds.

The fenugreek claims a history of great antiquity; the plant was much valued by the ancients both for food and medicine, and it was also grown for the purpose of feeding oxen. It is referred to by Hippocrates, and was prescribed by Aretæus both for internal and external application. Reduced to a powder, the seeds were recommended by Dioscorides to form cataplasms in inflammatory cases. Pliny refers very fully to its medicinal virtues, and other authors, especially Avicenna, treat of its properties at some length. Pomet, in his 'Compleat History of Druggs,' published in London in 1725, says, "The ancients and some Germans at this time make a decoction of this seed, and eat is as they do other pulse, to remove and expel wind; but I believe few or none will imitate them in this practice, which is so disagreeable to the nose and palate; it is much better for cattle, and especially horses, to mix with their oats to fatten them. It is of greater use externally than internally." These seeds continued to be used for external application, chiefly for cataplasms and fomentations, down to a comparatively recent period, but at the present time their chief uses with us are in veterinary practice, and as a condiment in curry powder. It is not many years since, however, that they were included in the Greek Pharmacopœia. Pomet's opinion that these seeds are "much better for cattle, and especially horses, to mix with their oats to fatten them," seems to have become fully realized, for at one time the powdered seeds of fenugreek were greatly in demand for feeding cattle, and it is said that the patent cattle foods so much advertized at the present time are largely composed of, or seasoned with, these seeds. Be this as it may, it is certain that, when crushed, they are much used for flavouring damaged hay.

Pomet, in the work before referred to, gives a quaint but tolerably accurate description of the plant, as well as a figure. He says:—"Fenugreek, which some call improperly Senegrè, and others Bucera or Aigoceros, because the pods which enclose the seed resemble in some manner a goat's horn, is a plant which grows in several parts of France. Its stalks are round, hollow, of a darkish colour, the leaves small, half-round, composed of three and three together, something after the nature of the trefoil, the flowers small and white, bearing a large pod, which is long and sharp, representing, as said before, a bull's, or rather, a wild goat's horn. The seed carries the name of the plant, and is the only part of it which is sold by the name of fenugreek. This seed ought to be fresh, of a lively yellow, towards a gold colour, but it becomes reddish, and changes brown if long kept; it is about half as big as a grain of wheat, hard and solid, and is of a triangular shape, but the smell and taste of it are both offensive. The farmers about Aubervilliers sow and cultivate this as they do coriander seed, which is sent to Paris, and from thence to Holland and other parts."

Woodville in his 'Medical Botany' refers to the plant as a native of Montpellier, and as having been first cultivated in Britain by Gerard. Southern France and Germany furnished this country with its supplies of fenugreek seeds at the time Woodville wrote, the plants being cultivated expressly for the seeds, which were largely exported. That these formed an article of import long prior to the date of the above work—1793—or even to that of Pomet, is clear, for in a curious little book called 'The Treasury of Drugs Unlocked,' by Jo. Jacob Beehe, of London, merchant in drugs, published in London, in 1690, we find in a simple alphabetical list of useful seeds and the places of their production, the following:—"Semen Fænugreci, Germany." The plant is now cultivated largely in India, also in Morocco, the South of France, some parts of Germany and Switzerland, as well as in other warm climates. In Alexandria the seeds are eaten as an article of food prepared in the following manner: They are put into cups, and kept wet to cause germination. In a few days the cups are filled with growing plants, in which state they are sold in the streets, and appear to be relished as a great delicacy. In India the fresh plants are eaten as a green vegetable, but the seeds are by far the most important product, as is proved by some statistics quoted by Dr. Flückiger and Mr. Hanbury in their new work on drugs, which show that the quantity of seeds imported from Sind to Bombay during the year 1872–73 amounted to 13,646 cwt., the value of which was £4405. From Bombay also were shipped in the same year 9655 cwt., of which quantity only 100 cwt. were sent to the United Kingdom.

CONTRIBUTION TO THE HISTORY OF ELEMI. —AMYRIN.*

BY DR. EUGEN BURI.

The constituents of elemi have been investigated by Professor Flückiger, who showed that bryoidin, a crystallizable substance occurring in that resin only in small quantity, corresponded with the formula $(C_{10}H_{16})_2 + 3\,OH_2$, and suggested that the preponderating constituent, named amyrin by Baup, might have a composition represented by the formula $(C_{10}H_{16})_2 + OH_2$.† The author's investigations were devoted to this substance.

Amyrin is present in elemi in microscopic crystals, which are left behind when elemi is treated with cold 90° alcohol, the other constituents being dissolved. It

* Abstract of a communication from the Pharmaceutical Institute of the University of Strassburg (*Neues Repert. f. Pharmacie*, vol. xxv. p. 193).

† *Pharm. Journ.* [3], vol. v., p. 142.

can be purified by recrystallization from boiling alcohol until it appears perfectly colourless, and gives up nothing further to boiling water. Amyrin crystallizes from the hot alcoholic solution on cooling in colourless doubly refracting needles, which are united into a spherical aggregations having a silky lustre. It melts at 177° C., and remains fluid far below the melting point.

In solidifying, it forms a transparent mass resembling colophony, but it can easily be obtained again in crystals from alcohol. In water it is insoluble. In hot alcohol of about 90° it dissolves plentifully, the greater part of it crystallizing out on cooling; a saturated solution at 16°C. contained 3·5 per cent. of amyrin. Its reaction in alcoholic solution is neutral. Amyrin is also soluble in ether, and especially so in chloroform and carbon bisulphide. It dissolves also in aqueous solutions of the caustic alkalies, but not when boiling. An alcoholic solution of amyrin rotates the plane of polarized light to the right.

Amyrin is not volatilized in the vapour of water at the ordinary atmospheric pressure. When heated in a retort it fuses, a very small quantity sublimes, and decomposition commences simultaneously. At 200° C. drops of a thick yellow oily liquid appear, the temperature rapidly rises, the liquid in the retort begins to boil, whilst the distillate becomes progressively thicker. Finally it solidifies in the neck of the retort while passing over, and when the retort commences to redden, a heavy vapour is formed that condenses in the neck of the retort to a yellow powder. A considerable quantity of a shining spongy coke is left as a residue.

By very careful heating of a thin layer amyrin can be sublimed in long extremely slender needles that become felted into a very light mass resembling a spider's web. But the yield of sublimate is very small, the greater part of the amyrin being decomposed into the above named products, by which also the sublimed portion is contaminated. The sublimed amyrin crystallizes from alcohol in the same manner as that which has not been sublimed, and it agrees with it in melting point and composition. Elementary analysis of the two kinds gave results corresponding with the formula $C_{25}H_{42}O$, or $(C_5H_8)_5 . H_2O$, which would represent amyrin as a terpene hydrate.

	Unsublimed. I.	II.	III.	Sublimed. I.	II.	Required.
C	83·31	83·77	83·73	83·63	83·34	83·80
H	11·39	11·65	11·63	11·76	11·81	11·73
O	5·30	4·58	4·64	4·61	4·85	4·47

Concentrated sulphuric acid dissolves amyrin with a yellow red colour; water precipitates it from the solution as a brown mass. Amyrin is slightly attacked by melted potash, on the surface of which it floats, but does not mix. Upon stronger heating it behaves as when dry distilled. When the fused mass is heated with water there remains a considerable residue. The solution contains oxalic acid, and gives on distillation only traces of volatile acid having a faint smell of butyric acid.

An atom of hydrogen in the molecule of amyrin can be replaced by the radical of acetic acid. One part of amyrin was heated for some hours to 150°, with four parts of anhydrous acetic acid, in a glass tube. After cooling, the solid contents of the tube were dissolved in boiling absolute alcohol, from which, after one recrystallization the acetyl-amyrin was yielded in dazzling white scales that appeared under the microscope as very thin tables. It melts at 198° C., and is more insoluble in alcohol than amyrin. Elementary analysis gave results corresponding with the formula $C_{27}H_{44}O_2$, or $C_{25}H_{41}O . C_2H_3O$.

Bromine acts very energetically upon solid amyrin, a greenish black mass being formed with a tumultuous evolution of hydrobromic acid. When a cold saturated alcoholic solution of amyrin was treated with excess of bromine a yellowish precipitate was formed in a few minutes, that after one recrystallization from warm alcohol was obtained as a colourless crystalline powder which could not be melted without decomposition. This compound contained about 30 per cent. of bromine.

Upon boiling with nitric acid amyrin yielded a clear yellow solution, which upon evaporation left a yellow spongy residue. This treated with water gave an acid yellow solution that contained oxalic acid and reduced Fehling's solution when heated. But the greater part remained undissolved. It was an acid resin, an alcoholic solution of which had an acid reaction. From a hot saturated solution it was deposited on cooling as a yellow powder. It dissolved in a solution of sodium bicarbonate when warmed, with evolution of carbonic acid gas, forming a brown liquid that frothed when shaken. Dry hydrochloric acid gas is without action on solid amyrin, neither does it attack amyrin dsssolved in chloroform.

The author compares these results with those obtained by Stenhouse and Groves with icacin derived by them from a drug which they call incense resin, but which Professor Flückiger considers to be an elemi resin. The melting point of icacin (175°) corresponds closely with that of amyrin (177°). The mean of analyses gave C 85·6, H 11·8, from which Stenhouse and Groves attributed to it the formula $C_{46}H_{76}O$. Professor Flückiger, however, thinks icacin is more closely related to amyrin, and suggests for it the formula $C_{45}H_{74}O = (C_5H_8)_9 + OH_2$, which would represent it also as a terpene hydrate. Icacin appears to replace amyrin in certain sorts of elemi.

If the formula suggested by Professor Flückiger be adopted, we have the following remarkable series of elemi constituents:—

Volatile Oil	$(C_5H_8)_2$
Icacin	$(C_5H_8)_9 + H_2O$
Amyrin	$(C_5H_8)_5 + H_2O$
Bryoïdin	$(C_5H_8)_4 + 3H_2O$

The Pharmaceutical Journal.

SATURDAY, AUGUST 19, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

AMERICAN VIEWS OF PHARMACOPŒIA REVISION.

AT a recent meeting of the Medical Society of the State of New York Dr. SQUIBB presented his report as a delegate to the American Medical Association which met in Philadelphia last month, and among other subjects dealt with was the revision of the Pharmacopœia. The time for undertaking this work is now very near, and the questions discussed had reference to the mode in which the work was to be done in future.

Hitherto the revision and publication of the U. S. Pharmacopœia has been in the hands of a special Convention, according to the plan adopted in 1820, and in dealing with the question whether this plan could not be improved upon, Dr. SQUIBB pointed out that at the time of the establishment of the National Convention there was no body in existence such as the National Medical Association that has since been formed, and he suggests that the revision of the Pharmacopœia would now be appropriately entrusted to that body. In support of his argument he urges that the American Medical Association is a truly national organization of the medical profession, having been originated in 1847 with a representation from about twenty-three States, and having grown since then to such an extent that it consists of representatives from nearly all the States.

As a contrast to this, Dr. SQUIBB points to the fact that the organization which has hitherto had the control and management of the national Pharmacopœia has been representative of only a comparatively small portion of the medical profession, only eight to twelve States being represented in the Convention. On this ground he argued that it is not sufficiently representative to be the fit custodian of the interests involved in the preparation of a national Pharmacopœia.

Another argument in favour of the suggested change is that while many of the men who originated the present plan, and worked laboriously in carrying it out, are no longer available for such active work, there is also the fact that in some of the later revisions of the U. S. Pharmacopœia the existing plan has not been so successful as it was formerly, and on the last occasion there was a direct antagonism between the Committee of final revision and the Convention by which it was appointed.

As regards the fitness of the decennial period for revision, adopted as suitable so long ago as 1820, it has frequently been thought that the revision should be at shorter intervals, in order to keep pace with the more rapid progress of general medical science, and many are of opinion that a supplement might well be issued with advantage every two years, or even annually, so as to keep the Pharmacopœia up to the level of current literature and knowledge. The long period of ten years has the advantage of allowing mere sensational novelties of materia medica to have their day and die out, without disturbing the standard authority, but at the same time there are, as pointed out by Dr. SQUIBB, intermixed with these worthless novelties all the real additions to our knowledge which claim a place in the national Pharmacopœia. It would, therefore, be a most valuable function of that work to furnish by the publication of supplements some aid to the profession in discriminating between the claims of new drugs.

Besides this the interval of ten years between the revisions gives occasion for such an amount of detail labour that the undertaking becomes almost impracticable. A more frequent review of the progress of medical science, besides reducing the labour on each occasion, would have the further advantage of furnishing fresher results to those engaged in medicine and pharmacy.

One of the most important points referred to in Dr. SQUIBB's report and the one which will most of all interest our readers is that relating to the representation of pharmacy in the organization which is entrusted with the revision and publication of a national Pharmacopœia.

On this point Dr. SQUIBB's views are no less distinct and decided than emphatically expressed, and coming from a member of the medical profession who is also an authority on pharmaceutical matters, we cannot do better than place them before our readers in his own words:—

"The next question is, if this Association be the proper custodian of the Pharmacopœia, and if it be wise for it to assume its right of management and control, whom can it invite to co-operate with it in the work? This question must be answered, that it cannot wisely nor safely avoid inviting the active co-operation of the "American Pharmaceutical Association," a national organization as general in its representative character, and nearly as old, as the "American Medical Association," and whose objects tend to the same general results, and belong to the same general interest. Indeed, pharmacy is the outcome and the expression of a Pharmacopœia, and a Pharmacopœia without pharmacy would be a theory without practice; and pharmacy without a Pharmacopœia would be but a desultory, roving occupation, and not a true art of medicine. Pharmacy was the first specialty that grew out of the general science and art of medicine, or rather, the first differentiation in the art of medicine; for when pharmacy began to grow out of medicine there was but little science behind the healing art. Pharmacy was the first specialty of medicine, surgery the second, and the art of the obstetrician perhaps the third. Then came ophthalmology and the other new numerous specialties. All are mechanical arts, and not sciences, and all derive their inspiration, their development, and their rate of progress from the general science or sciences of medicine, and all are on an equal footing, and equally subordinate to the general medical sciences and the general medical interest, and are but elements in the general art of medicine. The general art of medicine could no more do without the special art of pharmacy than it could without the special art of surgery. But, had there been no general art of medicine, the special arts of pharmacy, surgery, etc., would never have existed. Hence the general science and art of medicine, as represented in this and all other national associations, is superior, and the special arts are subordinate, and as streams, the special arts can never be independent of, nor can they ever rise higher than, their source. Medicine and pharmacy without their natural connection and dependence upon each other, would soon lose their utility to mankind, and pharmacy, first of the two, would die out, or degenerate into something else. And an imaginary antagonism between them, which has been too much cultivated of late on both parts, is exercising a degenerating effect on both.

"Such reflections, carried to their legitimate and logical conclusions, are so confirmed by the best experience of the time as to convince almost any one sufficiently conversant with the subject, that it would be almost as impracticable to manage the interests involved in the Pharmacopœia without the co-operation of pharmacy as for pharmacy to manage them without medicine, simply because pharmacy has accumulated an amount of knowledge and experience which medicine has long ceased to work for and accumulate, and which medicine cannot afford to do without or to disregard.

"Pharmacy is represented in the National Pharmaceutical Association just as medicine is represented in this Association; and pharmacy is essential to the Pharmacopœia; therefore, the co-operation of the American Pharmaceutical Association is the legitimate, the proper, and the best way in which to seek the aid of pharmacy in the management and control of the Pharmacopœia. And it is altogether probable that if this Association should, in a proper way, invite the co-operation of the American Pharmaceutical Association in this work, under the fully recognized leadership of the Medical Association, the invitation would be accepted."

ACCLIMATIZATION OF PLANTS.

THE Liberian Coffee, which it is hoped will be proof against the disease that has for some time ravaged the coffee plantations, and which, moreover, produces a very large seed, is reported as having been successfully introduced in most of the coffee-growing countries, whether colonial or foreign. Next in importance to the coffee experiment is that respecting the acclimatization of the Para Caoutchouc (*Hevea brasiliensis*) in India. Plants of this, the most valuable rubber known in commerce, have been raised from seeds at Kew and they are also capable of easy propagation by cuttings. Of the *Castilloa elastica*, from which the Central American rubber, also a fine quality, is obtained, 7000 seeds were received at Kew during the past year; all of these failed to germinate; a quantity of cuttings, however, arrived safely, from which many plants have been raised, and these will be transmitted to India shortly.

THE EUCALYPTUS GLOBULUS IN ITALY.

IN a paper read at the Evening Meeting of the Pharmaceutical Society in February last, Mr. GLOVER described the results following the cultivation of the *Eucalyptus globulus* in the unhealthy district of San Paolo fuori le mura di Roma by a band of Trappist monks. The *Lancet* states that the Italian Government, moved by the success of the experiment, is now supplying landholders with large quantities of slips of this tree for the formation of plantations in other malarious districts. It is also intended to plant trees along the boulevards of the large cities and on the banks of the various railways. The landowners are reported to be freely following the initiative of the Government, and it is expected that in a few years malaria will be as effectively expelled from Italy as ague has been from Lincolnshire.

In the report of the Kew Gardens to which we referred recently, Dr. HOOKER says, "The *Eucalyptus globulus*, which has been so largely distributed on account of its supposed prophylactic virtues, will probably turn out to be extremely useful for its timber in countries not too hot for its growth. The plant seems to be proof against parasitic plants, the bark being deciduous causes the seeds of any parasite to be dislodged before they have time to germinate and so obtain a footing in the tissues of the plant."

A STRIKE AMONG ANALYSTS.

THE post of public analyst, which in Great Britain is so frequently the object of a spirited competition, appears to be at a discount in the Empire city. According to *New Remedies* several cases of poisoning have recently taken place in New York city, and the coroners have to lament that they are unable to obtain the services of competent chemists who will undertake the labour or responsibility of the necessary analyses. It appears that bills for similar services are outstanding against the city treasury, payment of which has been refused. *Hinc illæ lachrymæ!*

"WHEN DOCTORS DISAGREE WHO SHALL DECIDE?"

THERE appears to be some diversity of opinion amongst our medical contemporaries as to the value of the addresses delivered recently at Sheffield to the members of the British Medical Association. Notably is this the case with respect to Dr. ALFRED CARPENTER's address in public medicine. This the *Medical Examiner* says is "colourless, and must have been intolerably boring to those who heard it." On the other hand, the *Medical Times and Gazette* devotes more than three columns of editorial comment upon the first half of "Dr. CARPENTER's very able and suggestive address," and commends the whole of it to the careful and considerate study of its readers. The *Lancet* also speaks of it as "eloquent and instructive."

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the members of this Association was held at the rooms, Halford Street, on Tuesday, the 1st inst. The report of the committee having been read was unanimously adopted.

The committee reported that the application made during the earlier part of the session to the Pharmaceutical Society for monetary aid in carrying on the work of the Association was favourably received, a grant of £15 being voted by the Council. With this sum several valuable additions have been made to the resources of the Association—viz.: a microscope, possessing polariscope, camera lucida, etc., as accessories; a bookcase, with secretary's cupboard; a small but choice selection of books has also been purchased. Messrs. Evans, Lescher and Evans, of London, had again placed the Association under a debt of obligation by presenting a considerable number of British Pharmacopœia preparations. The thanks of the committee were gratefully accorded to these gentlemen for their kindness. As in former sessions the society had had to sustain the loss of some of its more prominent members—two old teachers and committeemen having left the town. Forty-four meetings of classes had been held, conducted by Messrs. Clarke, Duncalf, Garrett, Hammond and Baron. The average attendance at each class had been 7·5, which was below the level of previous sessions. Four special lectures had been delivered by Messrs. Young, Cadoux, Bishop and Baron. At the recent examinations conducted by the various class teachers H. Fry and J. Garrett stood highest on the list of successful competitors, they will therefore receive the prizes generously offered by Messrs. Butler and Lloyd. The number of ordinary members during the past session has been 26, and of honorary members 27. The committee stated that several of the students had made marked progress during the past session.

After the transaction of routine business the members proceeded to elect the committee for the ensuing session with the following results:—W. B. Baron, President; W. Hammond, Vice-President; J. Garrett, Hon. Secretary; W. B. Clarke, Treasurer; E. H. Butler, C. B. Lomas and T. C. Raynor.

The statement of accounts showed that the receipts during the half-year amounted to £18 17*s.* 11*d.*, and the expenditure to £30 11*s.* 2*d.*, leaving a balance due to the treasurer of £1 3*s.* 8*d.*

Proceedings of Scientific Societies.

PHARMACEUTICAL SOCIETY OF VICTORIA.

The first annual dinner of the Pharmaceutical Society of Victoria was held on Wednesday, May 24th, at Clements's Hotel; there was a numerous attendance. Mr. Joseph Bosisto, M.L.A., the president of the society, occupied the chair, and Mr. D'Arcy Irvine, the vice-chair. The usual loyal toasts having been disposed of,

Dr. Neild proposed "The Pharmaceutical Society of Victoria, coupled with the name of the president." He observed that the large number present at this the first dinner promised well for the future of the society. The advantages of such a society were obvious, both scientifically and commercially, and he had great pleasure in coupling the name of the president with the toast, because Mr. Bosisto was not only respected as a man, but had also taken a high position in the pharmaceutical world. The public owed much to Mr. Bosisto for the discoveries he had made of the properties of the colonial vegetation, and he therefore called upon all present to drink the toast of the Pharmaceutical Society of Victoria, and the health of its president.

Mr. Bosisto, in responding, said that the object of the members of the society was to keep themselves up in pharmaceutical and chemical knowledge; to hold social meetings, so that the members of the profession might be joined together in a band of brotherhood, and to show forth a spirit of benevolence towards their brethren in misfortune. He thought that, altogether, their labours had not been in vain. Chemists stood between the public and the medical profession, and if they failed in their duty they failed towards both. Hence the necessity of their studying pharmacy. Another object of the society was to get a "Pharmacy Bill" passed through Parliament. They had a measure already drafted, and if it was not introduced by the Government next session, it would be brought forward by private members. The society was much indebted to Dr. Neild in connection with this bill, and to Baron von Mueller was due the credit of showing the pharmaceutical value of many of the native plants. There was a wider field for the society in this work of developing the chemical properties of the native vegetable products, and it would be the duty of the society to educate young pharmacists in this work, so that in the future they might have their own "Materia Medica," and be able to take their position among the pharmacists of the world, and so that pharmacy might take its place, side by side with the medical profession, in relieving the ills to which humanity was subject.

Mr. D'Arcy Irvine proposed the toast of "The Medical Profession of Victoria," which was acknowledged by Dr. Neild and the Baron von Mueller.

The remaining toasts were "The Pharmaceutical Society of Great Britain," "Kindred Societies," "The Press," and "The Ladies."

ROYAL SOCIETY.

PICROROCELLIN.*

BY JOHN STENHOUSE, LL.D., F.R.S., AND CHARLES EDWARD GROVES.

Through the kindness of Mr. C. Lavers Smith, the eminent orchil manufacturer of Spitalfields, we were furnished with a quantity of a lichen which he had observed to have a very bitter taste, and which came into the market through a Portuguese house. It is believed to have been brought from the West Coast of Africa; but our endeavours to ascertain the exact locality have hitherto been unsuccessful. From the appearance of the lichen it seems to grow on limestone rocks; and Mr. W. Carruthers, of the British Museum, and the Rev. J. Y. Crombie, to whom we submitted it, pronounced it to be a variety of *Rocella fuciformis*, the ordinary *Rocella* usually growing on trees. This lichen is remarkable for its intensely bitter taste; and the preliminary experiments showed that this is due to the presence of crystalline compound which is but slightly soluble in water.

Picrorocellin.—The lichen was accordingly first treated with water and hydrate of lime, in the usual manner, to extract the erythrin which it contains in common with other varieties of *Rocella*, and the residue, after being dried at the ordinary temperature, was extracted by boiling spirit. The alcoholic solution, which contained the bitter substance together with chlorophyll and various fatty and resinous impurities, was concentrated by distillation until almost the whole of the alcohol was removed. When cold, the dark-coloured pasty mass was pressed in a cloth, boiled up with a small quantity of strong spirit, and allowed to cool, pressed, and again

* Read May 18, 1876. From the 'Proceedings of the Royal Society.'

treated in the same manner. By this means much of the chlorophyll and almost the whole of the oily matters were dissolved out, leaving a dark green-coloured crystalline product. In order to remove the last traces of chlorophyll from this, it was boiled up twice or thrice with benzine, in which the crystals are only slightly soluble.

The spent "weed" from this variety of lichen which has been exhausted with ammonia in the ordinary process of the orchil manufacture also yields the same crystalline substance, but it is much more difficult to purify than that obtained from the lichen which has been exhausted with milk of lime. The erythrin in this lichen is identical with that from the ordinary kinds of *R. fuciformis*, yielding orcin and erythrite when boiled with lime or other alkalies.

The nearly colourless substance was now boiled for some time with about ten times its weight of spirit, and filtered whilst hot through a vacuum filter. In this operation it is necessary to use a hot-water funnel, as, otherwise, the crystals which separate soon choke up the filter. The filtered solution, which should be boiled until clear, on cooling deposits a large amount of crystals, which evidently consist of a mixture of two substances, one forming lustrous prisms, the other feathery tufts of minute flattened needles. These two substances can be easily separated mechanically by elutriation, the comparatively large prisms of picrorocellin, from their size and weight, rapidly sinking to the bottom of the solution, whilst the light feathery tufts of the other compound remain suspended. One or two recrystallizations from spirit generally suffice to purify the former; but if they have any green tinge, it is necessary to treat them previously with boiling benzine in order to remove the trace of chlorophyll to which the colour is due.

The new compound crystallizes in long prismatic crystals of considerable lustre, which are moderately soluble in boiling spirit, slightly soluble in ether and benzine, but almost insoluble in water, petroleum, and carbon bisulphide. It melts at 192°–194° C., and when more strongly heated boils and gives off vapours of an oily substance of a pleasant aromatic odour, leaving a small amount of carbonaceous residue. Cold concentrated sulphuric acid colours it of a deep brown; but when it is warmed it dissolves, forming a pale yellow solution, from which water precipitates a yellow compound. If the sulphuric acid solution be heated nearly to its boiling-point, it darkens and gives off sulphurous anhydride; the addition of water then gives no precipitate. It is also soluble in warm nitric acid, and the addition of water causes a yellow precipitate similar in appearance to that produced in the sulphuric acid solution; the nitric acid solution, when heated, gives off nitrous fumes. If boiled with dilute sulphuric or hydrochloric acid for a short time, the picrorocellin is decomposed, a compound, *xanthorocellin*, being formed which crystallizes from alcohol in long silky needles of a pale yellow colour. When picrorocellin is distilled with a mixture of dilute sulphuric acid and potassium dichromate, it is decomposed, an oil passing over having the odour of benzoic aldehyde, accompanied by a white crystalline substance. The latter, after being purified by recrystallization, melted at 121° and had the general appearance and properties of benzoic acid, with which it is identical. It was also found to be oxidized by an acid solution of potassium permanganate, but no odour of bitter-almond oil was observable.

The substance dried at 100° was submitted to analysis, with the following results:—

I. ·263 gram substance gave ·657 gram carbonic anhydride and ·151 gram water.

II. ·178 gram substance gave ·444 gram carbonic anhydride and ·100 gram water.

III. ·218 gram substance gave ·02285 gram ammonia.

IV. ·215 gram substance gave ·02219 gram ammonia.

		Theory.	I.	II.	III.	IV.	Mean.
C_{27} ...	324	68·21	68·13	68·03	...	...	68·08
H_{29} ...	29	6·11	6·38	6·24	...	..	6·31
N_3 ...	42	8·84	...	...	8·63	8·50	8·56
O_5 ...	80	16·84					
	475	100·00					

The numbers obtained from the results of these analyses agree very closely with those required by the formula $C_{27}H_{29}N_3O_5$: As this compound is obtained from a species of *Rocella* and possesses an exceedingly bitter taste, we purpose calling it *picrorocellin*. It is remarkable as being the first crystalline organic substance containing nitrogen which has been found in the lichens.

Occasionally specimens of *Rocella* are met with which have a comparatively feeble bitter taste; but hitherto we have been unable to isolate any crystalline compound from them to which this property might be ascribed.

We have not, as yet, examined the second substance crystallizing in minute, difficultly soluble needles, and which accompanies picrorocellin in this lichen, but hope to be able to do so ere long. We have ascertained, however, that it is not merely a fatty substance of a nature similar to rocellic acid, since on boiling it with a dilute solution of sodic hydrate, benzoic aldehyde appears to be produced.

Xanthorocellin.—When picrorocellin was heated above its fusing-point it decomposed, the products obtained varying with the temperature. When strongly heated, water and ammonia were given off, and a brown oily body distilled, which on being put aside for some time deposited crystals. These, after being separated from the fluid portion and recrystallized two or three times from spirit, formed colourless plates which are moderately soluble in alcohol but insoluble in water. This substance has been reserved for further investigation.

If, however, instead of subjecting the picrorocellin to destructive distillation it was merely heated for about ten minutes to 220°, it gave off water, and the fluid product if poured out and allowed to cool solidified to a resinous-looking mass. This, when finely powdered and dissolved in about three times its weight of boiling spirit, solidified on cooling to a pulp consisting of long, slender, yellow needles of xanthorocellin. This substance may be more conveniently prepared, however, by the action of dilute acids on picrorocellin, the proportions which gave the most satisfactory results being 1 part of picrorocellin to 4 of strong hydrochloric acid and 4 of water. The mixture was boiled for about 8 hours in a flask furnished with a return condenser, and the product, which still contained some unaltered picrorocellin, was collected, washed, and dissolved in boiling spirit. On cooling, the xanthorocellin was deposited in slender needles of a pale yellow colour, which amounted to about 70 per cent. of the picrorocellin originally employed. They were easily purified by two or three crystallizations from boiling spirit. When dilute sulphuric acid was substituted for the hydrochloric acid, the results obtained were not so good, oily impurities seeming to be formed at the same time. The compound as prepared by this process is identical with that obtained when picrorocellin is subjected to a temperature of 220° in the manner previously described, both substances melting at 183°.

Although xanthorocellin could be prepared with tolerable facility by the action of dilute hydrochloric acid on picrorocellin, yet it had the disadvantage that a portion of the latter always remained unattacked; this was due, no doubt, to its insolubility in the dilute acid. It seemed possible that this inconvenience might be obviated by employing an alcoholic solution of picrorocellin. On making the experiment, it was found that when an alcoholic solution of the substance was acidulated with hydrochloric acid and boiled, although xanthorocellin was readily formed, yet in order to recover it, it was necessary to partly distil off the spirit and then precipitate with water; the product was in this case accompanied with more or less of a tarry matter. These difficulties, however, were overcome by the use of glacial acetic acid. Picrorocellin dissolved readily in the boiling acid, and if sufficiently concentrated crystallized out again unchanged on cooling. On adding a drop of hydrochloric acid to the hot colourless solution and again boiling it, it almost instantly became of a yellow colour, and now no longer deposited crystals of picrorocellin when cooled. The addition of water to this solution immediately produced a precipitate of xanthorocellin.

After numerous trials, the following was found to be the best method of preparing xanthorocellin:—10 grams of picrorocellin are dissolved in 15 grams of boiling glacial acetic acid, 6 drops of concentrated hydrochloric acid are added and the whole boiled for 15 minutes in a flask furnished with an inverted condenser. On allowing it to stand for some time after it has become cold, it solidifies to a mass of crystals of the xanthorocellin. These are stirred up with water, thoroughly washed to remove adhering acid, and then recrystallized from spirit. The yield in this case was found to be 76 per cent. of the picrorocellin employed, and the alcoholic mother liquors when evaporated left neither tarry residue nor undecomposed picrorocellin. When dilute sulphuric acid was substituted for the hydrochloric acid in this experiment, the result was very similar to that observed with the aqueous acid; xanthorocellin was formed, but the yield was much smaller, only 56 per cent., owing, doubtless, to secondary decomposition; this supposition was corroborated by the fact that the addition of water to the glacial acetic acid solution precipitated the crude xanthorocellin as a yellow oil, which only crystallized after it had been standing for some short time. This substance is insoluble in petroleum, and but slightly soluble in hot carbon bisulphide or in ether. It is moderately soluble in hot benzine, and readily soluble in boiling spirit.

The substance dried at 100° gave the following results:—

I. ·247 gram substance gave ·692 gram carbonic anhydride and ·115 gram of water.

II. ·350 gram substance gave ·979 gram carbonic anhydride and ·171 gram of water.

III. ·160 gram substance gave ·450 gram carbonic anhydride and ·079 gram of water.

IV. ·261 gram substance gave ·02742 gram ammonia.

V. ·240 gram substance gave ·02415 gram ammonia.

These numbers correspond pretty closely with those required by the formula $C_{21}H_{17}N_2O_2$.

When xanthorocellin was boiled for some time with a moderately strong aqueous solution of sodic hydrate, it acquired a yellow colour, but did not appear to dissolve to any great extent. On collecting this insoluble compound and washing it, first with strong caustic soda and then with a saturated solution of sodium carbonate, a bright yellow powder was left. This yellow compound, when treated with a small quantity of spirit, to which a few drops of sodium hydrate solution had been added, dissolved only partially, leaving a residue consisting of colourless crystals. These were readily soluble in water; and on adding an acid to the solution, a white precipitate was obtained. The addition of a concentrated solution of sodium hydrate to the clear yellow alcoholic solution immediately produced a yellow precipitate. It was observed that xanthorocellin dissolved in boiling water to which a *few drops* of a solution of sodium hydrate had been added, and on cooling it crystallized out again apparently unaltered. If, however, instead of allowing it to cool, strong soda was added to the hot clear solution, a bright yellow precipitate was produced. A similar precipitate was obtained on heating xanthorocellin with spirit containing a little sodium hydrate in solution, pouring off the clear liquid from the colourless crystals which were formed, and adding excess of soda.

Xanthorocellin is soluble in warm concentrated sulphuric acid with a brilliant orange colour; but on adding water, the substance is precipitated unaltered. If the acid solution be strongly heated, however, it effervesces slightly, and becomes somewhat darker in colour: the addition of water to this no longer produces a precipitate.

Xanthorocellin dissolves in cold nitric acid, and if water be at once added the substance is precipitated apparently unaltered. On allowing the nitric acid solution to stand for some time, however, or on gently heating the mixture, decomposition takes place with the formation of new compounds. These may be more conveniently obtained, however, by the action of nitric acid on the substance dissolved in glacial acetic acid, in the following manner:—5 grams of xanthorocellin were dissolved in 10 c.c. of boiling acetic acid, and the solution rapidly cooled, but without agitation, so as to avoid as much as possible causing the substance to crystallize out; 5 c.c. of nitric acid (specific gravity 1·45) were then added, the whole thoroughly mixed and gently heated in a water-bath until the action had set in. When this took place, the source of heat was withdrawn, the heat developed by the reaction being sufficient to cause the liquid to boil; large quantities of nitrous fumes were given off, and lustrous scales soon began to appear in the liquid. If, as sometimes happened, the action became too violent and threatened to eject the contents from the flask, it was easily moderated by plunging the latter into cold water for a few seconds. As soon as the reaction was complete, the contents of the flask were poured into a beaker, and put aside for a few hours; the solid crystalline mass thus obtained was then thoroughly incorporated with 30 c.c. of spirit, which dissolved nearly everything except the scales. The latter were collected on a Bunsen filter, and washed thoroughly with cold spirit, in which they are almost insoluble. The yield of the new substance is about 35 per cent. of the xanthorocellin originally taken; it crystallizes in beautifully white hexagonal plates, which do not melt at 275°, but begin to undergo decomposition below that temperature. The spirituous washings from these crystals, obtained when the crude product was treated with alcohol, were allowed to evaporate spontaneously, until the latter had disappeared. On distilling the residue in a current of steam, some benzoic aldehyde passed over with the aqueous vapour, but no hydrocyanic acid could be detected in the distillate. The crystalline substance left in the retort appears to be a nitro-acid of high melting-point, totally different in its properties, however, from nitrobenzoic acid. We hope to be able, at some future time, to examine the products of this interesting reaction more fully.

Action of sodium hydrate on picrorocellin.—When picrorocellin was boiled with three times its weight of spirit, and an aqueous solution of sodium hydrate was gradually added until all the crystals had disappeared, a solution was obtained which, when filtered and rendered acid with acetic acid, deposited crystals of very pure unaltered picrorocellin equal in weight to about half those originally taken.

The alcoholic mother liquors on being evaporated left an oily residue insoluble in water. It was exceedingly soluble in hot water, however; and the solution, if sufficiently concentrated, deposited colourless crystals of a new substance mixed with more or less picrorocellin.

As from this experiment picrorocellin seemed to be altered by the action of alkalies, a quantity of it was boiled with a concentrated solution of sodium hydrate, when it became evident that it was rapidly being changed, and in a few minutes it became red, and fused to an oily mass enclosing crystals of the unaltered substance. The whole was then allowed to cool; and after the soda solution had been poured off, the red mass was gently heated with water, which readily dissolved most of it, leaving merely the unattacked picrorocellin. The addition of sodium hydrate to the deep yellow solution thus obtained threw down a yellowish-red resinous mass, whilst acids caused the formation of a voluminous, almost white precipitate. This readily aggregated to a plastic mass, which was washed by kneading it in tepid water. During the action of caustic soda on picrorocellin, a volatile substance is produced having a pleasant aromatic odour.

It was found, however, that the principal product of this reaction could be obtained far more readily, and in a purer state, by operating with dilute solutions of sodium hydrate. For this purpose 3 parts of solid sodium hydrate were dissolved in 180 to 200 of boiling water, and then 10 parts of finely powdered picrorocellin were added; the crystals dissolved rapidly in the boiling liquid, ammonia was given off in small quantity, and after about an hour's digestion the reaction was considered to be complete. When nearly cold, acetic acid was added to the solution in slight excess; this produced a glutinous kind of precipitate, which could be moulded under the warm liquid into a stick closely resembling bleached shellac in appearance, being lustrous and silky. The product was found, however, to be far from pure; and in order to obtain it in that state, it had to be crystallized successively from alcohol and from carbon bisulphide. The crude product was therefore digested with two thirds of its weight of boiling spirit until dissolved, and then set aside to cool. After standing a considerable time, it deposited the new substance in colourless crystals, which were collected on cotton wool on a vacuum filter, washed with *a very small quantity* of cold spirit, and dried. These crystals were then boiled with 30 times their weight of carbon bisulphide until dissolved, the solution filtered, and then concentrated to about half its bulk by distillation. On cooling, the substance crystallized out in large, brilliant, colourless prisms, amounting to from 40 to 45 per cent. of the weight of the picrorocellin originally taken. These may be rendered quite pure by crystallizing them first from a mixture of equal weights of alcohol and water (10 parts) and finally from strong spirit.

The crystals, whether prepared by boiling picrorocellin with an aqueous or with an alcoholic solution of sodium hydrate, are identical, both melting at 154° C. The fused compound remains quite liquid even when cold; but on adding a crystalline fragment of the substance it instantly solidifies. Dried at 100° C. and submitted to analysis it gave the following results:—

I. ·287 gram of substance gave ·778 gram carbonic anhydride and ·175 gram of water.

II. ·193 gram of substance gave ·523 gram carbonic anhydride and ·113 gram of water.

III. ·280 gram of substance gave ·760 gram carbonic anhydride and ·169 gram of water.

IV. ·368 gram of substance gave ·03264 gram ammonia.

V. ·297 gram of substance gave ·02611 gram ammonia.

VI. ·243 gram of substance gave ·02089 gram ammonia.

These numbers correspond very closely with the formula $C_{24}H_{25}N_2O_3$. This compound is almost insoluble in petroleum, and only very slightly soluble in ether, moderately so in boiling benzine. When strongly heated, it fuses and becomes deep yellow, being converted into xanthorocellin. Nitric acid oxidizes it, benzoic aldehyde being first produced, which, by a continuance of the action, is converted into benzoic acid. A similar result is obtained when it is treated with chromic acid mixture. The crystals dissolve in concentrated sulphuric acid by the aid of a gentle heat, and on adding water a precipitate of xanthorocellin is obtained.

As picrorocellin possessed such an extremely bitter taste, and was, moreover, a nitrogenous compound, it seemed not improbable that it might possess medicinal properties. It was therefore submitted to our friend Dr. T. Lauder Brunton, F.R.S., who kindly undertook its examination with especial reference to the possible resemblance between its actions and those of quinine. He says, "The results may be briefly stated as follows:—

"1. The substance when injected under the skin of an animal exerted no perceptible action whatever.

"2. When injected under the skin of a frog it diminished reflex action. This diminution appeared to be caused in the same way as that effected by quinine, namely by irritation of the inhibitory centres within the head. As the whole subject of the action of quinine on the functions of the spinal cord is at present unsettled, too much stress must not be laid on this action of picrorocellin.

"3. When an ethereal solution of picrorocellin is added to make an alkaline solution of sulphate of indigo, with blood and ozonized turpentine, in the manner recommended by Binz and employed by him in his researches on quinine, the production of isatin is not in the least retarded, whilst quinine retards it very greatly. Picrorocellin thus differs from quinine in not arresting oxidation, a most remarkable characteristic of the latter.

"I regret that I have been unable to test it chemically in a case of ague, as the patients I see come and go so irregularly that little or no information would be gained by administering it to them. The sparing solubility of picrorocellin is a serious objection to its use in medicine, even supposing it to have the same properties as quinine; and as it does not possess one of the most important of these properties, there is no probability that it can ever be used as a substitute for quinine."

ANN ARBOR SCIENTIFIC ASSOCIATION.*

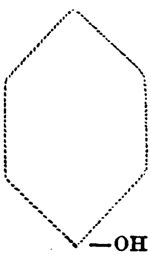
THE AROMATIC GROUP IN THE CHEMISTRY OF PLANTS.

BY PROFESSOR PRESCOTT.

(*Continued from page* 146.)

After the hydrocarbons, we next inquire as to the distribution of the *oxidized products* of the aromatic group: phenols, acids, aldehydes, etc.

The *phenols* are formed by substitution of OH for H attached directly to the C of the ring. The first phenol



known as purest grade of carbolic acid, is obtained by gentle decomposition of many plant constituents. Cymophenol, $C_{10}H_{13}OH$, is found in the oil of thyme, from the *Gymnospermæ*. Of the diatomic phenols, pyrocatechin, $C_6H_4(OH)_2$, is readily obtained from tannins by distillation and exists ready formed in *Ampelopsis Hederacea*. Creosote, obtained by destructive distillation of many bodies, contains two homologous phenols, diatomic and triatomic, each bearing methyl:

$$\text{Guaiacol, } C_7H_8O_2 = C_6H_4 \left\{ \begin{array}{l} O.CH_3 \\ OH \end{array} \right.$$

$$\text{Creosol, } C_8H_{10}O_2 = C_6H_3 \left\{ \begin{array}{l} CH_3 \\ O.\ CH_3 \\ OH \end{array} \right.$$

Pyrogallol (pyrogallic acid, largely used as a deoxidizing agent by photographers) is a triatomic phenol, $C_6H_3(OH)_3$,

* Reprinted from the 'Proceedings' for 1875-6.

and is readily formed from tannins and from gallic acid; while its isomer, phloroglucin, is obtained from resins and from glucosides by heating with potassa.

The orcins, isomers of $C_7H_8O_2$, substitutions of two molecules of hydroxyl and one of methyl for three atoms of hydrogen in benzene, are found ready formed in lichens. The dyes archil, cudbear and persio contain orcins,—as also litmus, from *Leconora tartarea*. Aloes, treated with potassa, yields orcins.

And now, in 1872, Schiff ascribes to *gallic acid*, $C_7H_6O_5$, a rational formula consisting of the introduction of one carboxyl and three hydroxyl molecules in place of four of the hydrogen atoms of benzene.* Farther, he

$$C_6H_2\left\{\begin{matrix}C\left\{\begin{matrix}O\\OH\end{matrix}\right.\\OH\\OH\\OH\end{matrix}\right.$$

presents and maintains a rational formula for fermentable *tannic acids*, the natural source of gallic acid.† Having at last synthesised tannic acid from gallic acid by working in accordance with his theory, it cannot be ignored. Schiff also traces a very interesting correspondence between the astringent acids and other aromatic compounds, in the bright colours which great numbers of them give with ferric salts; the most familiar instance being that of ink, and instances being familiar to analysts, in the identification of phenol, benzoic, salicylic and cinnamic acids, etc. The wide distribution of the tannins gives great significance to this insight into their construction. Of the 576 plants in Wittstein's summary, 35, or 6 per cent., are given as containing tannic acids; these plants being found in 17 per cent. of the natural orders.

The quinones claim attention in this inquiry, for though they are not found in plants they are next steps to plant constituents. They hold oxygen atoms united to each other, as before stated. Ordinary quinone, $C_6H_4(O_2)''$, is easily obtained from the quinic acid of the cinchonas and from the allied caffeic acid of coffee,—being in each case a means of recognition in analysis. Resins, by heat, yield umbelliferone, an isomer of quinone.

The quinone of anthracene (the triple-hexagon nucleus) is called anthraquinone, $C_{14}H_8(O_2)''$. From this, by displacing H_2 with $(OH)_2$, is now manufactured dioxyanthraquinone, the *alizarin of madder*, as hereafter to be described. Isomeric with alizarin is the chrysophanic acid found in rhubarb, senna, and the wall lichen (*Parmelia parietina*). Chrysammic acid, which is formed from the aloin of aloes in the common nitric acid test, also from the chrysophanic acid of rhubarb in the same way, has the composition of tetranitra-dioxy-anthraquinone, $C_{14}H_2(NO_2)'_4(OH)'_2(O_2)''$.

Taking next the *acids* derived from the benzene nucleus, with their aldehydes and alcohols, we have first benzoic acid and bitter almond oil, the well-known subjects of Liebig and Wobler's first advance into the aromatic group. Always classed with these are salicylic, cinnamic, cuminic, and anisic acids, aldehydes and alcohols; the alhehydes being essential oils of plants and the acids being the products of the natural oxidation of the aldehydes. In the following list, *each dash prefixed indicates the displacement of one atom of hydrogen from benzene*, C_6H_6, to the residue of which the additions are made. Thus, benzoic acid is $C_6H_5C\left\{\begin{matrix}O\\OH,\end{matrix}\right.$ etc. (the H of OH in acids being replaced by metals, forming salts).

	Acid.	*Aldehyde.*	*Alcohol.*

Benzoic acid is accompanied in the balsams,* and often complemented by cinnamic acid. It is formed from its aldehyde, bitter almond oil, by exposure of the latter to air. It is now manufactured from the naphthalin of coal tar (the double molecule benzene before described), by the process mentioned farther on. Benzoic aldehyde is hardly an educt; being a product, along with hydrocyanic acid and sugar, in the natural fermentation of amygdalin which is found in many plants of the almond family.

Salicylic acid does not exist uncombined in plants, that the writer is aware, but as methyl salicylate it makes the principal portion of "wintergreen oil," from *Gaultheria procumbens* and *Betula lenta* (sweet birch), and occurs in great purity and abundance in *Andromeda Leschenaultii*.† This acid, the new antiseptic, is now being manufactured on the large scale from carbolic acid, as presently to be described. It is not poisonous; $1\frac{1}{4}$ gramme doses being taken without apparent ill effect. It prevents most fermentive and putrefactive changes; including those, like the sinapous and amygdalous, which are not dependent upon an organized ferment, as well as the alcoholic and lactic. One-tenth per cent. prevents grape juice from fermenting, and 0·04 per cent delays the souring of milk 36 hour later than when the milk is not so treated.‡ It arrests putrefactive changes as well as fermentive. Unlike carbolic acid, its antiseptic power is destroyed by alkalies. The methyl salicyate has been to some extent manufactured for use instead of natural wintergreen oil. *Salicylic aldehyde* is known as the oil of spirœa, found in "meadow sweet" and "hardhack." It is readily obtained by fermentation of the glucoside *salicin*, the bitter substance of the willow and poplar, and found with its product in meadow sweet. Populin and helicin both readily yield salicin.

Cinnamic acid—phenyl-acrylic—is found in the balsams, and appears when its aldehyde cinnamon oil is exposed to the air. The balsams also contain,—in styrax, cinnamic alcohol, cynnyl cinnamate ($C_9H_9C_9H_7O_2$), and cinnamene, C_8H_8. Cinnamate of benzyl ($C_7H_7C_9H_7O_2$) forms a large part of Peru balsam and a small part of tolu balsam.

Cuminic aldehyde is found, with cymene, in cummin oil (from *C. Cyminum*).

The *Anisic series* is closely related to the oil of anise (*Pimpinella Anisum* and *Illicium Anisatum*).

The benzene nucleus has not been traced in many of *the alkaloids*. Atropia, however, yields an isomer of cinnamic acid, and it is conjectural that other alkaloids of the Solanaceæ contain the benzene nucleus.

In the Summary of Wittstein, before mentioned, $\frac{26}{116}$ or 22 per cent. of the natural orders contain aromatic bodies—terpenes and resins not being included as such.

After this slight survey of the constitution and natural distribution of the aromatic bodies, we will next consider what has been accomplised in their *artificial synthesis*.

† Broughton: *Phar. Jour.*, Oct. 7, 1871.

‡ Neubaur: Kolbe: Muller: *Jour. Chem. Soc.*, 1875, 459, 460.

Benzene itself, it will be observed, is a polymer of acetylene, C_2H_2. And by heat, in a bent tube over mercury, acetylene (13 times denser than hydrogen) is transformed into benzene (39 times denser than hydrogen). Acetylene is formed, from the elements carbon and hydrogen, in the electric arc, with a strong battery (one of 40 or 50 Bunsen's elements given 100 c.c. of the gas per minute).* Also from marsh gas, or from carbon disulphide with carbon monoxide, by electric discharge.

Toluene is formed from benzene, (1) by action of methyl iodide and sodium (Fittig and Tollens), (2) by marsh gas when both it and the benzene are nascent (Berthelot).† In the last reaction, xylene and cumene are also produced.

In these and other ways all *the hydrocarbons* expressed with the single hexagon may be synthesized from benzene. Naphthalene, of the double hexagon, is formed on passing toluene through a white-hot tube (Berthelot).‡

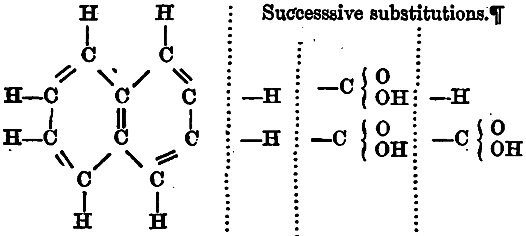
It is familar to every one that these hydrocarbons, with the phenols and many other aromatic compounds, are formed every day in every town, *from coal, by distillation*, at ten or twelve hundred degrees Fahrenheit, and this, it is submitted, is organic synthesis. Coal is a very simple if not completely mineralized mixture of carbon with bituminous hydrocarbon, and it seems a misnomer to style as "destructive distillation" the formation of the aromatic group from such material. It is *formative* distillation: prolific beyond parallel in the action of heat upon elements.

It may be safely stated in general terms that the formation of the aromatic compounds, from the elements, outside of living bodies is assured. And there are now at least four aromatic substances manufactured on a large scale from coal-tar; one being anilin and its homologues, and the other three being vegetable educts, benzoic acid, alizarin, and salicylic acid.

The manufacture of *benzoic acid* from naphthalin is carried on through two steps, namely:—

1. Oxidation, by hot nitric acid, to phthalic and oxalic acids.§
2. Removal of the elements of carbonic anhydride from phthalic acid, by heating with lime in a close vessel.||

Successsive substitutions.¶

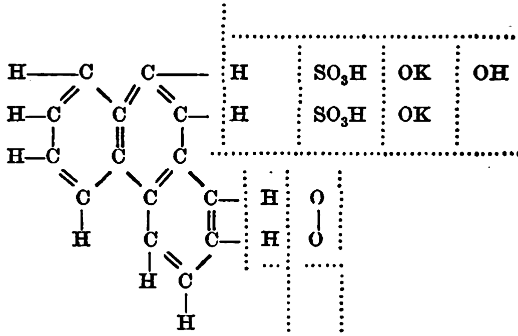


Naphthalin. Phthalic Acid. Benzoic Acid.

In the manufacture of alizarin from anthracene, there is:—

1. Oxidation to anthraquinone.
2. Farther oxidation to dioxyanthraquinone.**

Successive Substitutions.



Anthracene, C_{14}, H_{10}.

Anthraquinone, C_{14}, H_8, O_2.

Dioxyanthraquinone or Alizarin, $C_{14}H_6(OH)_2O_2$.

The history of this triumph may be indicated as follows:—*

Investigation of alizarin of madder—Schunck.........1848
of anthracene ....Anderson 1862
of the quinones ....Græbe 1868
Formation of anthracene from alizarin, Græbe and Lieberman...1868
of alizarin from anthracene, Græbe and Lieberman...1869

Purpurin, the less important colour compound of madder, having the ultimate composition of trioxyanthraquinone, is this year reported to be synthesized from alizarin.†

A ton of alizarin is saved from about 2000 tons of coal or 160 tons of coal tar. By this saving, large agricultural districts in Holland and Alsace and in Asia Minor, employed hitherto in producing colour, can be devoted to the production of food.

(*To be continued.*)

Parliamentary and Law Proceedings.

"Teaspoonfuls."

An inquest was held at Sidmouth on Tuesday Aug. 8, by Mr. S. M. Cox, county coroner, respecting the death of a child named Ernest Ward. The first witness examined stated that on the previous Friday the mother of the child called her in to look at it, and as it appeared to be very ill she advised her to send for a doctor. Mrs. Ward went herself, and Dr. Hodge came and examined the deceased. Mrs. Ward told the doctor that she had given the child something for diarrhœa that she had obtained from Mr. Talbot, chemist, and showed him a bottle. Dr. Hodge gave the child something, and then sent for Mr. Fox, surgeon. The child died the next day. She did not see any of the mixture given to the child, and did not notice particularly by the bottle how much had been taken, but should think about three spoonfuls. The mother told her that she had given the child only one teaspoonful, that she held the spoon over the glass, and let the child drink out of the glass.

Dr. Hodge gave evidence as to the appearance and condition of the child, and the treatment which it received from him. The mother told him that she had given the deceased a teaspoonful of the mixture, but very much more was missing from the bottle. He sent for Mr. Fox, and certain treatment was continued for several hours. The child was carefully treated up to its death. The term "teaspoonful" was frequently used.

Elizabeth Ward, the mother, deposed that the child was eleven months old, and was very healthy. It had been teething, and she had been in the habit of giving it Steadman's teething powders. She gave it one on Thursday evening last, as it was relaxed, and she thought it was teething as usual, but she believed it vomited it. The child was very restless all night, and the next morning was sick, and could not eat anything. She sent to Mr. Talbot's for something for diarrhœa, and he sent back a bottle of mixture labelled "Diarrhœa mixture, shake the bottle, and give a teaspoonful every four or five hours." She poured a teaspoonful of the mixture into a wineglass and gave it to the child. She gave only one spoonful; it did not run over. Some hours afterwards a change came over the child, its lips turned purple, and its eyes glazed. She afterwards went for Dr. Hodge.

Mr. Hugh Talbot, druggist, stated that the mixture contained 1 grain of opium, 2 drachms of sugar, ½ drachm of prepared chalk, and about 15 drachms of dill water. He thought it impossible for 1 teaspoonful to have hurt the child, but thought the whole quantity missing would kill it. Three teaspoonfuls were missing from the bottle. Put only 1 grain of opium in the bottle.

Dr. Pullin, who was present as a witness for Mr. Talbot, to give evidence as to the previous health of the deceased, etc., here stated that his son, Mr. F. B. Pullin, had during the inquiry measured the three spoons produced by the mother, out of one of which she had given the medicine, and that he had found one contained 120 minims, or 2 teaspoonfuls instead of 1, and the two others 90 minims, or 1½ teaspoonful instead of a single teaspoonful. The mixture, if given in the larger spoon, would be equivalent to $\frac{1}{8}$ of a grain of opium instead of $\frac{1}{16}$, as prescribed by Mr. Talbot, and if given in either of the smaller ones would reach almost the same excess, and might possibly account for all that had occurred.

The Coroner in summing up, strongly deprecated the the use of the word "teaspoonful" by medical men as a measure.—The jury after a very short deliberation, returned a verdict of "Died from an accidental overdose of opium," and also desired to express their strong disapproval of the use of the word "teaspoonful," inasmuch as the term was proved in the present instance to be deceptive and dangerous.—*Western Morning News.*

POISONING BY PRUSSIC ACID.

On Saturday last, an inquest was held respecting the death of Charles Porter, surgeon, Birmingham. On the previous Thursday night deceased came home intoxicated, and at his direction his wife mixed medicine for the patients. After a short sleep on the sofa he asked whether a detective had called, and receiving a negative reply, exclaimed, "Then it is a dream." A few minutes later he poured some liquid into a glass of ginger beer, and, drinking the same, exclaimed "If that is prussic acid, I am a dead man." Death ensued. Mrs. Porter said her husband was 38, and addicted to drink. Some weeks he was intoxicated every day, and was in the habit of taking drugs to sober himself, and boasted that he could make a drunken man sober in a minute. The jury found death resulted from an overdose of prussic acid, taken by misadventure.—*Echo.*

Notes and Queries.

[523.] INDIAN BAEL SHERBET.—Can any reader inform me through the medium of the Journal how Indian Bael Sherbet is made? It is, I am informed, a common drink in India. S. W.

[515.] CISTERNS FOR STORING TURPENTINE.—About 25 to 30 years ago, I had a cistern made for turpentine of good sheet tin, of the circumference of 9 feet, and 5 feet 3 inches high which holds about 190 gallons; it has hoops made of tin to cover the joints at the distance of every sheet; in the inside about the middle two pieces of iron about half inch thick cross each other, the ends bent down and soldered to the sides of the cistern; near to the bottom it has a tap of half an inch bore with a key to fit. Resin was used in the soldering of it, but muriatic acid would have been better; within the bottom hoop it is fitted with a circular piece of wood to support it on the cautery, and at the top a bung hole an inch and a half diameter for inserting the funnel. It has been painted about four times; the tap has lasted the whole time, it has only been emptied once, and that was when turpentine was dear in the American war; when a cask or two is put into it, the spirit is turbid for a day or two, and after that it is as bright as distilled water. I should recommend galvanized iron hoops now, but whither a galvanized cistern would be preferable I do not know, as I once had some in one and it became very red with rust, but it might have been rusty as it was not new. T. COLTON.

[519.] GODFREY'S ESSENCE FOR SMELLING SALTS.—In answer to Beta, I have used the following formula for years with general satisfaction:—W. SCOTT, Hamilton, July 31, 1876.

℞	Ol. Lavand. Ang.	
	Tinct. Moschi	āā ʒij.
	Ess. Bergamot. super. . . .	ʒj.
	Ol. Caryoph.	ʒss.
	Otto Di Rosa (Virgin) . . .	gtt. v.
	Ol. Cinnamomi	gtt. iij.
	Liq. Ammon. Fortissim. . .	℥x.
	Ess. Cocci	q.s.

I use Tinct. Moschi according to Beasley (ʒij to ℥xiii.)

[521.] GLYCERINÆ PHOSPHAS.—I observe in the Journal an inquiry for the form for Glycerinæ Phosphas. By this I presume is meant Glycerinum Phosphori, which is, I believe, prepared as follows:—

℞	Phosphori	gr. $\frac{1}{30}$th
	Glycerin	ʒj

Solve, more dictu pro Ol. Phosp. B. P.

THE COUNCIL AND THE BIRMINGHAM TRADE CONFERENCE.

Sir.—Permit me to express, with others, my surprise at the position taken up by a number of the leading members of Council on the action taken by the Conference held at Birmingham last month. It may be quite true that the trade generally does not know all with regard to the question of co-operative stores for instance, and that the Parliamentary Committee of the Council does, but why should the members of Council leave the trade in ignorance of what they know? From the remarks made by Mr. Atkins, who has only recently got behind the scenes, it would appear that the Council has not been idle, and that there are some difficulties in the way. But what is being done to remove those difficulties? This is just what prompted the Birmingham resolution, and what the whole trade have been for years loudly calling for, that some show of energetic action should be exhibited. With regard to the President's remark respecting the eloquence displayed at Birmingham, when there has always been such a lack of it of late years at the May Meetings at Bloomsbury Square, I think, Mr. Editor, you will support me when I say that most of the gentlemen whose names were associated with the Birmingham meeting have from time to time been quite as eloquent through the correspondence columns of your Journal, as well as in private letters to the Secretary; but what has resulted from them? Next to nothing, so far as outward appearance goes. I just fear that London influence is beginning to predominate too much again at the Council board. There has been not a little whispering about their conduct in placing a London man on recently when a country man retired, a step which was all the more unjustifiable when it is remembered that another gentlemen representing the country had been returned two years in succession at the top of the rejected list at the general election. I do hope that our London friends will remember that they are sent to the Council to legislate for the entire trade, otherwise some of us will have to transfer our subscriptions to another body that will do our work.

M.P.S.

CO-OPERATIVE STORES.

Sir,—I think but few of our brethren will deny that the thanks of the trade are due to Mr. Hampson for the able manner in which he treated the subject of co-operative stores at the Birmingham Conference.

Again, I believe there are but few who will question the wisdom of the resolution with which the discussion on that paper concluded. Would that I could add that the same feeling of satisfaction will follow the discussion which took place on the receipt of that resolution by the Council!

In the first place it struck me as somewhat remarkable that the apparently chief exponent of the feelings of the Council should happen to be one of the latest elected members of that board, who could only assert that he had "that morning learnt (presumably for the first time) that some of the more important questions did receive the most careful attention they could bestow," and yet subsequently the same gentleman, in a second speech, as with authority, kindly and most patronizingly assures the "struggling members of a trade rather than a profession, that the Council would entertain every fair and just representation which came before them." How it happened to be delegated to this gentleman, then, to speak in the name of the Council seems peculiarly strange.

The President, in his concluding remarks, expresses regret that "those gentlemen who were so eloquent at Birmingham did not come to the annual meeting of the Society and give them the benefit of their suggestions." I would remind the President that this question has repeatedly been ventilated—sometimes somewhat warmly—at the annual meetings, when the difficulty has not been in "keeping up a discussion for half an hour," but in restraining it within the bounds of a morning sitting; and yet what fruit has been borne? Where have been the direct efforts to remove the difficulty? Hence, I apprehend, comes the necessity (as has been the case before) of bringing outside influence to bear on the Council in order to awaken that body to action.

I know full well the solemn air of mysterious awe which shadows the countenance of some of our representatives at the bare mention of legal proceedings and the oft repeated tale that "the Council had been advised that such a step could not but be abortive as regards the object in view, and would but tend to advertise our opponents." It is time such fallacies were thrown to the winds; if the widow in her solitary loneliness and possible penury can be, and is, proceeded against by the Society, and debarred from a paltry pittance from a business carried on by a qualified assistant, on what principle of justice can the affluent and the titled be allowed with impunity to trade and to make large profits under the shelter of a co-operative company, to the untold injury of those who have spent time and money in acquiring that educational qualification which the law of the land demands?

The question having once more been brought to the front, and finding an exponent proof against the mesmeric influences of the Council chamber, it is to be hoped it will not be allowed again to slumber until it has been thoroughly sifted and tried in the courts of law. I cannot but regard it as the absolute duty of the Council to face the difficulty, and either to prove that the Pharmacy Act is, as it was intended and expected to be, a real protection to the public and a guarantee of some equitable return to those who enrol themselves under its power, or failing such evidence, one of two things remains, either to repeal or repair the Act.

EDWIN B. VIZER.

Belgrave House, Cliftonville,
Brighton, August 15, 1876.

[*** "*Fair Play*" writes to express his disapprobation of the "clipping trade" carried on by a Co-operative Drug Company in Brighton under the management of a registered chemist and druggist, and he instances several articles which are offered for sale at this establishment much below the ordinary prices. He also quotes from a circular the statement that prescriptions are "dispensed at considerably reduced prices." We agree with our correspondent in thinking that such a practice is neither wise nor commendable, but we fail to perceive any influence sufficient to deter persons from such a course unless it be the ruinous effect it eventually has upon themselves.—ED. PHARM. JOURN.]

A. Z.—Communicate with the Secretary, at 17, Bloomsbury Square.

H. and A.—Dissolve the borax in the glycerine; add gradually the oil and carbolic acid, and stir well; lastly, add the elder flower water and shake well until an uniform emulsion is formed.

"*Sixty-six.*"—We think aqua limonis might be extemporized by shaking oleum limonis with distilled water and filtering. For an answer to your second question, see "Notes and Queries," p. 167.

"*Lover of Stains.*"—*Mahogany Stain.*—Logwood, 2 oz.; madder, 8 oz.; fustic, 1 oz.; water, 1 gal.; boil two hours and apply it several times to the wood boiling hot; allow the wood to dry and brush it over with a solution of pearlash, 1 oz. in one quart of water; dry and polish. (Cooley.)

"*Catechu.*"—*Depilatories.*—A strong solution of sulphuret of barium with sufficient starch to make a paste has been recommended as a depilatory. Also one part of finely powdered crystallized sulphydrate of sodium and three parts of prepared chalk made into a paste with water. Neither of these should be allowed to remain in contact with the skin more than two or three minutes.

"*Bicycle.*"—See the recipe on p. 1018 of the *Pharm. Journ.* for June 17 last.

H. W. Langbeck.—We cannot say. It would depend probably upon conditions referred to in the Worcestershire Sauce case, reported before, p. 106.

"*Omega.*"—Applications for the appointment of Dispenser in a Naval Hospital have to be made in writing to the Director-General of the Medical Department of the Navy at the Admiralty.

COMMUNICATIONS, LETTERS, etc., have been received from Professor Dymock (Dymock), Mr. Dadford, Professor Attfield, "Devonian," H. A.,

ARROWROOT.

BY THOMAS GREENISH, F.C.S.

The origin of the term arrowroot is involved in some obscurity, and its application to the starch derived from the Maranta to the exclusion of that from every other source may, I think, be called in question. The authors of the 'Pharmacographia' dispute the opinion of Martius,* "that the name is derived from that of the Aruac or Aroaquis Indians of South America, who call the finest sort of fecula they obtain from the Mandioc Aru-Aru." Other writers consider that there is great probability in the explanation afforded by Martius, the word "aru," signifying meal or flour, and they are of opinion that "ara-ruta," which means mealy root, is the word from which arrowroot is derived.

An opportunity was afforded me of making some inquiries of old Brazilian residents with reference to this subject, and I learnt that the word "ara-ruta" is one well known in Brazil, that it originated with the native Indians, and that it certainly is not derived from our "arrowroot." That "ara-ruta" is a native Indian word is, I think, beyond dispute, and as it was the practice of the native Indians to eat the simple root without any further preparation than roasting it in hot ashes, it therefore appears natural that a native Indian would apply just such a word to a root that he found yielding so large a proportion of a farinaceous substance as the maranta or the cassava.

It is generally admitted that the manihot, which yields the starch known as cassava starch, is a native of Brazil; if therefore the maranta be an introduced plant, which agrees with common report, the probability is that the term "ara-ruta" originally applied to one or more varieties of the manihot, and if so, cassava starch has certainly equal claims with the maranta to the more popular and commercial name "arrowroot." The *Manihot utilissima*, Pohl., yields the cassava starch of commerce; it is also that used in the manufacture of tapioca. Another variety of manihot yields a starch having a little colour: this is kept for home consumption. I think it probable that at different periods, when a starch has been found capable of preparation so as to become an acceptable article of diet the term "arrowroot" has been applied to it, and thus we have other starches which have long been designated by the name of arrowroot.

Brazilian arrowroot (Manihot).
Tahiti arrowroot (Tacca).
Portland arrowroot (Arum).
East India arrowroot (Curcuma).

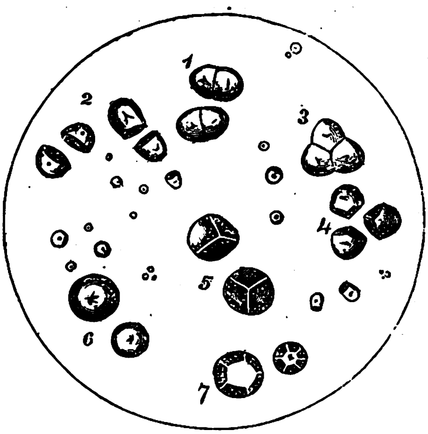
Some of these are rarely, if ever, found in commerce, although extensively used in the countries where they are produced.

The cassava is cultivated chiefly in Brazil for food purposes and home consumption, and, excepting as tapioca, there is little of the starch imported into this country. "The returns do not specify the quantity of starch apart from its product tapioca, but the value of farinaceous substances imported from Brazil, nearly all of which was tapioca, was in 1871, £14,092. Twenty years since 11,000 cwt. of tapioca used to be imported annually, now we only receive half that quantity."* Much of the cassava starch that is imported is used as a stiffening material in the Manchester district.

The tapioca is prepared from the starch of the bitter cassava by heating it whilst moist on metal plates; the starch grains for the most part burst and the product agglomerates into semi-opaque gum-like masses, with here and there grains but little altered.

The cassava starch has been found on several occasions mixed with that of maranta, and sold as arrowroot. One case occurred in the Borough, and Dr. Muter certified to its presence as an adulterant. Mr. Jones, of Birmingham,† has detected it in a maranta "as imported." It is beyond question that for some time marantas have been imported into this country adulterated with cassava. I have several times detected it as an adulterant of pepper, and have also found it mixed with a maranta, but I had no means of ascertaining whether this arrowroot was "as imported" or had been tampered with in this country.

The starch of the manihot, commonly called cassava starch, is one with which every pharmacist who has a microscope, and no pharmacy is complete without one, should be familiar. The accompanying woodcut shows the usual forms of this starch.



They are for the most part muller-shaped, with a fair sprinkling of the circular; some of the muller-shaped have truncate, others dihedral bases. If the starch be examined *in situ*, as in the meal of the cassava, there will be found a good many doublets and triplets, as shown in the drawing, but these combinations are rarely present in a commercial sample of the prepared starch. The separation of the grains composing the doublet gives the muller-shaped truncated granules and that of the triplet the muller-shaped with dihedral bases. The diameter of the granules ranges from 0·008 to 0·022 mm.

A very interesting and instructive experiment, with the view of determining the true forms of these grains to which the names muller-shaped and circular are given, may be witnessed with advantage. After having examined under the microscope a little of the starch, using as a medium some such a fluid as I mentioned in the Journal,‡ the single forms here

* 'Flor. Brasil.' iv., p. 416.

* Simmonds.
† *Pharm. Journ.* [3], vol. vii., p. 23.
‡ *Pharm Journ.* [3], vol. v., p. 923.

given will for the most part be seen in the field of the microscope. If now a drop of alcohol be placed on the edge of the covering glass, capillary attraction will cause it to run in rapidly, and in its course the grains will be rolled over several times. It will be observed that a granule which appears muller-shaped when seen from the side, with the nucleus indicated by a spot or a fissure a little out of the centre, or eccentric, when rolled over so as to be seen with its crown towards the observer, appears circular; also that one of the triplet grains with a dihedral base when seen with its base uppermost will give, with other grains having polyhedral bases, those angular forms of which the drawing indicates one or more examples. Careful illumination will occasionally show one or two zones indicating the lamination of the grain. If when the grains have ceased to revolve, another drop of spirit be applied to the opposite side of the covering glass the movement will be repeated.

I should be glad to see in published documents connected with adulteration or otherwise the word "arrowroot" less vaguely used, and instead of it the term "starch" employed in a generic sense to designate the organized structure observed, and its source added to distinguish the particular kind; thus, the starch of a maranta or the starch of a manihot; the starch of wheat or that of potato. I think that the time has arrived when we may expect from scientific men who hold public and responsible positions a little more exactness as regards the adulterant. Nothing can be more vague than a statement now before me, and which may be taken as typical. A tradesman is summoned for selling adulturated arrowroot; the public analyst's certificate states that "the arrowroot was adulterated with *tapioca* and *starch*." A sample of this "adulterated arrowroot" was sent to me for examination. It was the starch of a maranta, with a mixture of that of cassava. Tapioca is a granulated article, and not likely to be used as an adulterant, and arrowroot is itself a starch.

The starch of the tacca, called Tahiti arrowroot, is one resembling that of the cassava, but it is rarely found in commerce; the muller-shaped granules are, however, larger, and there are not proportionately so many circular ones. The diameter ranges from 0·026 to 0·045 mm.

The only other starch of this form is that of the *Castanospermum Australe*, or Moreton Bay chestnut. It was shown at the Paris exhibition, but from that time to the present it has not appeared as a commercial article, so that it is not likely by its presence to complicate matters, or embarrass the observer.

I believe that all the cassava of commerce is the produce of *Manihot utilissima*, Pohl.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from p.* 110.)

FERULA Sp? *The Seed.—Local Name*, DOOKOO.

Is said to be imported from Persia and Affghanistan. The carpels are broadly elliptical, and vary much in size, the largest are five-eighths of an inch long and three-eighths broad; foliaceous, convex in the middle, with a dilated border consisting of coarse cellular tissue; colour reddish brown over the seed, margin yellowish; dorsal ridges seven, the three central filiform; vittæ in dorsal furrows ten to thirteen; vittæ of commissure six. The vittæ contain a quantity of yellow oily fluid having a powerful lemon odour.

By distillation a light yellow essential oil was obtained with an odour like oil of orange leaf. This seed is used as a carminative and stimulant; it is also said to be diuretic.

LOBELIA NICOTIANÆFOLIA.

This gigantic lobelia is common on the Ghauts. The lower part of the stem is woody, an inch and a half or more in diameter, and almost solid; the upper portion is a hollow tube ending in a crowded head of flower spikes; the latter are about a foot in length, and when the plant is in fruit, are thickly set with globular capsules about the size of a pea, to which a portion of the dry flower is often adherent; the capsules are two celled, each cell containing a fleshy placenta. The seeds are numerous and very small ($\frac{1}{50}$th of an inch in length), oval, flattened and marked with delicate lines. Several small tubercles surround the site of the placental attachment; the colour is light brown. The leaves resemble those of tobacco, they are finely serrated, and covered with simple hairs. The whole plant when mature is studded with small spots of resinous exudation, and is hot and acrid when chewed. Six ounces of the dry spikes from which the seeds had fallen yielded half an ounce of dark brown resin when treated with rectified spirit. The native name, Bokenul, or tubular poison plant, would lead one to infer that the plant is poisonous, but I am not aware that this has ever been proved. It is said to be antispasmodic in the Pharmacopœia of India. Its acridity being due to the resin it contains, a tincture would be an efficient preparation.

PAVETTA INDICA. *The Root.—Local name*, PAPTEE CHE MUL.

This small shrub is very common, the root is much crooked, and from one inch to quarter of an inch in diameter. Its bark is grey with a light brown papery epidermis, and seems to be the most active part. It has a slightly bitter and subacrid taste. A section placed under the microscope showed large laticiferous vessels containing a greenish latex, and a cellular structure containing many small starch granules. Paptee is bitter and aperient; no exact observation of its action appears to have been made.

TRICHOSANTHES PALMATA.—*Local name*, KOUNDAL.

The fruit is round, oval, or pyriform, the size of a small apple, of a dirty yellow colour, marked at one end by a deep cicatrix with sharped raised edges, at the other there is a prominence to which a portion of the stalk sometimes remains attached. In the dry fruit, which has a thin brittle, very bitter shell, the segments of pulp with their seeds are loose, so that when sound the contents of the gourd rattle. If a dry segment be soaked in water it soon softens, yielding a dark green pulp which smells like savin and has an acrid and bitter taste. The seeds are flat, but very irregular in shape, generally somewhat triangular, and average seven-sixteenths of an inch in length, they have a hard blackish shell and sweet oily kernel. The vine is perennial, often as large as the middle finger, it has a warty grey bark marked by seven deep longitudinal fissures which correspond to the medullary divisions between seven wedge shaped vascular bundles into which the stem is divided. The vine is not bitter. With regard to the medicinal properties of this plant nothing definite appears to be known, the natives sometimes smoke it as a remedy for asthma.

AGATI GRANDIFLORA.—*Local name,* AGASTA.

The tree though not a native is now very common in this part of India. The bark is much fissured longitudinally, of a greyish brown externally, the dry portion nearly equal to the living in thickness; in the fissures may be seen numerous small tears of gum of a garnet colour when fresh, but soon becoming almost black. The suberous layer of the living bark is of a reddish colour, from a deposit of the same kind of gum in its cells. In the vascular zones of the bark are large laticiferous vessels which are filled with the gum in a fluid state and of a paler colour. The dry suber already mentioned is loaded with small deposits of gum. This is partially soluble in spirit, and also in water, leaving a gelatinous residue of small bulk. The bark and gum are intensely astringent; the former is not bitter. The leaves have an astringent taste. Neither bark, gum, or leaves, appear to be made use of in Bombay, but the juice of the flowers is a popular remedy in nasal catarrh; it is blown up the nostrils, and causes a very copious discharge of fluid.

POLANISIA ICOSANDRA.—*The Herb.—Local name* KANPHOOTEE.

An annual weed from one to two feet high, leaves 3—5 foliolate, leaflets obovate, flowers yellow. The whole plant is pubescent and extremely viscid, the hairs are surmounted by a round gland from which a reddish viscid secretion exudes. The plant has a powerful odour like a mixture of black currants and oil of mustard. The juice is used in purulent discharges from the ear.

CALOSANTHES INDICA.—*Local name,* TETOO or PHULPHURA.

A small tree remarkable for its terminal spikes of fleshy, lurid flowers, which appear at the commencement of the rainy season. The bark is light brown, marked with the large rough scars of the fallen petioles and also thickly studded with wart-like protuberances about the size of a pin's head; internal surface yellow. The minute structure of the bark does not call for remark, but upon placing a section under the microscope in a little water the whole field is seen to be filled with delicate needle-shaped crystals which have escaped from the cut cells of the parenchyma; in entire cells the crystals can be seen *in situ.* This bark is a favourite remedy in dysentery; it is faintly bitter and a little acrid to the taste, with no particular odour. I am not aware of any analysis having been made, or of its having been tried in European practice.

SIZYGIUM JAMBOLANUM.—*Local name* JAMBOOL, *The Bark and Fruit.*

The bark is grey and fissured externally, internally it is red and fibrous; its minute structure is remarkable in having several rows of very large, pitted, oblong-oval cells, which can be seen with the naked eye. The smell is something like that of oak bark, and the taste very astringent. The fruit is purple, the size and shape of an olive; the fleshy portion, which is very astringent, encloses a thin white papery shell containing a green coloured nut. The bark and fruit are excellent astringents. As the tree is very common they can almost always be obtained.

ARGEMONE MEXICANA.—*Local names,* DARURI, PEELA DHOTRA.

The plant is sufficiently well known; it is found abundantly on waste ground in Bombay. I can speak favourably of the oil of the seeds as a gentle aperient, free from taste, in doses of from 30 to 60 minims. In India it is necessary to express your own oil, otherwise it is sure to be adulterated: this has probably been the cause of the unfavourable reports of some medical men. The whole plant in flower was analysed by the late Dr. R. Haines of Bombay, who failed to find any trace of an alkaloid in it. At the same time an extract was made and administered in gradually increasing doses to a number of European patients in the general hospital; it was found to be aperient only.

NOTONIA GRANDIFLORA.—*Local name,* WANDER ROTEE.

Numerous experiments with this plant were made by the late Dr. R. Haines and myself upon animals and human beings, the result was that in large quantity it proved slightly aperient.

PSIDIUM POMIFERUM.—*The Bark.—Local name,* PEROO.

The external surface of this bark when fresh is brown and smooth, marked by superficial scars indicating the separating of squamous plates of dead bark. These plates sometimes remain partially attached. Beneath the brown epidermis the bark is green; its inner surface is marked by longitudinal striæ and is of a light brown colour. Sections show that it consists of an epidermis made up of two rows of brick-shaped brown cells, and alternate rows of vessels and parenchymatous cells, varied towards the inner part by three broken circles of liber cells. The medullary rays are numerous and together with the parenchyma of the outer part of the bark loaded with green colouring matter; in the rays this extends some distance into its substance, and makes them very conspicuous. The vascular system is loaded with crystalline deposit. Guava bark is astringent and agreeably acid; its astringent properties are noticed in the Pharmacopœia of India. The acidity is most likely due to the crystalline deposit, which is probably an acid salt of lime or potash.

MICHELIA CHAMPACA.—*Local name,* CHAMPA.

The fresh bark is externally covered with a light brown epidermis, which is easily removed; beneath this it is of a reddish brown colour mottled with longitudinal green stripes (not visible in the dry bark), and pale yellowish scars of very irregular form; the inner surface is yellowish and fibrous. The bark is feebly bitter and has a slight aroma. Its minute structure is chiefly remarkable for numerous bundles of liber cells and for aggregations of large stony cells of a bright yellow colour. The cells of the parenchyma contain much starch. Champa bark is mentioned as a febrifuge in the Indian Pharmacopœia, but I have not heard of its being tried in this neighbourhood. From its very feeble bitterness I should not think it likely to be of much use.

AMORPHOPHALLUS SYLVATICUS.—*Local name,* JANGLI SOORUN.

The tuberous root, Madan Must or Kummer Kas, is found in most of the shops peeled and cut into segments, which are strung upon a string; the segments are about the size of those of an orange, of a reddish brown colour, shrunken and wrinkled, brittle and hard in dry weather; the cut surface is mammillated. When soaked in water they swell up and become very soft and friable, developing a sickly smell like that of the spadix of the plant when in flower. A microscopic examination shows that the root is almost entirely composed of starch. Madan Must has a mucilaginous taste, and is faintly bitter and acrid; it is supposed to have restorative powers, and is in much request. It is probable that the roots of the wild *Amorphophallus campanulatus* form a part of the commercial article. The cultivated variety of the latter plant is largely used as a vegetable; under cultivation it loses its acridity, and grows to an enormous size.

ACACIA ARABICA.—*Local name,* BABUL.

The gum of this tree is yielded in great abundance in March and April. Much of it is of a bright red colour, and translucent; sometimes it is almost colourless; very large masses are met with. As a gum it is of little value, as it forms a very weak mucilage; the colour is also objectionable. It is entirely soluble in cold water, and tastes like gum arabic.

CONOCARPUS LATIFOLIUS.—*Local name,* DAVRA, *or* DAWARA.

The gum is in vermicular pieces, very slightly coloured, translucent; it tastes like gum arabic, is readily soluble in cold water, and forms a good, almost colourless mucilage, with a faint peculiar odour. The tree is common in the Concan and Khandesh.

(*To be continued.*)

THE PRESENCE OF AN ALKALOID IN PYRETHRUM CARNEUM.*

BY JOUSSEL DE BELLESME.

It is known that the powder of pyrethrum constitutes the basis of nearly all the insecticides at present in use. It has been thought, probably wrongly, that the pyrethrum acts only mechanically upon insects, by obstructing their spiracles. The author has brought under the notice of the Société de Biologie a number of cockroaches that had been kept ten hours in various inert powders—such as powdered dry leaves, wood, etc.—and showed that these insects did not present any morbid phenomenon. For comparison he exhibited others which having been kept one hour in pyrethrum powder, were already nearly dead, and showed convulsive movements very clearly. But if the powder is previously treated with alcohol it loses its insecticidal properties, whilst the alcohol becomes toxic. The author also combats the opinion which attributes the poisonous properties to the volatile oil it contains, he having isolated the oil and found it to be innocuous to insects. Having submitted pyrethrum powder to the treatment suitable for isolating alkaloids, the author succeeded in extracting a crystalline principle possessing in a high degree the toxic properties of the plant. This he considers to be an alkaloid, the composition and chemical properties of which remain yet to be investigated.

* *Journal de Pharmacie et de Chimie* for August, from he *Journ. Chem. Med.*

THE ESTIMATION OF ASTRINGENT MATTERS.*

BY F. JEAN.

The author has found that solutions of astringent principles, when added to an alkaline carbonate, absorb solution of iodine with an energy comparable to that of arsenite of soda. Numerous experiments have shown that this absorption takes place exactly in direct proportion to the quantity of astringent matter used, and that one part by weight of dry tannic acid absorbs four parts of iodine, forming a compound that has not yet been studied. Upon this reaction he bases a method of estimating astringent matter.

The solution of iodine used is made by dissolving four grams of iodine in iodide of potassium and adding sufficient distilled water to make the volume 1000 c.c. To standardize the iodine solution 10 c.c. of a solution of tannin (0·1 per 100) should be placed in a test tube; 2 c.c. of a solution containing 25 per cent. of crystallized sodium carbonate is added; then from a graduated burette the iodine solution is let fall drop by drop, until it gives a spot upon starched paper. With a solution containing four grams of iodine per litre the correction is usually 0·1 c.c. for a volume of 10 to 12 c.c.; but the greater or less purity of the sodium carbonate may cause this correction to vary slightly. For 0·01 gram of tannin dissolved in 10 c.c. of water it is usually necessary to employ 10·5 c.c. of solution of iodine containing 4 per 1000.

Under the influence of iodine the solutions of tannin, even when very dilute, take a rather intense orange red colour, so that it is impossible to seize sharply the coloration of the iodide of starch, when starch paste is added to the tannin solution. The author, therefore, uses for the purpose a sheet of white filter paper, over which is dusted a slight layer of starch. When half a drop of liquor containing free iodine is touched on such a paper it is immediately absorbed and the characteristic violet colour becomes perceptible even when the liquor is strongly coloured.

When the strength of the iodine solution in relation to a known weight of tannic acid has been established the test liquor can be employed in the titration of other astringent principles, by taking tannic acid as the type of the active principle of astringent matters, as is done by other authors. M. Jean has made experiments to test its value in the estimation of barks employed in tanneries and is quite satisfied with the results. Special experiments made to ascertain whether the astringent matters accompanying tannin in a decoction of oak bark had any action on the solution of iodine, showed that it could be safely used for such purpose, and that crystallized gallic acid acted upon the iodine solution exactly in the same proportion as tannic acid.

VIEWS OF THE NATURE OF HEAT.†

BY F. MOHR.

The phenomena of heat have been till now almost exclusively explained in text-books by the assumption of a heat-substance. The discoveries of Melloni have made this view inapplicable to the phenomena of radiant heat; they require the assumption of vibrations similar to those of the undulatory theory of light. The propagation, transmission, and polarization of radiant heat have

* *Comptes Rendus.*, vol. lxxxii., p. 982.

† Translated from Liebig's *Annalen,* vol. xxiv., 1837. Reprinted from the *Philosophical Magazine,* August, 1876.

been completely explained by these assumptions; and, with such facts to guide us, it is certainly no mere idle speculation to attempt to extend this view to the phenomena of common or stationary heat; rather it is in the highest degree seasonable to point out how this view, which depends upon the well-settled facts of Melloni, explains with overwhelming clearness most of the phenomena of stationary or conducted heat; and it is to be expected that, with this reform in our ideas, there will be a corresponding reform in our terminology.

Heat is thus no longer a particular kind of matter, but an oscillatory motion of the smallest parts of bodies. Radiant heat is propagated in straight lines; and the molecules vibrate in all directions in a plane perpendicular to the direction of the ray. A polarized ray vibrates in one direction only in this plane; on the contrary [the particles of] an ordinary hot body vibrate in all possible directions of space, and therefore propagate their heat uniformly in all directions. The propagation of heat by contact is thus a communication of motion by impact; and cooling is a relative coming to rest. The number of heat-vibrations per hour must, as in the case of light, be very large, since all bodies become luminous at a certain temperature; but even at this temperature waves of light and of heat are not identical; their difference has been hitherto just as little cleared up as that between rays of heat from different sources.

The difficult idea of imponderability is at once got rid of, since a body when vibrating cannot be either heavier or lighter than when at rest. The so-called absolute zero [of temperature] is therefore absolute rest—no doubt altogether unknown to us in reality, but presenting no difficulty to the mind.

Heat appears as force (*Kraft*). It overcomes the cohesion of bodies, which is a force; *but that which overcomes a force must be itself a force.* And the expansion of bodies by heat is a force-phenomenon of the highest kind; but that which produces motion or manifestation of force must be a force.

The expansion of bodies by heat is thus an extended amplitude of vibration. The bodies themselves do not expand, but only the space they occupy is increased by their larger vibrations. The compression of bodies is due to a change of the amplitude of vibrations by external power. At the absolute zero all bodies must be absolutely incompressible. One can measure the expanding force in certain bodies in terms of weight. Water expands by heating 0·00466 of its volume for 1° C. Experiment shows that water loses about $\frac{48}{1000000}$ of its volume under one atmosphere of pressure. To expand water thus much by heating there would be necessary $\frac{0\cdot000048^\circ}{0\cdot004660} = \frac{1^\circ}{97}$ C. The two forces would then be in equilibrium. Heating by $\frac{1^\circ}{97}$ C. produces in water a force of pressure of one tmosphere. 1° C. is thus to be considered = 97 atmospheres, and 10° C. = 970 atmospheres.

When a body passes from the solid to the liquid state, heat becomes latent. But one cannot understand how heat can be present in a body without becoming evident to our senses. The usual explanation is that the body is melted; but this is no explanation, merely the repetition of the fact to be explained. The easier explanation, from our point of view, is as follows: when heat-force is expended in overcoming another force, cohesion, it must itself cease to be perceptible as force; thus every case in which heat becomes latent is connected with production of motion or with alteration of state of aggregation—that is, with annihilation of material forces. Since matter cannot overcome any force, this explanation was not at command of the old view. A melted body cannot solidify without giving up to another body the force which destroys its cohesion:—*Evolution of heat in the solidification of melted bodies.*

In the production of gas the same thing takes place. In order to overcome the cohesion of water, some heat must be destroyed and become imperceptible. In the coming back to the liquid state this heat must be again disposable and able to put into vibration, *i. e.*, to warm, the thermometer or the hand. A gas vibrates so that its particles always tend to drive one another further off. The mere presence of a gas therefore acts like a material force. In a *solid body* the particles are by the vibration *not* driven out of the sphere of attraction, *in a liquid body partly, and in a gas entirely.* When one compresses a gaseous body so as to make its particles move within this sphere of attraction, they attract one another and become liquid:—*Liquefaction of gases by pressure.*

There is an essential difference between gases on the one hand, and the two other states of matter on the other.

In solids and liquids each temperature corresponds to a determinate expansion, or each number of vibrations to a definite magnitude of their amplitude; on the contrary in gases the endeavour is at all temperatures to indefinitely increase these amplitudes. This endeavour shows itself as tension (*Spannung*), and appears in gases only. The temperature is the number of vibrations which a body makes in a given time; this number increases with elevation of temperature. All heat which is not employed for this purpose disappears to our senses, and thus we have the simple distinction between sensible and latent heat: *Sensible heat increases the number of vibrations; latent heat increases their amplitude, or overcomes material forces,* i.e., *destroys states of aggregation.*

When a mass of gas is suddenly compressed, the excursions of the separate particles are diminished; and thus some of that force becomes disposable which before determined extent of vibration, and was therefore not perceptible by our senses. This force can now be employed only to increase the number of vibrations, since their extent is limited; that is, the gas becomes warmer. *Apparatus for inflaming tinder by compression of air.* (*Compressionsfeuerzeug.*)

When a gas is suddenly expanded, the separate particles are compelled to make larger vibrations, for which greater force is required. This can only be taken from the force which determines the number of vibrations (temperature), or from surrounding bodies, *i.e.*, the gas becomes cooled; which experiment verifies. Both phenomena are entirely unexplained by the old view.

Wide vibrations have greater force than narrow; but at high temperatures the vibrations always increase in extent. This increase corresponds, for equal increments of heat, to a definite fraction of the immediately preceding volume, and not of that at 0° C., which temperature has no definite relation to gases. Now, since this fraction must itself become absolutely larger with the already too much increased motion, a greater force must be required to heat a body from 90° to 100° C. than from 0° to 10°. This is the already generally *observed increase of capacity for heat at high temperatures.* All bodies which expand according to this law must show increasing capacity for heat. In the neighbourhood of the melting-point bodies expand rapidly and irregularly; thus much heat becomes latent—most of it, however, during the melting itself. In most cases, in melting, heat is rendered latent in two ways:—by expansion and by melting respectively; in the case of water, which contracts in melting, some heat is by this means given out; or, more correctly, the quantity of that rendered latent is diminished.

If any species of gas is heated more strongly, it strives not only to increase the number of its vibrations, but also to enlarge their amplitudes. If one prevents this expansion, it appears as increased tension. One would require therefore a smaller quantity of heat to warm a gas shut in by firm walls than a gas contained in yielding walls, since, if heat be the cause of the expansion, just as much heat must become latent as there would be cold developed if the gas were allowed to expand as much as before but without the supply of heat. An imprisoned gas, therefore, cannot show the phenomenon of increased capacity for heat. Were we able so to compress solids and liquids that they could not expand by heat, even these would show no increase of capacity for heat; and one could thus save an amount of heat which would, according to the previous calculation, be equal to the compressing force. On this account also the notion of changing, by pressure, liquids into solids is by no means impossible, although we do not as yet know what force would be necessary. The compression of water in a piezometer is in approximation to this.

The increased power of absorption of rough bodies for radiant heat is to be explained by the easily produced vibration of projecting points; while on polished closed planes the very cohesion is opposed to the assumption of vibrations. It would take us too far were we to attempt to reduce all heat-phenomena to this view. Those we have given suffice to show how they are all much more easily and intelligibly deduced from the assumption of vibrations than from that of heat-substance,—and that it is now time to give up, in science and in text-books, the indefinite nomenclature of the earlier view.

SIUM LATIFOLIUM, GRAY.*

BY ANDREW R. PORTER, PH.G.

Sium latifolium, an umbelliferous plant, growing in California and along the Pacific coast, in damp and marshy places, commonly known as wild parsnip, was brought to the notice of the people there about three years ago, by a man being poisoned by eating some of the root.

Sium latifolium has a short, upright root stock, varying in size from one-half to two inches or more in length, and about the same in diameter, so it becomes almost spherical in outline; bases of leaves are still attached to the crown. It presents a very rough, wrinkled appearance, and is of a grey or yellowish-brown colour. It branches at once into a number of large roots, from four to twelve, and even more. These are of the same colour, from $\frac{1}{8}$ to $\frac{1}{4}$ or $\frac{3}{8}$ inch in thickness, and 2 to 6 inches long, very much wrinkled longitudinally, somewhat flattened and contorted, and nearly uniform in thickness. On soaking in water, they become about twice as large. The dried root breaks with a very short fracture, is white inside, with a yellowish, spongy meditullium and numerous resin cells, which are plainly visible with the naked eye, scattered irregularly throughout the bark. The root has rather an agreeable aromatic odour, and a sweetish, aromatic and somewhat pungent taste.

In attempting to separate the proximate principles of the root, an alcoholic tincture was made, concentrated and precipitated by water. In the clear aqueous solution, Trommer's test indicated the presence of much *sugar*, besides some colouring matter. The precipitated oleoresin was distilled with water, the distillate containing some *volatile oil*, which was colourless, and had the aromatic odour and warm, pungent taste of the root. The soft residue was separated by hot petroleum benzin into a *fixed oil* and *resin*. The oil was thick, deep-red, of a slight odour and disagreeable taste, soluble in alcohol, chloroform, ether, oil of turpentine, benzin and carbon bisulphide.

The resin was easily rubbed into a reddish-brown powder, which had a very slight odour and but little taste, fusible when heated, and uncrystallizable, soluble in alcohol, chloroform and ether, insoluble in benzin and bisulphide of carbon. This resin appears to be the poisonous principle, since a small portion of it, given to a cat, produced in the course of two hours frothing at the mouth, considerable pain and then convulsions, from which, however, the cat recovered. This resin was not quite pure, since caustic potassa dissolved only a part, leaving a portion insoluble, and not fusible by heat.

The root exhausted by alcohol was found to contain *gum*, *albumen* and *pectin*, but no starch.

An alkaloid having been searched for with negative result in the alcoholic tincture, a decoction of the root was distilled with caustic potassa. The distillate had an alkaline reaction, and its odour reminded of that of conium; but, when neutralized with an acid, the distillate was neither precipitated by tannin nor by iodohydrargyrate of potassium; it was probably *ammonia* contaminated with some odorous product of decomposition.

THE CONSTITUENTS OF SYRUP OF PHOSPHATE OF IRON.*

BY E. B. SHUTTLEWORTH.

So long as the syrups and elixirs containing the salts of the acids of phosphorus retain their popularity the subject of their production will be regarded with particular interest by the pharmacist. The preparation of this extensive class of compounds generally falls to the lot of the retail druggist, and more seldom to the wholesale manufacturer. The processes involved require neither costly or special apparatus, nor great skill; are unattended with the evolution of injurious or disagreeable gases, and can therefore be readily carried out in the shop. Operations of this kind should always be performed when at all practicable. They tend to keep up an interest in chemistry, and keep before the mind the fact that the pharmacist is a chemist as well as a druggist; they also provide a means of diverting the mind from the tedious duties of mere shop-keeping, and are at the same time attended with considerable pecuniary gain.

During the past few years, and more particularly the last three months, there have appeared in the pharmaceutical journals numerous papers and notes on phosphate of iron and the syrups containing it. Several of these are exceedingly valuable. Amongst them may be mentioned a very lengthy and exhaustive paper read by Mr. W. L. Howie, F.C.S., before the North British Branch of the Pharmaceutical Society at Edinburgh; and that of Mr. Rees Price, read at an evening meeting of the Pharmaceutical Society of Great Britain. Both these papers elicited considerable discussion, drawing forth many interesting facts and practical details.

I think that a useful purpose may be served by reviewing the literature, and representing in as concise a form as possible the main points of the subject, omitting all unessential details. In order to perform this service in as systematic and useful a form as possible, I shall not encumber this paper with special references relating to authors or periodicals, and shall work in such observations of my own as may have been made during a fair experience with tolerably large quantities of materials. For those whose time and opportunities will permit more extended reading, a list of authorities is subjoined.†

Phosphoric Acid.—Of this substance there are several varieties. The *tribasic* acid, having the composition H_3PO_4, combining weight 98, is that used in medicines. In order to distinguish this form from the others, add a little tincture or solution of perchloride of iron; if the mixture remains clear, the tribasic acid is present—other-

Journ.*, January, 1875; Croft, *Can. Pharm. Journ.*, June, 1875; Maisch, *Amer. Journ. Pharm.*, October, and *Can. Pharm. Journ.*, December, 1875; Shuttleworth, *Can. Pharm. Journ.*, February, 1876; Price, *Pharm. Journ. and Trans.*, March 4, 1876, pp. 701-716; Howie, *Pharm. Journ. and Trans.*, April 7, 1876, and April 15, p. 834.

wise, a whitish precipitate is produced. The official form of this acid is the *Acid. phosphoric. dilutum*, but, in order to avoid disappointment, it is always well to submit this preparation to the above test. If a precipitate is produced, boil down the acid to the consistence of syrup, *allow it to cool*, and add water up to the ordinary bulk. If the official acid is not at hand the glacial acid may be substituted, being previously treated with nitric acid after the manner of the United States Pharmacopœia. This will not always furnish the tribasic acid, and simple solution and evaporation of the glacial acid, without the addition of nitric acid, often gives as good results. Neither method can be relied upon with all samples of acid. The preparation of phosphoric acid from phosphorus should never be attempted by the pharmacist. The process requires much care and experience, is not economical, except with large quantities, is attended with the evolution of poisonous and disagreeable gases, and, like all operations with phosphorus, is always more or less dangerous.

For preparing syrups, and, indeed, for most purposes, an acid stronger than that official (10 per cent. anhydrous acid), might be advantageously employed. The so-called *syrupy* acid, which can be obtained from some manufacturers, and which is about five time stronger than the other (49 per cent. anhydrous acid, and of specific gravity 1·5), will be found very useful.

Phosphate of Iron.—Five methods have been recommended for preparing this substance: (*a*) By mixing together solutions of sulphate of iron and phosphate of soda; (*b*) by using these salts with the addition of acetate of soda; (*c*) by substituting carbonate or bicarbonate of soda for the acetate; (*d*) by employing an excess of phosphate of soda; (*e*) by forming the phosphate by direct combination of phosphoric acid and metallic iron. By the first method, which is that of the United States Pharmacopœia and Parrish's 'Pharmacy,' about 30 per cent. of the phosphate of iron escapes precipitation, as the free sulphuric acid, liberated in the reaction, dissolves or holds this amount. The framers of the British Pharmacopœia sought to escape this loss by employing acetate of soda for neutralizing the free sulphuric acid, as in the second method. This addition has been shown to be an improvement, but is still in great part ineffectual, as from 22 to 28 per cent. of the phosphate is lost. In the third method, that of Mr. Schweitzer, in which carbonate or bicarbonate of soda is employed, the loss is reduced to less than one per cent. The fourth method, that of Mr. Rees Price, is said to yield results equally satisfactory, but nearly three times the usual quantity of phosphate of soda is required. On the score of economy this is quite a consideration. The fifth method, that of direct combination, answers well where time is not an object. If acid of sp. gr. 1·5 be used, it should be diluted with an equal weight of water, and the iron should be in the form of filings, preferably of Swedish, or wrought metal. In order to produce a preparation similar to the *Syr. Ferri Phosphatis*, B. P., and containing one grain of phosphate in each fluid drachm, the following formula may be employed:

Iron	38	grains.
Phosphoric Acid, sp. gr. 1·5	6	fluid drachms.
Water	6	„ „
Syrup	8½	„ ounces.

Mix, in a flask, the phosphoric acid and water; add the iron, and plug the mouth of the flask with cotton; when the iron is dissolved, filter the solution and add it to the syrup.

The blue phosphate of iron is not a substance of very definite composition, and it is questionable whether the above methods furnish compounds which are identical. Even when the same ingredients are used in proportions exactly alike, the products may differ if the details of manipulation be changed. In all cases the intention is to produce *ferrous* phosphate, but this is never altogether accomplished, as a great portion of the salt passes to the *ferric* condition; or, as may be better understood, passes from a *proto* to a *per* salt. An analysis of six samples of commercial phosphate showed a range of from 20 to 46 per cent. of ferrous salt. It appears likely that the last method noted above would yield a preparation richer in ferrous salt than any of the others, but it is said that the third method gives a salt containing 51 per cent., which is more than 5 per cent. better than the B. P. standard.

Taking everything into account, I much prefer this process, and have used it with satisfaction for several years. The proportions of the sulphate of iron and phosphate of soda, as given in the B. P. may be retained, but instead of one ounce of acetate of soda, about half that quantity of bicarbonate of soda must be used. A better form is that of Mr. Howie:

Sulphate of Iron	7½ parts.
Phosphate of Soda	6½ „
Bicarbonate of Soda	1½ „

Dissolve the salt in ten times its weight of water, which has been previously boiled, in order to expel air; and the phosphate of soda in a like quantity, similarly treated. Let the solutions cool to between 100° to 135° F., and pour the phosphate very gradually into the iron, with constant stirring. Add the bicarbonate, either in powder or solution. Let the precipitate subside; decant; wash well with previously boiled water; collect on a filter and squeeze out as much water as possible, either with the hand or an ordinary press. These details of manipulation must be rigidly adhered to—more especially those relating to the order of mixing and temperature—or uniform results cannot be obtained. If, in the above formula, the *parts* be held to indicate *drachms*, it may be read as part of Parrish's receipt for the so-called chemical food, published in his 'Practical Pharmacy,' p. 425, and the iron strength of the resulting preparation will accord with the compound sold as genuine.

Sugar.—Some English writers have enlarged considerably on the importance of obtaining pure cane sugar. It is said that beet sugar is very abundant in the English and French markets, and is largely substituted for that of the cane. I do not know that this adulteration is practised in America, but am quite certain that the sugars with which we are supplied are now anything but pure, and that a great many of the pharmacists' troubles relating to the fermentation and precipitation of syrups are referable to this cause. In Canada we formerly had an article which was unexceptionable, but since that refinery has been closed the average quality has become sensibly lower. Inferior grades of American and Scotch imperfectly refined loaf sugar have been introduced, and I doubt not but my brother pharmacists have already realized the effects of the change. It is a matter of prime importance to secure a good article, but I know of no other ready method of attaining this end than comparing samples and selecting that which has neither colour, odour, nor taste, other than that of sweetness, and which is in the hardest and most sparkling crystalline lumps.

SALICYLIC ACID IN THE DAIRY.*

BY L. MANETTI AND G. MUSO.

The authors undertook a series of experiments to elucidate the influence of salicylic acid upon (I.) the preservation of milk; (II.) the separation of the cream; (III.) the preservation of butter, and (IV.) the progress of caseification, the results of which have been recorded in the *Bullettino dell' Agricoltura*.

I. *Influence of Salicylic Acid upon the Preservation of Milk.*—The experiments undertaken to define this influence were executed upon volumes of milk varying from one-tenth of a litre to 400 litres and upwards, at temperatures between 10° and 25° C., and the acid was mixed in a manner to be described with the milk in varying proportions of 1 part of acid to from 250 to 10,000

* From the *Moniteur Scientifique-Quesneville* for August.

parts of milk. Milk was always used that had been drawn two to four hours and transported a distance of two or three kilometres, a circumstance that should be taken into account as interfering with the preservative efficacy of the acid. The results obtained in this first series of experiments confirmed the assertion of Kolbe that the preservative effect of salicylic acid depends essentially upon the temperature at which the milk is kept. In the proportion of 1 in 10,000, at 10° C., it retarded the coagulation of milk upwards of eight hours, especially when operating upon moderately large quantities, but at 25° to 30°, and if the quantity of milk was small, the acid did not notably retard the coagulation. In the proportion of 2 in 10,000 salicylic acid retarded on the average the coagulation of milk kept at 18° to 20° C. twelve hours, and milk kept at 12° C., twenty to twenty-four hours. With 5 parts of acid in 10,000 of milk kept at 15° to 20° C., coagulation was retarded two to four days, and at 12° C. three to five days. With 1 part in 1000° C. the milk was preserved in a liquid state much longer, but the acid communicated to it a sweetish taste that was perceptible to a delicate palate.

But besides the temperature and quantity employed the anti-fermentescible power of salicylic acid upon milk is dependent upon—(*a*) the chemical constitution of the milk; (*b*) the time elapsed between the milking and the addition of the acid; and (*c*) the electrical condition of the atmosphere. Thus a litre of milk treated with 0·5 gram of salicylic acid on the 15th of May, and kept at a temperature of 10° to 12°, coagulated after a lapse of time different from that taken by a litre so treated on the 21st of May, and kept under the same conditions.

On the 10th of June two glasses, each containing 100 c.c. of milk, were set aside, after first adding to one (B) 0·05 gram of salicylic acid, and to the other (A) a quantity of water corresponding to the salicylic acid solution. The glasses were covered with a sheet of paper, placed on the same table, and left for 24 hours at a temperature o 120° to 25° C. The lactin was estimated in the milk itself by Fehling's liquor.

	A.	B.
Lactin at the commencement . .	4·73	4·73
after 24 hours	2·06	3·35
Consumed	2·67	1·38

Both specimens were coagulated.

On the 13th of June this experiment was repeated, but adding 0·1 gram of salicylic acid to B.

	A.	B.
Lactin at the commencement . .	5·07	5·07
„ after 24 hours	4·59	4·98
Consumed	0·48	0·09

Another experiment made on the 17th of June gave similar results, the quantity of lactin transformed in a given time being smaller in proportion as the quantity of acid employed was increased.

Specimens of milk treated with 1 part in 250 and 1 part in 300 of acid had a pronounced sweetish taste. They did not allow of the time of coagulation being clearly noted, and when coagulated appeared as a white semi-liquid homogeneous mass, without any perceptible separation of serum. The longer the milk was kept the more blue it became; the upper stratum became more dense, and at last became the substratum of an abundant cryptogamic vegetation. When, in consequence of the above mentioned disturbing causes, milk treated with salicylic acid remained liquid longer than usual, it did not usually coagulate throughout simultaneously. It commenced to coagulate just below the cream, and this layer thickened until it reached the bottom, or met with another layer rising from the bottom.

In introducing the salicylic acid into the milk, a solution saturated at the ordinary temperature cannot be used, as that would introduce too much water; neither can a boiling saturated solution in water be used as it would coagulate the milk wherever it came into contact with it. The authors prefer to use a fine powder prepared from large salicylic acid crystals, which is thrown upon the milk a little at a time, and well stirred in. The large crystals are prepared by pouring boiling water upon one third of the quantity of salicylic acid it is capable of dissolving, and allowing the solution to cool slowly. Salicylic acid dissolves in 15 to 20 parts of boiling water, and 300 parts of cold water.

II. *Influence of Salicylic Acid on the Separation of the Cream.*—In all these experiments, which were made under varying conditions of temperature, and with different proportions of acid, it was found that after standing 24 hours, the salicylized milk formed a layer of cream equal to that formed on the milk to which acid had not been added, and that the salicylic acid did not exercise any influence on the separation of the cream. But it was noted that while the cream on the specimens of milk that had not been treated with acid and had been kept at a temperature above 15° to 20° C. presented after 24 hours an unsatisfactory appearance, being deficient in coherence and rather disposed to turn rancid, the cream on the salicylized specimens presented all the characters of fresh and sound cream. The fact that by means of salicylic acid milk can be preserved in a liquid and sweet condition for a relatively long time points to the probability that it would allow of a more complete separation of the cream taking place, as at certain seasons the operation of creaming has to be much hurried. It was found also that in operating upon large quantities of milk the same results were obtained with less acid in proportion than with small ones. Fifty grains of salicylic acid added to 430 litres of milk exercised a preservative influence equal to that of 150 grams of borax.

III. *Influence of Salicylic Acid upon the Preservation of Butter.*—By different experiments it was found that a solution of salicylic acid could not be incorporated with butter in sufficient quantity to affect sensibly its preservation. But when powdered salicylic acid was worked up with one thousand times its weight of butter, the butter kept at the ordinary temperature remained sound upwards of a week longer than butter that had not been so treated. Two parts of salicylic acid in a thousand of butter gave still better results so far as preservation was concerned, the rancidity being deferred upwards of a fortnight, but the butter acquired an easily perceptible sweetish taste. By placing butter in tin boxes and covering it with a solution of salicylic acid saturated at the ordinary temperature a still greater preservative effect was obtained, one specimen remaining without trace of rancidity five weeks, the greater part of the time at a temperature of 25° C. The best preservative effects would therefore appear to be attainable by incorporating uniformly the salicylic acid as a powder with the butter, in the proportion of 1 part in 1000, and keeping the mixture covered with a layer of solution of salicylic acid saturated at the ordinary temperature.

But although butter kept a fortnight or a month under solution of salicylic acid does not lose much colour, the odour and aroma disappear completely. Placed in the mouth it does not melt and diffuse so rapidly, but produces a disagreeable pasty impression. The authors, therefore, think that when salicylic acid is used for the preservation of butter, it would hardly yield a product fit for the table

IV. *Influence of Salicylic Acid upon Caseification by Rennet.*—The authors treat this section of the inquiry under three heads—(*a*) the promptitude of the coagulation, (*b*) the progress of the caseification and the success of the cheese, and (*c*) the yield of cheese.

a. Milk coagulates at the ordinary temperature, when it contains 0·55 to 0·66 per cent. of lactic acid; and at the boiling temperature when the lactic acid represents 0·20 per cent. of the milk. Other soluble acids act in the same manner as lactic acid. The action of rennet being thus facilitated by the presence of acids, it might be considered *à priori* that salicylic acid would accelerate the coagulation. But the coagulation of milk by rennet is the result of the action upon the casein of the milk of a peculiar ferment, to the activity of which is associated in certain cases that of other organic ferments (pepsin and lactic ferment) also obtainable from the gastric mucus of calves, and perhaps of all the vertebræ. The researches of Kolbe, Nebauer, and Kop have shown that salicylic acid diminishes the activity of certain ferments; J. Müller also has shown that the peculiar action of ptyaline and that of pepsin are stayed in the presence of certain proportions of salicylic acid. It remained therefore to ascertain whether salicylic acid exercises upon the ferment of rennet an action analogous to that it exercises upon the other ferments. The result of the experiment was that salicylic acid accelerates the coagulation, and consequently favours the action of rennet. In 370 litres of milk, treated with 100 grams of salicylic acid, this acceleration of coagulation was estimated at ten to fifteen minutes.

b. The next question, whether salicylic acid exercises any influence on the maturation of the cheese the authors' experiments lead them to answer in the negative. In fact this is what might be expected, as when, for example, a milk has been used to which salicylic acid has been added in the proportion of 1 in 4000 the quantity of acid introduced into the cheese is too small to produce sensible effects.

c. The investigation of the question of the influence of the presence of salicylic acid in milk upon the yield of cheese led the authors into a thorough experimental study of the phenomena of caseification, the description of which is too long for more than a reference here. Briefly the conclusions at which they arrived, and which they consider are likely to influence largely the manufacture of cheese, are as follows:—

1. The phenomenon of caseification with ordinary rennet is synthetically comparable to that of the gastric digestion of the albuminates.

2. During the caseification the lactic acid, which appears in considerable quantity, causes to redissolve and pass into the serum all the salts (phosphates) that the protein held in solution in the milk and which had been precipitated and enveloped by the coagulation.

3. *At the same time* a metamorphosis of the protein of the milk takes place which causes one part of the coagulated albuminates to assume new properties with the soluble state. This metamorphosis is due essentially to lactopeptic acid. The variable quantities of this acid, the degree to which the coagulated mass is agitated, etc., are causes that influence the transformation afterwards described.

4. Even after the apparent coagulation of the milk, all the protein precipitable by rennet is still not coagulated; but whilst the temperature rises and the operation progresses a fresh quantity of protein is precipitated by the rennet.

5. Two opposed phenomena are therefore in play during the course of caseification. On the one hand there is a further precipitation of protein; on the other there is produced an indefinite impoverishment in the shape of salts and a partial transformation of the coagulum into soluble products. These two phenomena are not produced to a parallel degree, but the decrease of the first probably coincides with the increase of the second.

6. Substances which, employed in suitable quantities, favour or impede the gastric digestion, also diminish or increase the yield of cheese.

7. Salicylic acid added to the milk to be used for cheese-making in the proportions of 2 to 4 parts in 10,000 does not augment perceptibly the yield of cheese, as it does not impede sensibly (in these proportions) the gastric digestion.

Previous experimenters had stated that when liquid rennet is used for converting milk into cheese, other things being equal, a larger yield of cheese was obtained then when rennet prepared according to the old method was used. Such a result the authors consider to be explained by their experiments, as through the method adopted in their preparation the liquid rennets would contain a much smaller quantity of *pepsine* than the rennet ordinarily employed.

The authors are of opinion that considering the low price of borax, its value as shown by experience, and the facility of its application, its use in the dairy will not be abandoned in favour of salicylic acid; but that probably salicylic acid might be used with economy in small dairies where butter is not made every day and for the preservation of butter where it cannot be stored in a sufficiently cool place or has to be sent to a distant market.

The following is stated to be the method of treatment adopted with the Swedish butter sent to the English market. After being removed from the churn it is spread out in a trough, powdered with one per cent. of its own weight of salt and worked up with a wooden spoon (the hands should never be allowed to touch the butter) so as to eliminate the greatest possible quantity of liquid. Then it is again spread out in the trough, and a mixture is scattered over it consisting of 3 parts of salt, $\frac{1}{2}$ of honey, and $\frac{1}{2}$ of nitre for every 100 parts of butter and it is again worked up with the wooden spoon. The butter is then placed in new square beech boxes which have been kept during six days full of pure water and then for two days full of salt water. A small layer of salt is placed on the bottom of the box, the butter is well rammed down on a linen cloth, and then is covered with another linen cloth, and above all is spread another small layer of salt. After some days the butter contracts a little and consequently separates from the sides, when the interval is filled with salt water; the box is then closed and is ready for dispatch.

SACCHARIFICATION OF AMYLACEOUS BODIES.*

BY L. BONDONNEAU.

The saccharification of amylaceous bodies in water has been explained in two different ways. In the one and oldest mode of explanation, starch yields at first dextrin, which by hydration forms glucose. In the second a dividing, together with hydration, is admitted, producing at the same time dextrin and glucose. The study of these reactions, and of the products formed by them, has proved to us that it is the first hypothesis which accords with the results obtained. In fact, from the hypothesis of division, admitted by many authors, at whatever moment the reaction, and however much there is still of the amylaceous matter, the saccharine portion should not contain less than 25 per cent. of glucose, according to the last formula given by M. Musculus:—

$$4(C_{12}H_{10}O_{10}) + 2HO = C_{12}H_{12}O_{12} + 3(C_{12}H_{10}O_{10}).$$

Now such a syrup, dessicated in the cold to render the "amylogène" insoluble, being taken up by cold water, gives a solution containing:—

Glucose	13·70
Dextrin	86·30

Also, there should exist in the solution only glucose and a single dextrin; we shall prove that the latter exists in three isomeric forms in every saccharification. On examining the products formed by the action of dilute acids, no matter at what stage of the reaction, it is observed at the first appearance of saccharification (the amylogène, if it *exists still*, being eliminated by a small quantity of alcohol), that the solutions are coloured red by iodine, and that the dextrin, separated by alcohol, then purified by the means which we have indicated, is composed of a variable mixture of colourable dextrin identical with that obtained by torrefaction, which we will indicate by the letter *a*, and of non-colourable dextrin, a mixture which can be recognized by the colorimetrical trials of red tints produced by iodine, comparatively with those furnished by pure dextrin. The action of the acid being continued the dextrin *a* diminishes more and more, and finally dis-

* *American Chemist*, from the *Bulletin de la Société de Chimique de Paris.*

appears; alcohol precipitates another dextrin, not coloured by iodine identical with that obtained by the action of the diastase on starch; we will designate this dextrin by the letter β. The alcoholic solutions, evaporated after the elimination of the above dextrins, are treated with absolute alcohol until all the substances soluble in this reagent are dissolved; by analysis we have obtained:

Glucose	75·40	70·20
Product non-reducing	24·60	29·80

This large quantity of soluble product, not reducing copper solution, is not a portion of the dextrin β held in solution by the presence of glucose, because, in a mixture of 90 parts of pure glucose and 10 parts of dextrin β, this latter is precipitated by the addition of absolute alcohol. Besides, this non-producing product is wholly transformed into glucose by the action of dilute acids, which indicates that this substance is a dextrin intermediate between dextrin β and glucose; we will designate it by the letter γ. The same products are formed under the influence of diastaste; the presence of the dextrin α, which is ephemeral, cannot be doubted, since the "amylogène" having completely disappeared, the solution is coloured red by iodine; dextrin β is the principal product, it is removed easily by alcohol, and finally the alcoholic solutions undergoing the treatment indicated above, show the presence of dextrin γ in large proportion. To complete this work we will indicate some new properties of these dextrins. The pure dextrins α and β, in concentrated solutions, cooled to +1°, are precipitated upon the bottom of the dish with a milky appearance, but upon raising the temperature, this precipitate becomes transparent, and by vigorous agitation is dissolved, without leaving traces of an insoluble product; a small quantity of glucose does not prevent this reaction, which is stopped, however, by a large quantity of this sugar. This action of diastase on dextrin α is remarkable, and explains the difficulty which is encountered in discovering its production in the treatment of starch with this substance. A solution of dextrin α, with the addition of diastase, is not coloured red by iodine after fifteen minutes or thereabouts of contact with cold; the rotatory power declines $\frac{1}{20}$c: the quantity of the existing glucose remains constant; the dextrin γ is not found in the reaction, which shows that the diastase is without action in the cold upon the dextrin β found in this experiment. In a warm place the dextrin α disappears almost immediately, even from the solutions at 25° and 40° Baumé; and, by prolonging the heat, there are formed dextrin γ and some glucose, the diastase acting under these conditions upon the dextrin β, of which a portion remains in the solution.

We are not able thus far to obtain the dextrin pure. The products formed in the oxidation of glucose by the copper solution are, after acidulation, soluble in alcohol, as is the dextrin; the aqueous solutions treated with baryta and precipitated by alcohol give equally a mixture of two products.

Under the influence of the yeast of beer this dextrin becomes hydrated rapidly, and ferments at the same time as the pre-existent glucose; 1 kilogramme of compact glucose of commerce, containing 12 per cent., has only given, after eight days of active fermentation, 40 grains of a syrup containing some glucose, some dextrin β, the presence of which we have ascertained in the original material, and lastly several grains of dextrin γ, of which we should have obtained a hundred grains. This dextrin becomes hydrated easily in presence of dilute acids, the hydration takes place equally as well by long contact with cold water; a solution with 20 per cent. of alcohol, to prevent mouldiness, including for 100 c.c.—

Glucose	23·70
Dextrin	4·80

contained, at the end of six months, only 2 per cent. of dextrin, the remainder was converted into glucose.

Finally, this solution having been diluted with water has given, after two months, for 100 c.c.—

Glucose	1°70
Dextrin	0·05
Rotatory power for 2 decimetres	1·85

The rotatory power of dextrin γ, determined by calculation from the deviation produced by its mixture with glucose, has been worked out in two different samples, equal to 165° 24′ and 163° 21′, average 164° 22′; taking as the rotatory power of glucose the numbers 47° 24′ for $C_{12}H_{12}O_{12}+2HO$, or 52° 8′ for $C_{12}H_{12}O_{12}$, found by M. Aimé Girard for pure glucose of fecula, examined with a large polariscope. Concerning the action of diastase on dextrin α, and of the presence of three isomers at the first appearance of the saccharification of amylaceous bodies, we are able to conclude then that it is not a dividing with hydration which takes place, but that each amylaceous molecule, in order to reach the last product, glucose, is obliged to pass successively through the following products:—

	Rotatory Power.	Action of Iodine.	Action of absolute Alcohol.
"Amylogène"	216°	blue	insoluble
Dextrin α	186°	red	„
„ β	176°	uncoloured	„
„ γ	164°	„	soluble
Glucose	52°	„	„

BRITISH PHARMACEUTICAL CONFERENCE.

The following is a list of the papers that up to the present time have been promised for reading at the thirteenth Annual Meeting of the Conference, to be held in Glasgow, on Tuesday and Wednesday September 5th and 6th:—

1. Liquid Extract of Pareira. Mr. Barnard S. Proctor.
2. Variation in the Strength of the Preparations of Opium. Mr. D. B. Dott.
3. Report on the Assay of Opium for Morphia. E. L. Cleaver, F.C.S.
4. Note on the Assay of Opium. Mr. Barnard S. Proctor.
5. New Derivatives from the Opium Alkaloids. Dr. Wright, F.C.S.
6. The Presence of Free Acetic Acid in Opium. David Brown, F.C.S.
7. New Excipients for the Official and other Pill Masses. Mr. G. Welborn.
8. The Preparation and Preservation of Phosphorus Pills. Mr. T. Haffenden.
9. Notes on some Salts of Pilocarpine. Mr. A. W. Gerrard.
10. Report on the Aconite Alkaloids. Dr. Wright, F.C.S.
11. The Solubility of Cinchona Principles in Glycerine. Mr. T. Andrews.
12. The Therapeutic Value of the Aloins. Dr. Tilden, F.C.S.
13. The Active Principle of Capsicum Fruit. J. C. Thresh, F.C.S.
14. Report on the Oxidation of the Essential Oils. Part IV. C. T. Kingzett, F.C.S.
15. Report on the Essential Oil of Sage. M. M. P. Muir, F.C.S.
16. Note on the Benzoates in Suint. Mr. A. Taylor.
17. Note on the Colouring Matter of *Crocus Sativus*. W. W. Stoddart, F.C.S.
18. Pekoe "Flower"—or, Hair of the Tea Leaf. T. B. Groves, F.C.S.
19. A New Form of Plaster of Cantharides. Mr. A. W. Gerrard.
20. A Proposed Solution of Citrate of Iron and Quinine. Mr. J. F. Brown.
21. Preliminary Report on the Chemistry of Ivy. R. H. Davies, F.C.S.
22. Supplementary Note on Phosphate Syrups. W. L. Howie, F.C.S.
23. On Filtering Papers. Thomas Greenish, F.C.S.
24. Further Experiments on the Antiseptic Action of Salicylic Acid. Mr. J. C. Hunter.
25. Strength of the Tincture of Nux Vomica. L. Siebold, F. C S.
26. Preparation of Milk of Sulphur. L. Siebold, F.C.S.
27. The Condition in which Salicylic Acid is excreted by Patients. F. B. Benger, F.C.S.

The Pharmaceutical Journal.

SATURDAY, AUGUST 26, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

BRITISH PHARMACEUTICAL CONFERENCE.

THE approaching Pharmaceutical Conference at Glasgow will probably be in no degree inferior to previous gatherings of the same kind as regards the scientific and practical interest of the subjects that will be brought forward for discussion, if we may judge from the list of papers to be read which we publish on another page. But in addition to the more purely technical interest attaching to the proceedings of this meeting there is another circumstance which may fairly be expected to have no inconsiderable influence in attracting to the Conference at Glasgow a much larger number of the trade than has ever met together on previous occasions. We refer to the proposal which has been announced in our advertisement columns of holding a meeting of the Chemists' Trade Association during the week in which the Pharmaceutical Conference is held.

It is now being made known by a circular addressed to every chemist and druggist on the register that this meeting is to take place at ten o'clock on Friday morning, the 8th of September, in the Central Hall of the Royal Hotel, St. George's Square, Glasgow, and invitations have been sent to all members of the trade. It will of course be understood that though this meeting is coincident in point of time and place with the Pharmaceutical Conference it is in no way otherwise connected with the Conference, and that the object of holding a meeting of the trade association immediately after the business of the Conference terminates is merely to take advantage of the fact that a number of pharmacists will then be assembled in Glasgow, who might not have an opportunity of attending the trade meeting at another place.

No definite plan of proceedings has yet been issued by the Committee that has organized the meeting, and in the circular that has been issued the desirability of such an association has been taken as an established fact, on the ground of the support that has already been given to its formation by the enrolment of members, and by donations towards the establishment of a fund, as well as by the numerous expressions of sympathy and promises of support that have been received. The Committee considers that it is unnecessary to enter into any arguments in proof of the desirability of a Chemists' Trade Association, since no question was more definitely and clearly put before the Birmingham Conference than the question whether existing associations did or did not render a trade organization unnecessary, and the Committee expresses a hope that there will be throughout the trade a general unanimity in the opinion expressed by the Birmingham Conference.

We cannot altogether agree with the anticipations which the Committee appears to entertain in regard to such general concurrence in the views of the Birmingham Conference, for in addition to expressions of dissent which have been publicly made there is a further and more cogent reason for doubting whether those views are held, in the trade, to any such extent as would be indispensable for the establishment of an association competent to carry out the work contemplated by the Birmingham Conference. As we have stated on a previous occasion, when the project of a trade association was in embryo, we consider that the beneficial action of such an organization, in fact the very continuance of its existence, must depend upon its being representative of the greater part if not of the entire trade, and so far as we can gather from the circular that is being sent out to announce the meeting in Glasgow there is in this essential particular a very signal deficiency.

Considering that a month has now elapsed since the Birmingham Conference, when the formation of the Chemists and Druggist's Trade Association became an established fact, and considering the stress that its promoters have always laid upon the necessity of very general support being given by the entire trade, it certainly seems to us unpromising, to say the least, that we find no mention of the number of enrolled members being at all in approximation to the number of those for whose benefit the establishment of the Trade Association was projected.

We trust that in making these remarks it will not be supposed that we disparage the opinions by which the promoters of this trade organization have been induced to attempt its realization, or that we are in the least disposed to discourage them in the task they have undertaken. On the contrary, we are so far in accord with them as to believe that whatever evils afflict the pharmaceutical body, they are to be ascribed in great measure to the absence of internal organization; and that one of the most essential conditions of the advancement of pharmaceutical interests is the union of the whole body for mutual benefit of its members. Whatever may be the fate of the Trade Association we sincerely trust that the steps taken for its establishment may in some way, directly or indirectly, have the effect of bringing about such advantages as have been gained in a partial manner by the Pharmaceutical Society and by the Pharmaceutical Conference.

There is one other point referred to in the circular of the Trade Association, viz., the possibility of interference with the functions of the Pharmaceutical Society. The letter of Mr. JONES, the President, which we publish among the Correspondence, distinctly disavows the existence of any such inclination on the part of those connected with the Chemists and Druggist's Trade Association.

In referring to the same point, in the circular just issued, the Committee denies the probability that the Association would compete with the Pharmaceutical Society in any work that is undertaken for the protection of trade interests, adding also the opinion that it would often be able to strengthen the Society's hands by co-operation, and to relieve it of some claims now made upon it for protection which are felt to be of an invidious or critical nature for a Society charged by the State with various administrative functions.

SPONTANEOUS COMBUSTION OF COAL CARGOES.

IN April, 1874, the Board of Trade decided to hold no more inquiries under the Merchant Shipping Act into casualties caused by explosions or fires in coal laden vessels. The decision was not based upon a decrease in the number of such accidents, for the returns of the previous sixteen months disclosed a serious increase in the risk to life that appeared to be involved in service in coal laden vessels; but the reason given was that no new facts were ever elicited in these inquiries and that the conclusions of the Courts had apparently been productive of no practical results. The upshot of this dead lock was the appointment of a Royal Commission which has just issued its report.

The inquiries of the Commission showed that following and possibly in consequence of a large number of fires that occurred in 1874 in coal ships bound to distant and tropical parts there was a falling off last year in the shipment of coals on long voyages amounting to 190,000 tons, or nearly 7 per cent., although the gross export of coal increased more than 500,000 tons. The connection between spontaneous combustion and long voyages becomes still more apparent in the light of statistics, which show that in the shipments to European ports, though amounting to six-sevenths of the whole number of shipments, only ten such accidents occurred, whilst the remaining one-seventh—shipments to Asia, Africa, and America,—suffered from sixty casualties.

It became evident also that "to a startling extent the proportion of casualties traceable to spontaneous combustion increases *pari passu* with the tonnage of the cargoes." Thus, not including the European trade, with cargoes under 500 tons the casualties were under ¼ per cent.; between 500 and 1000 tons they amounted to over 1 per cent.; between 1000 and 1500 tons to 3½ per cent.; between 1500 and 2000 tons to 4½ per cent.; and exceeding 2000 tons to 9 per cent. Of five ships sent to San Francisco in 1874 with cargoes of over 2000 tons of coal two came to grief.

The Commission requested two of its members, Professor ABEL and Dr. PERCY, to draw up a paper (see p. 184) which should describe simply and clearly the chemical conditions that tend to originate and develop spontaneous combustion or produce explosion. Armed with this document and various returns the Commission proceeded with the inquiry. The principal conclusions arrived at were that certain descriptions of coal are intrinsically dangerous for shipment on long voyages, and that even when the coal may not in itself be thus unfit its breakage during transit from the pit's mouth to the ship's hold, the shipment of pyritic coal in a wet condition, and, especially, *ventilation through the body of the coal cargoes*, are conditions conducive to spontaneous combustion. This latter conclusion respecting ventilation is directly opposed to what underwriters have enforced in many cases for greater security; but it is quite in accord with the evidence furnished by the returns and with the opinions expressed by Professor ABEL and Dr. PERCY in their memorandum.

The evidence disclosed, however, that to a considerable degree spontaneous combustion and explosions in coal cargoes are confounded with one another, although it is obvious they may arise from totally different causes. The Commission is of opinion that to guard against explosion free and continuous egress to the open air, independently of the hatchways, should be provided for the explosive gases by means of a system of *surface* ventilation.

One other subject alluded to in the report is of interest—the application of carbonic acid gas as a means of extinguishing such fires. Whilst granting that this gas might be useful by excluding the atmospheric air necessary for combustion, it is objected that it would not, as water does, exert any sensible cooling effect on the ignited coal. The Commission considers water and steam to be the only agents practically available for the extinguishment of fire in coal cargoes.

PHARMACY IN SOUTH CAROLINA.

THE Legislature of South Carolina has recently incorporated a Pharmaceutical Association, which through its examiners is to have "power to license pharmaceutists, apothecaries, and druggists within the State." There are to be two boards of examiners, one of them to have its seat at Charleston and the other at Columbia. Each Board will consist of six members, four of which are to be elected by the Association and two to be appointed by medical authorities. The appointments will last for one year. Mr. G. LUHN, of Charleston, has been elected the first President of the Association.

GERMAN PHARMACEUTICAL CONFERENCE.

AT the same time that the British Pharmaceutical Conference will be assembling in Glasgow the German Apothecaries' Union (*deutsch Apotheker-Verein*) will be holding a General Meeting in Stuttgart, the sittings commencing on the 4th and closing on the 6th of September.

Proceedings of Scientific Societies.

ROYAL SOCIETY.

Absorption Spectra of Iodine.*

BY SIR JOHN CONROY, BART, M.A., F.R.S.

Iodine, as is well known, when in very thin layers, appears red by transmitted light; and when in solution the colour of the liquid depends not only on the amount of iodine contained in it, but also on the nature of the liquid in which it is dissolved.

Schultz-Sellack has pointed out (*Pogg. Ann.*, vol. cxl. p. 334) that the liquids in which iodine is soluble may be divided into two classes:—first, those with which it gives reddish-brown solutions, like alcohol; and secondly, those with which it gives violet ones, as bisulphide of carbon; and also that the colours of these two solutions correspond respectively with the colour of solid iodine, when seen by transmitted light, and with that of iodine vapour.

Andrews ('Brit. Assoc. Report, 1871') has also remarked that iodine vapour and the solution of iodine in bisulphide of carbon are dichroic, while such is not the case with its solution in alcohol.

As I am not aware of any other observations on the absorption of light by iodine in solution or in the solid state having been published, I have the honour of having an account of some experiments I have recently made on this subject communicated to the Royal Society.

For these observations I have used one of Browning's spectroscopes with a single dense-glass prism of 60°, as with a greater amount of dispersive power it became more difficult to observe the beginning and end of the absorption. The spectroscope was firmly screwed to the wall of the room, with the collimator pointing vertically downwards, the light from a paraffin-lamp being reflected along it by a mirror—the width of the slit and the position of the mirror and lamp remaining unaltered during the course of the experiments, in order that the different absorption-spectra should, as far as possible, be comparable with each other. The solution whose absorption was to be observed was contained in a small beaker, supported by the ring of a retort-stand between the mirror and the slit of the collimator.

This arrangement was adopted in order to be able to observe the absorption through various thicknesses of the same solution, without having to use a wedge-cell, as some of the liquids in which iodine is soluble act very quickly on the cement with which such cells are fastened together.

A vertical scale was attached to the beaker, so that by gradually pouring a solution into it, the absorption through different known thicknesses could be observed, the solutions of the iodine in bisulphide and tetrachloride of carbon being covered with a thin layer of water to prevent their evaporating.

When the absorption-spectra of solid and liquid iodine were to be observed, the beaker was replaced by a large cork which fitted the ring of the retort-stand, and through which a hole had been bored in a line with the axis of the collimator, and the glass slips between which the iodine had been melted laid on this. In the case of the liquid iodine, the low conductive power for heat of the cork retarded the cooling of the glass, and facilitated the observation of the absorption.

The telescope of the spectroscope, the eyepiece of which was furnished with cross wires, was carried by an arm moving over a divided arc; and the position of 10 of the principal lines in the solar spectrum having been observed, from the measurements, and from the wave-lengths of the same lines, as determined by Angström, a curve was constructed, by means of which the readings of the spectroscope were reduced to wave-lengths.

* Read May 18, 1876. From the 'Proceedings of the Royal Society.'

Solid Iodine.

Layers of iodine sufficiently thin to be transparent can be readily obtained, as Schultz-Sellack has remarked, by squeezing melted iodine between two pieces of flat, well-polished glass; it is only necessary to place a small fragment of iodine between two pieces of glass which have been previously well cleaned with alcohol, and heat them over a spirit-lamp till the iodine melts, and then press them together. I have obtained the best results by heating the iodine till it just melts, placing the pieces of glass on a smooth block of wood and squeezing them together with a flat cork.

The layers of iodine thus obtained are not usually of uniform thickness; and, in addition to this, they contain so little iodine that I was unable to determine their thickness by ascertaining the weight and area of the film. When seen, however, by reflected and transmitted light, the iodine film usually appears surrounded by coloured, rings; and as these alter their position and shape when the glass slips are pressed together, they must be due to a thin layer of air, and not to any substance adhering to the glass; and consequently the layers of iodine are probably less than ·00004 inch, or ·001016 mm., in thickness.

When seen by transmitted light, these layers of iodine vary in colour from a deep brownish red, through different shades of brown, to a more or less pure yellow, according to the thickness and nature of the film; for, as is shown in the paper "On the Polarization of Light by Crystals of Iodine," the colour of the transmitted light apparently does not depend solely on the thickness of the layer of iodine through which it passes. These films correspond in colour with alcoholic solutions of iodine of different strength, and the absorption-spectra are very similar—the whole of the blue end of the spectrum being cut off, and the absorption extending further and further towards the less refrangible end of the spectrum, as the thickness of the film increases, till at length only light having a wave-length of about 650 (in "tenth-metres"), or slightly more refrangible than the C line, passes through; and a very slight increase in the thickness of the film is sufficient to stop this also.

Liquid Iodine.

With a little careful management it is usually possible to melt one of these thin layers of iodine by heating it over the flame of a spirit-lamp, without causing it either to be dissipated in vapour or to run together. The liquid iodine appears to be more transparent than the solid; for a layer which appears a deep red colour by transmitted light when hot, sometimes becomes perfectly opaque on cooling. When hot it is also of a deeper red than when cold; and the spectroscope shows that while the less-refrangible rays of the spectrum are freely transmitted, there is more absorption of those of mean refrangibility than is the case with solid iodine.

The absorption-spectrum as deduced from the mean of five observations showed that just as is the case with solid iodine, light of a wave-length of about 650 suffers the least amount of absorption during its passage through a layer of iodine.

Iodine in Solution.

As I have before mentioned, the liquids in which iodine is soluble may be divided into two classes; first, those with which it forms brownish-red solutions, as alcohol, ether, ethyl bromide, Dutch liquid, benzole, glycerine, potassium iodide in an aqueous solution, hydrogen chloride, etc.; second, those with which it forms violet solutions; this latter class is less numerous, and as far as I have hitherto been able to ascertain by actual experiment, only consists of the following substances—the bisulphide, tetrachloride, and monochloride of carbon, chloroform, phosphorus terchloride, tin tetrachloride, and under certain circumstances, as will be hereafter mentioned, hydrogen sulphate. In Watt's 'Dictionary of Chemistry,' vol. i. p

381, it is stated that the solution of iodine in chloral has a purple colour.

In order to obtain solutions of iodine of a known strength, some of the liquids in which it is soluble being very volatile, a small glass weighing tube closed with a cork was nearly filled with iodine which had been crushed small with the edge of a platinum spatula. A stoppered flask holding 25 c.c. was filled with the liquid in which the iodine was to be dissolved; and the tube having been weighed, a small quantity of iodine was shaken out of it, and the tube again weighed, and so on, till the desired amount had been added to the liquid.

In this way solutions of iodine in bisulphide and tetrachloride of carbon, chloroform, alcohol, and in aqueous solutions of potassium iodide were prepared, and the absorption produced by different thicknesses of these solutions observed.

Solutions of iodine in alcohol, and of iodine in an aqueous solution of potassium iodide, of different strengths were then prepared, and the absorption produced by layers of these solutions, varying in thickness from 5 mm. to 25 mm., was observed.

Solutions of iodine in both liquids were, when of equal strength, of the same colour and the absorption-spectra were similar, and also similar to that of the solid iodine, except that the absorption did not appear to extend quite so far down the spectrum; but as the transition from strong absorption to none at all is a very gradual one, it is somewhat difficult to determine the exact point at which the absorption ends.

Iodine dissolved in bisulphide of carbon absorbs most strongly light of mean refrangibility; and the absorption-spectrum resembles that of the vapour of iodine as represented in the map to M. Thalen's memoir, 'Le spectre d'absorption de la vapeur d'Iode' (Upsal, 1869), except that the absorption is continuous, and does not extend quite so far towards the less refrangible end of the spectrum.

The mean result of eighty-one measurements of the position of the absorption produced by different thicknesses of these solutions showed that the rays whose wave-lengths lie between 450 and 560 (approximately) are first absorbed; and as the thickness of the layer or the concentration of the solution is increased, the absorption extends towards both ends of the spectrum, though more rapidly towards the less-refrangible one.

Just as was the case with the solution of iodine in alcohol, and with solid and liquid iodine, light of a wave-length of about 650 passes unabsorbed through a considerable thickness of the solution; but a thickness which is sufficient to stop the whole of the red rays still allows the blue and violet ones to pass; hence, whilst dilute solutions of iodine in bisulphide of carbon and other liquids of that class appear of a kind of red, when the light passes through a greater thickness, or the solution is more concentrated, they appear blue or violet.

Iodine is insoluble in cold hydrogen sulphate; but when some fragments of iodine are placed in a test-tube, partially filled with strong hydrogen sulphate, and the tube heated, the iodine first melts, and then gradually colours the liquid, till it becomes about the same tint as a very dilute solution of iodine in bisulphide of carbon.

·0100 grm. of iodine was placed in a test-tube containing 25 c.c. of strong hydrogen sulphate, and the test-tube carefully heated over a spirit-lamp until the whole of the liquid iodine had disappeared; the acid appeared of the same colour as a solution of iodine in chloroform containing about the same amount of iodine. The colour of the acid did not alter on cooling; after standing 24 hours the upper layer of acid for a depth of about one centimetre from the surface had become colourless; but at the end of five months the acid in the lower part of the tube was still pink, the upper half having become colourless, and a small quantity of a black powder having settled at the bottom.

Only a very small quantity of iodine can be held in solution by the hydrogen sulphate when cold, as any excess separates out in minute crystals.

It does not appear probable that the difference in the colour of the solutions which iodine forms with liquids of these two classes depends on any chemical fact, as both classes contain substances of very dissimilar chemical composition. I have not, however, as yet been able to ascertain any common property possessed by all the liquids of either class, beyond (as, indeed, is obvious) that all those in which iodine forms violet solutions are volatile liquids of high specific gravity.

It has been shown by various observers (H. Morton, *Pogg. Ann.*, vol. clv. p. 573; Hagenbach, *Pogg. Ann.*, vol. cxlvi. p. 533; Kraus, 'Chlorophyllfarbstoffe,' p. 53) that the position of the absorption-bands of substances in solution vary to a certain extent with the liquid in which they are dissolved; but this would appear to depend on some other cause; for, in addition to the displacement being small, it differs in amount with different liquids; whilst in the case of iodine, as far as I have been able to observe, the position of the absorption is the same for all the liquids belonging to one of the two classes. The action on light of iodine dissolved in alcohol greatly resembles the effect it produces when in the solid state; whilst the absorption of its solution in carbon bisulphide, and in other liquids of that class, bears, as has been pointed out to me by Professor Stokes, the same relation to the absorption-spectrum of the vapour as the spectrum of the solution of a coloured gas (nitrogen peroxide for example) does to that of the gas.

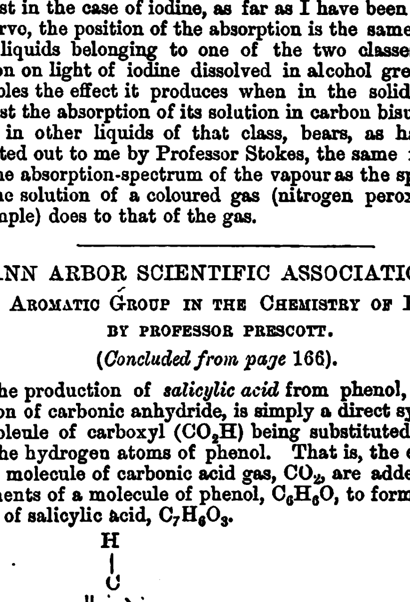
ANN ARBOR SCIENTIFIC ASSOCIATION.*

The Aromatic Group in the Chemistry of Plants.

BY PROFESSOR PRESCOTT.

(*Concluded from page* 166).

The production of *salicylic acid* from phenol, through action of carbonic anhydride, is simply a direct synthesis; a molecule of carboxyl (CO_2H) being substituted for one of the hydrogen atoms of phenol. That is, the elements of a molecule of carbonic acid gas, CO_2, are added to the elements of a molecule of phenol, C_6H_6O, to form a molecule of salicylic acid, $C_7H_6O_3$.



Phenol, C_6H_6O.

Salicylic acid, $C_7H_6O_3$.

This change was some time since effected by Professor Kolbe, through the action of carbonic acid gas on phenol in presence of sodium. Last year he gave preliminary notice of his present method, in which soda at elevated temperatures takes the place of metallic sodium, and early in the present year the manufacture of salicylic acid from carbolic acid and sal soda by use of carbonic acid gas commenced at Leipsic.†

It is singular that the reverse of this change, the manu-

facture of pure carbolic acid from the salicylic acid of wintergeen oil, was reported on by Broughton, the quinologist of the British Government in India, in 1871, as possibly a remunerative enterprise, at least "in case of war" or other occasion of increase in the English price. The oil was obtained from the *Andromeda Leschenaultii*, which grows in great abundance on the Neilgherry hills.*

These few instances of artificial synthesis in the aromatic group have acquired prominence on account of their relations to wealth and industry; but instances of almost equal scientific importance are thickly spread among the reports of every month.

The natural production of aromatic bodies does not wholly elude chemical investigation. Some of the chemical changes in the aromatic constituents of *the balsams* are striking illustrations of the well known characteristics of these bodies. Resins are produced from the terpene and cymene oils by atmospheric oxidation; and benzoic and cinnamic acids are produced from the aldehyde, alcohol, and ether of the cinnamic series, by oxidation; and without doubt these oxidations occur within coniferous trees, as well as more generally after exudation from the bark, and in the same way in the bottle on the shelf where light falls. As changes of oxidation, these are not representative of the vegetable kingdom; nevertheless they are in the direction of greater complexity of chemical structure.

The production of resins from terpene and cymene oils, now that these are seen to be aromatic hydrocarbons, explains the ease with which other aromatic bodies (benzene, toluene, phenol, etc.) are obtained from resins, —for it can now be more than surmised that in this round of changes the benzene ring is never broken.

In the summary of Wittstein, of the 114 natural orders, 28 are reported to contain resins; of these 28 orders, 16 contain essential oils with the resins and 12 do not. On the other hand, there are 45 orders containing volatile oils, 29 of them not being reported as containing resins. Of the 26 orders given as furnishing aromatic bodies other than resins and oils, one-half have resins.

To enter fully into an inquiry as to *the chemical history of the aromatic bodies in plants* would be to overstep the limits of this paper. Indeed, it may be thought that such an inquiry would overstep the present limits of science. Let us consider what preparation we have and what foundation we have for entering upon such an inquiry.

In the first place, we have some measure of acquaintance with the structure (or to be more modest, the chemical character) of aromatic compounds. We know something as to what a given aromatic substance can be formed from, and what can be formed from it, and the conditions needed in both cases. This knowledge is demonstrated by the large number of *syntheses* which chemical science has effected in the aromatic group. But we must be cautious about assuming that substances producible in the laboratory in a certain way must needs be formed in the plant in the same way. We must recollect that we have already often observed that a given chemical production may be effected in different ways. There are, well known, at least three different ways of bringing gallic acid out of gallotannic acid: fermentation by the natural ferment, "fermentation" by boiling, and oxidation. Bruise a bitter almond kernel with water, and by reason of the emulsin present, bitter almond oil and prussic acid arise in vapour and the solution becomes sweet with glucose. Again, boil the almond pulp with dilute sulphuric acid, and the bitter almond oil and prussic acid and glucose appear with another product, formic acid Vinegar may be rapidly formed from alcohol, in the air, (1) when at ordinary temperature there is the contact of a certain species of living cells; (2) when, without cells, there is platinum black present; (3) when, without cells or porous body, the oxygen is nascent; the change being in each instance through aldehyde by the same equation. Now, if the styrax benzoin contained naphthalin, it would not certainly follow that the benzoic acid of the plant was formed from this naphthalin, through phthalic acid, because such is the case in the factory.

In the second place, as foundation for a study of the chemical history of aromatic bodies in plants, we have but a very limited knowledge of the constituents of plants in general. The *analytical work* in organic chemistry is behind the synthetical work. The proximate analysis of plants needs to be made as thorough as possible: no constituent can be assumed to be unimportant. As an illustration, it was stated above that in a certain summary of plant constituents, of 45 orders reported to contain volatile oils, 29 were not reported to contain resins. Considering the known methods of analysis and the ordinary purposes of analysis, the question arises, how many of the plants analysed in these 29 orders do nevertheless contain resins? And, taking a given plant known to contain both resin and volatile oil, what results might not come from a series of careful quantitative analyses of the plant in different stages of its growth and of different parts of the plant? Before the natural formation of carbon compounds can be traced, and before generalizations as to nature's chemical methods can be attained, an enormous amount of work has to be done.

In this discussion, it is of course taken for granted that *the molecules of matter are formed and conserved by chemism;* as truly in the plant as in the rock. Chemism may be, as has been held, due to an attractive force; or it may be due to harmonies and co-ordinations of atomic motion, rotatory or oscillatory; molecules may be plane or solid forms, in gaseous or solid state; and it may be that we have in no case attained any correct conception as to what causes molecular combination; but, none the less, the effects we know, and their consummate order we know under the name of chemical law. For myself, this is quite enough. I have a profound sense that the cause of chemical action is beyond the comprehension of man and is near to the hand of God. I do not see that the chemist can assume any more responsibility for the construction of molecules in the test-tube than can the biologist for the growth of cells under the microscope. If we could see and measure the molecules we should doubtless be no nearer the comprehension of their formation than the biologist is to the formation of cells under his inspection. But whatever be the scope of the human mind in chemical science, it is a science that embraces all that we can know of the composition of matter. In living tissue, the elements (which in mixture would be but dust and gases) are *combined* into certain kinds of matter, and this combination (with transformation) fulfils the definition of chemical union.

In limitation, it hardly need be remarked, that when chemical action has formed the molecule it can do no more; it cannot make *the cell*, or any other structure or coherent mass formed of molecules, any more than the cell-making action can make the molecule. Now, as cohesion and as heat and other actions impel or retard or modify chemical action, it seems almost certain to be true that the action of cell organization must impel or retard or modify chemical action. We see that red-hot charcoal will, with oxygen, form carbonic anhydride, while cold charcoal will not; the heat is indispensable, but we do not conceive the carbonic anhydride to be a calorific compound. It is a chemical compound, whatever nonchemical actions are essential to its formation. And, if it should ever be settled that certain substances can only be formed in living cells, it is submitted that these substances must none the less be accepted and studied as chemical products.

Parliamentary and Law Proceedings.

PAPER PRESENTED TO PARLIAMENT.

SPONTANEOUS COMBUSTION OF COAL IN SHIPS.*

BY FREDERICK AUGUSTUS ABEL, F.R.S., AND JOHN PERCY, M.D., F.R.S.

The so-called spontaneous development of heat which occasionally takes place in coal, is due to chemical changes which certain substances occurring in it undergo through the agency of atmospheric oxygen, and which are liable to acceleration by some conditions attending the storage or transport of coal.

The substances, the oxidation of which is attended by the development of heat, are iron pyrites (and possibly some other combinations of sulphur), and some carbo-hydrogen compounds, forming part of the coal itself, which are comparatively readily oxidizable.

Iron pyrites is of almost universal occurrence in coal. The condition in which it exists differs considerably in different kinds of coal; in some it is distributed so as not to be detectable by ordinary inspection, in others it is in form of more or less conspicuous laminæ of a brass yellow colour; occasionally small distinct crystals of cubical form and bright metallic lustre are observed, and not unfrequently it is found in nodules (known as "brasses") and layers of considerable dimensions.

Iron pyrites, a compound of sulphur and iron known as disulphide of iron, occurs in the mineral kingdom in two crystalline forms, which are identical in chemical composition. Pyrites vary greatly as regards their stability or their liability to undergo oxidation by contact with the atmosphere. Some, after remaining unchanged during long periods of exposure, will undergo oxidation without any immediately apparent inciting cause. Others are perfectly stable, and with others oxidation follows with more or less rapidity upon their exposure to the atmosphere.

The presence of moisture in air promotes the oxidation of pyrites; it does so apparently by bringing the atmospheric oxygen into more intimate contact with the surfaces of the oxidizable material. Similarly, the absorption of moisture by mineral substances of laminated or porous structure, through which pyrites are disseminated, promotes the oxidation of the latter by bringing the atmospheric oxygen, which is dissolved by the water, into more intimate contact with the oxidizable material.

Thus, the oxidation of pyrites in alum schist is accelerated, in the manufacture of alum therefrom by occasionally watering loose heaps of the mineral which are piled in such a manner that the access of air to the interior can be regulated.

The oxidation of pyrites (as in most instances of chemical action) is accompanied by the development of heat, which may accumulate to such an extent as to lead to the ignition of highly oxidizable constituents of minerals through which it is distributed. Heaps of alum schist exposed to the air and moistened will become heated to an extent to lead to the ignition of the carbonaceous constituents of that mineral, and similarly coal, through which pyrites are disseminated, may become heated to the point of ignition by the oxidation of pyrites disseminated through it.

Sulphur exists in coal in other forms of combination than that of iron pyrites. Thus sulphate of lime is occasionally disseminated through coal; the existence of sulphur in this form cannot give rise to the development of heat, as it is already in the completely oxidized or burnt condition; however, so far as is known they have not been found to possess any liability to spontaneous heating by oxidation. Some descriptions of coal or shale have been found to contain sulphur in somewhat considerable quantity in combination with carbon and hydrogen. An example of this is furnished by the so-called "resiniferous shale" occurring in Tasmania, which has been found to contain as much as five per cent. of sulphur in combination with carbon and hydrogen.

So far as is at present known, the spontaneous heating of coal is not ascribable to any tendency of such sulphur combinations to oxidation by atmospheric agency.

Pyrites appear therefore to be the only sulphur combinations occurring in coal, which by their oxidation, promoted by the presence of moisture and by mechanical conditions favourable to the accumulations of the heat developed by such oxidation, are liable to give rise to the so-called *spontaneous ignition* of coal.

Coal varies considerably not only in chemical composition, but in structure, some varieties being comparatively open and porous, others compact or laminated, and very friable or readily broken up.

Carbon in a finely divided or porous condition has the property of absorbing and condensing within its pores large volumes of certain gases, among which is oxygen.

Thus, wood charcoal which has been recently produced, or which has been freshly heated sufficiently to expel moisture and gases which it may have absorbed, will condense within its pores more than nine times its own volume of oxygen, and seven times its own volume of nitrogen, which it is capable of absorbing by exposure to the air.

The condensation of a gas by a porous body is attended by the development of heat, proportionate to the extent of that condensation. Moreover, the tendency to oxidation which carbon, and certain carbon compounds existing in such a substance as charcoal, possess, is favoured by the condensation of oxygen within its pores, whereby the very intimate contact between the carbon and oxygen particles is promoted. Hence the development of heat and the establishment of oxidation occur simultaneously; the latter is accelerated as heat accumulates, and chemical action is thus promoted and may in course of time proceed so energetically that the carbon or carbo-hydrogen particles may be heated to igniting point.

A good illustration of this action is afforded by the very porous charcoal prepared for the manufacture of gunpowder. It has to be protected against rapid access of air for some considerable time after it has been removed from the carbonizing retorts (by transferring it at once from the retorts to metal receptacles which are kept tightly closed for a number of days), otherwise the charcoal, though it may have been allowed to cool down perfectly, will speedily become heated upon exposure to air, by the action above explained, to such an extent as to ignite spontaneously. Even after the stick charcoal no longer exhibits any tendency to heating when exposed, its pulverization by grinding has still to be delayed; otherwise, when the absorption and condensation of oxygen by the internal portions of the pieces of charcoal become favoured by the reduction of these to a fine state of division and the consequent exposure of large surfaces to the air, ignition of the charcoal will take place. (Instances of such ignition upon the mill beds at powder works are not unfrequent.)

The spontaneous ignition of oiled cotton or silk waste, or cloths, which is of not unfrequent occurrence, affords another illustration of the manner in which the heat developed by the action of atmospheric oxygen upon readily oxidizable substances, consisting chiefly of carbon and hydrogen, which are exposed to that action under conditions very favourable to it, will readily accumulate to an extent sufficient to give rise to ignition. The porous cotton or silk waste serve, in such cases of spontaneous ignition, as vehicles for exposing the readily oxidizable oil or grease in a finely divided condition to the air, and thus favouring its rapid oxidation.

The foregoing explanation of the manner in which the spontaneous heating and eventual ignition of certain carbonaceous substances by the action of atmospheric oxygen

* From the Report of the Royal Commission.

are brought about, has a direct bearing upon the spontaneous ignition of coal. The more porous and readily oxidizable portions of coal, which are known to be more or less largely disseminated through seams from different localities, undergo oxidation by absorption of atmospheric oxygen, and by the exposure of large surfaces to its action, and the heat developed by that action will accumulate under favourable conditions to such an extent as soon to hasten the oxidation and the consequent elevation of temperature, until some of the most finely divided and readily inflammable portions actually become ignited.

The breaking up of the coal, which occurs for a more or less considerable extent before and during its shipment, obviously favours the absorption of oxygen, and consequently increases a tendency to heating by the action above described.

In a series of valuable experiments on the weathering of coal, by Richters and others, it has been demonstrated that a considerable quantity of oxygen is absorbed by freshly gotten coal, and that carbonic acid and water are evolved from such coal after absorption of oxygen, while a portion of the oxygen absorbed is fixed by the formation of some solid oxygenated compound in the coal. Spontaneous oxidation of coal by the oxygen absorbed from the air is therefore satisfactorily established, and is unquestionably one, if not the chief, cause of the spontaneous heating of coal.

Spontaneous ignition of coal, when due to the oxidation of the porous and readily oxidizable carbonaceous substances occurring in coal, does not appear to be favoured by the presence of water in the coal or by its access to a cargo; on the contrary, these portions, by becoming wet, would have their pores more or less filled with water, and their power of absorbing oxygen would be proportionately diminished; hence the presence of water must be antagonistic to the oxidizing action of the latter in many instances, though, when iron pyrites is present, it may promote or accelerate spontaneous heating as already pointed out.

The gases which are occluded (or confined in a more or less condensed condition) in coal, vary considerably in quantity and composition in different kinds of coal, and they also gradually undergo various changes in composition by exposure or keeping of the coal.

Their chief inflammable constituent is marsh gas, and it is to the admixture of this gas with a *considerable* volume of air that *explosions* are due in freights or stores. In pits where explosions are liable to occur, the gas escapes either with more or less rapidity and force from fissures ("blowers"), or gradually from the freshly exposed surfaces of coal seams. When coal from such pits is brought to the surface it continues slowly to evolve inflammable gas for some time afterwards, especially if the coal be in large masses or stored in compact heaps.

If facility is not afforded for the ready escape or removal into the open air of the inflammable gas emitted from the coal composing a cargo or contained in bunkers on board ship, the spaces between the masses of coal, or any partially confined spaces not occupied by the coal but in close proximity to or communication with it, will in time become filled with a mixture of the gas with the air in those spaces, which, unless the former be present in very small proportions, would explode on the approach of a flame to it, and with a violence depending upon the proportion which the air bears to the inflammable gas which has become diffused through it,

As the application of flame (or of a body raised to a high red heat) is indispensable to the ignition of mixtures of air with the inflammable gas evolved from coal, it is obvious that *explosions* cannot occur spontaneously from this cause on board ship, but must be brought about by the accidental or incautious approach of a light to localities where the coal is stored, or where the explosive mixture is likely to penetrate.

If coal, from seams which are charged with marsh gas, is placed on board ship shortly after being raised from the pit, there is obviously great liability to the formation of an explosive atmosphere in the hold or bunkers, or spaces communicating with them, and every possible means should in such cases be had recourse to for facilitating the escape of gas from the coal into the open air.

But, as the gas requires a large admixture of air to render it violently explosive, it is obvious that any attempt to ventilate the coal by passing or drawing air into the body of the freight would be most likely to favour the production of a violently explosive mixture of gas and air. The only useful application which might be made of any special means of ventilation with a view to diminish the risk of *explosions* would be to pass a current of air *over* the coal and immediately into the open air, so as to accelerate the escape and removal of the inflammable gas.

As regards the application of ventilation with a view to reduce the liability to spontaneous *ignition* of a cargo of coal, the only useful object which could *possibly* be aimed at by ventilation would be the rapid abstraction of heat developed in the coal (by chemical changes set up as described) by causing cool air to circulate freely and rapidly throughout the *body* of a mass of coal. The attainment of such a result, even by powerful means of artificial ventilation, elaborately applied, and with the coal in the mechanical condition most favourable to its free permeation by air, appears, to say the least, very doubtful, and there can be no question that any system of ventilation practically applicable on board ship would fail to attain such a result, even disregarding the fact that the mechanical (finely divided) condition of much of the coal constituting a cargo is quite antagonistic to the free passage of air through its mass.

It does not appear practicable, therefore, to apply ventilation with any prospect of guarding against the accumulation of heat in some portion of a cargo of coal. Such circulation of air as may be established even in the less compact portion of the cargo is not likely to have any valuable cooling effect, and the circulation, if there be any, must be very feeble among the more closely lying masses of small coal, so that heat, if developed in these will accumulate undisturbed. Indeed, its development would possibly be favoured by the fresh supply of oxygen which a gradual replacement of the air surrounding these parts would convey, so that a period would be reached sooner or later when the development of heat would be most seriously promoted by ventilation, some time before actual ignition demanded the total exclusion of fresh air.

The evidence which has been submitted to the Committee on the subject of the ignition of coal cargoes bears out generally the conclusion to which the above considerations lead, namely, that it is inadvisable to attempt *through ventilation* of cargoes in coal-laden ships.

Alleged Poisoning in a Sewer by Refuse from a Chemical Works.

On Monday last Mr. Carter resumed, at the Duchess of York, Battersea, the inquiry into the cause of the death of John Thomas Lomas, a flusher in the employ of the Wandsworth and Battersea District Board of Works. It appeared from evidence that in the centre of the New Road, which connects the Wandsworth Road with the Battersea Old Road, are situate the works of the Messrs. Wallace, manufacturing chemists. From time to time the noxious emanations from the sewers had been so bad that an indignation meeting was called and a memorial drawn up asking the interference of the Metropolitan Board of Works. It was understood that some steps were about to be taken when the fatal accident in question occurred. Mr. Straight represented the Metropolitan Board of Works, Mr. Besley the District Board, and Mr. Pettengill, solicitor, the Messrs. Wallace.

George Gates, a flusher employed by the Wandsworth

District Board, said that on the 9th inst. he was working at the sewer in the New Road with the deceased and two men named Scott and Prester. At a distance of 14 yards from the manhole in St. George's Road, they proceeded to remove the deposit at the bottom, 14 inches of sand, gravel, and other matter which prevented the flow of water through the sewer. They had been working about five minutes when they perceived a smell as of gas and sulphur coming down the sewer. It soon became unbearable, and they endeavoured to reach the manholes. The gas seemed to come from Wallace Place. Witness went as fast as he could towards the Battersea Road, and the others the other way. He could not run, the sewer being only 3ft. 2in. high. He fell down before he got to the entrance and lost his senses in consequence of the dreadful smell. When he came to he found himself sitting on the ground at the opening of the sewer, and some one tending him. He went to the manhole at the other end and looked down, but could not see the others. He called, and, hearing nothing, went down. He first saw Scott lying in the water with his head on the step of the manhole. Procuring assistance he got him out of the sewer. He went for Prester, who was drawn out and placed on the pavement. He then went down for Lomas but the stench drove him back. He waited a little time, and then re-entering the sewer found the deceased lying about 6 feet inside in the water, dead. He was pulled out and laid on the pavement. Witness again became very ill. They had worked in the sewer four days, but smelt no sulphur during that time. It came upon them suddenly from the direction of Messrs. Wallace's works. They had not been so high up the sewer before, but they had had strong smells once or twice at night time, and the man who is dead and Scott were nearly killed on one occasion. By Mr. Besley.—The water as it came down made a hissing noise like opening ginger beer, They felt the effects of it before they heard it, and could only see it 4 yards off them. It was like sulphur combined with gas, and they had noticed this on their lamps before dinner. By Mr. Pettengill.—He did think when they turned the overflow water on from the waterworks that the flow was 3 miles an hour. There would be 18 inches of water then, and 8 or 9 when it was not on. The water did not flow fast enough at usual times to take the ordinary sewage with it, and it became solid at the bottom of the sewer. It was their work to clear away the solid matter. They knew by smell the difference between what came from private houses and what came from manufactories. He could not say what other works flowed into this sewer. They did smell gas in different sewers of different kinds but the smell that day was quite unusual, quite different from anything he had smelt before. There was a block in the sewer 18 yards from the St. George's Road manhole, and the water hardly flowed over it in consequence of the depth of the bank of deposit.

Mr. George Frederic Burroughs, surgeon, of Queen's Road, Battersea, said that on Wednesday the 9th inst., he saw the deceased and the other men brought up from the sewer. He believed the deceased had inhaled some noxious vapour, but could not say what it was. He might have become stupefied and falling into the sewage water been drowned. The most common gas generated in sewers was sulphuretted hydrogen, but he could not say how it was generated. The sensation mentioned by the last witness would not, however, be produced by that. His attention had been many times called to the foul gases coming from the sewer. Patients in St. George's Road, New Road, and Sussex Street had complained of illness and inflammation of the throat caused by the brimstone smell from the sewers and drains. The ventilators in the road near the chemical works were frequently emitting dense hot vapour in the evening, and he himself had felt its ill effects when driving over the spots.

John Scott said he had worked in the sewers. At the time in question the lanterns suddenly went out and witness felt a choking sensation in his throat and a smell like burning brimstone. He staggered back and fell down senseless. In reply to Mr. Besley witness said that just before the lights went out he noticed black froth coming down the tideway of the sewer. It made no noise, and the smell was like that of burning brimstone matches. On coming to his senses he saw a man in the employ of Messrs. Wallace standing at the window. He said to witness, "Well, Jack, they have put it on you three quarters of an hour too soon this time." The flushers were not able to go near the outfall from Messrs. Wallace's premises in consequence of the foul smells and the steam. They had another narrow escape two months ago, and he went up to the works and said to Mr. Wallace, jun., "Are you aware that you are putting that hot stuff in again?" The fireman said "No!" Mr. Wallace ordered some cold water to be turned on to cool it, but there was none to send down the pipe. Witness showed him the hot steam coming out of the sewer through the ventilator in the street and the manhole. In consequence of there being no cold water the men were unable to continue their work in the sewer that night. They always worked in safety except when the stuff was sent into the sewer from the chemical works. About Christmas last he assisted Prester to clean out a communication pipe and drain of Messrs. Wallace; but it was filled up with a hard deposit of lime and a blue substance, which burnt their hands fearfully, and turned them all sorts of colours. When put into water the pain increased. The smell from that drain was similar to that which pervaded the sewer when the deceased was killed. Mr. Pettengill cross-examined the witness with the view of showing that the deadly gas had escaped from the deposit in the bed of the sewer; but the witness said that he had no doubt that it came from the works. In reply to the jury, witness said Messrs. Wallace never gave the sewer men any warning when they were about to turn on the hot refuse. The inquiry was again adjourned for a fortnight.—*Times*.

Poisoning by Cyanide of Potassium.

On Friday August 18, Mr. W. J. Payne, held an inquiry at the Workhouse, Mint Street, Southwark, into the cause of the death of Edward Holmes, aged 39, hairdresser, who, it was alleged, died from the effects of poison, in a coffee-house in St. George's Circus, Blackfriars, on the morning of Tuesday last, under somewhat suspicious circumstances. The first witness was Mrs. Jane Holmes, wife of the deceased, who said that her husband suffered greatly in his head, and also from heart disease. He was in pecuniary difficulties, owing to his business not prospering. He took great interest in the Bravo case, and said it was a mistaken idea that poison could not be procured easily. He once remarked that the easiest death was from cyanide of potassium. On Sunday last he was greatly excited, owing to the outbreak of a fire at his shop, but it was only a slight one. On Monday morning he vomited a great deal, but, after partaking of a little brandy, he seemed to recover. Mr. Irving, a clerk, said he met the deceased on Monday last, when he appeared rather excited. Their conversation turned upon the Bravo case and the easiest methods of committing suicide. Dr. T. M. Donahoo, said he had made a *post mortem* examination of the body of the deceasad. He assigned the cause of death to an overdose of cyanide of potassium, as all the organs smelt strongly of that drug. He found a tumbler in the room containing a large quantity of this poison; and in a packet handed to him by the police was seven ounces of the poisonous drug. His death must have taken place within three minutes after partaking of it. He believed that the packet contained eight ouuces of the drug, and the word "poison" was marked upon it. Fanny Smith, 25, who stands charged on suspicion of having caused the death of the deceased, said she met the deceased on Monday night last, at about half-past eleven, in the Westminster

Bridge Road, after which he accompanied her to the coffee-shop in question. He was quite sober, but she was not. About a quarter to five she shook hands with him, and the deceased told her to tell the landlady not to call him until nine o'clock. She never saw anything of the poison. The jury returned a verdict of "Suicide while of unsound mind."

Poisoning by Phosphorus Paste.

On Friday, August 18, Mr. W. J. Payne held an inquiry at the City Arms, Old Kent Road, into the death of Eliza Mayberry, aged 70, who had destroyed her life by poison.

It appeared that deceased lived with her son. She became very querulous and unhappy, and said she was a burden to every one about her. On the previous Thursday week she told her son she had taken poison, having purchased two bottles of phosphorus paste, used for killing vermin, at an oil shop close by, and taken the whole quantity, as she was tired of her life. She succumbed to the poison on Thursday.

It came out in the course of the inquiry that a cabman, whose wife recently poisoned herself with phosphorus paste, frequented the son's shop, and the circumstance of the poisoning had frequently been the the theme of discussion in the family, the deceased having heard the facts detailed in the accounts of the inquest.

A verdict of "Suicide while of unsound mind" was returned.—*Standard.*

Poisoned by Paraffin.

On Wednesday an inquest took place in reference to the death of Captain Morgan Davies, of the ship Ocean Child, of Portmadoc. On Monday Captain Davies was assisting in superintending attempts made to float the Turkestan, a large iron vessel stranded on Harlech beach in February last. Tired and thirsty, he went into the cabin and incautiously seized a jar, believing it contained water. He hastily drank a quantity of the contents, which proved to be paraffin oil. Deceased became insensible, and expired within a few hours.—*Standard.*

Notes and Queries.

[523]. INDIAN BAEL SHERBET.—For notices of "Indian Bael Sherbet," S. W. should refer to Ainslie's 'Materia Indicæ,' vol. ii., p. 189; Pereira's 'Materia Medica and Therapeutics,' vol. ii., pt. ii. (1857), p. 550; Waring's 'Manual of Practical Therapeutics,' 2nd ed., p. 42; and 'Pharmacopœia of India,' p. 46. Waring gives the following formula for its preparation:—

"Take of the soft gummy substance from the interior of the fruit two fluid ounces, mix this with three to four fluid ounces of water, sweeten to the taste, and add—if procurable—a lump of ice."—R. B.

Obituary.

Notice has been received of the death of the following:—

On the 3rd of August, 1876, Mr James Wright, Pharmaceutical Chemist, Chesterfield. Aged 66 years. Mr. Wright had been a Member of the Pharmaceutical Society since 1853.

On the 7th of August, 1876, Mr. Reuben Madge Milton, Chemist and Druggist, 246, High Street, Exeter.

On the 14th of August, 1876, Mr. Charles Septimus Gibson, Chemist and Druggist, Haydon Bridge, Northumberland. Aged 60 years.

On the 24th of May, 1876, at his residence, East St. Kilda, Mr. William Ford, Chemist and Druggist, of Swanston Street, Melbourne. Aged 50 years. Mr. Ford was a native of Macclesfield, Cheshire, but had been nearly thirty years in business in Victoria. We gather from the local newspapers that the deceased gentleman was held in great respect in the colony, which was evinced by the attendance of leading citizens who followed his remains to the St. Kilda Cemetery, the procession being one of the largest which has followed any old colonist for some years. Though the funeral did not pass through Melbourne, a large number of the principal places of business partially closed their premises during the afternoon.

The Impurities in Sulphur Præcipitatum.

Sir,—It appears from the experiments made by Mr. Miller, and described in his letter published in your issue of the 12th inst., that sulphur præcipitatum contains other impurities besides that which I alluded to in the discussion of the subject at a meeting of public analysts, and that I was probably wrong in representing as persulphide of hydrogen the dark coloured mud that subsides after dissolving the sulphur in bisulphide of carbon. I should, perhaps, have said that it afforded evidence of that impurity in the sulphur. Mr. Miller found that after washing and drying the mud it consisted chiefly of calcium, iron, chlorine, and sulphur. If he had traced the reaction a little further he might have ascertained that sulphuretted hydrogen was given off. I considered the escape of this gas on allowing the solution to stand, and the presence of sulphur in the insoluble residue left, sufficient to justify the conclusion that persulphide of hydrogen existed in the mud, and gradually broke up into those products. Professor Rose came to the conclusion, many years ago, that precipitated sulphur contained persulphide of hydrogen, which was persistently retained there until broken up by the application of heat. I have found evidence of its being similarly broken up when the sulphur is dissolved in bisulphide of carbon.

The most important result of this inquiry, however, is, that precipitated sulphur contains impurities that are not present in milk of sulphur, and especially that when dissolved in bisulphide of carbon sulphuretted hydrogen slowly escapes and a residue of electropositive sulphur is left. Under similar circumstances milk of sulphur yields a clear solution of sulphur free from impurity, leaving a residue of a white and satiny crystalline salt of lime. A minute quantity of sulphuretted hydrogen escapes when the solution is made, but the result in this respect is very different from that which occurs when precipitated sulphur containing the same quantity of sulphur is similarly treated. Pure bisulphide of carbon should of course be used in this experiment.

I advise those pharmacists who are accustomed to lecture their customers on the folly of using what they are pleased to call impure milk of sulphur in preference to the so-called pure precipitated sulphur, to make themselves acquainted with the state in which the sulphur exists in those two preparations, by the simple experiments I have indicated. If they fairly represent the case and can induce the public to prefer the sulphur mixed with black mud which breaks up with evolution of sulphuretted hydrogen, to the comparatively pure, tasteless, and easily administered milk of sulphur, by all means let them do so. For my own part, having had some experience in the use of both, I prefer the latter and consider it quite as efficacious as the other, and far more agreeable.

I hope it will not be considered that anything I have said here or elsewhere has been intended in the slightest degree to justify or excuse the substitution of milk of sulphur for precipitated sulphur, when the latter is asked for or ordered. I should be glad to see the two names always similarly applied, the latter to the preparation ordered in the British Pharmacopœia, and the former to the more generally used and popularly appreciated article prepared in accordance with instructions given in the London Pharmacopœia of 1721. If pharmacists acted consistently in this respect, it would facilitate the supplying of the public with the articles they prefer or require, and relieve druggists from an imputation which has been frequently cast upon them unjustly.

T. Redwood.

Chemists and Druggists' Trade Association.

Sir,—From the remarks expressed at the last meeting of the Council I consider it fair to infer that the President regards the new trade association as in some degree antagonistic to the Society; I therefore beg to state that so far as I can learn no such feeling animates the minds of the members. Our object is to establish a large and compact association to protect and advance the trade interests of chemists and druggists. I would ask are there not questions to be considered which may affect us in a pecuniary point of view, such as the working of the Adulteration Act and other matters which I need not here specify? Every one, will, I think, answer in the affirmative. "Making up one's mind" is an operation that takes different durations of time in various individuals, but as the meeting of the Chemists and Druggists' Trade Association convened to meet in Glasgow on Friday, September 8, will welcome any member of the trade, I trust that all who have the opportunity will come and ascertain for themselves whether our objects are desirable, and if the proposed plans of obtaining them are reasonable.

S. U. Jones.

4, *Upper Parade, Leamington,*
August 21, 1876.

"Spoonfuls."

Sir,—The untimely death of the child, Ernest Ward, reported in your issue of last week, by an overdose of medicine, apparently through its being measured in an ordinary household spoon, causes me to pen these few lines in the belief that the suggestion therein contained will be of some practical value. In the early days of my apprenticeship I well remember a medical man coming into the shop in a terrific rage declaring he would never order medicines by tablespoonfuls as long as he lived, as his patient for whom he had prescribed some powerful drug had swallowed in five doses what should have made him three more. Fortunately no unpleasant result followed, but it might have done. From the circumstance I learnt a lesson which I have constantly borne in mind. I have always been educated that in medical use the terms tea, dessert, and tablespoonfuls represent one, two, and four drachms respectively; there can be no doubt that this is the general acceptation of the terms, both in the trade and the profession; there may be a few exceptions, but I think a dispenser would never be censured for adhering to this rule. I do not think the term spoonfuls can be discarded with any advantage. When practical I always use well graduated bottles and translate "spoonful" with an explanation in brackets, thus: coch. mag. duo—two tablespoonfuls (*i.e.*, one-eighth part). This division into parts, however, becomes inconvenient when dessert and teaspoonful doses are ordered; thus one thirty-second part of a 4 oz. mixture would require a skilled hand to pour out correctly. The following label is one I have long used and I think gets over all difficulties:—"Household spoons should not be used for measuring medicines. This bottle contains —— doses." It gives a caution; and if it does not give the whole information required, it gives sufficient to cause the individuals to seek the remainder at the proper source and if they do not then choose to supply themselves with correct measures the dispenser has shown his carefulness and exonerated himself from all blame.

What we have need to do is to impress upon the public the fact that a medicinal spoon and a household spoon are two distinct measures, and not for us to alter a custom which has worked well for ages; for to try and adapt our directions to spoons of such variable capacity as those found in general use would only make matters much more complicated than they are at present.

John Ingham.

Upper Tooting, August 22, 1876.

Sir,—A most striking case of the danger attending physicians ordering teaspoonful doses came under my notice on Friday, the 18th inst.—viz.: a prescription was brought to me to be dispensed containing the following:—

℞	Quinæ Disulph.	ʒj
	Aqua Dest.	℥iij
	Acid. Sulph. Dil.	ʒ
	Syr. Aurant.	℥j

Sign. One teaspoonful twice a day in a wineglass of water.

Knowing the great difference in teaspoons I asked the person to let me see the teaspoon she was going to use, which she did, and it measured just 120 minims, equivalent to two medicinal teaspoons; so instead of the patient getting not quite 4 grains, she would get over 7 grains of quinine a day.

Harry Hyne.

J. B. W. (who should have sent his name and address).—We do not recognize the book you describe. Perhaps Beasley's 'Chemist's Receipt Book,' published by Churchills, would meet your requirements.

J. Arnold.—(1) The sulphate containing two molecules of quinine to one molecule of sulphuric acid is the true neutral sulphate corresponding to sodium sulphate Na_2SO_4. For a description of the Sulphates of Quinine, and their formulæ see Dr. Hesse's 'History of the Cinchona Alkaloids,' *Pharm. Journ.*, 3rd series, vol. iv., p. 570. (2) The formula of cellulose is now usually represented as $C_6H_{10}O_5$. See Watt's 'Dictionary,' vol. i., p. 818.

Communications, Letters, etc., have been received from Mr. Courtenay, Mr. J. Garrett (Leicester Association), Mr. Wilkinson.

THE WATER OF CRYSTALLIZATION IN QUININE SULPHATE.

BY A. J. COWNLEY.

Whilst the quantity of water of crystallization existing in freshly prepared and uneffloresced quinine sulphate is enveloped in some doubt, owing to the efflorescent character of this salt of quinine, and the question whether it contains 7 molecules of water according to Regnault, 7½ as given by Jobst and Hesse, or 8 molecules as stated by Schorlemmer, has still to be determined, it seems to be very generally stated that the anhydrous sulphate is only obtained at a temperature exceeding 110° C.

Jobst and Hesse, as quoted by Watts, state that at 110° to 120°C. the salt loses the whole of its water of crystallization, and the same temperature is given by Millon and Coumaille as well as in Husemann's 'Pflanzenstoffe' for 1870, with the additional statement that at 100° C. the sulphate contains 2 molecules of water. This latter view and the opinion that the salt is then identical with the air dried salt as regards hydration, seem to have been adopted as correctly representing the condition of quinine sulphate at that temperature.

The following experiments show that quinine sulphate really becomes anhydrous at 100° C., and when freely exposed to the air in this condition it rapidly absorbs water until it has the composition of a sulphate with two molecules of water, but when the access of air is retarded the water of crystallization is of a varying quantity and bears no constant relation to the salt until 2 molecules have been absorbed; also that freshly prepared quinine sulphate probably does contain, as stated by Jobst and Hesse, 7½ molecules of water, and that the salt in this condition when freely exposed to air rapidly effloresces until it attains the composition of a sulphate with 2 aq.

(1) Quinine sulphate dried at 100° becomes anhydrous. No further loss ensues when the temperature is increased to 120°.

Sample (*a*)

(1) ·2765 grm. gave ·0865 grm. SO_4Ba = ·03638 grm. SO_4H_2 = 13·15 per cent. SO_4H_2.

(2) ·287 grm. gave ·090 grm. SO_4Ba = ·03715 grm. SO_4H_2 = 13·18 per cent. SO_4H_2.

Sample (*b*)

(1) ·2475 grm. gave ·077 grm. SO_4Ba = ·03238 grm. SO_4H_2 = 13·08 per cent. SO_4H_2.

(2) ·3955 grm. gave ·1245 grm. SO_4Ba = ·05193 grm. SO_4H_2 = 13·13 per cent. SO_4H_2.

Sample (*c*)

(1) ·26325 grm. gave ·08225 grm. SO_4Ba = ·03459 grm. SO_4H_2 = 13·13 per cent. SO_4H_2.

(2) ·32425 grm. gave ·10175 grm. SO_4Ba = ·04279 grm SO_4H_2 = 13·19 per cent. SO_4H_2.

	Theory.		Found as mean of six experiments.
$(C_{20}H_{22}N_2O_2)_2$ =	648 =	86·86	
SO_4H_2 =	98 =	13·14 =	13·15
	746	100·00	

(2) Freely exposing to air on watch glasses—(*a*) the anhydrous sulphate; (*b*) the sulphate containing 7½ aq.:—

(*a*) The anhydrous sulphate—

1·269 grm. in 3 hours became constant, and – 1·333 = ·064 gain, or 4·8 per cent. of water contained in air-dried salt.

	Theory,		Found,
$(C_{20}H_{24}N_2O_2)_2$ =	648 =	82·81 . . .	——
SO_4H_2 . . . =	98	12·53 . . .	——
$2OH_2$ . . . =	36	4·60 . . .	4·80
	782	100·00	

(*b*) The sulphate containing 7½ molecules of water as determined in Experiment 4—

1·015 grm. required 28 hours to become constant, and gave ·9045 = ·1105 loss = 10·88 per cent. lost by the fully crystallized salt.

Theory requires 11·24 per cent. to be lost for the salt to contain 2 molecules of water.

(3) Not freely exposing to air the salt which has been dried at 100° C., but exposing it in an unstoppered tube. The same quinine sulphate was taken as in Experiment 2:—

(*a*) 1·37975 grm. constant at 100° in 4 hours = 1·393 gram = ·01325 gain = 0·96 per cent. of water in hydrated salt.

1·37975 grm. constant at 100° in 19 hours = 1·421 gram = ·04125 gain = 2·96 per cent. of water in hydrated salt.

(*b*) A smaller quantity was taken—

·9015 grm. constant at 100° in 4 hours = ·9175 gram = ·01575 gain = 1·71 per cent. of water in hydrated salt.

·9015 grm. constant at 100° in 19 hours = ·94225 gram = 0·4075 gain = 4·32 per cent. of water in hydrated salt.

It appears, therefore, that when quinine sulphate which has been rendered anhydrous is exposed to the air it very slowly absorbs the quantity of water corresponding to normal air-dried sulphate, that is to $(C_{20}H_{24}N_2O_2)_2SO_4H_2 + 2Aq$.

In Watts' 'Dictionary' it is stated that the anhydrous sulphate on exposure to moist air absorbs 4·87 to 5·1 per cent. of water, a statement which is borne out by my experiments, but it is stated in a note that "4 atoms = 4·82 per cent."; but inasmuch as the formula for quinine sulphate is given in the new notation at the head of the article, this evidently should be 2 atoms = 4·82 per cent., a result theoretically required. I am induced to refer to this point as it was assumed in some quinine experiments published a short time since, and on which certain conclusions were based, that the air-dried salt contains 4 atoms of water of crystallization.

(4) The composition of freshly prepared and uneffloresced quinine sulphate—

(*a*) 1·49775 gram lost 0·22875 = 15·27 per cent.

(*b*) 2·32275 grams lost 0·3555 = 15·3 per cent.

No further loss at 120° C.

(*c*) Dried at 120° C. 1·061 gram lost 0·16 = 15·08 per cent.

(*d*) ·2485 gram gave 0·066 SO_4Ba = ·02776 SO_4H_2 = 11·17 per cent.

(*e*) ·35375 gram gave 0·095 SO_4Ba = ·03995 SO_4H_2 = 11·29 per cent.

	Theory,		Found,		
			Water determined at 100° C,		Water determined at 120°
$(C_{20}H_{24}N_2O_2)_2$ =	648 =	73·56			
SO_4H_2 . . =	98 =	11·12	11·17	11·29	——
$7\frac{1}{2}OH_2$ . . =	135 =	15·32	15·27	15·30	15·08
	881	100·00			

These last experiments also give additional evidence that quinine sulphate is rendered anhydrous at 100° C.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from p.* 172.)

BOSWELLIA SERRATA.—*Local name in Khandesh,* GUGAL.

The gum resin, Gugal. I am indebted to Dr. Jones, Civil Surgeon, Dohud, for specimens of this tree and its produce, which corresponds exactly with the Gugal of commerce—viz., irregular lumps, covered more or less with dirt and hair, to which portions of papery bark as well as the thick inner bark sometimes adhere; of a greenish yellow colour, with an occasional tinge of red; consistence waxy; odour peculiar and balsamic; taste bitter and balsamic. Gugal forms a greyish-white emulsion with water. In the Indian Pharmacopœia and other works it appears to have been confounded with Indian Bdellium, or as it is sometimes called, Bysabol Gugal. This has a peculiar mushroom odour, and is in appearance much like African Bdellium; it is the produce of a Balsamodendron. Through the kindness of Dr. Holmsted I have received a specimen from Sind as the produce of *B. Mukul,* which exactly corresponds with the commercial article; when fresh it is moist and of waxy consistence, but by keeping it becomes quite dry and brittle, and loses much of its peculiar odour. Gugal is used as an incense principally, and has on this account probably been confounded with olibanum. I know of no Indian olibanum.

POGOSTEMON PURPURICAULIS.—*Local name,* PHAUGLA.

A tall suffruticose perennial plant, about six feet high, with a purplish smooth stem; leaves often six inches long, broadly ovate, acuminate, serrated, smooth; flowers very small, pale purple, in axillary and terminal panicles; seeds very small, black and shining. The whole plant has a strong black currant odour; it is common in the Kokun. The fresh leaves have a slightly pungent taste. When bruised they are applied as a cataplasm in order to clean wounds and stimulate healthy granulation.

RHINACANTHUS COMMUNIS. — *Local name,* GUJKARNEE.

A shrubby perennial plant, 3—4 feet high, generally cultivated in gardens as a domestic remedy. The leaves are 2—3 inch s long, ovate oblong; the inflorescence is in axillary and terminal panicles, bitrichotomous and spreading, flowers insignificant, white, tube of corolla long, slender and compressed. The leaves are a popular remedy for what is called Indian Ringworm; they are applied bruised and mixed with lime juice; when chewed they taste like fresh cassia bark. The roots, which are small and fibrous, are said to have aphrodisiacal properties, but I have not seen them used in Bombay.

CONVOLVULUS Sp.?

The Tukm i Nil of Persia, imported into Bombay. These seeds are much larger than the Indian Kala Dana. They are imported in considerable quantities and have to a great extent displaced the native drug. The seeds grow freely in Bombay. The following is a description of the plant: Annual, herbaceous, climbing; root small, tapering, with many thin rootlets; stem branched, covered with aerial rootlets, not hairy; leaves broadly cordate, acuminate, smooth, on long petioles; flowers axillary; peduncle long having rootlets like the stem, 2—4 flowered; calyx divided; sepals 5 broadly ovate, mucronate, smooth, persistent; pedicel large, fleshy and pearshaped, of a light green colour, 1½ inches long; corolla purple, about 2 inches in diameter, expanding at sunset, and closing before sunrise, Capsule two celled, composed of four segments which separate from the central partition; cells two-seeded; seeds dark brown, smooth, the shape of the segments of an orange, but with rounded angles, average length $\frac{5}{16}$ of an inch, breadth ¼ of an inch, weight three grams each. Tukm i Nil can readily be distinguished from the Indian varieties of Kala Dana by their larger size, lighter colour, and thick testa; their action as a medicine seems to be the same, but acurate observations are required. For a full account of Indian Kala Dana see 'Pharmacographia' page 402 and the appendix to the Pharmacopœia of India by Moodeen Sheriff.

PLUMBAGO ROSEA.—*Local name,* LAL CHITRA.

The root bark is reddish brown externally, transversely fissured, thick and suberous; internally it is white when first removed, but soon turns red upon exposure to the air. It has a rancid heavy odour. A section of the root shows a central woody column, with a very large vascular system, surrounded by a bark almost entirely made up of thin-walled parenchymatous cells loaded with large oil globules and containing some starch. There is a good summary of the medicinal uses of this drug in the Pharmacopœia of India. I think it might be used in this country as a substitute for Mezereon in the Lin. Sinapis Comp. and in Decoct Sarzæ Comp. The active principle Plumbagin being soluble in ether an ethereal extract might be made.

CLITOREA TERNATA.—*Local name,* KAJALEE.

The root and seeds.

The root is large, fleshy, branched, and spreading, often one inch or more in diameter, white, with an acrid bitter taste; the root bark is soft and thick and easily separated. Under the microscope it is seen to consist of a thin-walled cellular tissue, containing a little granular matter and here and there a few small starch cells. The central portion of the root is composed of very large dotted vessels, easily visible with the naked eye. The seeds are rather more than ⅜ of an inch long and resemble vetch seeds; they are mottled green and black. The testa is hard and contains two cotyledons made up of elongated thin-walled cells full of large starch granules; they have an acrid bitter taste. The seeds exhausted with spirit yield a light brown resin with an odour exactly like Jalap. The medicinal uses of both root and seeds are noticed in the Indian Pharmacopœia and its supplement by Mr. Moodeen Sheriff. I would suggest a trial of the resin.

Bombay.

(*To be continued.*)

THE BEHAVIOUR OF SOLUTIONS OF SOME SUBSTANCES TO POLARIZED LIGHT.*

BY O. HESSE.

For some years past the author has been induced to make experiments to ascertain whether the optical behaviour of solutions of cinchona alkaloids would allow of this property being used in determining their quality. The results were not very satisfactory, and the author has therefore sought to investigate the causes to which the irregularities in the behaviour of different solutions might be due.

That many liquids are capable of diverting a ray of polarized light has been known since 1815. Biot, and almost simultaneously Seebeck, then recognized this property in oil of turpentine, solution of camphor, and several other substances. Later, in 1832,† Biot enunciated the law, according to which a ray of polarized light is deviated by quartz (rock crystal) in the same manner as by liquids possessing similar property. Biot was of opinion that this power of deviating a ray of polarized light not only had its seat in the molecule, but that it was inseparable from it and therefore characteristic of it.

The amount of this molecular power can evidently only be determined by the intensity of its action. If therefore a represent the amount of curve through which the ray of light is deviated by a substance, λ the length or thickness of the active layer, and δ the quantity of the active substance contained in the mass ($=1$), the amount of the molecular power may be represented thus—

$$(a) = \frac{a}{\lambda \cdot \delta}$$

For λ Biot took 1 mm. of quartz. But as the liquids which he examined caused a relatively small deviation, he considered it more convenient in these cases to use a thicker layer of the active material. He fixed upon 100 mm., and established that length as unity in the above formula, and used (a) to represent the molecular or specific rotatory power of a body.

When an inactive body is present simultaneously in the same volume with the active body, as in a solution, the relation of the quantity of the active body to the entire weight—*i.e.*, the degree of concentration must be taken into account. If ϵ represent the concentration the rotatory power of a body occurring in solution will be represented by the following formula:—

$$(a) = \frac{a}{\lambda \cdot \epsilon \cdot \delta}$$

The same result is attained by the calculation of the rotatory power of the active substance which is contained in the unity volume. If p indicate the weight of this substance, and P that of the menstruum, then—

$$\epsilon = \frac{p}{p + P}$$

On the other hand, δ or the specific weight of a solution is obtained by comparing its weight with an equal volume of water ($=$V) at 4° C. Consequently—

$$\delta = \frac{p + P}{v}$$

From this it follows that—

$$\epsilon \cdot \delta = \frac{p}{p + P} \cdot \frac{p + P}{v} = \frac{p}{v}$$

Therefore—

$$(a) = \frac{a}{\lambda \cdot \epsilon \cdot \delta} = \frac{a \cdot v}{\lambda \cdot p}$$

According to the first formula the specific weight of the solution will be required. But the ascertaining of this is often a difficult matter, especially if the menstruum be very volatile. By using the second formula it is only necessary to weigh the substance in a small vessel the capacity of which is accurately known and then to fill the vessel up to the mark which represents the volume with the menstruum.

More recently Biot's way of indicating the rotatory power has been declared to be inconsequent, and now a distinction is made between the specific and the molecular rotatory powers of a body. According to this arrangement, by the specific rotatory power is understood the amount which is indicated for a certain body by the before mentioned method, whilst the molecular rotatory power of a body is the value which it gives when the specific rotatory power of the body is brought into relation with its molecular weight. Assuming the molecular weight of a body to be m the relation between its molecular figure and its absolute weight is represented by $\frac{p}{m}$

Accordingly the molecular rotatory power of a body (m) will be found by the following formula:

$$(m) = m\,(a) = \frac{a \cdot v \cdot m}{\lambda \cdot p}$$

Since, however, the molecular weight of most of the substances coming under consideration is very high, a very high figure would be obtained as the expression of the molecular rotatory power with a relatively small deviation. At the same time unavoidable experimental error is correspondingly magnified. To obviate this inconvenience, Krecke* took the molecular rotation of a column 1 mm. long, or what amounted to the same thing, divided m by 100, calculating according to the formula:

$$(m) = \frac{a \cdot v \cdot m}{100 \cdot \lambda \cdot p}$$

In this way Krecke made calculations of (m) for a large number of bodies, and believed that he had discovered two laws which determine the behaviour of bodies to polarized light. These "laws of simple relations," as he called them, were asserted to extend to all known bodies, with the exception of tartaric acid, and were to the following purport:—

1. When an optically active body enters into combination with an optically inactive one, or when it becomes modified by chemical agents, either the molecular rotatory power remains unaltered, or it is so modified that the molecular rotatory power of the new body is a simple multiple of that of the mother substance.

2. Isomerous bodies possess molecular rotatory powers which are multiples of one and the same number.

These laws presume that the rotatory power of the body when used in different quantities is of constant magnitude; but as this presumption does not turn out to be correct, as the author proceeds to show, no value can be attributed to them.

The author's experiments were made with an excellent Wild's polaristrobometer. a represents the mean value of a large number, about twenty, of observations; $v = 100$ c.c.; p expresses the quantity by weight of the so-called active substance contained in 100 c.c. The use of these terms the author finds advantageous, as compared to those in which the weight of active substance is in relation to 1 c.c. For λ 0·1 m. is taken; l on the contrary is given in mm. The unity λ is therefore $= \frac{l}{100}$

At first, with the object of better comparing the results, the whole of the experiments were made at one temperature, 15°C. But as in summer time this temperature was difficult to obtain, it was determined to carry out a series of experiments at a higher temperature in order to avoid delay in the investigation. As a source of light the

sodium flame was used. This, however, excluded the use of strongly coloured yellow solutions, as through their intensity of colour the extinguishment of the fringes could only with difficulty be observed. In such cases the use of the red light was indicated. But as the relation of the yellow light, in consequence of concentration, temperature, and other conditions, is not always as 30 : 23, the situation is variable, and the author has therefore reserved estimation by means of the red light for future comparisons with the yellow light.

Sometimes, in consequence of the internal dispersion of the light, the disappearance of the interference rays cannot be well recognized. This inconvenience the author dealt with, either by examining a smaller layer of the substance or diminishing the quantity of the active substance; for this dispersion of light increases both with the length of the layer and the concentration of the solution. The solvents used in the author's experiments exercised no influence upon the ray of polarized light.

The chemical condition of a body has an important influence upon its rotatory power. An extremely small quantity of a foreign substance, adhering to that to be examined, often notably modifies its behaviour. Special caution was therefore taken that the substances used were absolutely pure.

Cane Sugar.

Seebeck found in 1816, that a solution of cane sugar exercised an influence upon polarized light, and thereby laid the basis for the optical saccharimetry afterwards announced by Biot. Crystallized cane sugar exercises scarcely any circular polarization. Nevertheless, Biot thought it could be assumed that this property still existed within the molecule, though, in consequence of the special building up of the molecule in the crystallization, an expression of it could not be obtained; but, as soon as the hindrances were removed by fusion or solution of the substance, the property could again be made manifest.

Biot* found for cane sugar $\alpha r = +52 \cdot 46°$ (mean); but Dubrunfaut† thought that Biot had used for his observations impure sugar, and gave for his own asserted quite pure material $\alpha j = +73 \cdot 84°$. Clerget ‡ afterwards indicated that this figure was too high, and gave $\alpha j = +65 \cdot 91°$. But this figure also eventually proved not quite correct, and had to be slightly raised, so that at present, almost generally, the rotary power of cane sugar is taken $\alpha j = +66 \cdot 4°$. According to the recent observations of Tuchsmid § it is, $\epsilon = 0 \cdot 294$ and $t = 10°$, $\alpha j = +66 \cdot 417°$. According to Oudemans, jun., ‖ with $\epsilon = 0 \cdot 056$, $t = 17°$, $\alpha j = +66 \cdot 9°$ for an aqueous solution, and for a solution of almost equal strength in 50 per cent. alcohol $\alpha j = +66 \cdot 4°$. Bakhoven¶ found $\alpha j = +66 \cdot 42°$ and L. Weiss** $\alpha j = +66 \cdot 064°$.

According to Tuchsmid the rotatory power of cane sugar does not alter with the temperature, and the small differences which are observed at different temperatures are entirely dependent upon the expansion of the solution, and consequently the alteration in its concentration. Notwithstanding that Biot†† and Arndtsen‡‡ made observations according to which the rotatory power of sugar would alter with the concentration of the solution, Biot was of opinion that the small differences in his experiments might be attributed to errors of observation. Therefore there is a disposition at present to ascribe to cane sugar a rotatory power invariable in all cases.

The author's experiments, however, do not favour this latter view. The sugar used by him was ordinary loaf sugar of the best quality. After having been repeatedly recrystallized from strong alcohol, the crystals were pulverized and dried in an exsiccator. The solution of the sugar was effected in the cold, although heating of the solution did not affect injuriously its rotatory power. With this sugar the following observations were made:—

Solvent.	Temp.	l	p	$\alpha° +$	$\alpha j° +$	Mean for $\alpha j° = +$
Water	15°	220	1	1·49	67·72	67·95
Water	15°	220	1	1·50	68·18	
Water	15°	220	2	2·96	67·27	67·39
Water	15°	220	2	2·97	67·50	
Water	15°	220	3	4·42	66·97	67·05
Water	15°	220	3	4·43	67·12	
Water	15°	200	6	8·00	66·67	66·67
Water	15°	100	10	6·65	66·50	66·50
Water	25°	200	10	13·30	66·50	
Water	15°	100	20	13·29	66·45	66·45
Water	25°	100	20	13·30	66·50	—
50 per cent. Alcohol	15°	200	5	6·67	66·70	—
Water and 1 mol. SO_3	15°	200	6	8·00	66·67	—
Water and 1 mol. Na_2O	15°	200	5	6·00	60·00	—

For the solution of cane sugar at 15° C. the rotatory power for 0 to 10 p inclusive may be calculated according to the following formula:—

$$\alpha j = +68 \cdot 65 - 0 \cdot 828p + 0 \cdot 115415p^2 - 0 \cdot 00541666p^3$$

This gives for —

	αj	Found.
1 p	+67·94°	+67·95°
2 p	+67·42°	+67·32°
3 p	+67·06°	+67·05°
6 p	+66·67°	+66·67°
10 p	+66·50°	+66·50°

Above 10 p the rotatory power of the sugar remains almost constant, the decrease for each 1 p between 10 and 20 p amounting to only 0·005. With still greater concentration this difference presumably would become still smaller.

It further appears that, compared with water, 50 per cent. alcohol exercises no influence upon the rotatory power of sugar. Sulphuric acid of the indicated strength behaved in a similar manner, provided that the solution was freshly prepared, and was not heated. On the other hand, soda lowered the rotatory power of sugar to a considerable degree.

(To be continued.)

REMARKS ON THE PRIORITY OF THE ANCIENT SYSTEMS OF MEDICINE.*

BY THOMAS A. WISE, M.D., F.R.C.P., F.R.S. EDIN.,

Late of the Medical Staff of the Bengal Army.

Both sacred and profane history render it probable that when mankind emerged from their primitive home they possessed great energy and organic activity, accompanied with a corresponding degree of intellectual force. This enabled them to select a fruitful country as their home, where they soon became rich and powerful, and at an early period assigned a particular class for the acquisition of knowledge. These individuals, distinguished for their power of observation and sound reasoning, opened a vast and interesting field for the exercise of their mental faculties, in the region of abstract speculation. Their knowledge and progress in civilization was aided by their possessing the advantage of high rank in a regular and peaceable government, and a religion abounding in moral precepts.

The most ancient traditions and records of the Western nations refer to the "learning and wisdom of the East,"

without any distinct mention of the race or nation. Modern investigations tend to prove that the original seat of the Indo-Germanic, or Aryan family of man was the high table-land contiguous to the lofty range of mountains extending eastward from the Caspian Sea.

Thence they descended to the fruitful plains in a southern and eastern direction, and at an early age another portion of the Aryan race commenced their wanderings towards the mysterious West. In both countries they distinguished themselves by their knowledge of the medical profession, and each prepared systems of medicine, the priority of which remains still an undecided question.

The age in which the ancient Hindu system was arranged cannot be directly stated, in consequence of their despising dates, as they considered life a transitory state of trial and suffering, and history of too little importance to occupy the attention of rational beings.

It is hoped that the following deductions will aid us in arriving at an approximate date when the two great works on Hindu medicine were composed, and enable us to compare them with the Greek system. The perishable material on which the ancient Hindu MSS. were written, rendered it necessary to have them frequently copied, in the course of ages, by scribes, often ignorant of the subject, and sometimes, perhaps, careless in their transcriptions. In ancient times the sources of error were to a certain extent avoided. The MSS. were regarded as of a sacred character, and only a limited few were permitted to copy them.

The sacred Hindu Vedas were more studied than the ancient Hindu medical shastres; as the latter were not considered sacred, greater liberties were taken with them, interpolations and clerical errors were introduced by illiterate transcribers. These causes render it very difficult to discover the age of the writings, except by comparing them with other Sanscrit works, the age of which is known. The ablest Sancript scholars allow that Charaka and Susruta, the two great commentators of the Ayur Veda, the supposed sacred revelation regarding medicine, are more recent than the grammarian Panini,* as neither work is mentioned by him, while both are noticed several times in the Mahâbhârata. Professor Wilson supposed this great epic was written in the second century before Christ; and, like Panini, was added to, in the course of centuries. Hessler, in his work on Susruta, considered that it was written a thousand years before Christ.†

We have, at this early period, two systems of Hindu medicine, complete in all their parts, founded on anatomy, exhibiting an extensive knowledge of materia medica and the practice of medicine, an expertness in the manipulations of pharmacy, and a bold and skilful knowledge and practice of surgery. We find the Hindu systems of medicine were originally written on the ancient form and construction of the Sanscrit language, so old, as to be considered the production of the Deity, when there was no prejudice of caste, before Polytheism was introduced into the Hindu religion, and in the heroic age, previous to the Mahâbhârata.

In considering the Greek system of medicine, we find their physicians and philosophers were indebted to the East for a portion of their knowledge. Pythagoras and Plato obtained many of their philosophical ideas from the Hindus, and the internal evidence of the Greek works proves that the schools of Hippocrates derived a considerable share of their knowledge from the East. Galen mentions that Hippocrates was often at Smyrna in Asia Minor,‡ and Mercurialis believed that he travelled in Lybia in Africa, and Scythia in Asia.§ Hippocrates may have visited this northern country to examine the enlightened and skilful Indo-Scythian people, whom Alexander the Great found so expert in the cure of diseases; and in these northern parts of Asia he may have consulted the Hindu sages, and studied their drugs and medical records. The learning he was in search of was there, and the following statements prove his acquaintance with their writings:—

1. The systematic works of the Hindus were most probably prepared from the third to the sixth century B.C.; and long before the age of Hippocrates the original Ayur Veda existed from which the other classical works were derived.

2. As medicinal plants have their properties developed in particular soils and climates, they indicate the nations among which they were first used for medicinal purposes, and explain the antiquity of the cultivation of medicine by certain races. The names and medicines recommended in the medical works of Hippocrates often indicate the schools of medicine from which they were borrowed. We find that Hippocrates used in his practice a number of Indian plants, imported from that country into Greece, for their well-known properties, such as *Sesamum Indicum*, Lin., *Hyperanthera morunga*, *Cardamomum Amomum*, *Laurus cinnamomum*, *Valeriana Jatamansi*, *Boswellia thurifera*, *Galbanum ammoniacum*, *Sagapenum assafœtida*, etc.* He also used black and long pepper, ginger, cassia, spikenard, *Calamus aromaticus*, etc., which are all the products of India or neighbouring countries.

3. The internal evidence of the works of the school of Hippocrates proves them to have been compilations, derived in part from nations further advanced than the Greeks in the knowledge of particular departments of the healing art. The ancient Hindu physicians considered dissection as a necessary part of the education of the medical practioner. Their method was rude and imperfect, but many of their conclusions were correct, as we have proved by the result of their osteological enumeration, and the accuracy of their description of the internal organs, and of the large vessels of the body.†

The ancient Hindu surgeons performed the most difficult operations; such as the Cæsarean section, embryotomy, lithotomy, etc. The first description of the last-named operation was given by Susruta, and was afterwards made known by Celsus,‡ who derived his information from Egyptian surgeons, and they again acquired their knowledge from the East. Hippocrates, the judicious surgeon and benevolent practitioner, allowed, it is incorrectly stated, the performance of this operation only by uneducated quacks.§

From these facts it would appear that at an early age the Hindus had made very considerable progress in the healing art, which enabled them to prepare systematic works on medicine, based on their own practical knowledge of anatomy, to which, at that time, the prejudice of mankind in general was so much opposed. Susruta informs us that an accomplished physician must possess an acquaintance with books, or theoretical knowledge, with the dissection of the human body, or anatomy, and a familiarity with the appearance of disease, or practice of medicine. This knowledge explains how the ancient system of Hindu medicine was so complete in all its parts, and warrants the inference that several centuries were required to complete them.|| While the nations of the

West have been slowly advancing, and mutually aiding one another, during the last two thousand years, the Hindus, by the depressing influence of Brahmanical intolerence and internal warfare, are now in a lower social condition than they were three or four centuries before the Christian era.

AMBER.*

BY M. REBOUX.

Amber was known to the ancients, who made from it ornaments and graven images of their divinities. It was called by the Assyrians *Electra* (*i.e.*, Stone of the Sun), from which the Greeks formed the word *Electron.* The name *Ambre*, from the Arab word *Ambar*, was introduced into France by the Crusaders. This name is less significant than that given to it by the Romans—*Lapis ardens.* The Germans call it *Bernstein.* Amber has been met with in many localities; formerly it was found upon the sea-shore after storms, and it has also been obtained from the earth. Sicily has produced a large quantity of it, but at the present time the borders of the Baltic supply the entire world.

During the eocene epoch the site of the Baltic Sea was occupied by an immense forest, which covered nearly the whole of the northern continent. There have been obtained by dredging thirty-two species of conifers, a poplar, an alder, two willows, a chestnut, and some junipers. From these conifers there exuded a resin which underwent a transformation in the bosom of the earth and became amber. More than a dozen different kinds of objects,—animal, vegetable, and mineral,—have been found in amber, such as insects, reptiles, pyrites, shells, salt water, plants, leaves, seeds, fruits, etc.

Amber can be distinguished from copal, or factitious amber, by the following characters:

Copal is of a yellow colour, more or less dark, but always of one colour; at some points of its surface it presents the appearance of crystallized sulphur. Pieces of amber have a different shade at their two extremities.

Amber rubbed upon the palm of the hand exhales a strong aromatic odour. Copal and factitious amber are inodorous.

Amber can be bent under the influence of heat, which is not the case with copal or factitious amber. Copal crumbles under the teeth like dried bread, and can be penetrated by the finger nail. Amber presents more resistance and can be cut, sawn, or polished. Two pieces of amber cannot be soldered together like two pieces of copal. Amber will scratch copal.

Heated to 100° C. copal gives off the vapour of water in abundance, then it becomes liquid, preserving its yellow colour. Amber does not melt below 400° C., when it becomes black and gives off a penetrating odour of succinic acid. If 33 per cent. of linseed oil be added, amber melts at 130° C.

A pinch of powdered amber thrown into the light of a candle inflames like gunpowder, giving a bluish flame. Copal gives a pale yellow flame.

Natural amber yields to distillation crystals of succinic acid, which the different copals do not.

The specific gravity varies from 1·09 to 1·11; that of copal is 1·04; that of factitious amber is 1·05.

An analysis of natural amber by Schrotter gave—C, 78·82; H, 10·28; O, 10·90. An analysis of copal from Elæocarpus yielded—C, 79; H, 10·40; O, 9·90.

---

* Extract from a memoir read before the French Academy (*Comptes Rendus*, vol. lxxxii., p. 1374).

THE INDIARUBBER ACCLIMATIZATION EXPERIMENT.

The following extracts are quoted in the *Gardeners' Chronicle* from Mr. Cross's report on the collection of seeds and plants of the indiarubber (*Castilloa elastica*) in the forests of the Isthmus of Darien. The original is given at length in the last number of the *Indian Forester*.

"I remained at Panama for fifteen days in order to gain all information regarding the size and yield of the rubber trees of the various districts. The tree is found growing from 1° S. latitude to 20° or more north of the equator, but in such a wide expanse of country there are probably several varieties, most of which, however, may bear a close resemblance to each other, although some may be of more robust habit than the rest, and attain to a greater size. Experience has proved that such is the case with most families of wild plants when brought under cultivation. Of late years a good deal of indiarubber has been brought from the forests on the Pacific coast, south of Panama, near to a scattered village called Darien. The Indians in this region have been rather hostile to the collectors, and the export has in consequence been much reduced. The greater portion of the interior of the isthmus has been explored, and the largest trees have been cut down. North of Panama, in the district of Chorera, there were once considerable numbers of trees, but these have been to a great extent demolished by the natives who usually cut down the trees in order to tap or bleed them more easily. The replies to my inquiries respecting the size to which the indiarubber trees grow in the forests about the village of Darien did not fully satisfy me; therefore I proposed to examine the woods on the confines of the larger tributaries of the river Chagres, where trees of large dimensions were formerly met with. The period of my arrival at Panama happened to be the wet season of the year, which in the region of swamp and forest is considered particularly unhealthy. Indeed, on this account Captain Mallet, H. M.'s Consul at Panama, thought I should await the return of the dry season. I afterwards found that his remarks concerning the climate were quite correct, and, except for the experience I had previously obtained while travelling in the hot valleys in the interior of New Grenada, I should in all likelihood have been prostrated with fever. But the seeds ripened during the rainy season, so that it was important to examine the forests for seed-bearing trees at this period.

"*Journey to the Forests.*—On June 9, I left Panama by the railway, and stopped at a place called Gatun, about 8 miles from Colon; leaving the railway tract, I crossed the Chagres and took up my quarters in the village of Gatun, which is built on the northern bank of the river. The town is formed of two streets 150 yards long, with rows of houses on both sides thatched with palm leaves. In most instances the walls of these houses are patched up in a miserable manner. Alligators swarm in the river, and any one who might attempt to bathe in it would soon be devoured. Water is obtained for domestic purposes from barrels sunk in the ground in low situations; they are provided with lids, and must be kept constantly covered to prevent toads and snakes from entering. The village contains about 300 inhabitants, the greater number of whom are of negro extraction. The situation is so low that during high floods the streets are inundated, and people ply about from house to house in canoes. On both sides of the river the country is swampy, although in great part clothed with forest. Penetrating into these woods I found the place swarmed with mosquitos, frogs, and uncountable millions of ants, and the snakes, instead of getting out of the way, raising their heads in a position of defence, ready to strike at any one who approached. These swamp forests present a dismal aspect and reminded me of the mangrove forests (*Manglares*) which grow in the flat deposits of fetid mud that occur on the margin of the Gulf of Guayaquil, and other places along the Pacific coast. The native with whom I was located at Gatun was a good fellow, but the greater number of the inhabitants were disobliging and uncivil. They were positively the worst class of people I have yet met with in any country. Everywhere the land, if cultivated, produces abundantly, but such is the indolence of these people that bananas, rice, and mandiocas are raised in limited quantity, scarcely, indeed, sufficient to maintain them. I found on inquiry that no indiarubber trees existed in the swamp forests, and that to find them it would be necessary for me to ascend the river for some distance, and then travel up to the dry land of the interior. The person with whom I lived collected indiarubber, and he had a hut in the heart of the forest, where the collectors often stayed for the night. A few days after my arrival he proposed going to this place, and, although the weather was unfavourable, I resolved to accompany him, as I was anxious to become well acquainted with the habitat of the tree, and also to ascertain if any seeds were to be found. Leaving at early morn in a canoe we ascended the river Chagres for a number of miles and then entered a small river called Vino Tinto, which rises from a large swamp in the interior. The water of this river was full of decayed vegetable matter, appearing as if vast quantities of the trunks and leaves of trees had been systematically ground up and mixed with it. On the banks, which were high, grew an astonishing rank growth of large trees and bamboos, and many of these had fallen into the water and lay partially submerged, thus forming serious obstacles for even the navigation of a canoe. Beyond the landing point a short distance of swamp land was travelled over, on which grew principally thickets of palm trees and bamboos; then the way ascending led to drier land, with some flat undulations, the greater portion of which had an elevation of about 50 feet above sea level. An indiarubber tree (*Castilloa*) was first seen in this locality growing near to a little stream in a very moist situation. Saplings or young rubber plants were subsequently met during the rest of my journey. After passing the flat land, we ascended a ridge of low hills, and undulating inequalities, which were clothed with the stateliest forest I have ever witnessed. Many of the trees, belonging to the order *Lauraceæ*, had straight smooth stems, which rose often to a height of 150 feet without a branch, and a massive species of bombax, called by the Indians *quipo*, grew mostly on the summits of the hills, and had frequently a clear trunk of 200 feet high, with a flat crown of green foliage like an umbrella, giving to these hills a grandly-imposing and majestic appearance. Palms of various species were tolerably abundant, and in places the undergrowth was composed of extensive thickets of a species of bromelia, which had formidable prickly leaves 10 feet in height. Both the trunk and branches of the trees were destitute of mosses (*Selaginellas*), although a robust species interwoven with *Adiantums* formed luxurious clusters on the ground. A species of Cacao (*Theobroma Cacao*) grew wild on the hill sides and in the ravines; its short slender trunk and branches were adorned with many fruits, each of which encloses a number of Cacao beans. However, these, on ripening, are duly visited by monkeys, hundreds of which were jumping about and screaming among the tops of the trees. The rubber saplings always appeared to grow most freely on the banks of little cool clear streams, the roots often running down to the edge of the water; they abounded also in deep rich soil along the base of the hills, and in both deep and shallow ravines. Plants were likewise met with on the summits of the ridges, and in fact in all localities where there was no swamp or marsh land. Some plants were observed growing among masses of volcanic rock, where there was not much soil but plenty of decaying leaves and particles of *débris*. Prostrate trunks were observed on the way, some of which had attained to a great size. We reached the rubber hut rather late, having travelled two days' journey in one. The hut was situated on an eminence between two ridges of hills. A stream of water flowed past the dwelling; it swarmed with incredible numbers of little fishes about the size of needles. A small portion of forest had been cut down, and a little Indian corn and a few roots had been planted. The trunks of some of the felled forest trees were 5 feet in diameter. Formerly a great many large rubber trees were found at this spot, which had yielded to the collectors a rich harvest; probably for this reason they called the place La Providencia. In the surrounding forest grew some young rubber trees, a few of which averaged from 50 to 70 feet in height; one of these bore a considerable number of unripe fruit. It was evident the fruit would take from ten to fifteen days to ripen.

"Meanwhile I resolved to search for some young plants to experiment with. An Indian who was employed to take care of the hut and its stores lent me one of his sons, a lad about fifteen years of age; he came away with me completely naked, and entering the forest we succeeded in collecting forty good plants. Returning to Gatun I rested a few days, and made two more journeys without finding any quantity of seeds. But the fruit of the tree already alluded to was approaching maturity, and it was necessary that these should be watched. Revisiting the place on July 18 I found the seeds had ripened. To facilitate the work of collection the tree was cut down and all the mature fruit was gathered. The fruit has a short stalk and springs from the axils of the leaves; it resembles in some measure a Jargonelle pear, but is shorter and is diversified with rough scales. The crown is flat, and, when ripe, assumes a beautiful scarlet colour, while all the rest of the fruit remains green. The seeds in size and appearance resemble coffee beans, and are immersed in an orange-coloured pulp; the soft pulpy matter was washed away, and the seeds were put to dry. I was disappointed on observing that some of the seeds had already begun to germinate; this, indeed, was to be expected, for they have no hard covering, and when ripe are nearly as easy to bruise as green peas. In fact it seems natural for these seeds enveloped in a soft juicy mass to begin to grow whenever the fruit falls to the ground, or even sooner. I now resolved to go on to Gatun without delay, and dispatch the seeds as early as possible from Panama. On the 5th the seeds, amounting to upwards of 7000, were kindly forwarded by Captain Mallet, H. M.'s Consul at Panama.

"*Return to the Forest for Indiarubber Plants.*—I now made arrangements for bringing home some plants. On my return to Gatun the rains came on with increased violence, and the river was greatly swollen; yet, even with the unfavourable weather a collection of plants was got together from various localities around La Providencia. Although found growing in varied aspects the plants were not met with very plentifully, but in one locality upwards of 100 plants were found growing under a good sized tree; the seeds had fallen on a bed of decaying leaves and germinated in great numbers, so thickly indeed that many of the plants had smothered each other. In all 600 plants were collected, but a good number were bruised while being carried through the forest, or during the journey to Gatun. A quantity of the milk of the tree was also secured.

"I next turned my attention to the plants, and dressed them very carefully. These were young saplings cut down, and the tap-roots, which were often of great length, were also much shortened. The roots were packed in three boxes with dry leaves, a process which facilitated transport but demanded an extraordinary amount of attention. Shortly after my first arrival I collected a few plants, which, with some stout pieces of the stems of saplings cut into lengths, I planted to experiment with. The greater number prospered wonderfully, and some natives were surprised at the quickness of the result. I put the most advanced of these plants into a small box, and although some lost a few leaves, yet I brought the best portion home alive. Thus I saved sufficient plants from this little collection for the formation of stock for the plantations in India.

"*Method of Collecting Rubber practised by the natives on the Isthmus of Darien and other places.*—One of the oldest rubber collectors of the district where the plants were procured assured me that at first they sometimes met with a tree at which three or four axemen could go to work at once to cut down. Such a tree would probably be about 8 feet in diameter, 200 feet in height, and yield at least 150 lb. of indiarubber. In general full grown trees do not much exceed 160 to 180 feet, with a diameter of 5 feet, and a produce of 100 lb. of rubber. The bark of the trunk is thicker than that of most trees of the same dimensions; the wood is spongy and soft, and decays rapidly wherever injured. The slender branchlets that crown the trunk terminate with four or five large leaves alternately arranged and thickly covered with short brown hairs. Many of the leaves measure 14 inches in length and 7 inches in breadth, and exceed in size those of any other tree of tropical America. According to the natives, the leaves fall off the trees in January, after which they begin to flower. In April the new leaves push, and attain their full size in May; but I was assured that young plants and saplings retained their leaves throughout the year. The milk-like juice of the tree, which, when congealed, forms indiarubber, is obtained by cutting out a groove or ring of bark around the base of the trunk; the milk exudes from the bark into the channel thus formed, and large leaves are placed so as to receive it as it trickles down. The tree is then felled, and rings or channels are cut out around the prostrate trunk, at about 12 or 14 inches apart. Beneath these leaves the vessels are placed into which the milk flows. The contents of all the vessels are afterwards put in a hole previously dug in the ground. The milk left in this way becomes curdled in about two weeks. In the Republic of Ecuador most collectors use the soft green stem of a climber—a species of *Ipomœa*—which when bruised and stirred about in the milk congeals it in a few minutes. By this last process the milk takes up all the watery particles it may contain, and the produce seemed to be of an inferior kind, possessing a strong peculiar smell, and continually sweating a black, ink-like water. Soap is resorted to by some collectors, and also wood ashes which contain potash. Collins mentions that alum is used in Brazil, and salt in the East. It seems to me that whatever method is adopted the rubber ought to be prepared rapidly, and to be perfectly dry and free from impurities. Powerful presses might no doubt expel the moisture, but I should expect that the goodness of the article would by this operation be depreciated. My own opinion is that the quality of the milk-like rubber juice obtained from various species of plants—some of which are climbers and shrubs, while others become large trees —is at first exactly the same, and that the difference in value of various parcels is explained by a different mode of preparation. The collectors, indeed, always aim to keep it as wet as possible, as it is bought by weight. At Nicaragua, and some other places of Central America, the trees are not usually felled; the practice is to cut winding channels in the bark leading to the base of the trunk, where the milk is collected. But I was informed by an intelligent person from that region that this operation is so rudely and carelessly performed that a tree invariably dies after it has been bled or tapped a second or third time. This would never take place if the thin filmy lining of the inner bark (cambium) which covers the wood was not bruised or injured.* Not only do the natives cut through the cambium, but they also make large notches in the living wood of the tree, and these under no possible class of circumstances or conditions can ever be healed. In collecting the milk the cambium need not be hurt, as the vessels which contain it really occur in the middle of the bark; such, at least, is the case with the Darien rubber tree. The employment of any simple implement so formed as to make a groove in the bark to about one-half its thickness is all that is required. Such an operation would require to be directed by an intelligent, careful person, who thoroughly understood how much success depends on the proper performance of the work. In this way not one single tree in a thousand would be lost, and the trees might, in my opinion, be operated on annually, instead of once in three years, which I have been informed is the practice at Nicaragua.

"*Climatic Conditions of the Indiarubber Regions.*—The temperature of the forest in the interior of the Isthmus ranged from 75° to 88° Fahrenheit. Frequently I have observed the thermometer standing 80° at eleven o'clock at night, and the same on various occasions at one or two o'clock in the morning. When there occurred a shower of rain accompanied by a north wind the thermometer went down to 74° for one or two hours; but this was the lowest point to which it fell. I have not been able to ascertain to what altitude the tree grows, as no high hills exist on the Isthmus, but I am pretty confident, from observations made while travelling on the Pacific coast, that it ascends at most to an elevation of about 1500 feet. At this height the lowest temperature experienced at any time throughout the year would be 62° or 60° Fahrenheit. As regards moisture, I happen to have lived and travelled in various rubber districts, where the rainfall varied considerably. On the Pacific coast the tree grows near the Gulf of Guayaquil, on flat or gently sloping land, in deep deposits of a very sandy loam. The vegetation is moistened by humid fogs, but showers of rain very rarely occur. On the whole the atmosphere is unusually dry.

"At Esmeraldas the soil is a heavy loam or clay. There are about five months of dry or summer weather, and the remaining months are rainy.

"In the neighbourhood of Buenaventura the tree is found dispersed over a broken and dislocated region of narrow ridges of nearly naked conglomerate, with steep shelving ravines more than 1000 feet in depth. Where there is soil it is loam or a kind of clay, or made up of vast heaps of decomposing *débris*. The rains here are almost unceasing, day and night, throughout the year. This part of the coast, and on as far as the river San Juan, has been considered by intelligent travellers as the most unhealthy tract of country in the world.

"The region proper of the Isthmus of Darien lying farther northward, and including Portobello, Colon, Chagres, and Panama, is very wet, with an excessively damp atmosphere, although the weather is generally better, with some sunshine, during the months of January, February, March, and April. The deposit of the low flat hills is more or less of a clay character, but along the banks of streams or rivers the deposit is mostly of rich but deep sandy loam.

"Many of the localities bordering on the Magdalena possess deep beds of sand and loam resting on a stratum of yellow gravel. The climate is often parched and dry. Rain falls in May, June, July, and August.

"It will thus be seen that this rubber-producing tree is subjected to a variety of climatic conditions, which might have been expected from the wide extent of country over which the species extends. These circumstances appear to me to present a favourable prospect for its successful cultivation in India.

"*Growth of the Plants.*—On arriving at Kew (early in October, after experiencing shipwreck in the West Indies) with the plants, I had every facility afforded me by Mr. Smith, the Curator of the Botanic Gardens, for getting them re-established. On being sorted out I found fully one-half had been injured or dried up; the remaining plants were put in a proper place to make growths, but these at first pushed very slowly, as the season at which

* Experience with *Ficus elastica* has raised serious suspicions with us that the trees will die if tapped repeatedly, whether the operation is performed carelessly or not.—ED. *Indian Forester*.

they arrived is the worst in the year for the development of most kinds of tropical plants. At this time also the temperature in the warmest hothouse in Great Britain is generally 10° or 15° below the natural heat in the forests of the Isthmus of Darien. Besides this there is a diminished amount of light, which is an item of importance. On the whole, everything considered, I have thought myself extremely fortunate."

LIEBIG—HIS LIFE AND WORK.

The following interesting notice of the life and works of the great German chemist is taken from the address of the President at the annual meeting of the Royal Society:—

Justus Liebig was born at Darmstadt on the 13th of May, 1803. He went to school at the Gymnasium of that town. His father was a dealer in drugs and colours. Experiments in the production of colours and chemical products undertaken by his father early excited in the youthful Liebig a fondness for chemistry, which was further developed by the study of the chemical works in the Darmstadt Library. It is stated that in the fourteenth year of his age there was not a volume of a chemical journal in this large library that he had not read through, and that there was no chemical experiment which he had not repeated when his means permitted. The ease with which he obtained all that was requisite for experimenting procured for him early great dexterity in the art of analysis.

His was one of those fortunate natures which early becomes conscious of its power, and he soon made up his mind to be a chemist. His father yielded to his wish to devote himself wholly to chemistry; and Liebig took the only means then available of cultivating the science and placed himself under the tuition of a druggist at Heppenheim. He remained there, however, for only ten months. His taste for analysis found there no scope, and at last an explosion of fulminating silver in the house of his master suddenly terminated his pharmaceutic career. He then returned to Darmstadt, where he passed half a year in further study. At the age of eighteen we find him at the University of Bonn, and he afterwards studied at Erlangen, where he took a degree, and where he published his first chemical paper in 1822.

This paper first appeared in Büchner's 'Repertorium für die Pharmacie,' Band xii., under the title "Ueber die Bereitung und Zusammensetzung des Brugnatellischen und Howard'schen Knallsilbers, von Herrn Liebig, der Chemie Beflissenen aus Darmstadt." Professor Kastner accompanies this paper with the following notice:—"The readers must receive with indulgence this first attempt of a young chemist. The author has already studied chemistry zealously in Bonn, and has pursued his studies here in Erlangen in the same spirit."

Liebig had felt while at Erlangen the necessity of going to Paris to complete his education; and he was fortunate enough to obtain from the Grand Duke of Darmstadt a travelling stipend for that object. In 1823 we find him in Paris. It was his earnest wish to be admitted to Gay-Lussac's Laboratory; this, however, could not be as Gay-Lussac at that time admitted no young people. He succeeded, however, in entering Thénard's Laboratory, and there he resumed his investigation of fulminating silver.

This research brought him to the meeting of the French Academy of Sciences, in July, 1823, which was to form an era in Liebig's life. He read a paper "On an Analytical Examination of Howard's Fulminating Silver and Mercury Compounds." At the conclusion of the meeting, as he was engaged in packing up his preparations, a Member of the Academy came forward and entered into conversation with him. With the most captivating friendliness the stranger made inquiries about Liebig's studies and other occupations and plans, and invited him to dinner at the Palais Royal. They separated without Liebig having had courage to inquire who the stranger was. It was Alexander von Humboldt, who had returned to Paris the day before from Italy after a long absence. Humboldt now recommended his young countryman, who had so quickly and completely won his heart, to his friend Gay-Lussac, for Humboldt knew too well from his own experience the value of working under Gay-Lussac.

The time which Liebig spent with Gay-Lussac is indisputably the most interesting part of his student life. We may imagine the pleasure these two men must have had in their intercourse; the one 45 years of age and at the summit of his fame, the other scarce 20 years old, but full of promise of future greatness. It is related by Liebig that when they had accomplished some difficult work, such, for instance, as satisfactorily finishing a difficult analysis, Gay-Lussac would often take him by the hand and the two would dance together around the laboratory table.

The result of Liebig's study under Gay-Lussac was that the latter recommended the youth so strongly to the Grand Duke Ludwig, that the Grand Duke on his own responsibility appointed him Professor Extraordinary of Chemistry at the University of Giessen. It will easily be understood that Liebig was regarded with jealousy by the majority of his elder colleagues, and found but little support and sympathy in his endeavours for the reform of chemical instruction.

Liebig, however, was able to overcome all obstacles. Two years afterwards he was promoted to the Professorship of Chemistry. He made every arrangement within his power, even at his own personal expense and risk, for his own and his students' work. His reputation rapidly increased; and when it had at last spread to such an extent that young chemists came from all parts of Europe to work under him, the State at length resolved to build him a large chemical laboratory outside of Giessen.

Liebig's scientific activity may be divided into two periods, the first from 1824 to about 1829, which was specially devoted to pure chemistry, and the second from 1840, when his labours in the department of applied chemistry began to be prominent.

There is scarcely a branch of chemistry into which Liebig's activity did not extend. Perhaps no other chemist excepting Berzelius had accomplished so many difficult ivestigations. The 'Annalen der Chemie und Pharmacie,' which he edited conjointly with others, contain more than 200 papers on various branches of pure and applied chemistry.

Great as were Liebig's service in all branches of the science, that of organic chemistry is chiefly indebted to him, and he is accordingly called the founder of organic chemistry. There may be a difference of opinion as to how far its foundation was already laid, but it cannot be denied that Liebig contributed more than any other chemist of his time to the edifice.

The so-called organic substances originating in plants and animals, had, at the period when Liebig entered on his scientific career, been already the subject of many chemical researches, and it was already known that all, unlimited as they are in number, contained carbon combined with hydrogen, and sometimes oxygen or nitrogen in regular proportions; but just as it was supposed that they owed their origin to other than chemical forces, it was imagined that their relation to each other was something quite different from that subsisting between inorganic mineral substances.

But Liebig soon came to the distinct conviction that even if there were a generic difference between organic and inorganic substances, no chemical difference could be assumed. He was convinced that there could be only one chemistry, and took upon himself the task of effecting a scientific connection between the two branches. His investigation of fulminic acid had already carried him in this direction. He and Gay-Lussac had found it to be a compound of carbon, nitrogen, and oxygen, and he then discovered the corresponding compound of cyanogen with sulphur, and investigated melam and its other products of decompostion.

After Graham had established the tribasic character of the common phosphates, Liebig showed that some organic salts had a similar constitution. But peculiar difficulty was presented by the constitution of certain neutral organic substances, such as alcohol, ether, essential oils, etc. Liebig endeavoured to get a key to their constitution by investigating the action of simple materials upon them, such as chlorine and bromine, etc., and often led his students into this line of work.

In this way a great number of the most remarkable substances were discovered, some of which in future years were of practical use, though the object of the investigator was purely scientific. Thus Liebig discovered chloral long before Liebreich discovered its medicinal qualities.

These labours of Liebig appeared at first to the masses as a useless toying with chemistry, and were often laughed at. To this the very unusual names selected may possibly have contributed: as an instance we may mention the following:—When he found out the composition of a to him most important compound, which he looked upon as alcohol which had parted with some of its hydrogen, he named the new substance aldehyde, an abbreviation of alcohol dehydrogenisatus. This strangely sounding word excited the astonishment or even the derision of those who had been accustomed to hear new mineral substances named either after the places where they had been discovered or after their inventors, or after distinguished or influential persons, or to hear people speak of Scheele's and Schweinfurt green or Berlin blue.

For Liebig the chief difference between organic and inorganic substances was that the former contain compound radicals, whereas the latter are similarly built up of elements. A joint research of Liebig and Wöhler on the subject of compound radicals was fruitful of important results. They examined oil of bitter almonds and benzoic acid, and discovered the radical benzoyl, a group of three elements, which was capable of combining like an element with chlorine, hydrogen, etc.

Berzelius was greatly interested in this discovery, and declared that it was the dawn of a new day in vegetable chemistry. He went so far as to say that he would like to see the first radical discovered, which consisted of more than two simple substances, named Proin and Orthrin.

No man is infallible; and Liebig, of course, made occasional mistakes. It is said by Dr. Pettenkofer that if he thought a substance was this or that, or contained some particular body, he would frequently ask a student in whom he had confidence to examine the substance. If the student failed to find at once what Liebig expected his confidence in the skill of the student always fell much more quickly than his confidence in the justice of his original idea. He would even naïvely say, "But you must find it." If the student still failed to find it he would sink still lower in Liebig's opinion, but would be sure to raise himself again if he took an independent tone and gave indisputable proofs that Liebig's idea was erroneous, and suggested a better explanation of the phenomena. Of course it was natural that this habit of adherence to an idea once taken up increased on Liebig with years.

But what furthered Liebig's progress so much alongside with his unusual mental gifts and quickness of comprehension was his methodical way of working. He saved himself and others an immense amount of time in research by adopting good methods.

Liebig had learnt elementary analysis with Thénard and Gay-Lussac; but when he set to work with such intensity at Giessen to determine the carbon, hydrogen, and nitrogen of organic bodies, it must have been most annoying to him to require so much time and apparatus. Just as he had in his early years at Erlangen made up his mind that he must go to Paris to complete his education, so he now saw that he must contrive a simpler method of elementary analysis if organic chemistry was to be developed. This important task occupied him for some years, but he accomplished it at last. By degrees he got the apparatus into such a simple and sure form that it surpassed in quickness and accuracy the ordinary methods of mineral analysis. This being accomplished, the questions about the quantitative composition of organic bodies could now be easily answered.

The five-bulb apparatus which Liebig contrived to make out of glass tubing enabled him to absorb with facility and accuracy the carbonic acid formed by the combustion of organic bodies. It has become an emblem of the Giessen school. Probably the most important service rendered by Liebig to science was the establishment of the Giessen School of Chemistry. He had experienced in his own person the difficulty of getting a training in the higher branches of the science from the lack of chemical schools. This difficulty had at length been overcome in his case; but only his individual wants were thus satisfied by his accidental meeting with A. von Humboldt, by whose means he was admitted to Gay-Lussac's laboratory. What he had obtained by a happy accident he made accessible to all in Germany. The founding of the chemical laboratory in Giessen, for purposes of public and practical instruction, was quite an epoch in the history of science. What unexampled activity reigned in those chemical halls! There met and worked from morning to evening the future professor of chemistry, the future manufacturer. All the dialects of Germany might be heard there—nay, every European language, and in one hall, somewhat predominating, the English language—all mixing and yet in order, for every one felt that he was striving for a noble object—he was serving science; in other words he was a pupil of Liebig. And how inspiriting was this meeting together of earnest youths under such a master! Many a noble and lifelong friendship was founded by community of work and aims. And Liebig had mostly a bit of good advice or a happy thought, which helped one who had got into either a scientific or an experimental difficulty, and which would float him again in the right direction.

All who know what this school of Liebig on the Lahn was, and what other opportunities there existed for chemical study, will easily comprehend that there was a time when any one who had a longing for thorough chemical study felt an irresistible call to Giessen. Liebig is much to be applauded and admired in that he knew so clearly the kind of school he must make in order to effect real good. Others before him had felt that chemical students ought to do practical work in the laboratory; but they had not the support of public opinion, or of the governing bodies of educational institutions, and were not strong enough to break through the hindrances around them. It is even told that when one professor at a small university attempted to have a little practical school of chemistry his colleagues regarded it as a useless squandering of reagents and coals; and the few students who went to this class were quite pitied by the rest for their credulity in fancying the professor would be so foolish as to show them the right operations and make them professors too.

From the very first Liebig went on the principle of teaching his pupils chemistry without any reference to special applications, and of putting them in possession of the knowledge which they were afterwards to apply. The application he left to themselves. Just then many so-called technical schools were being founded where it was intended that only such parts of natural science should be taught as were useful for some branch of industry. In such a school the future brewer should study malt and hops, the dyer colours, the agriculturist soils and manures, and so on, but not be burdened with subjects of which the pupil in his future career was not likely to make any practical application. Liebig stedfastly opposed this unintelligent utilitarianism.

People in great technical businesses soon began to see how perfectly in the right Liebig was in this idea; and he was constantly applied to, not merely for chemical teachers, but even for chemists; and not merely for chemists to assist in chemical works and soda manufactories, but for paper manufactories, colour works, breweries, etc.

In this way not merely eminent investigators and teachers came forth from Liebig's school, but many very distinguished practical men. Two other subjects yet remain to be mentioned to complete the picture of Liebig's scientific activity—'The Annals of Chemistry and Pharmacy,' and his 'Letters on Chemistry.'

Before Liebig's time there was no periodical which was exclusively devoted to chemistry. Chemistry was then more nearly connected with pharmacy; and as in the practice of pharmacy the results of chemistry came so closely into application, Liebig's first researches were published in the 'Magazine for Pharmacy,' founded by the apothecary Hänle, and afterwards continued by the apothecary Geiger, in Heidelberg.

In the year 1832 Liebig founded, in conjunction with Geiger, the 'Annalen der Pharmacie,' which now became entirely his organ. With the publication of the 33rd volume, Wöhler became one of the editors, and the title was changed to 'Annalen der Chemie und Pharmacie,' in order, as Liebig said, to bring the title and the contents more into unison. Later on, Kopp, and still later, Erlenmeyer and Volhard, all pupils of Liebig, joined in the editing.

The 'Chemical Letters,' as is well known, originated in a series of essays published in the *Augsburg Gazette*. These letters were remarkable specimens of exact science popularized for educated people.

Liebig's active mind led him to an earnest consideration of the chemical processes involved in agriculture and physiology. Having paid more attention to the study of organic bodies than any other chemist, he naturally felt a desire to consider these substances in connection with their functions, and the circumstances under which they were developed. How fruitful his labours were in this direction is already well known.

What is called Liebig's agricultural chemistry was developed in two periods. The first period from 1840 to 1846 in Giessen, and the second from 1856 to 1862 in Munich, whither he migrated in 1852. His views on vegetable and animal physiology were first expounded in a work which was published by Vieweg, in Brunswick, in 1840, with the title 'Die Chemie in ihrer Anwendung auf Agricultur und Physiologie.'

This book originated in the following manner:—The British Association for the Advancement of Science, at its Liverpool meeting in 1837, requested Liebig to publish a report of the present state of knowledge in the department of organic chemistry. He expressed his willingness to do so, but proposed that Dumas should share the task with him. Dumas seemed disinclined, and Liebig brought out his 'Agricultural Chemistry.' The result of its publication was astonishing. It went through no less than six important editions in six consecutive years, and excited an immense amount of interest. The stir made by this book was so great that Dumas, as the first chemical authority in France, felt it necessary one year later to publish a somewhat similar work in the French language, and formally to claim for France on this occasion the main principles enunciated in Liebig's work—'Elles appartiennent à notre école dont l'esprit est venu s'exercer sur ce terrain nouveau.'

Many of Liebig's countrymen expressed strong dissent from his views; and Berzelius at first expressed himself as very doubtful about them, and after some years got into actual hostility with Liebig about this application of chemistry, which he called 'Probabilitäts-Theorien.' In his 'Jahresbericht,' of 1841, Berzelius said that Liebig's book was executed with all the talent which one would expect of so distinguished an author, but he does not conceal his opinion that Liebig had erected an edifice which was but too insecure. He said that Boussingault was working in the same field as Liebig, but was taking the long and difficult road, answering every inquiry by one or more experiments, that he did not give his answers so quickly, but they might be relied on.

This partly cautious, partly dissentient, and partly actually hostile attitude of the agriculturists, physiologists, and chemists seemed only to tune to a louder key the enthusiasm and applause of the general public; but this was probably no satisfaction to Liebig, for all of the applauding crowd who besides his own pupils surrounded him, not one was able to bring Berzelius over to different views, to weaken the experiments of Braconnot, and the objections of Boussingault, or to convince the sceptical agriculturists and controversial physiologists.

Then, perhaps, for the first time in his life, Liebig may have oft felt right lonely, despite the homage of the masses; for even his best friends and scholars saw too well that Liebig in his high flight (this book) had often maintained more than he had proved, that the proof was in many points still wanting.

At no time did Liebig profess to be the first who had made chemical experiments in agriculture. In fact, in the dedication of this book to Alexander von Humboldt he says, "I hardly know whether even a part of the little work which I make bold to dedicate to you is my own."

What, then, was it which caused so much excitement? It was the idea which Liebig brought so prominently forward, that plants alone are capable of assimilating inorganic materials, such as carbonic acid, water, and ammonia, and of building up complex substances such as albumen, starch, and fat, etc.; while animals live upon these complex products and reduce them to simpler ones.

Liebig undertook the determination of the ashes in several parts of many varieties of plants and from different localities. He cared little for analyses of soils hitherto considered so important, especially how much humus an earth contained, but he wanted specially to know what each plant did with the earth on which it grew.

It soon appeared that all plants leave qualitatively the same mineral constituents in their ashes, but that every kind of plant, so to say, yields its own peculiar ash, inasmuch as different kinds, even when growing on the same soil, take up its mineral constituents in very different proportions. It was soon found that wheat, rye, barley, etc., have their distinct ashes, also the grains of a corn compared to the corresponding straws.

As it was not enough to know the ashes of a particular plant grown in a particular region, but was desirable to get them from as many different plants, fields, and regions as possible, so Liebig procured ashes from all possible localities. Just as a merchant writes letters of business to all parts, so Liebig sent about letters everywhere for analyses of ashes.

In order to make the work of analysis as easy as possible, his pupils Will and Fresenius had worked out and published an excellent method of ash-analysis; and in a short time thousands of analyses were made of the most different plants and parts of plants in very different localities. He found that each plant takes an exact quantity of mineral matter and in an exact proportion, which may be recovered again from its ashes; and he concluded that whatever else the plant requires for the formation of its combustible constituents is derived from the carbonic acid, water, and ammonia of theair. From these views Liebig laid down the rule that to keep a wheat or corn-field fertile one has only to return to it the mineral constituents which have been taken out by the crops, and in the proportions in which those minerals are present in the ashes of each crop.

Liebig induced the distinguished alkali manufacturer Muspratt, in Liverpool, to prepare mineral manures for wheat, rye, oats, clover, potato, and other fields. The different manures were manufactured according to a method invented by Liebig, which consisted in melting together the necessary substances, so that salts easily soluble in water were brought into an almost insoluble form that the rain might not carry them off out of reach of the germinating seed. Liebig was as much convinced of the soundness of his mineral theories as of the working power of his mineral manure. But matters turned out differently from what he anticipated, and a heavy trial was in store for his great genius.

The English agriculturists saw no result from his artificial manure, ceased to buy it, and again had recourse to dung and other substances, and the factory in Liverpool ceased to work. Nay, even Liebig was himself convinced by his unsuccessful experiments in agriculture in Giessen that his mineral manure could not make a barren soil more fertile. One single ray of hope came to cheer him after years of failure. It turned out that after a length of time those fields when no longer manured at length became more fertile. But here again was a new riddle for him.

Meanwhile adversaries rose up, not merely to expose the uselessness of his manure, but also to show that new methods must be adopted in order to reach a practical end.

In the foreground stood an English agriculturist, Lawes, who soon joined with an excellent chemist, Gilbert, and made on one of his estates experiments with all sorts of manures, which they manufactured and tried in many different ways. It was shown that the more soluble a substance is, the more effect it has; that the yield of a field is often increased merely by the addition of bone-ash rendered soluble by sulphuric acid (so-called superphosphate); but that above all ammonia and ammoniacal salts, or, as they at last boldly stated it, combined nitrogen must be added to the fields in order to secure good crops; and for a while the value of a manure was simply estimated by the amount of nitrogen it contained, whereas Liebig's theory had pointed out the atmosphere as a sufficient source of supply of ammonia.

Liebig's adversaries were at this time banded together under the application of Nitrogenists (*Stickstöffler*). They thought they had driven Liebig for ever from the field.

In spite of all Liebig remained true to his theory and would not yield. He controverted the conclusions of Lawes and Gilbert, but without success. The President of the English Agricultural Society, Pusey, ranged himself distinctly on the side of Lawes and Gilbert. As the masses only judge by results, the sale of the book 'Chemie in ihrer An wendung auf Agricultur und Physiologie,' which at first could not be printed fast enough, became smaller and smaller, and after 1846 no new edition appeared.

In his latest writings on the subject of the mineral theory Liebig acknowledged that ammonia may with advantage be supplied to cereal and some other crops in the manure: but contended at the same time that it was naturally included among "mineral substances" which he had originally referred to. As, however, he had clearly explained that the ashes of a plant contain the mineral substances which ought to be added to the soil for the growth of such plant, the statement that ammonia is really a mineral compound, and ought to be included in his rule regarding mineral substances, really conceded in substance the argument of his opponents.

Since the year 1845 Liebig had paid more and more attention to the second part of the task which he had set himself in 1840, the application of chemistry to animal physiology, and was in full work at this time when King Maximilian II. entered into a correspondence with him with the view of calling him to Munich. Liebig had in the course of his distinguished career declined so many calls (shortly before this one a brilliant call to Heidelberg), that they had little hope of persuading the eminent man to come to Munich, but they induced him nevertheless. To his honour be it said he did not in the least render the task more difficult by great pretentions, merely stipulating that he should not be required to conduct so large a laboratory as he had done at Giessen, so that he might have more time for his own work. His migration took place in the autumn of 1852, when in his 49th year.

After some time he resumed at Munich his agricultural experiments, and at last found out why his mineral manure had not the desired effect, and why dung and even mere ammoniacal salts alone had so great an effect.

In the year 1862 appeared his great work, in two volumes, 'Der chemische Process der Ernährung der Vegetabilien und die Naturgesetze des Feldbaues.' This was the crowning work of Liebig's agricultural labours, and his doctrine is now universally recognized; and no thoughtful agriculturist ever now supposes that he need but add superphosphate or nitrogen or guano and his fields will be for ever fertile. It is now in agriculture but a question of the best appliances necessary to do justice to the theory of Liebig. In Germany agriculturists have thankfully acknowledged this by the foundation of the Liebig Stiftung.

In close connection with the subject of nutrition is Liebig's work on flesh, which first gave us a more exact idea of the chemical composition of muscle, that is by far the greatest and most massive part of our bodily organs. One result of this work is the Liebig Meat Extract, now well known in the whole world, of which so much has been said, and whose value has been as often over- as underrated.

Liebig spent the remainder of his life at Munich, where he died on the 10th of April, 1873.

THE OIL OF ELÆOCOCCA AND ITS SOLID MODIFICATION PRODUCED BY THE ACTION OF LIGHT.*

BY S. CLOEZ.

The action of the more refrangible rays of light causes the neutral liquid oil of *Elæococca* to solidify into a buttery substance, the melting point of which is 32° higher than that of the oil. When saponified with potash, and acidified with phosphoric acid, this fat decomposes into glycerin, and a mixture of two acids, one solid and the other liquid; they were separated by pressure between bibulous paper. The solid acid was purified by crystallization from alcohol, and combined successively with potassium, barium, lead and silver. Instead of acidifying with phosphoric acid, the solution of the potassium salt of the new solid acid, which the author names *margarolic acid*, may be cooled; the potassium salt crystallizes out in a nearly pure state, and may be completely purified by recrystallization from alcohol of 0·85 specific gravity. The acid may be prepared from potassium margarolate by addition of phosphoric acid. Margarolic acid crystallizes in rhomboidal plates; it melts at 48°, is insoluble in water, soluble in ether, carbon disulphide, liquid hydrocarbons, and aqueous alcohol; it rapidly absorbs oxygen, and is converted into a soft transparent body, which gradually becomes hard and assumes a resinous appearance. The acid gains 8·5 per cent. in weight on exposure to air for a fortnight. It may be kept without alteration in a sealed tube, or under water.

The analysis of the acid and of its salts led to the formula $C_{17}H_{30}O_3$ for the acid, and $C_{17}H_{29}O_3R$ for the salts.

On addition of water to the potash salt, an acid margarolate crystallizes in small nacreous scales.

The liquid acid separated from margarolic acid by pressure, is purified by formation of the calcium salt, which is treated with ether, and the portion which has dissolved is decomposed with hydrochloric acid. The author gives it the name *elæolic acid*. Lead oleate is soluble in ether, whereas lead margarolate dissolves. These acids appear to indicate two glycerin ethers in the elæococca, viz., *elæolin* and *margarolin*.

The solid product formed by the action of light gives, when saponified, a mixture of fatty acids, from which one melting at 72° was separated, containing less oxygen than margarolic acid. The author names it stearolic acid.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 2, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

EXCISE PROSECUTION OF CHEMISTS.

THE recent prosecution of chemists and druggists in Glasgow for selling wine without a licence forcibly illustrates the necessity of exercising some caution in regard to the articles sold in pharmaceutical establishments. In addition to the Food and Drugs Act, which requires the retailers of drugs to satisfy themselves as to the purity of their wares, the various excise regulations affecting the sale of alcoholic liquids bear very closely upon certain features of the retail drug trade, and are capable of being so interpreted as to cause considerable trouble and inconvenience.

Most of our readers will remember that in the Hull morning tonic case the excise authorities manifested some readiness to contest the question whether the sale of a mixture consisting chiefly of tincture of gentian and tincture of cardamoms was a legitimate part of the chemist and druggist's trade, or a specious infringement of the law relating to the sale of spirituous liquors as beverages.

On that occasion, however, the scientific advisers of the excise were not particularly successful in the support they gave to the prosecution, and the outcome of the case was not satisfactory to either party, inasmuch as it left the entire question at issue undecided.

The vigilance of the excise officials is now directed into a different channel, and the sale of an article designated LIEBIG'S Liquid Extract of Meat has been selected as constituting a breach of the law relating to the sale of alcoholic beverages. This preparation has already appeared in court, and a report of the circumstances under which it did so was published in this Journal last October twelvemonth. According to the account then given of it by the Borough Analyst of Bradford it is a concoction of Tarragona wine, sweetened with sugar, flavoured with pimento or allspice, and containing only a very small portion of extract of beef, but about 15 per cent. of pure alcohol. Consequently the seller of this preparation was prosecuted under the Sale of Food and Drugs Act for selling an article which was different from what it was described to be by the vendor, who represented that it was composed chiefly of pure extract of beef, together with wine and a small quantity of fine old brandy and quinine. This representation was contradicted by the Bradford Borough Analyst, who declared that the preparation in question contained only a trace of extract of beef, no quinine and no brandy.

The defence in this case was merely the plea of ignorance of the composition or character of the article sold, and a disclaimer of any intention to mislead; but although this view of the case might not unreasonably have been accepted by the magistrates, they formed a different opinion, and fined the defendant forty shillings and fifty shillings expenses, or in default one month's imprisonment, and refused to grant a case for appeal.

We have stated thus much of the details of this case chiefly in order to make known what was the nature of the preparation it referred to; there was, however, another point put forward which bears upon the more recent case at Glasgow—viz., the opinion of the Bradford public analyst that the use of this preparation appeared to him to be merely "a sly way of drinking." This does not seem very consistent with the account given of the composition of the article, but it has been adopted by the excise officials, and it is upon this ground that the prosecutions have been instituted at Glasgow.

It must no doubt be admitted that there are persons whose appetite for alcoholic stimulants is sufficiently strong to induce them to have recourse to the drinking of articles which the majority of mankind would regard merely as physic to be taken under compulsion and as being far too unpalatable for purposes of indulgence. At the same time circumstances may exist which will so far counterbalance the distastefulness of such preparations as to lead to their being used as beverages. This however is only exceptional, and it seems an unfair proceeding to make the vendors of such preparations amenable for the misuse to which they may be put by persons who purchase them. We have known cases where nominal teetotallers have been in the habit of consuming, under medical advice, large quantities of pharmacopœia tinctures and there was no doubt that they did so to supply the place of an abandoned habit of drinking ordinary alcoholic liquors.

Without going into the question of the propriety of such a proceeding we cannot fail to perceive on what ground a chemist should be made the sufferer for it. The sale of medicated tinctures is not subjected to the excise regulations applying to the sale of ordinary alcoholic beverages, and it is a great hardship on the chemist and druggist to be placed in the position of a wilful offender when these preparations are used in such a way as we have mentioned. At any rate if restrictions are to be placed upon the sale of medicinal alcoholic preparations such as tinctures, it should not be done in an arbitrary way according to the caprice or officiousness of some particular excise officer but should apply alike to all persons similarly engaged in the trade.

In America this has been done, druggists being there required to take out licences for the sale of alcoholic drinks, and being in this respect placed on a level with the publican. We are far from admitting that this course is justifiable though we must confess it is at least rational, if druggists are to be made accountable for the misuse of medicinal preparations by those who purchase them.

Moreover the Liquid Extract of Meat to which the Glasgow prosecution relates was avowedly sold as a medicinal preparation, whatever may have been its value in this respect, and if its sale was in any way a contravention of the law we take it that the ends of justice would have been more logically served if the makers had been prosecuted for selling it without the patent medicine licence.

In any case this prosecution affords support to the suggestion we have thrown out that chemists and druggists will do well to consider how far their interests may be compromised by selling articles of this description, and we venture to think it would be better to refrain from selling them than to incur the risk of prosecution.

Before leaving the subject it will be as well to mention for the information of those who may have been misled by the newspaper reports of this case, that the Liquid Extract of Meat is a totally distinct thing from LIEBIG's Extract. We have received several letters on this point which show that considerable alarm exists among chemists and druggists lest they should be pounced upon by excise officers for selling LIEBIG's Extract of Meat, and therefore we take this opportunity of stating that the apprehension is groundless.

THE CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

SOME objection is expressed to the doubt we suggested last week as to whether the development of this Association is progressing so rapidly as will be necessary if it is to effect any benefit to the trade. In a letter which appears in our correspondence columns Mr. HUMPAGE controverts to a certain extent the inference that the trade is for the most part indifferent, and he supports his objection to this inference by a statement of his own experience. We admit the force of the facts he mentions as proving that so far as they go there is no apparent ground for suspecting indifference. The Association has reason to be thankful to Mr. HUMPAGE for the good offices by which he has secured the support of fourteen members, and probably if there were in the trade many more like himself, who took a lively interest in the well-being of the body to which they belong, we should have no opportunity for doubting as we have done whether the roll of members of the new Association is growing as it should do.

The letter from a member of the Committee, though no doubt intended to convince us of the error of our views, nevertheless fails to do so, and we venture to believe that it will also fail to convince many of his colleagues on the Committee that the Association can be regarded as a success unless it comprises among its members a large proportion of the 14,000 registered chemists and druggists in the country. The figures which he gives rather confirm than remove the doubts we have expressed. It may be that the result of the Glasgow meeting will be to bring a very large accession of members, but until that result is realized we shall be under the necessity of preferring our own estimate of the situation to that of the "Member of the Committee."

But, whatever be the result of the attempt to form this trade association we cordially concur with the opinion expressed in the concluding sentence of Mr. HUMPAGE's letter that there need not, and should not, be any antagonism between existing societies and the one recently started, since there are ample fields for both to exercise their influence in the particular directions they are intended to work. We believe that the Committee of the new Association possesses such a preponderance of wise men as will fully ensure the observance of this principle.

MEDICAL SHOPKEEPING IN TORONTO.

THE druggists of Toronto rejoice in a Pharmacy Act that has been of "incalculable advantage," but like all human workmanship, it has its defects. Whilst on the one hand a rigid law prevents the druggist from taking the position of prescriber, on the other the doctors are exempt from the operation of the Pharmacy Act. The consequence is a state of affairs as bad or worse than that which is reported to exist in the West of Scotland.

"Cœlum, non animum, mutant, qui trans mare currunt".

The *Canadian Pharmaceutical Journal* states that unsuccessful candidates who fail to pass the pharmaceutical examinations sometimes "manage to borrow the name of some unscrupulous doctor," and thus evade the spirit of the law. Drug stores are also said to be kept by young doctors and so-called medical men, who are not capable of practising their profession. That accidents occur under such conditions is not surprising, and we quote from our contemporary an account of one that has recently happened.

A man went into the drug store of a certain "Dr. RICHARDSON and Co.," and asked for a dose of salts. The "assistant" in the store said that they were out of that drug, but that the applicant could be supplied with "distilled salts," which would answer the same purpose. An ounce of the "distilled salts" was therefore bought by the man, and a few days after, feeling unwell, he prepared to take a dose. The salts were placed in a tumblerful of water, but this not being sufficient to effect solution, a considerable quantity more water was added and the whole swallowed. Shortly afterwards the victim was seized with a severe attack of vomiting, followed by cramps in the stomach and legs. Medical assistance was called in, but for several days the man hovered between life and death from the effects of the poison he had swallowed, which is supposed to have been oxalic acid.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The opening meeting of the sixteenth session was held at the rooms, Halford Street, on the 10th inst., Mr. Hammond occupying the chair. After the numerous company had partaken of a substantial tea, the President was called upon to deliver the customary inaugural address.

The President (Mr. Baron), in complying, stated that he intended to take as the basis of his remarks—Knowledge, what it is? How it may be acquired? How it should be valued? Walker defines knowledge thus: certain perception, learning, illumination of the mind, etc. This the speaker said was perfectly correct. Yet, if we rest satisfied with nothing higher than this we shall not make any very distinguished mark in life. A savage fulfils all the requirements of this definition, the wants of his animal nature have prompted his mind to the acquirement of a certain amount of learning, impressions have been made on his sensorium by the things outside him, and using the powers of inductive reasoning he has learnt how to defend himself against his foes, has discovered how to chase and capture the game that is necessary for his subsistence, and he may perchance have acquired some knowledge, albeit very crude, of the natural phenomena by which he is surrounded. So far his mind has been illuminated. A certain amount of knowledge we are bound to acquire, we cannot escape from it, we learn it, as it were, automatically. Men stand to some extent on a level in one thing, viz., that the mind is a blank, an entire blank, on entry into this world. But there comes the stage in which, our will becomes the mainspring of our action. When we feel the consciousness of our existence, and that we were made for higher, nobler ends than the mere satisfaction of our animal necessities, and when we feel that we can satisfy those nobler purposes, then we determine that our mind's needs shall be satisfied, that it shall be illuminated, that its perceptive powers shall be awakened and made certain; then we determine that whatever may be the branch or branches of learning we pursue, that we will never rest satisfied with half measures, but that we will push on towards the acquirement of perfection.

As to how knowledge might be obtained? The speaker reminded his hearers that there is "No royal road to learning." No method has been or ever will be invented by human ingenuity, by which we can dispense with trouble and toil in its acquirement. If they wished to reap a rich harvest they must rise early and work late and hard, carefully till the soil, and as carefully sow good seed in that soil. The habit of systematic study once acquired would never desert them, it would become as it were a part and parcel of their nature. We all know the force of habit. We see manifestations of its power for good and evil every day. This tendency to habitual action is so universally recognized as an important part of our physical nature, that man is not unfrequently said to be a bundle of habits. When the habits have been judiciously formed in the first instance, this tendency is a most useful one, often prompting us to do spontaneously what would otherwise require a strong exercise of will. Then a second thought in connection with this subject was the time for study. He considered it extremely desirable that his hearers should work before their brains were jaded. They would make much more satisfactory progress if they studied when their perceptive powers were clearest, consequently they should make an effort to seek knowledge when she can most easily be found, either by rising earlier in the morning, or otherwise, for the sake of the high pleasure that accompanies her possession.

The speaker concluded by asserting that knowledge is to be valued for its own sake, and not merely for the adventitious advantages that might be associated with its acquirement, and he urged his hearers to make the most of the faculties with which they had been endowed.

After a unanimous vote of thanks had been accorded to the President for his instructive address, and responded to by Mr. Baron, songs, readings, and addresses were given by several members of the Association during the remainder of the evening,

Proceedings of Scientific Societies.

ROYAL SOCIETY.

On the Gaseous State of Matter.*

BY PROFESSOR T. ANDREWS, LL.D., F.R.S.,

Vice-President of Queen's College, Belfast.

The following is an abstract:—

"After referring to certain modifications in his former method of working at high pressures, the author describes some preliminary experiments which were undertaken to determine the change of capacity in the capillary bore of the glass tubes under the pressures employed. From these experiments it appears that, on raising the pressure from 5 to 110 atmospheres, the capacity was increased for each atmosphere by only 0·0000036, and that this change of capacity was chiefly due to compression of the internal walls of the glass tube. Another set of experiments was made to ascertain whether air or carbonic acid gas is absorbed at high pressures to any appreciable extent by mercury. For the method of operating and other details reference must be made to the original memoir: but the general result is that no absorption whatever takes place, even at pressures of 50 or 100 atmospheres. The pressures are given according to the indications of the air-manometer in the absence of sufficient data (which the author hopes will be soon supplied) for reducing them to true pressures. In the meantime it is probable, from the experiments of Cailletet, that the indications of the air-manometer are almost exact at 200 atmospheres, and for lower pressures do not in any case deviate more than $\frac{1}{80}$th from the true amount.

In a note which was published last year in the 'Proceedings' of the Society (No. 163), it was stated that the coefficient of expansion (α) for heat *under constant pressure* changes in value both with the pressure and with the temperature. The experiments on this subject are now completed, and are described at length in this paper. The final results will be found in the two following Tables. In the first Table the values of α are referred to a unit volume at 0° and under one atmosphere. In the first column the pressure p in atmospheres is in terms of the air-manometer.

p.	α (0°–7°·5).	α (0–64°).	α (64°–100°).
17·09	.. .	0·005136	0·004747
20·10	0·00607	0·005533	0·004958
22·26	....	0·005811	0·005223
24·81	0·00700	0·006204	0·005435
27·69	0·00782	0·006737	0·005730
31·06	0·00895	0·007429	0·006169
34·49	0·01097	0·008450	0·006574

For higher pressures than 35 atmospheres a different unit volume must be taken, on account of the liquefaction of the carbonic acid. The next Table contains the value of α, *referred to the unit volume at* 64°, between 64° and 100° at constant pressures up to 223 atmospheres.

* From the 'Proceedings of the Royal Society.'

p	α (64°–100°).	p.	α (64°–100°).
17·09	0·003572	46·54	0·004946
20·10	0·003657	54·33	0·005536
22·26	0·003808	64·96	0·006512
24·81	0·003892	81·11	0·008033
27·69	0·004008	106·90	0·013150
31·06	0·004187	145·50	0·018222
34·49	0·004266	223·00	0·008402
40·54	0·004596		

As the value of α changes with the temperatures, the coefficients given above are average coefficients for the ranges of temperature specified. It will be observed that the value of α increases with the pressure until a very high pressure is attained, when it changes its direction and diminishes. This apparent anomaly depends upon the carbonic acid at the high pressure having passed from the gaseous state proper to the intermediate conditions, which the author has formerly described as establishing a continuity between the gaseous and liquid states of matter.

If we designate by α' the coefficient of elastic force when a gas is heated under a constant volume, we shall have in the case of a perfect (ideal) gas

$$\alpha = \alpha'.$$

In the ordinary gaseous state the value of α' diverges widely at high pressures from that of α, as will appear from the two following tables. In the first table the values of α' are referred to a unit pressure at 0°, and p is the initial pressure in atmospheres :—

p.	α′ (0°-6°·5).	α′ (0°-64°).	α′ (64°-100°).
16·42	……	0·004754	0·004607
21·48	0·00537	0·005237	0·004966
25·87	0·00588	0·005728	0·005406
30·37	……	0·006357	0·005861
33·53	0·00734	0·006973	0·006334

In the next table the value of α' between 64° and 100° referred to a unit pressure at 64° is given for a large range of pressure. Both the initial and final pressures are given.

p,	α′ (64°-100°),	p.	α (64°-100°).
21·42, 24·19	0·003526	48·40, 56·16	0·004387
28·65, 32·60	0·003718	67·65, 80·99	0·005392
35·29, 40·44	0·003956	94·27, 118·60	0·007018
42·74, 49·25	0·004166		

As the general result of this investigation it follows that in the ordinary gaseous state the law of Gay-Lussac does not hold good, either in the case of α or of α', and that the dilatation *by heat of a body in the ordinary gaseous state, whether measured by its expansion under constant pressure or by the increase of elastic force under constant volume, is not a simple function of the initial volume or initial-elastic force, but a complex function changing with the temperature.*

In the second part of the paper the general properties of the ordinary gaseous state are considered. As the basis of this inquiry the following table of the compressibility of carbonic acid at 6°·5, 64°, and 100° is given, in which ϵ is the ratio of the observed volume of the carbonic acid at the pressure p and temperature t' to its volume under one atmosphere at the same temperature t'.

p.	t′=6°·5, ε.	p,	t′=64°, ε.	p.	t′=100°, ε.
12·01	$\frac{1}{12{\cdot}05}$	17·60	$\frac{1}{18{\cdot}57}$	20·17	$\frac{1}{20{\cdot}98}$

34·49	$\frac{1}{45{\cdot}80}$	54·33	$\frac{1}{65{\cdot}97}$	64·27	$\frac{1}{73{\cdot}97}$
		64·96	$\frac{1}{83{\cdot}44}$	80·25	$\frac{1}{96{\cdot}65}$
		81·11	$\frac{1}{114{\cdot}0}$	105·69	$\frac{1}{137{\cdot}6}$
		106·88	$\frac{1}{185{\cdot}5}$	145·44	$\frac{1}{218{\cdot}0}$
		145·54	$\frac{1}{325{\cdot}9}$	223·57	$\frac{1}{370{\cdot}3}$
		222·92	$\frac{1}{446{\cdot}4}$		

If we put $\rho = \epsilon p$, and calculate the values of ρ for each of the above experiments, it will be found that these values diminish regularly as the pressure increases at each temperature, with the exception of the last observation at 64°, where the value of ρ is greater than at the preceding observation. This change of direction in the value of ρ is explained by the circumstance already mentioned, that the carbonic acid at the higher pressure has been reduced to the liquid volume (although no liquefaction has taken place) in passing through the conditions of matter intermediate between the gaseous and liquid states.

The relations between the volumetric curves in the ordinary gaseous state for different temperatures are determined by means of what the author calls the homologues or homologous points of those curves—that is, the points in any two isothermals where the values of ρ are equal, or—

$$p\,v = p'\,v' \quad . \; . \; . \; . \; . \; . \; . \; . \; . \; . \quad \text{(A)}$$

From a careful analysis of the experiments described in this communication and in his former Bakerian lecture, the author shows that the ordinary gaseous state is characterized by the ratio of the external pressures for all the homologues of any two given temperatures being constant, or—

$$\frac{p}{p'} = \mathfrak{m} \quad . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \quad \text{(B)}$$

where $\mathfrak{m}$ is a constant. It must be carefully observed that v and v' in equation (A) are the volumes of the gas on different isothermals.

It follows from these results that, in the case of a body in the ordinary gaseous state, if the relations of pressure and volume are known at any one temperature, the corresponding relations at any other temperature can be calculated from the observation of a single homologue at the second temperature. Thus the whole relations of volume and pressure will be known from a set of primary observations at a fixed temperature and the determination of one homologue for each of the other temperatures.

The general form of the primary curve itself, or curve exhibiting the relations of pressure and volume at a given temperature, is next investigated; and the author finds as the result of all his experiments under very varied conditions of temperature and pressure, that the value of $\epsilon\,(1-\rho)$ is constant for the same temperature. Hence we have for the third equation of the ordinary gaseous state—

$$v\,(1 - pv) = c \quad . \; . \; . \; . \; . \; . \; . \; . \; . \; . \quad \text{(C)}$$

From this last equation the relations of homologous points as defined by equations (A) and (B) may be deduced.

The author concludes with some general observations on the action of the internal attractive forces in the ordinary gaseous state, and also on the resistance to diminution of volume which, under certain conditions, modifies largely the effects both of external pressure and of internal attraction.

FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The annual congress of this association for the present year commenced at Clermont-Ferrand, Auvergne, on the 18th of August, under the presidency of M. Dumas, the permanent Secretary of the French Academy of Sciences. The session included sectional meetings in which questions in various branches of science were discussed; general sittings in which scientific questions bearing upon the natural features and industries of the district were brought forward, and public conferences, at one of which M. Wurtz dealt with the new colours. During the Congress the meteorological observatory at the Puy de Dome was inaugurated.

M. Dumas, President, in his opening address, said:—"In 1851 I was present in London at the first Exhibition, and I soon found that among my fellow-members of the different juries, the great number and importance of the French articles exhibited in the industrial arts were quickly acknowledged, especially in those which depend upon Science. England had the largest chemical works in the world, and there was no lack of able, practical men. But France had long possessed schools like the Ecole Polytechnique and the Ecole Normale, affording the highest class of chemical instruction, and whose pupils, in their after life, imparted to the various manufacturing works the benefit of the lessons taught at them. A very eminent English juror acknowledged this superiority in the following terms:—'England has erred so far in doing too little for science, which is money; henceforth let us follow the example set us by France.' Similar also was the expressed opinion of one of the English juries—that on the silken and other fabrics of Lyons. This fact once acknowledged, and there arose at once schools of Science and Art throughout the British Isles. There exists in that country a body—the British Association for the Advancement of Science—always in the van, leading and guiding the efforts of Science. To us, with its lengthened existence of nigh half a century, it affords a model. Under its auspices has English Science assumed and preserved its high position. It contains among its members not merely the men of Science, but also those bearing noble names long known and respected throughout the land, many of whom, together with the late Prince Consort, it has placed upon the list of its Presidents. The British Association at its very commencement marked out for itself its course, which it has unhesitatingly and unremittingly followed ever since—to stimulate, without in the slightest degree interfering with existing institutions, in all parts, the efforts of the votaries of Science, to urge on and aid the efforts of individual research. One striking contrast exists between the world of Science in France and in England. In the latter, until of late years at least, all the universities and important seats of learning were away from the capital, while in France all Science centred in Paris, the provincial schools and universities being deemed but of secondary importance. To remedy this, to extend the domain of Science and to restore to the Provinces some of their ancient scientific eminence, is one of the objects of the French Association for the Advancement of Science. France must not forget that Science is a great power, and that its effects are visible in every branch of social and domestic life. When the Revolution of 1792 isolated us from the rest of Europe, and left us at once destitute of all those external products upon which we had so much depended, it was to our men of science that we looked to remedy these wants, and persons of such eminence as Lavoisier, Bertholet, and Chaptal laboured with their own hands to fill the void. To Science are due those terrible engines of war and likewise the steam-engine, which has peaceably revolutionized all our manufacturing and domestic life. Science also it is that causes the noisome tar, the refuse of our gasworks, to afford us some of our brilliant dyes and some of our most delicate perfumes, and shows that in the production of a stearin candle there also lies a substance so terrific in its effects as is nitro-glycerine. Science follows us everywhere, whether we like or not. It must be our companion, to possess it or to be possessed by it. If ignorant of it we are its slave, if learned it obeys us."

The Mayor of Clermont, M. A. Moinier, in a few well-chosen expressions, welcomed the Association to Clermont.

The Report of the Council, which was extremely satisfactory, was read by the General Secretary, M. Cornu. It announced that Government had recently decreed that the Association was of public utility, this Decree being equivalent to a charter in England, and gave details of the rapid progress of the Association. The Treasurer's statement was likewise very satisfactory.

In the evening the Mayor gave a reception, which was numerously attended, at the Hôtel de Ville, to the members of the Association and many distinguished officers, Clermont being the centre of a military division. It is supposed that about 600 members attended the Association meeting, but the town was also full of strangers and quite *en fête*, many of the public buildings being decorated.

On the 20th. the Association paid a visit to Vichy, during which, M. Daubrée, a member of the Institute, gave "The Health of Lord Houghton, Vice-President and Representative of the British Association, the elder sister of the French."

Lord Houghton, in returning thanks, congratulated the Association on extending to the Provinces the benefits of Science. He would not speak of decentralization, as he was speaking in the centre of France. They were assembled in the grand Republic of Science, on the platform of truth, on which liberty, equality, and fraternity were to be found. His own life had been rather that of a man of letters than of a *savant*; but even profound science did not exclude the warmest imagination. Lord Houghton concluded his speech, which was delivered in excellent French and much applauded, by toasting the "Universal Republic of Letters."

FRENCH PHARMACEUTICAL CONGRESS.

The fourteenth session of the French Pharmaceutical Congress was commenced at Clermont-Ferrand on the 17th of August. The greater part of the local pharmaciens appear to have held themselves aloof from the proceedings, but there was a fair attendance, delegates being present from about twenty societies. M. Perrens, of Bourdeaux, was elected as president.

One of the principal questions before the Congress was the proposed establishment of a society called the General Association of the Pharmaciens of France. This was approved of, and a code of rules suggested by the Seine Society was with a few slight alterations adopted. It was agreed that it would be necessary to preserve still to local societies complete autonomy and independence. Other questions that were considered were the proposed impost upon pharmaceutical specialties, the organization for medical relief in the country, and the revision of the law relating to the sale of mineral waters. Of the scientific memoirs submitted to the Congress, there were three "*couronné*," viz:—"An Anatomical Study of the Cinchonas," by M. Collin.; "A Study of *Calophyllum inophyllum*," by Professor Heckel;" and "A History of Poisons," by M. Gilbert.

The Congress was brought to a close on the 19th by a "*banquet confraternel*."

Parliamentary and Law Proceedings.

Liebig's Liquid Extract of Beef a Wine.—Prosecution of Druggists.

On Thursday August 24, several druggists were brought before the Justice of Peace Court, at the instance of the Excise, on the charge of having sold wine without a licence. Messrs W. W. Watson and John White were on the bench, with the assistance of Mr. Gray as assessor. Mr. Douglas, the Procurator-Fiscal, appeared for the Board of Trade.

The first case called was that of Thomas Davision, 126, Buchanan Street, who was charged with having, on the 13th of April, 1876, sold spirits without a licence; and there was a second charge of having, on the same day, sold foreign wine without a licence, the penalty in each case being £50.

Mr. Lindsay, who appeared for Mr. Davison, lodged a plea of guilty to the second charge.

Mr. Douglas accepted the plea.

In mitigation of sentence,

Mr. Lindsay said that Mr. Davison sold this article in ignorance that it required a license. It was sold on the understanding that it was a proprietary medicine, as it was sealed and capsuled. It was not sold in bulk, and it was advertised in the usual way as other medicines, as "Liebig's Liquid Extract of Beef." It had been recently introduced as a medicine, and had been sold by Mr. Davison on the order of medical men who had recommended its use to their patients. It was sold at the price of 3*s.* per bottle, which was equivalent to about double the ordinary price of the quantity of wine, so that the price precluded its having been sold as a beverage, for there was no one who wanted a beverage who would pay double the price for such a wine. There was a number of medicines such as that sold by chemists and druggists, and as they were all sealed up it could scarcely be expected that every medicine which a druggist sold was to be analysed by him. Mr. Davison acted on the general understanding that it was a proprietary medicine, and sold it on the understanding implied and expressed by the sellers in positive terms that it was not a medicine which required any licence to sell. The medicine had been found really to be a medicated substance, and although he had not got it analysed yet its taste was proof enough to him that it was medicated, and that there were other substances in it. According to the bill issued it contained besides wine, quinine or Peruvian bark, glycerine, syrup, spices, etc. It was true that the liquid was not unpleasant to the taste, and that it could be drunk not unpleasantly; but that was not an argument to prove that it was a breach of the Act to sell it. There were a good many other things used as beverages for the purposes of intoxication, and all these were daily sold under the authority of the British Pharmacopœia, such as sal volatile and tincture of cardamoms. Another article named methylated spirits was medicated with shellac for the purpose of preventing it being used as a beverage. Coming back to the case of the Liebig's liquid extract of beef, Mr. Lindsay said that Mr. Davison did not wish to sell it at all, and he understood the Excise authorities objected to its being sold without a licence. The makers had led the retailers on the ice, and the latter would be entitled to reparation for any damage or fine inflicted by the Court; but unfortunately the makers were now in liquidation, and the retailers were thus deprived of any remedy against them. He believed the Excise authorities could not come upon the makers, because they held a licence for selling it, but to show that the retailers would have no remedy against them their agent in Glasgow had received a card that morning which stated "Being now in liquidation, can do nothing to help anyone." He had, therefore, to submit to their honours that there was no intentional infringement of the law. It was done entirely in ignorance, and in the belief that it was no infringement of the law, and he thought that the end of the Excise authorities would be served by the justices cautioning Mr. Davison not in future to sell it, and to dismiss the case.

Mr. Douglas said the object of the prosecution was certainly not with the view of stopping this or any other wine, or any other compound. It was merely with the view of compelling people who sold wine or spirits under any guise to take out the usual licence. If their honours were curious to know the ingredients of this compound the analyst was present in court, and it would be shown that it was simply a wine—a wretched wine—what was called Tarragona wine—the lowest species or imitation of port, with almost no appreciable—indeed he might say no appreciable quantity whatever of quinine in it, and very little if indeed any of the extract of beef. The bill says, "This liquid extract has most invigorating and strengthening qualities. Railway travellers unable to obtain regula meals, and travellers by sea, will find it most beneficial." Indeed, there was 84 per cent. of wine in it.

Mr. W. West Watson said the Bench had no alternative but to impose a penalty on account of Mr. Davison's having pleaded guilty. The highest penalty was £50, and they had only power to mitigate it to one-fourth—to £12 10*s.*; but they would recommend that the Inland Revenue Commissioners should further modify the penalty.

Mr Heathwood was charged with having on the 2nd of May last retailed spirits and foreign wines without a licence. When asked to plead,

Mr. Heathwood said—I gave a bottle to the exciseman when he called—that's all I ever sold.

The Clerk—Did you sell it to him?

Mr Heathwood—I gave it to him, and he gave me the money. (A laugh.) I was the agent for the makers, and I made it as public as possible. I did not know anything about a licence.

The Bench imposed the modified penalty of £12 10*s.*, with a recommendation to the Inland Renvenue Commissioners to still further modify the penalty.

There were other five cases—Messrs John Currie, James Macconnochie, James Macdonald, Daniel Frazer, and William Greig, all of which were continued for a fortnight.

Poisoning by Chloral Hydrate.

An inquest was held at Silloth, Cumberland, on Thursday, August 24th, upon the body of the Rev. John Mitchell Harvey, D.D., who, until the beginning of the present year, was minister to a large congregation in Edinburgh. In March failing health compelled him to resign and he has since been seeking rest in England. On reaching Allomby, about seven miles from Silloth, on Tuesday, he had a slight refreshment. On arriving at Silloth he complained of being exhausted. He rested for an hour or so, and at half-past nine went to bed. He could not sleep, and at midnight got up and took a narcotic, consisting of 60 grains of bromide of potassium, and what he considered would be a teaspoonful of hydrate of chloral, though he did not measure it. About five o'clock next morning his wife became alarmed by his breathing, and found he was unconscious. Medical aid was sought, and Dr. Leitch, the local medical practitioner, was soon in attendance. He found the patient in an almost comatose state and took measures to try and rouse him, and succeeded so far that he induced him to walk about the room. His physical powers, however, soon failed him, and, on lying down, he again became unconscious, in which state he remained until his death at eight o'clock. Dr. Leitch was of opinion that death had resulted from a dose of hydrate of chloral, not in excess of what the deceased had been the habit of taking, but so large that his weakened physical condition had been unable to resist its action. The jury found that Dr. Harvey met his death through taking a dose of chloral for the purpose of procuring sleep.—*Times.*

Poisoning by Laudanum.

An inquest was held on Tuesday, Aug. 29, before Mr. W. Emsley, Leeds deputy-coroner, on the body of William Taylor, 33 years of age. Deceased, who was a master brickmaker, was addicted to drinking, and some time ago Dr. Hopkins advised that he should be taken to the asylum. This was not done, and last week he was drinking for several days. On Saturday he was in a low desponding state, and about half-past eleven that night called at the shop of Mr. Longley, druggist, North Street, and asked for eight ounces of laudanum and four ounces of turpentine mixed. He was told it would be 4s., and he then said he would have half that quantity. It was given to him and the bottle marked poison. About twelve o'clock he was found on Roundhay Road, with the bottle in his hand empty. He was removed home, and died on Sunday.—Dr. Hopkins said the quantity of laudanum was sufficient to have poisoned a dozen people.—The Coroner inquired of Mr. Longley, the druggist, if it was usual to supply such a large quantity of poison to a person who was not known; to which Mr. Longley replied that when a person ordered laudanum and turpentine mixed it was understood to be as a medicine for horses, and it was regularly supplied by druggists as such. There was nothing in the Act regulating the sale of poisons which required the druggist to ascertain the names of persons to whom laudanum was sold.—The Coroner said he could not understand a law which required a druggist, when he sold a penny packet of Battle's vermin-killer, to have the same entered in a book and the purchaser identified, because the powder contained strychnine, and yet required no such caution if the sale was of any quantity of laudanum.—Dr. Hopkins said very few persons had any idea of the quantity of laudanum that was drunk, and for some years he had thought the law as to the sale of it was not strict enough.—The jury returned a verdict "That deceased committed suicide when in an unsound state of mind, caused by excessive drinking."

Poisoning by Carbolic Acid.

Mr. Humphreys, on Tuesday, held an inquest at the London Hospital on the body of Timothy McCarthy. Deceased was an inmate of St. George's Union, and on Saturday was on a visit to his son. The latter kept carbolic acid in a bottle, to kill vermin with, and during his son's absence deceased seems to have reached down the bottle, which was a precisely similar one to that in which the son used to bring his father wine to the union, and supposing it to contain wine he drank a quantity from it. As soon as the accident was discovered deceased was conveyed to the London Hospital, but he died from exhaustion from the effects of the acid on the following day. A verdict of "Poisoning by inadvertence" was delivered.

Review.

Étude sur les principaux produits résineux de la famille des Conifères par A. Herlant. Bruxelles: H. Manceaux.

A great deal of confusion exists in many works on materia medica concerning the various medicinal products of the Coniferæ, their exact botanical source, and the means of distinguishing one from another. In the little work before us the author has endeavoured to arrange these particulars in something like order, so that it will be an easy matter to refer to any particulars required either by the scientific or the commercial man. The pamphlet is divided into three parts, the first giving the author's idea of the best method of classifying the medicinal products of the Coniferæ, the second treating fully of the products themselves, and the third part consisting of a list of the principal coniferous plants yielding products useful in the arts or in domestic economy.

The author bases his classification of the produce upon the principle that the resins or oleoresins are the result of the more or less complete oxidation of essential oils existing in the plants; the unoxidized oils being volatile, and the oxidized oil or resin being fixed. He accounts for the variation in consistence by pointing out that the volatile oils vary much according to circumstances; the period of collection, temperature, etc., having considerable effect in modifying their tendency to oxidation.

The coniferous products are arranged in the following groups—Turpentines, pitches, tars, resins, and essential oils; and these groups are again subdivided according to their natural or artificial production, and their drying or non-drying properties. Under each article is given a list of its synonyms in different countries, its botanical source and botanical synonyms, an account of the way in which it is obtained, its chemical and physical characteristics, its composition and uses.

The text is written in a very clear and readable style, and the paragraphs are well arranged. The information given is much more condensed than is now usually the fashion in French works; and references are given so that those who wish for fuller information may know where to find it. Although the author does not advance much that is new, yet the information which he has grouped together is of so practical a nature that it cannot fail to be useful to the analyst or tradesman who has occasion to test or otherwise examine coniferous products, as well as to the student who is in a "fog" as to the source of the resins or turpentines of commerce.

Among the English synonyms we notice a few which show that the author is not well acquainted with the familiar names for some of the fir trees cultivated in this country—thus the larch is said to be called the larch fir in England; *Abies excelsa*, the common pitch fir, whereas it is commonly known as the Norway spruce; huile de cade as cade oil, although in English commerce it generally goes either by its French name or by that of juniper tar oil; the resin of *Dammara alba*, Rumph., as Catseye resin, instead of gum dammar. We notice also that the essential oils of *Pinus sylvestris* and *P. Pumilio* appear to have been forgotten. Several pages are devoted to amber, which the author considers to be of coniferous rather than of leguminous origin, for the following reasons:—(1) Because it is rich in succinic acid, a body not found in copals; (2) because it is not attacked by alcohol; (3) because when heated it burns and does not melt drop by drop like copal.

In this part twenty-two substances in all are treated of.

In the third part eighty-six coniferous plants are enumerated which yield useful products; and their botanical synonyms, a description of the part used, and its uses, with occasional references, are given.

Chemists and Druggists' Trade Association.

Sir,—Allow me to say a few words in reference to your remarks in last week's Journal on the Chemists' Defence Association.

You infer because the trade has not come forward to a great extent to support the movement, they are indifferent to it.

I give the following facts which may convey a different impression:—

A week after the Conference at Birmingham, I, in company with a neighbouring chemist, called on all our brethren in Hammersmith, Turnham Green and Shepherd's Bush, to ask them their opinions on the movement. Three were from home, two leaving the trade, the remaining fourteen cordially approved of the step, signed a paper to that effect, became subscribers and several also gave a donation.

Not one of them had taken action individually (and probably would not have done so), and therefore, may have been regarded as indifferent had not my friend and I called upon them, whereas, the very courteous manner in which they received us proved how pleased they were to aid the cause.

I may just add that about half who subscribed are members of the Society,—who hold the Council in high esteem, but who think there is work to be done for the trade generally, which in detail is incompatible with their position as the Council of a Society whose object is to raise the scientific and educational status of its members.

There need not and should not be any antagonism, but the one regarded as the scientific and the other as the commercial branch of the institution.

BENJ. HUMPAGE.

Turnham Green.

Sir,—Some who have followed in imagination the disembodied soul to its final judgment, have told us that it is there confronted by a ghostly shade charged with the duty of public accuser, who scruples not to lay against the prisoner some charges which are only too true, and also others lacking the quality of truth.

Now, Sir, since you have in your leader of the 26th ult., goodnaturely undertaken the office of "Advocatus Diaboli" in the matter of the Chemists and Druggists' Trade Association, I can promise that the promoters will not hesitate to confront their accuser, and make those confessions as to the numbers of their accomplices which you point out as not yet furnished to the public. One might perhaps raise some objection to the scales of justice used for our assessment; their owners are numerous, and the least bias given to the centre of gravity may have disturbed the equilibrium; but let that pass, we now come to the counterpoise which you have put into the opposite scale, and which you say must be overbalanced by the Trade Association under the penalty of being weighed in the balance and found wanting.

You reiterate the opinion that such an association cannot exist permanently unless representative "of the greater part, if not of the entire trade," and you add, that when so much as a month (! !) has elapsed since the association was formed "it seems to us unpromising, to say the least, that we find no mention of the enrolled members being at all in approximation" to the members of the trade.

Taking as a datum the trade to number 14,000, it appears that you will have no hopes for the new association until its numbers exceed 7000. This estimate of "ayes" and "noes" overlooks altogether the mass of indifferentism which is known to students of social economy as the condition of the average of mankind.

Let us look at the way the same body of men acted in relation to two other Societies; did they supply 7000 members to the Pharmaceutical Society? No, nor much more than one-third of 7000, and yet here is the Society, which injudicious friends declare has for 30 years past striven to remove every trade grievance and is doing so now with all its powers. Would your scales declare the Pharmaceutical Society to have no *raison d'être* because it is not "representative of the greater part if not of the entire trade?" How did the same set of men receive the British Pharmaceutical Conference?

Well, after a year's work, its treasurer reported to the Bath meeting that 153 persons had paid their subscriptions of membership.

In another year, at Birmingham, the total was 117, and after three years the Nottingham meeting reached a total of 258 members. How would your test figure of 7000 have affected that most flourishing Society?

And now for the promised confession as to both men and money belonging to the Chemists and Druggists' Trade Association. It has 752 enrolled members, and the list of donations (irrespective of annual subscriptions) amounts to £505 2s.

The handsome way in which the members of the wholesale trade have met the appeal made to them deserves special recognition; there has been no such unanimity of support from the wholesale houses to a trade object during the present generation.

Your renewed expressions of good wishes for the Trade Association will be most acceptable to its members. Its promoters may fairly ask that the Glasgow meeting shall be held before they are charged with too slow progress, and having confidence that success will ultimately bring them its usual crowd of friends, they will recollect that the present is the best opportunity for those who have any genuine friendship to bestow.

A PHARMACEUTICAL CHEMIST AND MEMBER OF THE COMMITTEE.

PHARMACEUTICAL CHEMISTS AND THE JURY LISTS.

Sir,—Pharmaceutical chemists, although exempt from serving on juries, often find their names inserted in the jury lists; when such is the case they cannot claim their exemption, and it would be well therefore for every one to examine the list of jurors placed on the door of his church or chapel on the first three Sundays in September, and if he find his name included therein, he should at once inform the churchwardens and overseers (in writing) of his exemption, and attend when the lists are revised by the Justices in Petty Sessions, and see that his name is omitted.

I hope the day is not far distant when all registered chemists will be exempt from this service.

FREDERICK ANDREWS.

23, *Leinster Terrace, W.*

A DANGEROUS PRESCRIPTION.

Sir,—The following is a copy of a prescription left with my firm to be dispensed a day or two ago:—

℞ Pulv. Arsen. Alb. ʒx.
Gr. ij pro dosi
Pulv. i at 12 and 4 o'clock.
Mitte xxiv. pulv.

Fortunately the assistant into whose hands it fell, knew more posology than the *Lancet* considers, or did consider, necessary in dispensers. On examining the prescription I found that it bore the stamp of a London homœopathic chemist, and at once suspected that it had been accidentally left with us instead of with a neighbour of that persuasion.

This proved to be correct, and I was afterwards informed by the homœopathic chemist that the ʒx meant "3 x," and denoted the extent to which the "Arsen. Alb." was to be diluted.

This is only another illustration of the reckless way in which prescriptions are often written, and of the extent to which the public safety is dependent on the knowledge and intelligence of dispensers.

F. BADEN BENGER.

7, *Exchange Street, Manchester.*

J. Garrett.—We do not think it would be correct to term a balance in hand at the commencement of the half-year a receipt during the half year.

"*Galen.*"—(1). The subscription to *The Analyst* is 3*s.* 6*d.* annually, and should be sent to Mr. Wigner, 79, Great Tower Street, E.C. (2). The 'Annuaire de la Pharmacie,' edited by Dr. Méhu, is published at 12, Rue de Buci, Paris.

A. L. F. B.—If you will send better specimens we will do our best to name them. We cannot undertake to name fragments. Leaf, flower, and fruit of each plant should be sent.

W Thirlby.—We have no recollection of such a proposition, and have failed to discover any trace of it in the Journal.

"*A Plymouth Student.*"—See vol. v., pp. 425 and 25.

"*Macdui.*"—The information may be obtained by applying to the Secretaries of the respective Societies.

G. H. P.—A stamp should be used with the label sent, as it relates to a proprietary article which it also recommends for the relief of disease.

H. S.—A method of proceeding that probably might be modified to meet your requirement will be found described in the Journal for March 27, 1875, p. 770.

"*Syrupus.*"—*Artemisia vulgaris.*

COMMUNICATIONS, LETTERS, etc., have been received from Dr. Morel (Ghent), Mr. Kinninmont, Mr. Barclay, Mr. Benger, Mr. Finch, W. F. C.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 9, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MEETINGS AT GLASGOW.

IT may appear to be but a repetition of what has been said in former years to announce that the latest meeting of the British Pharmaceutical Conference, held at Glasgow during the past week, has been at least as successful as that of any former year. But this is not a mere formal statement. Glasgow pharmacists may even boast of having been able to secure for this year's scientific meetings larger and more evenly sustained audiences than have supported the readers of papers on any previous occasion, whilst it is no wonder that with the beauties of the Clyde,—to say nothing of other inducements,—they were able to tempt a large company to take part in the excursion. But to the serious business first.

It will be seen that the Executive Committee was again able to present a favourable report, showing an income during the year in excess, by about £240, of the expenditure, including the cost of the Year-Book and the grants in aid of research. With respect to this latter branch of the operations of the Conference, we are informed that the Executive Committee has made the following fresh grants: £5, extended, if necessary, to £10, to Mr. J. C. THRESH, F.C.S., for the purchase of materials in connection with an extended research on the active principle of capsicum fruit; £10 to Dr. ARMSTRONG, F.R.S., for the purchase of strychnine, etc., with which to conduct a research on the oxidation products and bromo-derivatives of that alkaloid; £20 to Dr. TILDEN, F.C.S., for the purchase of essential oils; and £50 to Dr. C. R. A. WRIGHT, F.C.S., Mr. J. WILLIAMS, F.C.S., and Mr. T. B. GROVES, F.C.S., to defray expenses in connection with extended researches on the aconitines.

The President's address is printed on another page, and amply justifies the cordiality with which it was received. In it Professor REDWOOD sets forth in an extremely clear and definite manner his views respecting the position that can be taken justifiably by pharmacists in respect to giving advice as to the use of the drugs they handle daily, and this portion of the address forms a valuable contribution to the literature of a subject which has been too frequently discussed under a cloud of self-interest. Good service in another direction is done by the interesting illustration of our comparative ignorance respecting much of the history of the materia medica, and there can be no doubt that the suggestion as to the application of some of the scientific energy and the funds of the Conference for the testing and comparing of results already obtained by various investigators, if effectively carried out, would at least clear the ground of some of the confusions and contradictions with which it is now covered. During the reading of the address the large room of the Royal Hotel was filled with an evidently much interested audience, nor was the President less successful when in inviting discussion upon the several papers he showed in a few lucid and suggestive sentences the bearing which each had on pharmacy.

Twenty-eight papers were read. In the first, Mr. B. S. PROCTOR described the strength of four samples of liquid extract of pareira as varying between one and six. This result he attributed to the vagueness of the words "coarse powder," used for indicating the degree of comminution, although it might well be due to the crude materials not having had an identical origin. During the discussion the President expressed an opinion in favour of a clearer definition of the degrees of fineness of powders in the next edition of the British Pharmacopœia. The next note was by Mr. STODDART, on the action of hydrochloric acid on the colouring matter of *Crocus sativus* in the presence of sugar. Five papers on opium followed. Mr. DOTT, induced by variations he had met with in the morphia strength of opium preparations, expressed himself strongly in favour of the use of definite chemical principles instead of crude drugs; Messrs. PROCTOR and CLEAVER gave some valuable information respecting the assay of opium; Dr. WRIGHT described his continued research on the opium alkaloids; and Mr. BROWN announced the presence of free acetic acid in opium. Next the use of gum tragacanth and glycerine for a pill excipient was advocated by Mr. WELBORN; afterwards Mr. HAFFENDEN described his method of making phosphorus pills. Jaborandi this year furnished but one paper, that in which Mr. GERRARD described the action of various solvents upon "some salts of pilocarpine;" these he appeared to look upon as compounds of the alkaloid to which Mr. KINGSETT recently attributed a definite formula, but Mr. KINGZETT hardly acquiesced in the assumption. The next paper, by Dr. WRIGHT, showed that with respect to the aconite alkaloids also there still exists considerable haziness. In the last paper read on Tuesday, Mr. THRESH gave some further information respecting the active principle of capsicum fruit and described some painful physiological experiments he had performed upon—himself.

The second day's proceedings opened with Mr. KINGZETT's fourth report on the oxidation of essential oils, a research which the author indicates will probably eventuate in the manufacture commercially of a valuable antiseptic. Mr. MUIR made a preliminary report on oil of sage. A preliminary report was also made on the chemistry of ivy, by Mr. DAVIES. Dr. TILDEN summarized the results obtained from the administration of the varieties of aloin to patients in the Bristol Hospital, an account of which has already been published in this Journal. Mr. ANDREWS suggested a formula for a Glycerinum Cinchonæ. Mr. GERRARD recommended the substitution of Canada balsam for the resin and suet in the B.P. cantharides plaster, which he considers to be insufficiently adhesive and flexible. Mr. BROWN proposed a solution of citrate of iron and quinine, to be preserved by addition of chloroform. Such an addition, however, was generally disapproved of, and it was stated that a strong solution could be kept without it. Mr. HOWIE, whose recent valuable paper on the compound syrup of the phosphates will be fresh in the memories of our readers, now submitted to the Conference the importance of deciding what should be considered the standard strength of this preparation. Mr. GREENISH described the constituents met with in various filtering papers, and exhibited a specimen of Japanese filtering paper, prepared from the liber tissue of the paper mulberry (*Broussonetia papyrifera*). Three papers had for their subject salicylic acid. In consequence of the impurities met with in commercial salicylic acid, and the difficulty experienced in purifying, by recrystallization, salicylate of soda prepared from it, Mr. WILLIAMS's attention has been turned to the sulphosalicylate of soda. This salt gives with perchloride of iron the purple colour characteristic of salicylic acid, from which Mr. WILLIAMS infers that the salicyl radicle remains in it unchanged. Mr. HUNTER has confirmed by fresh experiments the antiseptic properties of salicylic acid. Some experiments made by Mr. BENGER to ascertain the condition in which salicylic acid is excreted by patients seemed to indicate that it then was no longer in an active or uncombined state. Mr. SIEBOLD sent two papers, one on the preparation of a pure sulphur præcipitatum by only partial precipitation; the other, on the strength of tincture of nux vomica. Mr. GROVES exhibited a specimen of so-called Pekoe "Flower," concerning the origin of which Mr. GREENISH contributed some information. This was the last of the papers.

The Conference then proceeded to the election of officers. Professor REDWOOD was re-elected President. and it was decided to accept an invitation to meet next year at Plymouth. Enthusiastic votes of thanks to the local committee and to the President closed the proceedings.

On Tuesday evening, an interesting gathering took place at the Royal Hotel, where many visitors to the Conference sat down to supper with a large number of the junior pharmacists of the city. The Chairman in a few well-chosen words introduced successively to his young friends the representative pharmacists present, and they in their turn addressed the company in words that will be found briefly reported on p. 226. The plain speaking of Professor REDWOOD will no doubt be relished in many quarters and equally disliked in others.

Soon after six o'clock on Thursday morning pharmacists and their friends began to make their way to Glasgow Bridge, near where the *Eagle* lay at her moorings. By seven a numerous company was on board and to the music of the band and the pipers of the Cameronian regiment the boat made her way down the Clyde to the Western coast, visiting successively the beautiful lochs that lay in her way. If anything could have repaid the local committee for their unbounded kindness during the whole meeting it must have been the manifest appreciation on the part of their visitors of this crowning hospitality. And when the company met in the cabin after dinner there could be no mistaking the enthusiasm with which they toasted the health of their hosts, and especially of those upon whom the work had principally fallen, Messrs. DAVISON, FRAZER, KINNINMONT, STANFORD and FAIRLIE.

We have but little space left to speak of the other meetings of the week, but we must not omit to call attention to the admirable address, printed in another part of this Journal, with which on Wednesday evening Professor ANDREWS inaugurated at the Glasgow University the meeting of the British Association for the Advancement of Science. It is true that one of the local journals ventured to stigmatize it as "bald disjointed chat about science," unsuited for a Glasgow audience; but we venture to say that the motive for such an attack must be sought for outside the Address itself. At any rate the passage where Dr. ANDREWS speaks of the clouds of smoke which darken the atmosphere of our manufacturing towns, and even of whole districts of country, as indications of waste arising from imperfect combustion, and alludes to the depressing effect of this atmosphere upon the working population, is a passage which appears to us to be worthy of the particular attention of the citizens of Glasgow. The remarks of Dr. ANDREWS respecting the endowment of research are well worth pondering. He is not so enthusiastic as some are as to the benefit to be derived from endowing a body of men devoted exclusively to scientific research, without the duty of teaching or other occupation, and he confesses that after careful consideration he fails to discover how such a plan could be worked so as to secure the object in view. Moreover, he thinks that great injury would be done by thus separating the influence of the master intellects of the country as teachers from the flower of its youth.

On Friday morning a meeting of the newly-formed Chemists and Druggists' Trade Association was held in the Royal Hotel, Glasgow, when it was announced that the Society now numbers twelve hundred members. A Secretary and Solicitor have been appointed. The Society aspires to be thoroughly representative and claims the support of the whole trade. Some of the speakers pointed out that a difficulty in this respect had prevented the Pharmaceutical Society from exercising protective functions. The task which the Association undertakes is that of uniting the trade in regard to trade interests, and thus supplementing the efforts of the Pharmaceutical Society and Conference. We hope to give a fuller report of the proceedings next week.

THE MEETING OF THE COUNCIL.

THE Meeting of the Council which should have taken place on Wednesday last was postponed in consequence of a *quorum* not having been formed.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The thirteenth annual meeting of the British Pharmaceutical Conference commenced on Tuesday last, September 5, in the hall of the Royal Hotel, Glasgow. Professor Theophilus Redwood, Ph.D., F.C.S., London, presided.

Reception of Delegates.

The first business was the reception of Delegates to the Conference from provincial associations of pharmacy.

Professor Attfield said that delegates had not hitherto brought formal communications from their associations, nor had the Conference up to the present year ordered them officially to represent to their associations the work that was done at the Conference. There had been no occasion for their doing more in that way than what was implied by their presence. Many good results had been experienced from that position of the delegates in relation to the Conference. It was to be hoped that in future years every association for the promotion of pharmacy throughout the country, and every Pharmaceutical Society, for there were now more than one, would be represented at these annual gatherings.

Professor Attfield then read the following list of delegates:—

North British Branch of the Pharmaceutical Society.—Mr. William Ainslie, Mr. H. C. Baildon, Mr. William Gilmour, Mr. John Mackay, F.C.S., Mr. J. R. Young.

Bristol Pharmaceutical Association.—Mr. G. F. Schacht, F.C.S., Mr. W. W. Stoddart, F.G.S.

Glasgow Chemists and Druggists' Association.—Mr. Daniel Frazer, Mr. A. Kinninmont, Mr. James M. Fairlie.

Liverpool Chemists' Association.—Mr. Alfred H. Mason, F.C.S., Mr. Robert Sumner, Mr. John Shaw.

Nottingham and Notts Chemists' Association.—Mr. J. H. Atherton, F.C.S.

Sunderland Chemists' Association.—Mr. J. Harrison, Mr. J. J. Nicholson, F.C.S., Mr. Robinson, Mr. D. B. Sharp.

Wolverhampton Chemists and Druggists' Association.—Mr. W. Y. Brevitt, Mr. F. J. Barrett.

Hull Chemists' Association.—Mr. C. P. Bell, Mr. F. Earle.

Manchester Chemists' Association.—Mr. Brown, Mr. Darling, Mr. Johnson, Mr. Benger.

Mr. Benger read the following—

Report of the Executive Committee.

In this their thirteenth annual report your Committee have endeavoured to lay before the members of the Conference an outline of the work which has occupied them since the annual meeting at Bristol last year, and of the various questions on which it was necessary for them to deliberate and act, on your behalf, during that period.

Meetings of the Executive Committee, chiefly to entertain applications for grants of money in aid of chemical and pharmaceutical research, were held on the first Wednesdays of November and December of last year, in the rooms of the Pharmaceutical Society of Great Britain (by the kind permission of the Council of that Society), at 17, Bloomsbury Square, London.

After the confirmation of the minutes of the previous meeting, which included a resolution raising the salary of the Editor of the Conference 'Year-Book' from £100 to £150 per annum, the following applications from members for grants were read, several being sent in response to requests or suggestions from the Committee:—

1. From Mr. A. W. Gerrard, £10 to cover cost of extraction of pilocarpine from jaborandi, with a view to its further chemical and pharmaceutical investigation.

2. From Dr. C. R. A. Wright, £20 to defray expenses in connection with the extended researches on the aconitines. Respecting this application Messrs. Hopkin and Williams had stated that they would gladly furnish Dr. Wright with concentrated extracts of the raw material for the mere cost.

3. From Mr. M. M. Pattison Muir, £5, with which to purchase the required quantity of essential oil of sage, for a research.

4. From Mr. C. T. Kingzett, £10, to pay a portion of the cost of materials necessary for continued researches on the oxidation of essential oils.

5. From Mr. E. L. Cleaver, £10, with which to purchase opium for a thorough examination of the methods of ascertaining the proportion of morphia in the drug, and a report on a trustworthy mode of assaying opium.

6. From Mr. R. H. Davies, £5, to defray part of the cost of an investigation of the definite proximate principles of ivy berries.

7. From Dr. H. E. Armstrong, £10, for the purchase of strychnine with which to conduct a research on the oxidation products and bromo-derivatives of that alkaloid.

8. From Dr. W. A. Tilden, £5, to be expended in carrying on further investigations of the aloins.

Total number of applications, 8.

Total amount of grants, £75.

On the motion of the President it was resolved unanimously to grant to the gentlemen named the sums mentioned, to thank them for undertaking the several researches, and to request them to communicate results to the next general meeting of the Conference at Glasgow, on the 5th and 6th of September, 1876.

The Treasurer was ordered to invest in Consols the balance he had in hand, pending the consideration of the best mode of dealing with surplus income.

A letter was read from a member suggesting that the Conference should nominate a travelling professor of pharmacy, who should lecture in the provinces at different centres, and that the Conference should contribute towards his remuneration £150 per annum. After thoroughly discussing the proposal, the Committee were unanimous in the opinion that at present it would be unwise to include direct pharmaceutical education among the objects of the Conference.

At a meeting of the Executive Committee, held at 17, Bloomsbury Square, on July 5th, 1876, thirteen candidates were elected to membership. The names of several members whose subscriptions were more than two years in arrear, and to whom repeated applications had been made by the Secretaries, were removed from the list of members.

Twenty-six subjects proposed for research were received and considered.

Professor Attfield suggested that some competent member should be employed to revise and somewhat elaborate the "subjects for papers" in the current list issued by the Conference. In the course of thirteen years the Conference had proposed some two hundred subjects for research, of which nearly one hundred had been investigated, resulting papers forming about one-third of the three hundred papers which had been read at the twelve annual meetings of the Conference. The remaining subjects on the list, especially the fifty or sixty which had been down for several years, required careful revision, information concerning any work already accomplished being added to each subject, and some hints given as to the direction which further investigation should take. Probably a few of the subjects might now be excluded from the list altogether. The Secretaries were ordered to give effect to the suggestion.

Professor Attfield reported that since the previous meeting he had issued about 2500 copies of the current 'Year-Book.'

It will be gratifying to those members of the Conference who have, rightly, regarded its mission to promote pharmaceutical research as all-important, that there should have been so many applications for grants in aid of this object, and that those applications should have been made by such eminent investigators of pharmaceutical and chemical problems as are included in the list of names just read. The Conference has been largely indebted to one gentlemen for the means at its disposal to furnish "encouragement" in this very practical form,—but the Bell and Hills Library and Research Fund will in a few years be exhausted, and it rests with the pharmacists of Great Britain—principals and pupils—to sustain what has been so generously established by Mr. Hills. Our membership roll of between 2000 and 3000 names includes less than 20 per cent. of those engaged in pharmacy in this country, it may, therefore, be reasonably hoped that the British Pharmaceutical Conference does not yet include all those who feel an interest in its objects, and whose interest, will, ere long, assume the active form of application for membership. An increased number of subscriptions might enable the Conference to give still more substantial aid to research.

During the first eleven years of the existence of the Conference its annual income only sufficed for its annual expenditure. Last year the income was nearly £240 in excess of expenditure. This year income is again in excess by about £225, of which £35 has been already expended in grants to aid research. There is now, therefore, a total balance in favour of the Conference of about £430, nearly the whole of which is temporarily invested in Government securities, until the Conference shall decide on its disposal. The Committee fully anticipate an excess of income of at least £200 or £225 in the year just commencing. Of this excess a portion, however, will be absorbed by the addition to the salary of the editor, while most of the remainder will probably be appropriated as grants in aid of research. The Committee expect, therefore, that in the coming year the whole of the income of the Conference will be devoted to the leading object of the Conference, namely, the encouragement of pharmaceutical research. The major part will, as heretofore, be expended in the printing and publishing of that annual collection of all European and American researches, termed the *Year-Book of Pharmacy*—a copy of which it will be remembered, is presented, post free, to each of our members; a not inconsiderable part will be expended in the direct payment of expenses incurred by some of our members in carrying on costly researches; while a third portion will defray the cost of necessary printing, postage, etc., in connection with books and meetings.

At a meeting of your Committee held last evening, forty-five candidates for membership were elected. The MS. of the 'Year-Book for 1876,' was laid on the table by the editor, Mr. Louis Siebold. About two months will be occupied in passing this through the press, and in the preparation of the report of the transactions of the Conference at the forthcoming meeting. The volume will, therefore, be issued as usual in December.

Mr. G. F. SCHACHT, Treasurer, read the financial statements:—

Mr. BENGER then read the following letter having reference to this Fund:—

"Dear Dr. Attfield,—

"In 1872 the Executive Committee of the British Pharmaceutical Conference, with my entire concurrence, devoted part of the money I then gave (£200) to purposes of research as well as to the continuance of the Library Fund I started in 1869.

"During the last three years, however, I notice that the Conference income has considerably exceeded expenditure, and that although grants in aid of research have been freely made from the Conference Fund as well as from the Bell and Hills Fund the Conference is still growing richer.

"Under these circumstances I venture to propose that grants in aid of research be drawn from the income of the Conference alone, and that the £150 of the Bell and Hills Fund still in hand, together with another £50 Russian Bond which I will present to the Conference, be permanently retained as the source of an annual income of £10, which £10 be, as heretofore, devoted to the purchase of books for presentation to the library of the pharmaceutical association of the city or town in which the Conference meets from time to time.

"If the Committee will adopt the suggestion and offer I now make and thus convert the Bell and Hills Fund from a temporary to a permanent institution I will purchase and send the £50 Russian Bond as soon as possible.

"With best success to the Conference,

"I remain, yours sincerely,

"Professor ATTFIELD, "T. H. HILLS.
Hon. Gen. Sec."

Professor ATTFIELD said: This letter almost explains itself, but I may state for the information of some of the members present the history of this Bell and Hills Fund. At Exeter in 1869, Mr. Hills presented the Conference with £50, suggesting that annually £10 should be expended in purchasing books to present to the library of the pharmaceutical association of the town visited by the Conference; if there was no library then the books should be presented with the view of starting a library. In 1872 when the fund was getting low, Mr. Hills presented £200 to the Conference, telling the Committee he should be satisfied if it did what it pleased with that amount. The Committee accepted this money and continued the practice of giving £10 worth of books annually to the town visited; but in addition, a proportion of the sum was set apart to aid gentlemen who were engaged in costly researches. That practice has been continued now for three years. Now, although the Conference was perfectly in order in accepting Mr. Hills' aid for research, I should say so long as it had no funds of its own to perform this most obvious duty, it seems to me, as Secretary, it was perhaps scarcely in order when once the Conference began to get rich. I represented this view of the matter to Mr. Hills. He agreed, and at once set himself to solve this problem—how to make the Conference do what his fund had done before, and that his fund should do no less. He solved that problem in the very generous and ingenious way which you have heard described in this letter. He converts what was a diminishing fund into a permanent fund, by adding positively to his previous gifts; the interest of that permanent fund thus enabling the Conference to do what he always desired it should do—to present £10 worth of books annually to the library of the town visited.

THE PRESIDENT'S ADDRESS.

The PRESIDENT then delivered the following address:—

Gentlemen,—In accordance with the usual practice on these occasions I purpose bringing under your notice, as an introduction to the business we are about to enter upon, some of the evidences of pharmaceutical progress which events of recent occurrence afford, and some of the questions which appear to have special claims upon our attention. It is to me a source of much gratification to find myself surrounded and supported by the members of an association in which there are so many able and earnest workers seeking the attainment of an object which is worthy of our highest ambition. We meet here as pharmacists anxious to promote the improvement of the art of pharmacy. All whom I have the honour of addressing are interested in the cultivation of this art, and desire by every available means to increase its usefulness and elevate it as an essential department of the practice of medicine. It would be difficult to select a more worthy object than that we have before us, or one which more largely partakes of a benign and philanthropic character, affecting as it does the well-being not only of man but also of those sentient beings which, while they are made subservient to the wants and contribute to the happiness of man, are entitled to his sympathy, care and protection. The power of alleviating the sufferings of disease by the use of material remedies places the art of medicine in the highest rank among human occupations and gives to the physician a claim to respect and gratitude which has ever been freely conceded by every class of every people throughout the world. It is our privilege to be humble ministers in the work of healing the sick. We do not pretend to that high qualification which enables the physician to search out and determine the nature, the seat, and the cause of disease; nor do we profess to be able to indicate what are the agents best suited for the relief of those who suffer from its effects. Diagnosis and therapeutics are among the highest attainments in medical knowledge, and require for their successful exercise and application an intimate acquaintance with the mechanism, the physiology and pathology, of the animal body. We make no pretensions to such knowledge; but we have a province and sphere of action which is specially ours, and the fulfilment of its requirements is as essential to the successful practice of medicine as is the exercise of what we may concede to be, as compared with ours, the higher mental qualifications of the skilled physician. It belongs to our province to produce, to collect and prepare for administration, and supply to the public, the various remedies which medical men prescribe. These are the legitimate duties of the pharmacist, and when performed as they should be, by those who possess the requisite qualifications for them, they involve the application of much scientific knowledge, and of cultivated faculties both of body and mind.

But while pharmacy is designed thus to occupy a position of great importance and usefulness in relation to the practice of medicine, the highest fulfilment of its mission involves a certain amount of submission to, and dependence upon, those who constitute the medical profession. The physician and the pharmacist are indeed each dependent one on the other, for while the physician relies upon the compounder of medicines for the exercise of the knowledge and skill required for producing the remedies which medical experience approves, the pharmacist must be guided by those who possess that experience, in directing his efforts to the attainment of required results. The exercise of too much independence on either side would be fraught with evil, and could not fail to retard the progress of improvement which so prominently characterizes the state of medical practice in the present day.

Fortunately the most friendly relations exist between the medical profession and the body which this Conference represents. We are anxious to fulfil our mission, and they are willing and ready to afford encouragement and aid, not only by the expression of approval when such is merited, but by active co-operation in furthering the objects in which we are mutually most interested.

That there should be, or appear to be, to some extent, a clashing of interests at or near to the border line which separates the respective domains of the prescriber and dispenser of medicines, is inevitable, so long as the requirements of the public and the regulations relating to medical practice remain as they are. The pharmacist occupies a position in which there cannot fail to be frequently occurring conflicts between the temptation to prescribe and the restraint which sound judgment would impose on the exercise of a function for which he is at least but imperfectly qualified. It is often difficult to define the limit at which the dealer in drugs and medicines should cease to advise those who purchase and intend to use such articles without consulting a qualified medical man. If every individual were so circumstanced as to be able to place his health under the constant supervision and care of a skilled physician who was ready to attend to all his ailments, and able to interpret and treat them correctly, he might, no doubt, by adopting such a course, contribute to his comfort, and perhaps to his longevity. But this would involve a concurrence of circumstances that falls to the lot of comparatively few, and even among those who might command the conditions there are not many who think it worth while to do so. Men are prone to think that they are sufficiently able to gauge the extent and purport of slight and often occurring sensations, which although unpleasant are not considered to imply anything more than a mere passing disturbance of the functions of some of the organs, which may be easily restored to their natural state by resorting to the use of simple popular remedies. It is so among those who can afford to pay for skilled advice in trivial cases; but how much more so among the far more numerous class who study economy from necessity, and seek the cheapest method of attaining their object. The family medicine chest is an essential department of every household, although it may consist only of a glass of cold water to be taken at bed time. That mistakes are sometimes committed in this system of home treatment is certain, but the amount of evil resulting from it is probably small as compared with the benefits, real or imaginary, and the satisfaction arising from a sense of independence, which a judicious exercise of knowledge founded on such experiences as most intelligent individuals have the means of acquiring, may and generally do produce. The extent to which medicines are thus administered, may be inferred from the fact that of the 14,000 chemists and druggists in Great Britain, the greater part have but little to do with the dispensing of physicians' prescriptions, while all are engaged, and most are principally engaged, in supplying medicines to be used by the public on unprofessional responsibility. If individuals and the heads of families are justified in thus treating slight ailments by the use of remedies which they have seen used in the same way by others similarly circumstanced, it would be unreasonable to object to their extending or improving their knowledge of the use of such remedies by information obtained from those who being engaged in the preparation and sale of medicines are supposed to have a general acquaintance with their properties and uses. I hope and believe there are not many among the class of men thus appealed to who travel beyond the bounds required for the safety and at the same time the convenience of the public, under the circumstances prevailing in different localities; but it is essential that there should be some control exercised over the assumption of a duty which so obviously affects the interests of the public as does that of the treatment of diseases. There must be a limit to the extent to which unqualified pretenders may be allowed to claim the confidence and impose upon the credulity of those whose sufferings often make them easy victims to imposition. And then comes the question, where shall we draw the line and say, 'Thus far, but no further'?

With reference to this question I would venture to suggest that the responsibility of the pharmacist in prescribing for those who apply to him in cases of sickness is far greater than that of an individual unconnected with any department of medicine who may prescribe either for himself or for others. The pharmacist is supposed to possess—and, indeed, he ought to possess—a certain amount and kind of medical knowledge—that is, a knowledge of medicines and their properties; but beyond this, the public, judging, perhaps, from the insignia by which he is surrounded and the atmosphere he lives in, often credit him with other knowledge than that which he can justly lay claim to. Founded, it may be, on credit thus acquired, they place confidence in his power to advise, not only with regard to the properties and doses of medicines, but also in the treatment of diseases, with regard to which he possesses no real qualification. In this direction, from simple questions and trivial cases, he may be led on step by step; and unless he has strength of mind and firmness enough to resist the temptation which a desire to satisfy customers, to retain and not to discredit or weaken the favourable opinion previously formed of his knowledge, experience, and judgment, with other considerations natural to a man of business, he may be drawn almost imperceptibly into a habit of prescribing, for which no sound justification can be advanced.

It has been urged by the advocates and promoters of the improved system of pharmaceutical education from which this association has sprung, that as pharmacists and druggists become better qualified for their legitimate duties they will be less disposed to engage in those for which they have no real qualification. This is a result that would be naturally looked for; and impartial observers of the state both of medical and pharmaceutical practice and the changes they have undergone during the last thirty or forty years will readily admit that while much yet remains to be accomplished, much has been done towards defining the limits within which pharmacy on the one hand and medical practice on the other should be restricted, not only with a view to the interests of practitioners in each of these departments, but with the broader view of advancing the knowledge and improving the practice both of medicine and pharmacy.

We may look to the Pharmaceutical Conference—which seeks to lead its members into habits of scientific research—for efficient aid in raising and maintaining a high standard of ethics with reference to what is called counter practice. Those who have learnt to appreciate the importance in scientific pursuits of having a sufficient groundwork on which to base their theories and practice, and have acquired the habit of cautiously and logically connecting cause and effect, will be naturally disinclined to speculate in the empirical treatment of diseases of which they have no thorough fundamental knowledge.

Materia medica and pharmacy are our legitimate subjects and they offer ample scope for study, research, and application. Diligent search has already been made among natural objects for those which possess therapeutical properties, but can it be said that the resources of nature have been exhausted, and that there are no other drugs to be found than those we have which may either be used in their natural state, or from which valuable medicinal agents may be extracted? It is true that the past year has not been prolific of new medicines of any importance, but we have jaborandi among those of recent introduction, and we have yet to learn something of this drug and its active principle.

It is chiefly from the vegetable kingdom that our most valuable drugs are derived, some of which by simple processes of pharmacy afford to the physician the means of modifying in a variety of ways the condition and the action of animal organisms, while others afford scope for the exercise of chemical knowledge and skill in extracting their more active constituents. Intimately associated with, and closely allied to, many of the drugs of vegetable origin are some of the substances used as food, indeed it would not be easy to draw a line that should indicate sharply the distinction between alimentary and medicinal substances. Medical knowledge may be and to some extent is brought to bear upon the selection and preparation both of alimentary and medicinal substances, but it is especially required in regard to the latter. If we broadly represent as articles of food those which are intended to support vital action, to afford the means of development, and to reproduce what is daily passing and wearing away in our bodies; and as medicines those which affect the organs and their functions when in an abnormal state, or which alter their normal condition, it will be readily admitted that our sensations more clearly and safely indicate and assist us in selecting the former than the latter. Articles of food must comprise the constituents of every part of the body, and if there be a pressing want of any particular constituent beyond the daily supply, nature soon indicates the want by a craving desire for that which is deficient. The same kind of natural selection applies to a certain extent, no doubt, to medicinal agents, but the same liberty of choice in meeting the wants as they arise cannot be safely admitted here as in the case of food. With agents of so much power as these often possess it cannot be left to the unaided judgment of those who have no medical or pharmaceutical knowledge to undertake their selection, preparation, and use. Special education is required for the safe and successful performance of these duties. Until scientific and practical knowledge in botany, materia medica, and chemistry, was recognized as the ground work on which alone pharmaceutical qualifications and reputations could be based, some of the most important duties relating to pharmacy were necessarily performed by medical men who possessed those qualifications. Medical botany, materia medica, and pharmaceutical chemistry have had no representatives among the class of pure pharmacists in this country until recently. Happily the time has arrived when we may look, and already we have not looked in vain, for worthy disciples and followers of Lindley, Pereira, Christison, Anthony Todd Thomson, and Fownes, among those who have been trained and educated as pharmacists, and who are satisfied to devote themselves to the cultivation and extension of pharmaceutical knowlege. With such subjects as those I have named offering the reward of credit and renown to successful cultivators and explorers, no one need say that pharmacy is barren of profitable work, even of a high intellectual character, for those who are able and willing to work. We have only to look at what has been done and is now doing with reference to cinchona bark, ipecacuanha, and opium, to be satisfied that much yet remains to be done in those departments, and much of a similar description to be undertaken in connection with the cultivation of jalap, scammony, rhubarb, and other drugs, of which the supplies are imperfect and uncertain. We are no longer dependent on the precarious supplies of cinchona bark from the forests of South America, and may probably look forward to the time when our possessions in India will yield us all and more than all the bark we require. Hitherto we have been dependent on China for the production of our medicinal rhubarb, although it is grown in this country, and some samples of English rhubarb are hardly distinguishable from Chinese. May we not look forward to the improvement of English-grown rhubarb by cultivation or change of species, so that we may be independent of foreign importation and unaffected by changes such as that caused by the breaking up of the Russian monopoly in the trade?

It is often a subject of complaint by those who are interested in the use of good drugs, and sometimes it is urged as an excuse for dealing in such as are of inferior quality, that many of these articles are collected and prepared for sale by the native inhabitants of countries remote from advanced civilization, where much control cannot be exercised by merchants, who are therefore obliged to take what they can get. But admitting the force of this excuse as applied to some cases, it ought not to prevent our doing what is possible towards securing a supply of good drugs. We have seen what can be done by the combined influence of a body of pharmacists in that direction in the case of senna. About thirty years ago all the Alexandrian senna was mixed with a large proportion, often a fifth of its weight, of argel leaves, but a vigorous protest judiciously advanced by pharmacists in the early days of the Pharmaceutical Society, and supported by the wholesale dealers and merchants, induced those engaged in collecting the drug to supply it in a pure or less adulterated state. Improvement of a similar description has also been brought about in a similar way in the quality of much of the scammony and some of the varieties of opium, as well as of less important drugs, which are brought from distant countries.

But not only may the expression of opinion be thus brought to bear upon the improvement of our drug supplies, there is scope for the profitable application of chemical and pharmaceutical knowledge, both at home and abroad, in practically producing drugs and medicines. The Conference may take credit for having supplied in the person of one of its late officers a successful investigator and operator who is carrying out the objects of the Government by the production of cinchona alkaloids, in a partially purified state, from the acclimatized bark trees of India. The mixed alkaloids so obtained would hardly be received with favour in this country, and they are not, I believe, intended for exportation, but for use among the inhabitants of India, where they will supply an important want at a low price, and at the same time afford the means of fully testing the efficacy of the mixed as compared with the isolated alkaloids and their salts. There are other cases in which the question occurs as to whether the active constituents of vegetable substances are more advantageously used in the state in which they naturally occur or in an isolated and purified condition. The discovery and introduction of morphia has not superseded the use of opium and its preparations, and a similar remark may be made with reference to other drugs which yield definite chemical compounds to which their efficacy has been ascribed, but to which it probably is not wholly due.

The search for alkaloids in drugs of vegetable origin has been actively pursued since the early part of this century, and has resulted in many important discoveries by which the names of Sertürner, Pelletier, Caventou, Robiquet, and others have acquired well merited distinction. This search is still no less active than ever. No sooner is a new vegetable drug introduced than it is made the subject of an investigation with a view to the discovery of its active constituents, that is, of such as can be isolated as definite chemical compounds with marked therapeutical properties. The inquiry is sometimes attended with difficulty, and the results obtained are, not unfrequently, of doubtful practical value. Take, for instance, the case of ergot of rye. There has been a long standing inquiry with many experiments from time to time made, for the purpose of ascertaining what is the active therapeutical constituent of this drug. The ergot yields to ether about thirty per cent. of a fatty substance, partly consisting of fixed oil, partly of volatile fatty acids, and partly of resinous matter. This ethereal extract was considered by Dr. Wright to be the efficacious part of the ergot, but Neidhardt ascribed the efficacy it possessed to the resin, while others have represented that the fatty matter not only is devoid of hæmostatic properties but possesses others which are poisonous. From the part of the ergot insoluble in ether but soluble in alcohol, Wiggers extracted his ergotine, which Ludwig represents as modified albumin, insoluble in water, but soluble in alcohol and in caustic alkalies. Bonjean again denied the medicinal efficacy of Wiggers' ergotine, and claimed that property and the name for an extract made by percolation with cold water, and evaporation to the solid state after removal of albumin by heat and precipitation of other inert matter by means of alcohol. Subsequently Wenzell obtained two alkaloids which he has named ecboline and ergotine, both of which are described as soluble in water, with an alkaline reaction, and bitter taste. More recently still Tanret, in a paper read before the Academy of Sciences of Paris, claims to have discovered another alkaloid in ergot, which for distinction he has named ergotinine. It exists only in very small quantity, is strongly alkaline in its reaction, and capable of neutralizing acids. The presence of methylamine at one stage of the process by which this alkaloid is obtained and the further development of the same amine by the action of potash on the ergotinine are suggestive facts which will no doubt lead to further investigation. Lastly, we have the announcement, by Dragendorff, that the active principle of ergot is not an alkaloid but an acid which he names sclerotic acid, and which is present in ergot to the extent of two or three per cent. of its weight. Now, in the face of these various, and to some extent discrepant results of the attempts made to discover and isolate the active principle of ergot, we may be satisfied for the present to rely on the use of less definite preparations, such as the powder, decoction, or liquid extract.

Some difficulties have been experienced in obtaining in a state of purity the active principles of ipecacuanha and foxglove, but important improvements have been recently made in the processes for the preparation of both these bodies. For practical use emetine is perhaps hardly required, but if it should be, the process of Glenard seems to leave nothing to be desired. He obtains hydrochlorate of emetine in colourless crystalline nodules, from which pure emetine may be separated by an alkali. With regard to digitalin, the discovery of a good practical process yielding the active principle of digitalis in a pure, crystalline, definite and stable condition has long been an important desideratum in medicine. The various processes that have been recommended have yielded under the same name products that have differed in composition and properties, and none of which have been of such a definite nature as to ensure in different samples perfect uniformity of effects. The digitalin of the British Pharmacopœia is obtained by a process for which we are indebted to Homolle, but it cannot be looked upon as the pure active principle of the foxglove, and in an article of so much potency, the fact of its being amorphous leaves some doubt with reference to any sample of it as to the amount of care and skill that have been exercised in its preparation. Some years ago Nativelle succeeded in getting digitalin in a crystalline state for which, in 1872, the Orfila prize of 6000 francs was awarded; but the process by which the product was then obtained was considered troublesome and difficult. More recently the process has been simplified, and we may shortly look for the substitution of pure crystalline digitalin for the less definite preparation now ordered in the Pharmacopœia.

No doubt, I believe, is entertained that digitalin possesses all the valuable medicinal properties of the plant from which it is extracted. It is strictly, therefore, the active principle of the foxglove, but it cannot be classed among the alkaloids because in common with picrotoxin it lacks that essential constituent of an alkaloid, nitrogen. We thus have two powerful organic poisons digitalin and picrotoxin, forming remarkable exceptions to what would otherwise appear to be an almost universal law, that the element nitrogen, which in its isolated state is the most harmless of all the elements and apparently incapable of mischief, is nevertheless, when in combination, the fomenter of evil and a constant element of things vile and poisonous. There are problems to be solved with reference to nitrogen which have hitherto baffled the efforts made for their solution by our most able chemists. We live at the bottom of an immense ocean four-fifths of which consists of this tame and toothless nitrogen which is here inert and indisposed to union, but when united it becomes not only a fertilizer of the land and a constituent of our nutritious food, but also the fruitful source of diseases and the cause of many human miseries. We have boundless supplies of it ready to our hands, but we cannot turn it to its most required purpose of yielding ammonia, with which we might greatly increase the produce of the earth and thus feed many hungry mouths. We cannot by artificial means produce the alkaloids containing it which nature elaborates in the recesses of vegetable organs, leaving man by the exercise of his chemical and other knowledge to extract and isolate them, and to discover and control their useful applications for the relief of suffering humanity.

Morphia was the alkaloid first discovered, yet even now, after a lapse of sixty years, we are not only dependent upon nature for its elaboration, but avail ourselves of her further aid in supplying us by a process of natural elimination with the milky juice from which alone we extract the alkaloid. The collection of the opium seems a slow and labour-wasting process, in which at last we probably but imperfectly exhaust the poppies of their valuable constituents, and the question naturally arises, if the morphia be in the capsules before the incisions are made, why do we not resort to some process for its extraction more direct and exhaustive than that of partial exudation, more mechanical and at the same time more in accordance with modern manufacturing operations?

We are indebted to Mr. Groves, my predecessor in this chair, for some interesting experiments made many years ago on the direct separation of alkaloids from poppy capsules. I have referred on several occasions to Mr. Groves' paper in the *Pharmaceutical Journal*, and have always risen from its perusal with a feeling of the importance of the subject and of the desirableness of further investigation with reference to it. I must add, however, that experiments which I have seen conducted on a large scale with the same object have not afforded encouraging results.

In another case, under somewhat similar circumstances, the direct method of extraction from the vegetable source has been attended with good success. Resin of scammony is now produced from the root much more economically than it can be indirectly through the process of natural elimination.

But how long shall it be said that man, with all his boasted knowledge which has enabled him to outstrip Nature herself in the number of organic compounds he can make, including many of the natural products known to us, has nevertheless proved powerless to produce the vegetable alkaloids, with perhaps a single exception? It is the more surprising since we have every reason to believe that we have the right clue to their constitution as compound ammonias, a class of substances that has been largely and successfully investigated by Wurtz and Hofmann, who, with Fownes and others, have produced many bodies resembling the natural alkaloids. This is a field of investigation that may be looked upon as the future El Dorado of pharmacy, the successful exploration of which may possibly be reserved for some fortunate member of this Conference.

Chemistry has hitherto failed to unlock the secret of the mode of producing by artificial means the vegetable alkaloids, but she has to some extent made amends by supplying valuable therapeutical agents, some of which are efficient substitutes for them. There have been no recent additions made to our chemical materia medica, but among articles of modern introduction, hydrate of chloral, with croton-chloral—or, as it is now found to be, butyl-chloral—nitrite of amyl, and salicylic acid, occupy prominent positions.

The increased attention which has recently been given to the use of antiseptics and disinfectants in connection with surgical operations and the treatment of diseases has tended to bring many substances belonging to those classes into notice, and to afford occasion for testing their respective powers when applied under various circumstances. Several additions have thus been made to the substances used for those purposes, both by the introduction of new agents, such as salicylic acid, and the discovery of new applications of those which had previously been used for other purposes, such as chromic and boracic acids and borax.

In the discussions which have taken place respecting spontaneous generation, and the germ theory of the propagation of diseases, it has been shown by Tyndall that the atmosphere in which we live swarms with minute vital organisms and other floating particles, the presence of which is indicated by their power of scattering a beam of light, and that these bodies, some of which are too small to admit of their being individually examined or detected with the most powerful microscopes, may, nevertheless, be removed from the air by filtration through various media, such as cotton-wool—especially if this be moistened with glycerine. The investigations of Pasteur tend, like those of Tyndall and others, to show that in air and other denser forms of matter freed from these and similar vital organisms, no living beings, either animal or vegetable, can be developed; while, on the other hand, if the vital organisms or germs be present, together with the elements of nutrition, and conditions favourable to life and its development, living beings speedily appear, the propagation and growth of which are necessarily attended with the destruction of other forms of matter. It is to the breaking up in this way of one kind of matter to provide for the development of other forms of it that we may ascribe most of the changes affecting the health and well-being of man. In our living bodies the transformations caused by the development of minute and unseen forms of life produce various sorts of diseases, while in dead matter similar transformations cause putrefactive decomposition attended with its repulsive effects. This view of the way in which diseases are propagated has induced Pasteur to express the opinion that it may be possible to exterminate parasitic diseases from the earth, and it has given an impetus to the inquiry after the most efficient disinfectants, antiseptics, and deodorizing agents, and the best means of using them for the desired purposes. The subject is one the investigation of which pharmacists may engage in without subjecting themselves to the charge of poaching in other men's preserves. The inquiry belongs to the departments of physics, materia medica, and chemistry, as well as to that of pathology. Appeal is frequently made to the pharmacist for his aid not only in supplying but suggesting the agents that may be most relied upon for preventing the outbreak or spread of disease, and for destroying offensive effluvia. It is important as a basis on which alone sound judgment can be exercised in advising or acting in such cases, that there should be a clear and correct apprehension as to the objects to be sought and the means of attaining them. There is not unfrequently found to be a confusion of ideas with reference to the application of the terms deodorizer, antiseptic, and disinfectant. A closer connection is sometimes thought to prevail than we have good grounds for assuming the existence of, between things that are offensive to the senses, and those which are injurious to health. That many offensive gases possess deleterious properties when inhaled is unquestionable, but it would not be safe to conclude that a gas is injurious to health simply because it is not agreeable to the sense of smell. The sensations resulting from the action of external objects on our senses depend to some extent on habit and education, as forcibly illustrated by the practice of the retired tallow-melter who always returned to his former place of business on melting days.

But misapprehension is liable to exist not only with reference to the efficacy of deodorizing agents in relation to health, but also with reference to the peculiar action of antiseptics and disinfectants. An antiseptic is a substance that prevents or retards putrefaction, and putrefaction is the decomposition of animal or vegetable bodies accompanied with the evolution of offensive gases. The putrefactive change occurs only in dead matter, and requires the presence of water, heat, and a ferment. There is no putrefaction in the absence of water, nor at very low temperatures, nor in the absence of those minute vital organisms to which I have referred, and which constitute the ferment from which the decomposition originates. At one time it was thought that complete exclusion of air and oxygen from moist animal or vegetable substances was essential for their preservation from putrefactive decomposition, but that theory has been exploded, and it has been shown that although oxygen and atmospheric air may conduce to other changes, yet if free from the germs of the class of organisms alluded to, they do not favour but rather tend to retard putrefaction.

The substances used as antiseptics act either directly on the bodies in which putrefaction is occurring or might occur, forming with them combinations that are not susceptible of the decomposing action of a ferment, or they act indirectly by destroying the vitality or otherwise preventing the development and propagation of the organisms of which the ferment is composed. In this respect antiseptics are distinguished from disinfectants; the action of the latter being directed only towards the exciting causes and offensive or deleterious products of a class of changes which are themselves more comprehensive than those implied by the term putrefaction.

Disinfectants are agents possessing the property and employed for the purpose of destroying the contagia of infectious diseases, or depriving them of their specific infective power. The influence of these contagia being exerted only in living bodies the products of their action are distinct from those of putrefactive decomposition, and they are not necessarily perceptible to the senses. With a wider signification of the term, disinfectants may be said to act on, and render harmless, the products of putrefactive and other changes when these are capable of injuring health or inducing disease. There is thus a marked difference between the objects contemplated in the use of disinfectants and antiseptics, but the agents used for these purposes are for the most part the same, and differ only to the extent to which their actions are required to be adapted in one case to living and in the other to dead matter. Disinfection, also, may attend and result from, but is not a necessary consequence of deodorization, for not only may there be infection without a bad smell, but there may be odours that are not agreeable and yet are not injurious to health.

Much has been done towards defining the special objects to be attained by the use of these three classes of substances, and several new and efficacious agents suitable for such uses, have been added to the lists of those previously known or thus employed, but there is still room for the exercise of practical knowledge and judgment, in classifying, adapting, and preparing, these various agents with proper instructions for their use in cases in which they are required. Errors are often committed and the attainment of required objects frustrated, from the want of information on these points. Among the mistakes made in connection with the use of deodorizing and disinfecting agents, is that of covering one smell by another, that is of concealing instead of destroying the source of evil. It may even in some cases be an error to destroy a bad smell by an agent that is not capable at the same time of destroying imperceptible miasms which accompany it, and which of the two may be the only real source of danger to health. In the use of disinfectants there is often a great want of judgment manifested in the selection of those adequate to the production of the required effect. Who, for instance, with thorough knowledge of the subject, would think of using Condy's fluid for purifying a cesspool, or Sir William Burnett's disinfecting solution for destroying the contagion of a fever-stricken apartment. There is ample room for study and research with reference to subjects such as these, and if any one doubts it I would commend to his notice the experiences of Faraday many years ago in connection with the purification of the infected wards of the Millbank Penitentiary.

The use of disinfectants and antiseptics lies at the foundation of the treatment of some of the most inveterate diseases which medical men have to contend against, and it appertains to the pharmacist as well as the physician to be conversant with all that relates to the preparation, the mode of action, and the use of these important agents. They are comprised in our materia medica et hygienica. Some of them are included in our Pharmacopœia, but others are not. As pharmacists it devolves upon us to assist in the study and selection of members of this and other classes of articles that are contained, or may be thought worthy of being admitted among the officially recognized agents employed in medicine.

The Pharmacopœia is the standard of orthodoxy, with reference to medicines. It is supposed to contain all the most valuable therapeutical agents, and many of those required for hygienical purposes in connection with the treatment of diseases and the maintenance of health. These agents being intended for the use of medical men the success of whose practice depends upon the production of the expected results of their administration, those who prescribe them and who, of all the parties concerned, are the most deeply interested in their proper selection and preparation, are held to be the first and highest authorities in determining what they should be and how they should be defined. But prescribers of medicines may be, and indeed they mostly are, inexperienced in the commerce of drugs and the arts by which manufactured medicines are produced. The knowledge relating to these departments of pharmacology lies within the province of the pharmacist, and a large amount of this knowledge is required for the successful production of a pharmacopœia. That in former days those exclusively engaged in the practice of pharmacy were not ostensibly employed or consulted in the preparation of our national Pharmacopœias, necessarily resulted from the then undeveloped and generally unsatisfactory state of pharmacy as an occupation distinct from the practice of medicine. Since pharmacy with a scientific basis, and the Pharmaceutical Society which has furnished that basis, have simultaneously sprung into existence and rapidly grown to maturity in this country, the claims of pharmacists to be consulted by those to whom the legislature has committed the responsibility of preparing, and from time to time modifying, our national Pharmacopœia, have been practically recognized, by the appeals which have been made directly to individuals, and generally through the Pharmaceutical Society, for such assistance as could be obtained in that way. Much of the value of the British Pharmacopœia may be ascribed to the use made of information obtained from these sources, which has so far enhanced the estimation in which the work is held by members of the medical profession that even now, after a lapse of nearly ten years and the sale of 30,000 copies, very little disposition, or perhaps I should rather say a decided indisposition, is manifested to have any alteration made in its matter or form. Hence the frequent appearance of reprints instead of new editions. But in a work of this description, additions and alterations must be sometimes made to adapt it to the existing state of knowledge and of medical practice, and members of this Conference are furnishing matter which will facilitate the preparation of a new edition of the Pharmacopœia when such is called for.

If I might venture to suggest to the Conference what I conceive would be a valuable application of some of the scientific energy and the funds at its command, it would be to appoint one or two committees, not for original research, but for the practical testing and comparing of results which have been already obtained in the investigation of subjects relating to the preparation of medicines. There is a vast amount of work of this description that is much wanted, and is more suited for a committee acting under instructions from a public body than it would be for an individual voluntarily engaging in it. Work of this kind partakes to some extent of an invidious character as affecting other investigators, and while it necessarily involves the expenditure of much labour, it is not calculated adequately to enhance the scientific reputation of those engaged in it. When such work is undertaken by individuals there is a tendency generally to branch off somewhere into original research and leave the projected investigation imperfectly performed, with results which are of little practical value; whereas if delegated to a committee the inquiry would be deprived of much of its invidiousness, the work rendered less onerous, the temptation to depart from the original design greatly weakened, and the conclusions arrived at, being the result of combined action with unity of purpose, followed by a concurrence of opinion, would carry increased influence and command a greater amount of the confidence of those for whose use they were intended.

Among subjects which appear to me most urgently to call for this kind of inquiry I would place the preparation of digitalin and aconitine in the most forward rank; but there are others of less importance, such as the preparations of ipecacuanha, ergot of rye, and opium, which have strong claims for similar investigations. Any one of these subjects fully worked out would form a contribution from the Conference in its corporate capacity that would greatly enhance the credit it derives from the separate work of its members. In the investigation of these subjects reference would of course be made to processes used abroad as well as in this country, and comparisons would thus be made of the pharmacopœias of different nations. Such comparisons, accompanied with a desire, for which there are obvious reasons, to assimilate the composition of medicines bearing the same name but emanating from different authorities, would no doubt tend gradually to remove the more important discrepancies which now exist in that direction. How far it may be possible or even desirable to make one pharmacopœia serve for all nations, is a question I do not propose to discuss, beyond simply expressing the opinion that such a result, if attainable, could only be reached at some far distant period. But there is an object more within our reach, and at the same time of less questionable utility, which is the assimilation of the strength and composition of the more powerful medicines ordered under the same names in the pharmacopœias of different nations. For the accomplishment of this object it would be necessary to study the various processes, to freely discuss their relative merits, to ascertain what reasons there are for the adoption of special processes in particular localities, and finally to consider how far it is possible by an international convention of medical authorities, and possibly accompanied by mutual concessions, to agree to a standard of strength and composition that should be applied to all. It would be useless to attempt this with reference to more than a very small number of medicines at a time, and the value of its adoption would principally apply to powerful medicines. What we want is the gradual step by step introduction of a sort of international copyright in the use of names as applied to officially recognized medicines. This, of course, must be founded upon a convention to which the bodies legally authorized to issue pharmacopœias would be parties, that a distinctive name once accepted by general consent as applied to a medicine shall be used by all in the same sense. Such a convention might, in the first instance, apply only to a small number of the medicines now in use, with reference to which the parties to it may be able to agree in fixing their strength and composition, and subsequent additions might be made to the list as the result of further agreement. It might be also stipulated with reference to new forms of medicine that the names first officially applied to such by any member of the convention should not be used by other members to represent medicines differing from those in strength or composition. This obviously would be the easiest part of the arrangement to carry out.

And now, gentlemen, I must draw these discursive remarks to a conclusion. I have endeavoured to bring under notice some of the subjects which appear to me to have strong claims upon our attention and to present to the mental vision a fertile field for the application of those powers of cultivation by which nature and art may be made to bring forth "a balm for every ill that flesh is heir to." This field is committed to our special charge, and it is worthy of all the pains we can devote to the hedging in of its boundaries, the rooting out of all that is rank and uncongenial to the objects to which it should be exclusively devoted, and the formation of a garden, rich in those treasures which nature presents in the vegetable kingdom, and which man is striving, but vainly or with partial results, to imitate. In this field we have things that are lovely and those that are loathsome, yet all are applicable to some wise and beneficent purpose for which they are designed. It is our duty to discover their useful applications, and to adapt them for their proper uses.

Mr. DANIEL FRAZER said: It is my pleasing duty as I also consider t my privilege to ask you to return a vote of thanks to our Chairman for his able, clear, practical, and seasonable address. We in the north, I think, have great reason to be proud of the presence of such a man as Professor Redwood. He has been long known to us pharmacists in the capacity of author and as editor of the old household book, 'Gray's Supplement.' All of us know how valuable it is on account of the minute details in it—details which are not found in the ordinary Pharmacopœia. As professor of pharmacy, appointed by the Pharmaceutical Society, Professor Redwood has proved himself to be the round man in the round place, his previous training having admirably fitted him for the office. As a public analyst, appointed as he is by two of the largest districts in London, we may well say that in this case we honour ourselves in honouring Professor Redwood. The honour shown to him by London is refracted upon us when we have him as our head. The paper read is valuable from the seasonableness of the remarks offered, particularly regarding the line to be drawn between prescribing and dispensing. There was one point mentioned as to private prescribing not being so dangerous as prescribing by us intermediate men. I feel that strongly. I may say in a sentence that I never shared this dread of medical men interfering with us. They cannot do it. They cannot prevent John Smith prescribing for John Brown. But we ourselves ought to feel a responsibility attached to us on that account. Then the only other thing I would remark upon is that this meeting, I believe, is about the most successful that has ever been held. But it is a rebuke to us in the north when I see such a number of men from the south. Indeed I could name more gentlemen from the south than I could from the north as being present. I cannot but feel that a debt of gratitude is due to them. Many of them have been at all our meetings since 1870 and when the meetings have been in England, I shall not say how few of us from the north were present. I hope the result of the visit of the gentlemen from the south will stimulate the Scotch members to attend the meetings in the south, even that which is to be held next year at Plymouth. I propose a hearty vote of thanks to Professor Redwood for his able and valuable address.

Mr. E. C. C. SANDFORD: I have great pleasure in seconding that resolution. In common with many here I have had many opportunities of listening to Professor Redwood, but I never listened to him with so much pleasure as on the present occasion. There is one portion of his address to which I must take a slight exception. He stated there were many men in this room and elsewhere in the Pharmaceutical Society, who had derived their training from a number of eminent men, the names of whom he gave. But he did not mention among these his own name. I venture to say the students of Professor Redwood would outnumber the whole of the students of those gentlemen to whom he has referred. I am sure his remarks on nitrogen, deodorizers, antiseptics, and disinfectants, will be widely read, and much appreciated. They show to us, who know him, that his freshness and originality have not decreased with his increasing years. I was struck too with his remarks about the advantage of a family medicine chest. I had once to go to one of the outside Hebrides to introduce a new industry. I was almost the only English-speaking man amongst the Gaelic race. I had a medicine chest, about which I could tell many curious stories. It was very useful, but it had its disadvantage. I was pestered by half of the people of the place. They would not have the doctor. They would come to me. You may imagine how little I understood about their complaints when I tell you they were generally translated into English by an interpreter. There was one man who came late at night and told me his daughter was "nearly dead." That was all I could get out of him, I asked him what medicine he would suggest for that complaint. He thought whiskey would do. It occurred to me it might be judicious to ascertain the age of the young lady. When I found that she was only ten months old, I did not prescribe that remedy. I may state the medicine I most used was not in the Pharmacopœia. It did not contain that poisonous element, "nitrogen." It was labelled "usquebah," which is the Gaelic" for sudden death." There was another portion of Professor Redwood's address with which I was much pleased, that was the able manner in which he touched the delicate subject of prescribing. I hope that the result of this Conference may be to considerably reduce the proportion of Englishmen, and considerably increase the proportion of Scotchmen attending these annual meetings. I do trust that in this city there will be a change in another respect. I consider that pharmacy is in wrong hands. I do hope when I next drive through the streets of Glasgow I shall cease to see painted up "Medical Hall," but I shall see in place of that designation "Pharmaceutical Chemist."

Mr. STODDART: As our Chairman cannot put this motion I shall do so. I am sure it will be carried unanimously and heartily.

The PRESIDENT: I beg to thank Mr. Frazer and Mr. Stanford for the far too favourable terms in which they have alluded to me in proposing this vote of thanks. I also beg most emphatically to thank you for the manner in which you have received the proposal. I will not further take up your time, as I fear I have already too lengthily trespassed upon your patience, and I will only say I am very much obliged to you.

(To be continued.)

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The meeting of the British Association for the Advancement of Science took place on Wednesday, September 6, at Glasgow, under the presidency of the distinguished chemist and physicist, Professor Thomas Andrews, LL.D., F.R.S., of Belfast, who, according to usual custom, delivered the following opening address:—

THE PRESIDENT'S ADDRESS.

Six and thirty years have passed over since the British Association for the Advancement of Science held its tenth meeting in this ancient city, and twenty-one years have elapsed since it last assembled here. The representatives of two great Scottish families presided on these occasions; and those who had the advantage of hearing the address of the Duke of Argyll in 1855 will recall the gratification they enjoyed while listening to the thoughtful sentiments which reflected a mind of rare cultivation and varied acquirements. On the present occasion I have undertaken, not without anxiety, the duty of filling an office at first accepted by one whom Scotland and the Association would alike have rejoiced to see in this chair, not only as a tribute to his own scientific services, but also as recognizing in him the worthy representative of that long line of able men who have upheld the pre-eminent position attained by the Scottish schools of medicine in the middle of the last century, when the mantle of Boerhaave fell upon Monro and Cullen.

The task of addressing this Association, always a difficult one, is not rendered easier when the meeting is held in a place which presents the rare combination of being at once an ancient seat of learning and a great centre of modern industry. Time will not permit me to refer to the distinguished men who in early days have left here their mark behind them; and I regret it the more as there is a growing tendency to exaggerate the value of later discoveries, and to underrate the achievements of those who have lived before us. Confining our attention to a period reaching back to little more than a century, it appears that during that time three new sciences arose—at least, as far as any science can be said to have a distinct origin—in this city of Glasgow—experimental chemistry, political economy, and mechanical engineering. It is now conceded that Black laid the foundation of modern chemistry; and no one has ever disputed the claims of Adam Smith and of Watt to having not only founded, but largely built up, the two great branches of knowledge with which their names will always be inseparably connected. It was here that Dr. Thomas Thomson established the first school of Practical Chemistry in Great Britain, and that Sir W. Hooker gave to the chair of botany a European celebrity; it was here that Graham discovered the law of gaseous diffusion and the properties of polybasic acids; it was here that Stenhouse and Anderson, Rankine and J. Thomson, made some of their finest discoveries; and it was here that Sir William Thomson conducted his physico-mathematical investigations, and invented those exquisite instruments, valuable alike for ocean telegraphy and for scientific use, which are among the finest trophies of recent science. Nor must the names of Tennant, Mackintosh, Neilson, Walter Crum, Young and Napier be omitted, who, with many others in this place, have made large and valuable additions to practical science.

The safe return of the "Challenger" after an absence of three and a half years is a subject of general congratulation. Our knowledge of the varied forms of animal life, and of the remains of animal life which occur, it is now known, over large tracts of the bed of the ocean, is chiefly derived from the observations made in the "Challenger" and in the previous deep-sea expeditions which were organized by Sir Wyville Thomson and Dr. Carpenter. The physical observations, and especially those on the temperature of the ocean, which were systematically conducted throughout the whole voyage of the "Challenger," have already supplied valuable data for the resolution of the great question of ocean currents. Upon this question, which has been discussed with singular ability, but under different aspects, by Dr. Carpenter and Mr. Croll, I cannot attempt here to enter; nor will I venture to forestall by any crude analysis of my own the narrative which Sir W. Thomson has kindly undertaken to give of his own achievements and of those of his staff during their long scientific cruise.

Another expedition, which has more than fulfilled the expectations of the public, is Lieutenant Cameron's remarkable journey across the continent of Africa. It is by such enterprises happily conceived and ably executed that we may hope at no distant day to see the Arab slave-dealer replaced by the legitimate trader, and the depressed populations of Africa gradually brought within the pale of civilized life.

From the North Polar Expedition no intelligence has been received; nor can we expect for some time to hear whether it has succeeded in the crowning object of Arctic enterprise. In the opinion of many the results, scientific or other, to be gained by a full survey of the Arctic regions can never be of such value as to justify the risk and cost which must be incurred. But it is not by cold calculations of this kind that great discoveries are made or great enterprises achieved. There is an inward and irrepressible impulse—in individuals called a spirit of adventure, in nations a spirit of enterprise—which impels mankind forward to explore every part of the world we inhabit, however inhospitable or difficult of access; and if the country claiming the foremost place among maritime nations shrink from an undertaking because it is perilous, other countries will not be slow to seize the post of honour. If it be possible for man to reach the poles of the earth, whether north or south, the feat must sooner or later be accomplished; and the country of the successful adventurers will be thereby raised in the scale of nations.

The passage of Venus over the sun's disk is an event which cannot be passed over without notice, although many of the circumstances connected with it have already become historical. It was to observe this rare astronomical phenomenon, on the occasion of its former occurrence in 1769, that Captain Cook's memorable voyage to the Pacific was undertaken, in the course of which he explored the coast of New South Wales, and added that great country to the possessions of the British Crown.

As the transit of Venus gives the most exact method of calculating the distance of the earth from the sun, extensive preparations were made on the last occasion for observing it at selected stations—from Siberia in northern, to Kerguelen's Land in southern latitudes. The great maritime powers vied with each other to turn the opportunity to the best account; and Lord Lindsay had the spirit to equip, at his own expense, the most complete expedition which left the shores of this country. Some of the most valuable stations in southern latitudes were desert islands, rarely free from mist or tempest, and without harbours or shelter of any kind. The landing of the instruments was in many cases attended with great difficulty and even personal risk. Photography lent its aid to record automatically the progress of the transit; and M. Janssen contrived a revolving plate, by means of which from fifty to sixty images of the edge of the sun could be taken at short intervals during the critical periods of the phenomenon.

The observations of M. Janssen at Nagasakin, in Japan, were of special interest. Looking through a violet-blue glass he saw Venus, two or three minutes before the transit began, having the appearance of a pale round spot near the edge of the sun. Immediately after contact the segment of the planet's disk, as seen on the face of the sun, formed, with what remained of this spot, a complete circle. The pale spot when first seen was, in short, a partial eclipse of the solar corona, which was thus proved beyond dispute to be a luminous atmosphere surrounding the sun. Indications were at the same time obtained of the existence of an atmosphere around Venus.

The mean distance of the earth from the sun was long supposed to have been fixed within a very small limit of error at about 95,000,000 miles. The accuracy of this number had already been called in question on theoretical grounds by Hansen and Leverrier, when Foucault, in 1862, decided the question by an experiment of extraordinary delicacy. Taking advantage of the revolving mirror, with which Wheatstone had some time before enriched the physical sciences, Foucault succeeded in measuring the absolute velocity of light in space by experiments on a beam of light, reflected backwards and forwards, within a tube little more than thirteen feet in length. Combining the result thus obtained with what is called by astronomers the constant of aberration, Foucault calculated the distance of the earth from the sun, and found it to be one thirtieth part, or about 3,000,000 miles, less than the commonly received number. This conclusion has lately been confirmed by M. Cornu, from a new determination he has made of the velocity of light according to the method of Fizeau; and in complete accordance with these results are the investigations of Leverrier, founded on a comparison with theory of the observed motions of the sun and of the planets Venus and Mars. It remains to be seen whether the recent observations of the transit of Venus, when reduced, will be sufficiently concordant to fix with even greater precision the true distance of the earth from the sun.

In this brief reference to one of the finest results of modern science, I have mentioned a great name whose loss England has recently had to deplore, and in connection with it the name of an illustrious physicist whose premature death deprived France, a few years ago, of one of her brighest ornaments—Wheatstone and Foucault, ever to be remembered for their marvellous power of eliciting, like Galileo and Newton, from familiar phenomena the highest truths of nature!

The discovery of Huggins that some of the fixed stars are moving towards and others receding from our system, has been fully confirmed by a careful series of observations lately made by Mr. Christie in the Observatory of Greenwich. Mr. Huggins has not been able to discover any indications of a proper motion in the nebulæ; but this may arise from the motion of translation being less than the method would discover. Few achievements in the history of science are more wonderful than the measurement of the proper motions of the fixed stars, from observing the relative position of two delicate lines of light in the field of the telescope.

The observation of the American astronomer Young, that bright lines corresponding to the ordinary lines of Fraunhofer reversed, may be seen in the lower stata of the solar atmosphere for a few moments during a total eclipse, has been confirmed by Mr. Stone, on the occasion of the total eclipse of the sun which occurred some time ago in South Africa. In the outer corona, or higher regions of the sun's atmosphere, a single green line only was seen, the same which had been already described by Young.

I can here refer only in general terms to the observations of Roscoe and Schuster on the absorption-bands of potassium and sodium, and to the investigations of Lockyer on the absorptive powers of metallic and metalloidal vapours at different temperatures. From the vapour of calcium the latter has obtained two wholly distinct spectra, one belonging to a low, and the other to a high temperature. Mr. Lockyer is also engaged on a new and greatly extended map of the solar spectrum.

Spectrum analysis has lately led to the discovery of a new metal—gallium—the fifth whose presence has been first indicated by that powerful agent. This discovery is due to M. Lecoq de Boisbaudran, already favourably known by a work on the application of the spectroscope to chemical analysis.

Our knowledge of aerolites has of late years been greatly increased; and I cannot occupy a few moments of your time more usefully than by briefly referring to the subject. So recently as 1860 the most remarkable meteoric fall on record, not even excepting that of L'Aigle, occurred near the village of New Concord in Ohio. On a day when no thunderclouds were visible, loud sounds were heard resembling claps of thunder, followed by a large fall of meteoric stones, some of which were distinctly seen to strike the earth. One stone, above 50 pounds in weight, buried itself to the depth of two feet in the ground, and when dug out was found to be still warm. In 1872 another remarkable meteorite, at first seen as a brilliant star with a luminous train, burst near Orvinio in Italy, and six fragments of it were afterwards collected.

Isolated masses of metallic iron, or rather of an alloy of iron and nickel, similar in composition and properties to the iron usually diffused in meteoric stones, have been found here and there on the surface of the earth, some of large size, as one described by Pallas, which weighed about two-thirds of a ton. Of the meteoric origin of these masses of iron there is little room for doubt, although no record exists of their fall. Sir Edward Sabine, whose life has been devoted with rare fidelity to the pursuit of science, and to whose untiring efforts this Association largely owes the position it now occupies, was the pioneer of the newer discoveries in meteoric science. Eight and fifty years ago he visited with Captain Ross the northern shores of Baffin's Bay, and made the interesting discovery that the knifeblades used by the Esquimaux in the vicinity of the Arctic highlands were formed of meteoric iron. This observation was afterwards fully confirmed; and scattered blocks of meteoric iron have been found from time to time around Baffin's Bay. But it was not till 1870 that the meteoric treasures of Baffin's Bay were truly discovered. In that year Nordenskiöld found, at a part of the shore difficult of approach even in moderate weather, enormous blocks of meteoric iron, the largest weighing nearly twenty tons, imbedded in a ridge of basaltic rock. The interest of this observation is greatly enhanced by the circumstance that these masses of meteoric iron, like the basalt with which they are associated, do not belong to the present geological epoch, but must have fallen long before the actual arrangement of land and sea existed,—during, in short, the middle Tertiary, or Miocene period of Lyell. The meteoric origin of these iron masses from Ovifak has been called in question by Lawrence Smith; and it is no doubt possible that they may have been raised by upheaval from the interior of the earth. I have indeed myself shown by a magneto-chemical process that metallic iron, in particles so fine that they have never yet been actually seen, is everwhere diffused through the Miocene basalt of Slieve Mish in Antrim, and may likewise be discovered by careful search in almost all igneous and in many metamorphic rocks. These observations have since been verified by Reuss in the case of the Bohemian basalts. But, as regards the native iron of Ovifak, the weight of evidence appears to be in favour of the conclusion, at which M. Daubrée, after a careful discussion of the subject, has arrived—that it is really of meteoric origin. This Ovifak iron is also remarkable from containing a considerable amount of carbon, partly combined with the iron, partly diffused through the metallic mass in a form resembling coke. In connection with this subject, I must refer to the able and exhaustive memoirs of Maskelyne on the Busti and other aerolites, to the discovery of vanadium by R. Apjohn in a meteoric iron, to the interesting observations of Sorby, and to the researches of Daubrée, Wöhler, Lawrence Smith, Tschermak, and others.

The important services which the Kew Observatory has rendered to meteorology and to solar physics have been fully recognized; and Mr. Gassiot has had the gratification of witnessing the final success of his long and noble efforts to place this observatory upon a permanent footing. A physical observatory for somewhat similar objects, but on a larger scale, is in course of erection, under the guidance of M. Janssen, at Fontenay in France, and others are springing up or already exist in Germany and Italy. It is earnestly to be hoped that this country will not lag behind in providing physical observatories on a scale worthy of the nation and commensurate with the importance of the object. On this question I cannot do better than refer to the high authority of Dr. Balfour Stewart, and to the views he expressed in his able address last year to the Physical Section.

Weather telegraphy, or the reporting by telegraph the state of the weather at selected stations to a central office, so that notice of the probable approach of storms may be given to the seaports, has become in this country an organized system; and considering the little progress meteorology has made as a science, the results may be considered to be on the whole satisfactory. Of the warnings issued of late years, four out of five were justified by the occurrence of gales or strong winds. Few storms occurred for which no warnings had been given; but unfortunately among these were some of the heaviest gales of the period. The stations from which daily reports are sent to the meteorological office in London embrace the whole coast of Western Europe, including the Shetland Isles. It appears that atmospheric disturbances seldom cross the Atlantic without being greatly altered in character, and that the origin of most of our storms lies eastward of the longitude of Newfoundland.

As regards the velocity of the wind, the cup-anemometer of Dr. Robinson has fully realized the expectations of its discoverer; and the venerable astronomer of Armagh has been engaged during the past summer, with all the ardour of youth, in a course of laborious experiments to determine the constants of his instrument. From seven years' observations at the Observatory of Armagh, he has found that the mean velocity of the wind is greatest in the S.S.W. octant and least in the opposite one, and that the amount of wind attains a maximum in January, after which it steadily decreases, with one slight exception, till July, augmenting again till the end of the year.

Passing to the subject of electricity, it is with pleasure that I have to announce the failure of a recent attempt to deprive Oerstedt of his great discovery. It is gratifying thus to find high reputations vindicated, and names which all men love to honour transmitted with undiminished lustre to posterity. At a former meeting of this Association, remarkable for an unusual attendance of distinguished foreigners, the central figure was Oerstedt. On that occasion Sir John Herschel in glowing language compared Oerstedt's discovery to the blessed dew of heaven, which only the master-mind could draw down, but which it was for others to turn to account and use for the fertilization of the earth. To Franklin, Volta, Coulomb, Oerstedt, Ampère, Faraday, Seebeck, and Ohm are due the fundamental discoveries of modern electricity—a science whose applications in Davy's hands led to grander results than alchemist ever dreamed of, and in the hands of others (among whom Wheatstone, Morse, and Thomson occupy the foremost place) to the marvels of the electric telegraph. When we proceed from the actual phenomena of electricity to the molecular conditions upon which those phenomena depend, we are confronted with questions as recondite as any with which the physicist has had to deal, but towards the solution of which the researches of Faraday have contributed the most precious materials. The theory of electrical and magnetic action occupied formerly the powerful minds of Poisson, Green, and Gauss; and among the living it will surely not be invidious to cite the names of Weber, Helmholtz, Thomson, and Clerk Maxwell. The work of the latter on electricity is an original essay worthy in every way of the great reputation and of the clear and far-seeing intellect of its author.

Among recent investigations I must refer to Professor Tait's discovery of consecutive neutral-points in certain thermo-electric junctions, for which he was lately awarded the Keith prize. This discovery has been the result of an elaborate investigation of the properties of thermo-electric currents, and is specially interesting in reference to the theory of dynamical electricity. Nor can I omit to mention the very interesting and original experiments of Dr. Kerr on the dielectric state, from which it appears that when electricity of high tension is passed through dielectrics a change of molecular arrangement occurs, slowly in the case of solids, quickly in the case of liquids, and that the lines of electric force are in some cases lines of compression, in other cases lines of extension.

Of the many discoveries in physical science due to Sir William Grove, the earliest and not the least important is the battery which bears his name, and is to this day the most powerful of all voltaic arrangements; but with a Grove's battery of 50 or even 100 cells in vigorous action, the spark will not pass through an appreciable distance of cold air. By using a very large number of cells, carefully insulated and charged with water, Mr. Gassiot succeeded in obtaining a short spark through air; and lately De la Rue and Müller have constructed a large chloride of silver battery giving freely sparks through cold air, which, when a column of pure water is interposed in the circuit, accurately resemble those of the common electrical machine. The length of the spark increasing nearly as the square of the number of cells, it has been calculated that with 100,000 elements of this battery the discharge should take place through a distance of no less than eight feet in air.

In the solar beam we have an agent of surpassing power, the investigation of whose properties by Newton forms an epoch in the history of experimental science scarcely less important than the discovery of the law of gravitation in the history of physical astronomy. Three actions characterize the solar beam, or, indeed, more or less that of any luminous body—the heating, the physiological, and the chemical. In the ordinary solar beam we can modify the relative amount of these actions by passing it through different media, and we can thus have luminous rays with little heating or little chemical action. In the case of the moon's rays it required the highest skill on the part of Lord Rosse, even with all the resources of the observatory of Parsonstown, to investigate their heating properties, and to show that the surface of our satellite facing the earth passes, during every lunation, through a greater range of temperature than the difference between the freezing- and boiling-points of water.

But if, instead of taking an ordinary ray of light, we analyse it as Newton did by the prism, and isolate a very fine line of the spectrum (theoretically a line of infinite tenuity), that is to say, if we take a ray of definite refrangibility, it will be found impossible by screens or otherwise to alter its properties. It was his clear perception of the truth of this principle that led Stokes to his great discovery of the cause of epipolic dispersion, in which he showed that many bodies had the power of absorbing dark rays of high refrangibility and of emitting them as luminous rays of lower refrangibility, of absorbing in short, darkness and of emitting it as light. It is not, indeed, an easy matter in all cases to say whether a given effect is due to the action of heat or light; and the question which of these forces is the efficient agent in causing the motion of the tiny disks in Crookes' radiometer has given rise to a good deal of discussion. The answer to this question involves the same principles as those by which the image traced on the daguerreotype plate, or the decomposition of carbonic acid by the leaves of plants, is referred to the action of light and not of heat; and applying these principles to the experiments made with the radiometer, the weight of evidence appears to be in favour of the view that the repulsion of the blackened surfaces of the disks is due to a thermal reaction occurring in a highly rarefied medium. I have myself had the pleasure of witnessing many of Mr. Crookes' experiments, and I cannot sufficiently express my admiration of the care and skill with which he has pursued this investigation. The remarkable repulsions he has observed in the most perfect vacua hitherto attained are interesting, not only as having led to the construction of a beautiful instrument, but as being likely, when the subject is fully investigated, to give valuable data for the theory of molecular actions.

A singular property of light, discovered a short time ago by Mr. Willoughby Smith, is its power of diminishing the electrical resistance of the element selenium. This property has been ascertained to belong chiefly to the luminous rays on the red side of the spectrum, being nearly absent in the violet or more refrangible rays and also in heat-rays of low refrangibility. The recent experiments of Professor W. G. Adams have fully established the accuracy of the remarkable observation, first made by Lord Rosse, that the action appeared to vary inversely as the simple distance of the illuminating source.

Switzerland sent, some years ago, as its representative to this country the celebrated De la Rive, whose scientific life formed lately the subject of an *éloge* from the pen of M. Dumas. On this occasion we have to welcome, in General Menabrea, a distinguished representative both of the kingdom of Italy and of Italian science. His great work on the determination of the pressure and tensions in an elastic system is of too abtruse a character to be discussed in this address; but the principle it contains may be briefly stated in the following words;—"When any elastic system places itself in equilibrium under the action of external forces, the work developed by the internal forces, is a minimum." General Menabrea has, however, other and special claims upon us here, as the friend to whom Babbage entrusted the task of making known to the world the principles of his analytical machine—a gigantic conception, the effort to realize which it is known was one of the chief objects of Babbage's later life. The latest development of this conception is to found in the mechanical integrator of Professor J. Thomson, in which motion is transmitted, according to a new kinematic principle, from a disk or cone to a cylinder through the intervention of a loose ball, and in Sir W. Thomson's machine for the mechanical integration of differential equations of the second order. In the exquisite tidal machine of the latter we have an instrument by means of which the height of the tide at a given port can be accurately predicted for all times of the day and night.

The attraction-meter of Siemens is an instrument of great delicacy for measuring horizontal attractions, which it is proposed to use for recording the attractive influence of the sun and moon, upon which the tides depend. The bathometer of the same able physicist is another remarkable instrument, in which the constant force of a spring is opposed to the variable pressure of a column of mercury. By an easy observation of the bathometer on shipboard, the depth of the sea may be approximately ascertained without the use of a sounding-line.

The Loan Exhibition of Apparatus at Kensington has been a complete success, and cannot fail to be useful, both in extending a knowledge of scientific subjects and in promoting scientific research throughout the country. Unique in character, but most interesting and instructive, this exhibition will, it is to be hoped, be the precursor of a permanent museum of scientific objects, which, like the present exhibition, shall be a record of old, as well as a representation of new inventions.

It is often difficult to draw a distinct line of separation between the physical and chemical sciences; and it is perhaps doubtful whether the division is not really an artificial one. The chemist cannot, indeed, make any large advance without having to deal with physical principles; and it is to Boyle, Dalton, Gay-Lussac, and Graham that we owe the discovery of the mechanical laws which govern the properties of gases and vapours. Some of these laws have of late been made the subject of searching inquiry, which has fully confirmed their accuracy, when the body under examination approaches to what has not inaptly been designated the ideal gaseous state. But when gases are examined under varied conditions of pressure and temperature, it is found that these laws are only particular cases of more general laws, and that the laws of the gaseous state, as it exists in nature, although they may be enunciated in a precise and definite form, are very different from the simple expressions which apply to the ideal condition. The new laws become in their turn inapplicable when, from the gaseous state proper, we pass to those intermediate conditions which, it has been shown, link with unbroken continuity the gaseous and liquid states. As we approach the liquid state, or even when we reach it, the problem becomes more complicated; but its solution even in these cases will, it may confidently be expected, yield to the powerful means of investigation we now possess.

Among the more important researches made of late in physical chemistry, I may mention those of F. Weber on the specific heat of carbon and the allied elements, of Berthelot on thermo-chemistry, of Bunsen on spectrum analysis, of Wüllner on the band-and line-spectra of the gases, and of Guthrie on the cryohydrates.

Cosmical chemistry is a science of yesterday; and yet it already abounds in facts of the highest interest. Hydrogen, which, if the absolute zero of the physicist does not bar the way, we may hope yet to see in the metallic form, appears to be everywhere present in the universe. It exists in enormous quantity in the solar atmosphere, and it has been discovered in the atmospheres of the fixed stars. It is present, and is the only known element of whose presence we are certain, in those vast sheets of ignited gas of which the nebulæ proper are composed. Nitrogen is also widely diffused among the stellar bodies, and carbon has been discovered in more than one of the comets. On the other hand, a prominent line in the spectrum of the aurora borealis has not been identified with that of any known element; and the question may be asked:—Does a new element, in a highly rarefied state, exist in the upper regions of our atmosphere? or are we with Angström to attribute this line to a fluorescent or phosphorescent light produced by the electrical discharge to which the aurora is due? This question awaits further observations before it can be definitely settled, as does also that of the source of the remarkable green line which is everywhere conspicuous in the solar corona.

I must here pause for a moment to pay a passing tribute to the memory of Angström, whose great work on the solar spectrum will always remain as one of the finest monuments of the science of our period. The influence, indeed, which the labours of Angström and of Kirchhoff have exerted on the most interesting portion of later physics can scarcely be exaggerated; and it may be truly said that there are few men whose loss will be longer felt or more deeply deplored than that of the illustrious astronomer of Upsala.

I cannot pursue this subject further, nor refer to the other terrestrial elements which are present in the solar and stellar atmospheres. Among the many elements that make up the ordinary aerolite, not one has been discovered which does not occur upon this earth. On the whole we arrive at the grand conclusion that this mighty universe is chiefly built up of the same materials as the globe we inhabit.

In the application of science to the useful purposes of life, chemistry and mechanics have run an honourable race. It was in the valley of the Clyde that the chief industry of this country received, within the memory of many here present, an extraordinary impulse from the application by Neilson of the hot blast to the smelting of iron. The Bessemer steel process and the regenerative furnace of Siemens are later applications of high scientific principles to the same industry. But there is ample work yet to be done. The fuel consumed in the manufacture of iron, as, indeed, in every furnace where coal is used, is greatly in excess of what theory indicates; and the clouds of smoke which darken the atmosphere of our manufacturing towns, and even of whole districts of country, are a clear indication of the waste, but only of a small portion of the waste, arising from imperfect combustion. The depressing effect of this atmosphere upon the working population can scarcely be overrated. Their pale, I had almost said etiolated, faces are a sure indication of the absence of the vivifying influence of the solar rays, so essential to the maintenance of vigorous health. The chemist can furnish a simple test of this state of the atmosphere in the absence of ozone, the active form of oxygen, from the air of our large towns. At some future day the efforts of science to isolate, by a cheap and available process, the oxygen of the air for industrial purposes may be rewarded with success. The effect of such a discovery would be to reduce consumption of fuel to a fractional part of its present amount; and although the carbonic acid would remain, the smoke and carbonic oxide would disappear. But an abundant supply of pure oxygen is not now within our reach; and in the meantime may I venture to suggest that in many localities the waste products of the furnace might be carried off to a distance from the busy human hive by a few horizontal flues of large dimensions, terminating in lofty chimneys on a hillside or distant plain? A system of this kind has long been employed at the mercurial mines of Idria, and in other smelting-works where noxious vapours are disengaged. With a little care in the arrangements, the smoke would be wholly deposited, as flue-dust or soot, in the horizontal galleries, and would be available for the use of the agriculturist.

The future historian of organic chemistry will have to record a succession of beneficent triumphs, in which the efforts of science have led to results of the highest value to the well-being of man. The discovery of quinine has probably saved more human life, with the exception of that of vaccination, than any discovery of any age; and he who succeeds in devising an artificial method of preparing it will be truly a benefactor of the race. Not the least valuable, as it has been one of the most successful, of the works of our Government in India, has been the planting of the cinchona-tree on the slopes of the Himalaya. As artificial methods are discovered, one by one, of preparing the proximate principles of the useful dyes, a temporary derangement of industry occurs, but in the end the waste materials of our manufactures set free large portions of the soil for the production of human food.

The ravages of insects have ever been the terror of the agriculturist, and the injury they inflict is often incalculable. An enemy of this class, carried over from America, threatened lately with ruin some of the finest vine districts in the south of France. The occasion has called forth a chemist of high renown; and in a classical memoir recently published, M. Dumas appears to have resolved the difficult problem. His method, although immediately applied to the *Phylloxera* of the vine, is a general one, and will no doubt be found serviceable in other cases. In the apterous state the *Phylloxera* attacks the roots of the plant; and the most efficacious method hitherto known of destroying it has been to inundate the vineyard. After a long and patient investigation, M. Dumas has discovered that the sulphocarbonate of potassium, in dilute solution, fulfils every condition required from an insecticide, destroying the insect without injuring the plant. The process requires time and patience; but the trials in the vineyard have fully confirmed the experiments of the laboratory.

The application of artificial cold to practical purposes is rapidly extending; and, with the improvement of the ice-machine, the influence of this agent upon our supply of animal food from different countries will undoubtedly be immense. The ice-machine is already employed in paraffin-works and in large breweries; and the curing or salting of meat is now largely conducted in vast chambers, maintained throughout the summer at a constant temperature by a thick covering of ice.

I have now completed this brief review, rendered difficult by the abundance, not by the lack of materials. Even confining our attention to the few branches of science upon which I have ventured to touch, and omitting altogether the whole range of pure chemistry, it is with regret that I find myself constrained to make only a simple reference to the important work of Cayley on the mathematical theory of isomers, and to elaborate memoirs which have recently appeared in Germany on the reflection of heat- and light-rays, and on the specific heat and conducting-power of gases for heat, by Knoblauch, E. Wiedemann, Winkelmann and Buff.

The decline of science in England formed the theme, fifty years ago, of an elaborate essay by Babbage; but the brilliant discoveries of Faraday soon after wiped off the reproach. I will not venture to say that the alarm which has lately arisen here and elsewhere on the same subject will prove to be equally groundless. The duration of every great outburst of human activity, whether in art, in literature, or in science, has always been short, and experimental science has made gigantic advances during the last three centuries. The evidence of any great failure is not, however, very manifest—at least, in the physical sciences. The journal of Poggendorff, which has long been a faithful record of the progress of physical research throughout the world, shows no signs of flagging; and the Jubelband by which Germany celebrated the fiftieth year of Poggendorff's invaluable services was at the same time an ovation to a scientific veteran who has perhaps done more than any man living to encourage the highest forms of research, and a proof that in Northern Europe the physical sciences continue to be ably and actively cultivated. If in chemistry the case is somewhat weaker, the explanation—at least, in this country—is chiefly to be found in the demand on the part of the public for professional aid from many of our ablest chemists.

But whatever view be taken of the actual condition of scientific research, there can be no doubt that it is both the duty and the interest of the country to encourage a pursuit so ennobling in itself and fraught with such important consequences to the well-being of the community. Nor is there any question in which this Association, whose special aim is the advancement of science, can take a deeper interest. The public mind has also been awakened to its importance, and is prepared to aid in carrying out any proposal which offers a reasonable prospect of advantage.

In its recent phase the question of scientific research has been mixed up with contemplated changes in the great universities of England, and particularly in the University of Oxford. The national interests involved on all sides are immense, and a false step once taken may be irretrievable. It is with diffidence that I now refer to the subject, even after having given to it the most anxious and careful consideration.

As regards the higher mathematics, their cultivation has hitherto been chiefly confined to the Universities of Cambridge and Dublin, and two great mathematical schools will probably be sufficient for the kingdom. The case of the physical and natural sciences is different, and they ought to be cultivated in the largest and widest sense at every complete university. Nor in applying this remark to the English universities must we forget that if Cambridge was the alma mater of Newton and Cavendish, Oxford gave birth to the Royal Society. The ancient renown of Oxford will surely not suffer while her material position cannot fail to be strengthened by the expansion of scientific studies and the encouragement of scientific research within her walls. Nor ought such a proposal to be regarded as in any way hostile to the literary studies, and especially to the ancient classical studies, which have always been so carefully cherished at Oxford. If, indeed, there were any such risk, few would hesitate to exclaim, "Let science shift elsewhere for herself, and let literature and philosophy find shelter in Oxford!" But there is no ground for any such anxiety. Literature and science, philosophy and art, when properly cultivated, far from opposing, will mutually aid one another. There will be ample room for all, and, by judicious arrangements, all may receive the attention they deserve.

A university, or studium generale, ought to embrace in its arrangements the whole circle of studies which involve the material interests of society as well as those which cultivate intellectual refinement. The industries of the country should look to the universities for the development of the principles of applied as well as of abstract science; and in this respect no institutions have ever had so grand a possession within easy reach as have the universities of England at this conjuncture, if only they have the courage to seize it. With their historic reputation, their collegiate endowments, their commanding influence, Oxford and Cambridge should continue to be all that they now are; but they should, moreover, attract to their lecture halls and working cabinets students in large numbers preparing for the higher industrial pursuits of the country. The great physical laboratory in Cambridge, founded and equipped by the noble representative of the house of Cavendish, has in this respect a peculiar significance, and is an important step in the direction I have indicated. But a small number only of those for whom this temple of science is designed are now to be found in Cambridge. It remains for the university to perform its part and to widen its portals so that the nation at large may reap the advantage of this well-timed foundation.

If the Universities, in accordance with the spirit of their statutes, or at least of ancient usage, would demand from the candidates for some of the higher degrees proof of original powers of investigation, they would give an important stimulus to the cultivation of science. The example of many continental universities, and among others of the venerable University of Leyden, may here be mentioned. Two proof essays recently written for the degree of Doctor of Science in Leyden, one by Van der Waals, the other by Lorenz, are works of unusual merit; and another pupil of Professor Rijke is now engaged in an elaborate experimental research as a qualification for the same degree.

The endowment of a body of scientific men devoted exclusively to original research, without the duty of teaching or other occupation, has of late been strongly advocated in this country; and M. Fremy has given the weight of his high authority to a somewhat similar proposal for the encouragement of research in France. I will not attempt to discuss the subject as a national question, the more so as after having given the proposal the most careful consideration in my power, and turned it round on every side, I have failed to discover how it could be worked so as to secure the end in view.

But whatever may be said in favour of the endowment of pure research as a national question, the Universities ought surely never to be asked to give their aid to a measure which would separate the higher intellects of the country from the flower of its youth. It is only through the influence of original minds that any great or enduring impression can be produced on the hopeful student. Without original power, and the habit of exercising it, you may have an able instructor, but you cannot have a great teacher. No man can be expected to train others in habits of observation and thought he has never acquired himself. In every age of the world the great schools of learning have, as in Athens of old, gathered around great and original minds, and never more conspicuously than in the modern schools of chemistry, which reflected the genius of Liebig, Wöhler, Bunsen, and Hofmann. These schools have been nurseries of original research as well as models of scientific teaching and students attracted to them from all countries became enthusiastically devoted to science, while they learned its methods from example even more than from precept. Will any one have the courage to assert that organic chemistry, with its many applications to the uses of mankind, would have made in a few short years the marvellous strides it has done, if science, now as in mediæval times, had pursued her work in strick seclusion,

> Semota ab nostris rebus, seiunctaque longe,
> Ipsa suis pollens opibus, nil indiga nostri?

But while the Universities ought not to apply their resources in support of a measure which would render their teaching ineffective, and would at the same time dry up the springs of intellectual growth, they ought to admit freely to university positions men of high repute from other universities, and even without academic qualifications. An honorary degree does not necessarily imply a university education; but if it have any meaning at all, it implies that he who has obtained it is at least on a level with the ordinary graduate, and should be eligible to university positions of the highest trust.

Not less important would it be for the encouragement of learning throughout the country that the English Universities, remembering that they were founded for the same objects, and derive their authority from a common source, should be prepared to recognize the ancient universities of Scotland as freely as they have always recognized the Elizabethan University of Dublin. Such a measure would invigorate the whole university system of the country more than any other I can think of. It would lead to the strengthening of the literary element in the northern, and of the practical element in the southern universities, and it would bring the highest teaching of the country everywhere more fully into harmony with the requirements of the times in which we live. As an indirect result, it could not fail to give a powerful impulse to literary persuits as well as to scientific investigations. Professors would be promoted from smaller positions in one university to higher positions in another, after they had given proofs of industry and ability; and stagnation, hurtful alike to professorial and professional life, would be effectually prevented. If this union were established among the old universities, and if at the same time a new university (as I myself ten years ago earnestly proposed) were founded on sound principles amidst the great populations of Lancashire and Yorkshire, the university system of the country would gradually receive a large and useful extension, and, without losing any of its present characteristics, would become more intimately related than hitherto with those great industries upon which mainly depend the strength and wealth of the nation.

It may perhaps appear to many a paradoxical assertion to maintain that the industries of the country should look to the calm and serene regions of Oxford and Cambridge for help in the troublous times of which we have now a sharp and severe note of warning. But I have not spoken on light grounds, nor without due consideration. If Great Britain is to retain the commanding position she has so long occupied in skilled manufacture, the easy ways which (owing partly to the high qualities of her people, partly to the advantages of her insular position and mineral wealth) have sufficed for the past, will not be found to suffice for the future. The highest training which can be brought to bear on practical science will be imperatively required; and it will be a fatal policy if that training is to be sought for in foreign lands, because it cannot be obtained at home. The country which depends unduly on the stranger for the education of its skilled men, or neglects in its highest places this primary duty, may expect to find the demand for such skill gradually to pass away, and along with it the industry for which it was wanted. I do not claim for scientific education more than it will accomplish, nor can it ever replace the after-training of the workshop or factory. Rare and powerful minds have, it is true, often been independent of it; but high education always gives an enormous advantage to the country where it prevails. Let no one suppose I am now referring to elementary instruction, and much less to the active work which is going on everywhere around us, in preparing for examinations of all kinds. These things are all very useful in their way; but it is not by them alone that the practical arts are to be sustained in the country. It is by education in its highest sense, based on a broad scientific foundation, and leading to the application of science to practical purposes—in itself one of the noblest pursuits of the human mind—that this result is to be reached. That education of this kind can be most effectively given in a university, or in an institution like the Polytechnic School of Zürich, which differs from the scientific side of a university only in name, and to a large extent supplements the teaching of an actual university, I am firmly convinced; and for this reason, among others, I have always deemed the establishment in this country of Examining Boards with the power of granting degrees, but with none of the higher and more important functions of a university, to have been a measure of questionable utility. It is to Oxford and Cambridge, widely extended as they can readily be, that the country should chiefly look for the development of practical science; they have abundant resources for the task; and if they wish to secure and strengthen their lofty position, they can do it in no way so effectually as by showing that in a green old age they preserve the vigour and elasticity of youth.

If any are disposed to think that I have been carrying this meeting into dream-land, let them pause and listen to the result of similar efforts to those I have been advocating, undertaken by a neighbouring country when on the verge of ruin, and steadily pursued by the same country in the climax of its prosperity. "The University of Berlin," to use the words of Hofmann, "like her sister of Bonn, is a creation of our century. It was founded in the year 1810, at a period when the pressure of foreign domination weighed almost insupportably on Prussia; and it will ever remain significant of the direction of the German mind that the great men of that time should have hoped to develop, by high intellectual training, the forces necessary for the regeneration of their country." It is not for me, especially in this place, to dwell upon the great strides which Northern Germany has made of late years in some of the largest branches of industry, and particularly in those which give a free scope for the application of scientific skill. "Let us not suppose," says M. Wurtz in his recent report on the artificial dyes, "that the distance is so great between theory and its industrial applications. This report would have been written in vain, if it had not brought clearly into view the immense influence of pure science upon the progress of industry. If unfortunately the sacred flame of science should burn dimly or be extinguished, the practical arts would soon fall into rapid decay. The outlay which is incurred by any country for the promotion of science and of high instruction will yield a certain return; and Germany has not had long to wait for the ingathering of the fruits of her far-sighted policy. Thirty or forty years ago, industry could scarcely be said to exist there; it is now widely spread and successful." As an illustration of the truth of these remarks, I may refer to the newest of European industries, but one which in a short space of time has attained considerable magnitude. It appears (and I make the statement on the authority of M. Wurtz) that the artificial dyes produced last year in Germany exceeded in value those of all the rest of Europe, including England and France. Yet Germany has no special advantage for this manufacture except the training of her practical chemists. We are not it is true, to attach undue importance to a single case; but the rapid growth of other and larger industries points in the same direction, and will, I trust, secure some consideration for the suggestions I have ventured to make.

The intimate relations which exist between abstract science and its applications to the uses of life have always been kept steadily in view by this Association, and the valuable reports, which are a monument to the industry and zeal of its members, embrace every part of the domain of science. It is with the greater confidence, therefore, that I have ventured to suggest from this chair that no partitition wall should anywhere be raised up between pure and applied science. The same sentiment animates our vigorous ally, the French Association for the Advancement of Science, which rivalling, as it already does, this Association in the high scientific character of its proceedings, bids fair in a few years to call forth the same interest in science and its results, throughout the great provincial towns of France, which the British Association may justly claim to have already effected in this country. No better proof can be given of the wide base upon which the French Association rests, than the fact that it was presided over last year by an able representative of commerce and industry, and this year by one who has long held an exalted position in the world of science, and has now the rare distinction of representing in her historic Academies the literature as well as the science of France.

Whatever be the result of our efforts to advance science and industry, it requires no gift of prophecy to declare that the boundless resources which the supreme Author and Upholder of the Universe has provided for the use of man will, as time rolls on, be more and more fully applied to the improvement of the physical and, through the improvement of the physical, to the elevation of the moral condition of the human family. Unless, however, the history of the future of our race be wholly at variance with the history of the past, the progress of mankind will be marked by alternate periods of activity and repose; nor will it be the work of any one nation or of any one race. To the erection of the edifice of civilized life, as it now exists, all the higher races of the world have contributed; and if the balance were accurately struck, the claims of Asia for her portion of the work would be immense, and those of Northern Africa not insignificant. Steam-power has of late years produced greater changes than probably ever occurred before in so short a time. But the resources of Nature are not confined to steam nor to the combustion of coal. The steady water-wheel and the rapid turbine are more perfect machines than the stationary steam-engine; and glacier-fed rivers with natural reservoirs, if fully turned to account, would supply an unlimited and nearly constant source of power depending solely for its continuance upon solar heat. But no immediate dislocation of industry is to be feared, although the turbine is already at work on the Rhine and the Rhone. In the struggle to maintain their high position in science and its applications the countrymen of Newton and Watt will have no ground for alarm so long as they hold fast to their old traditions, and remember that the greatest nations have fallen when they relaxed in those habits of intelligent and steady industry upon which all permanent success depends.

BRITISH PHARMACEUTICAL CONFERENCE.

The Supper.

On Tuesday evening, the 5th inst., the members of the British Pharmaceutical Conference met with the local pharmacists and their assistants at a supper in the Royal Hotel. The hall was crowded. Mr. Daniel Frazer presided, supported by Professor Redwood and a number of the office-bearers of the Conference. The cloth having been withdrawn,

Mr. Frazer, as chairman of the local committee, explained that, at first, it was intended to have a conversazione, but circumstances occurred which had caused the entertainment to assume the form of a supper. It was intended on that evening to give up the old routine system of toast drinking, as it was desirable to get quickly to the real business of the meeting. He was very much indebted to the Pharmaceutical Conference for bringing them together. He believed that the present Conference included the largest attendance of distinguished pharmacists that had ever met together in that country. He considered it a very high compliment paid to Scotland that the Conference should be held there, and that gentlemen should come from such distances in the south to attend. It was thought that this opportunity of asking them to speak a few words of advice, especially to their younger friends, should not be missed. With regard to their friend Professor Redwood, his career should be an incentive to all the young men present. He was once an assistant pharmacist in Cardiff, and had worked on steadily until now he had attained the position of President of the British Pharmaceutical Conference. Professor Redwood had rendered great assistance to their profession in his capacity of editor of the British Pharmacopœia, and editor of the old-fashioned 'Gray's Supplement,' which was one of their right-hand books. As had been stated in the morning their President was also analyst for two of the largest districts in London. As Professor Redwood was at the head of the Conference, the honour which he enjoyed was reflected upon the members.

Professor Redwood, said he had come into that room with feelings of gratification. Although he had been in Glasgow before, he never spent any time in it until the present. He had come to that city with the hope of finding in the great emporium of Scottish commerce evidence that pharmacy was highly prosperous; but his anticipations had been completely destroyed, because he observed when passing through the streets that pharmacy, so far as he could make out, was nowhere. He saw many establishments designated Apothecaries' Hall, or Surgeons' Hall, representing those places which he had been accustomed to regard as the establishments of pharmacists, but which he was informed were nothing of the sort as they all belonged to the medical profession. He learned this with great regret, and he concluded perhaps too hastily that pharmacy must indeed be at a very low ebb in Glasgow; but on entering that room his anticipations were again greately revived. He had felt gratified at seeing the many young men and men of mature age who he understood were all engaged in pharmacy. This led him to the consideration how important was the duty which devolved upon them. But it was as President of the Pharmaceutical Conference that he had been called upon to address them. What did such a Conference imply? It implied pharmaceutical progress. How was this advancement to be effected? It devolved upon them to solve that question. Now the Pharmaceutical Conference had originated in pharmaceutical union. But one of the first duties which devolved upon them in carrying out the great objects of the Conference, so far as they related to that part of the country, was to effect a pharmaceutical divorce of the pharmaceutical union. What did the pharmaceutical union mean in that part of the country? It was an unnatural union—a union of medical practice with that which did not properly and legitimately belong to the medical practice, and was derogatory to the medical practice. In his part of the country it would be considered highly derogatory for three-fourths—for such appeared to him to be the state of the case in that country—of the medical men to be keeping open shops, dealing in all the etceteras which were usually associated with the practice of pharmacy. He held, then, that the great object to be attained here was to effect a divorce of the union of two unnatural and inappropriate associations—of a profession on the one hand and a trade on the other. But how was this divorce to be effected? how to set about it in a spirit not of antagonism to those engaged in medical practice? He would address himself to that section of the community who were designated in his country as young England, but there he must call the "young Scotland." The duty devolved upon them of accomplishing the divorce of the unnatural union referred to. To attain that end they must qualify themselves for the position they were called to occupy. In proportion as they became highly qualified as pharmacists this unnatural union would cease.

The CHAIRMAN then called on Mr. Groves.

Mr. GROVES said he had hardly been twenty-four hours in Glasgow, and as this was his first visit he could not be supposed to know much about the state of pharmacy in Scotland; but he must say he was pained to see the vast number of spurious pharmacists preying upon the vitals of true pharmacy and injuring the prospects of those whom he saw before him. Such a condition of affairs stood in the way of that advancement which the Conference was intended to promote. He hoped they would take the advice of Professor Redwood and concert together to bring about the divorce which he had recommended. There had been in that city a gross intrusion on the part of surgeons and doctors—an interference with the practice and the profession of a trade of which they could know so little. It would benefit themselves to discontinue the prevalent mixed practice. He hoped that the coming of the Conference would make the pharmacists less isolated, and induce them to direct their efforts to the mitigation of the evil. In the south they knew a little about it; but in Glasgow pharmacists had every reason to put their shoulders to the wheel, to bring about a reform.

Mr. WILLIAMS, President of the Pharmaceutical Society, having been called upon to address the meeting, expressed the pleasure he felt at being present, and remarked that the want which should be met was that pointed out by Professor Redwood. They should endeavour in Glasgow, and elsewhere, to place pharmacy in that position which it should occupy. It was not until that object had been attained, that pharmacy would be able to advance. He had been glad to see how well the young men who came up to London and Edinburgh passed their examinations, and he hoped that after they had passed, they would join the Pharmaceutical Society, which could better advance the real interests of their trade than isolated efforts could do.

Mr. GREENISH said, if he had to give his opinion of the condition of pharmacy in Glasgow, he thought he should lose many a friend to whom he could now hold out the hand. But if he did not mistake the earnestness which he had witnessed in that room, he thought, if he waited for a year or two and then had to speak of the condition of pharmacy in Glasgow, it would be very different from what it now was.

The CHAIRMAN said they all regretted the absence of Mr. Sandford, who had had more to do with the Pharmacy Acts than any one. As to their friend Mr. Hills, he was a man of generosity. In every part of the country, testimony was borne to his large-heartedness. He also regretted very much the absence of Mr. Bottle, who had been unable to attend the Conference. He would now ask Mr. Savage to tell them something about matters in Brighton, which, he believed? were worse in some respects than in Glasgow. He was in that town two months ago and he observed close to the premises of Mr. Savage things that he never saw in Glasgow.

Mr. SAVAGE said he had been exceedingly amused with the remarks of the Chairman. He talked a great deal about civilization, and now he came to the Savage. But as previous speakers had spoken about the Pharmaceutical Society, he would only add "ditto, ditto," to their remarks.

Mr. E. BREMRIDGE, Secretary and Registrar of the Pharmaceutical Society, having been called upon, said he had great pleasure in attending these annual meetings. He never came to Glasgow without receiving the greatest kindness, and experiencing the greatest pleasure. He believed this was the case with all the strangers present. The President of the Conference had recommended to the young men present a divorce; he (the speaker) would recommend matrimony, and as a registrar he would not only register them all upon passing their examination, but he would like to register them as members of the Pharmaceutical Society. He believed there was nothing like union, and it was only by union that any great object whether social or parliamentary could be accomplished.

The CHAIRMAN said, that as the Pharmaceutical Conference was indebted for its organization and progress to the able way in which the Secretary carried on the details of the work, he was sure that they would be glad to hear what Dr. Attfield and Mr. Benger had to say to them. The former gentleman in particular had devoted a great deal of time and labour to the work of pharmaceutical education.

Professor ATTFIELD said he had been taken somewhat at a disadvantage in being asked (he a Southerner) to come to Scotland and say something about education, for he should like to know what an Englishman could tell a Scotchman about education? Was he to instruct them in the art of hospitality? Certainly not, after the experience they had had; nor could he teach the Scotchman anything in the matter of large-heartedness. He could not educate Scotchmen as regards the organization of local gatherings, for, though he knew something about organization in connection with this Conference, still he could not tell Scotchmen about organization. He need not tell gentlemen that pharmaceutical education up to the present time was education divorced from examination. There was a pharmaceutical compulsory examination. A man was not asked where he received his knowledge so long as he had it. That involved an erroneous assumption, namely, that a man's education could be tested by examination.

It was thought, twenty or thirty years ago, this could be done. Now it was known it could not. It was scarcely six weeks since that one of the greatest of English colleges, Owens College, Manchester, set forth a scheme by which it expected to become not only an educating but an examining body. The authorities were tired of sending men to be examined because education divorced from examination led not to real education but to the superfluity commonly called cram. He had learned something of education in Scotland. There he found that education and examination were married and not divorced. He looked on the medical profession in England and there he found the so-called examining boards asking a man first of all not what he knew, but where he had been educated; show them he had been recognized by an eminent school for so many years, and then they put a few questions to him to see whether he had done his duty and whether his teachers had done theirs. Now he wanted to see in pharmacy such a system as prevailed with regard to the medical profession; in a word, he wanted to see education married to examination. He was interested in the question because he loved pharmacy. He was an apprentice to pharmacy and had the good fortune to be the student of the men of whom he was now the colleague. The anxiety of his life was to see pharmacy prosper in Great Britain. He was convinced it would never prosper as it did in other countries until the system of mere examination was done away with, and until there was a real education married to examination.

Mr. Benger said that every year they were more and more indebted to the local committees for the success of the Conference. He also referred to the hospitality shown to members during their present visit.

Mr. Reynolds, having been requested to speak, alluding to provincial education, said there was no great encouragement to be derived from the view of its prospects, the progress it made seeming to be slow. It was well known there was a variety of unfavourable influences at work. They would need to maintain their privileges against foreign attack, but the whole question was mixed up with that of secondary education in this country. With respect to that matter, Englishmen had no reason to boast. At one of the meetings of the Conference in London two years ago, his friend Dr. De Vrij, of Holland, told him that in a few weeks there would be celebrated at Leyden, the tercentenary of the university of that town. A university had been conferred upon the town in consequence of its successful defence against its Spanish enemies. The greatest boon which it could ask from the Government was to have a university. That was an instance of what education had done for Holland. Of course they congratulated themselves upon the progress which their institution had made, but he was afraid they had to recognize still more the importance of secondary education in this country before they came up to such a standard as existed in Holland. If he were a Glasgow man he should feel proud of its splendid streets, noble warehouses, iron works, and shipping, but he should be still more proud of its university set upon a hill. Such institutions were calculated to spread scientific education throughout the country. Last year Mr. Forster said that England had entered upon this task of supplying secondary education. Manchester was always to the front; Bristol was not far behind; and Nottingham had received a great development. He hoped when these movements were taking place that pharmaceutical chemists would play their part in developing natural science, because their own art depended upon natural science for its scientific treatment.

Mr. Schacht, having been introduced to the meeting, said it was the duty of every member of their trade to forward the progress of their common calling, and this he personally had endeavoured to do. He was free to confess, in common with his friend Mr. Reynolds, that they had felt some disappointment at the meagre success which had attended their efforts in the provinces. Perhaps they were a little too sanguine, and it was not right for him to utter a word of complaint because they had not everywhere found the same amount of enthusiasm that they possessed themselves. Perhaps they had a little over-reached their own powers of stirring the enthusiasm of others. However, they could console themselves with the reflection that the seed had been sown, and that it would bring forth fruit even in their own time. The whole business rested with the young. He perfectly agreed that examination without education was valueless. No one should think that examination would qualify, although it was a test of qualification.

Mr. John Mackay having been called upon by the Chairman to make a few remarks, said how much pleased he was to meet so many pharmaceutical friends at this social gathering. Referring specially to what had fallen from Professor Redwood, he said he had heard the word divorce with something like a feeling of trembling and shame, because it was a word seriously disliked in Scotland; but he was glad to find in the remarks of Mr. Bremridge, which had almost immediately followed, that the word union had been brought forward; and therefore he felt satisfied that while the separation of medical practice from practical pharmacy was one that could be desired, the union spoken of in regard to chemists and druggists joining the Pharmaceutical Society would form a means of strength that would ultimately prove of the greatest assistance in furthering the progress of the true interests of the pharmaceutical body. He also made some allusion to the remarks of Professor Attfield on compulsory education, and said that he had for some time had the same feeling in this matter as that which Professor Attfield had so strongly enunciated, with this difference, that Professor Attfield was actuated by a feeling which he might denominate high pressure, or, in other words what was rather in advance of the present state of matters, although he had had no hesitation in stating that many in this room would live to see the day when a regular curriculum would be impending, and when chemists and druggists as well as pharmaceutical chemists would be compelled to attend certain classes, and produce such evidence before they could be admitted to their examinations. This, however, he felt was not for the present but for the future. In closing he asked the meeting to allow him to express his strong regret that Mr. Sandford and Mr. Hills had not been able to attend this successful meeting of Conference in Glasgow. In regard to the former he might well be styled the Attorney-General, for few men knew more intimately the legal aspect and working of anything connected with the existing Acts of Parliament, while the good work he had done on behalf of the Society during the six years he was President, could never be known or fully estimated. Of his old and true friend Mr. Hills words could not convey to the meeting his own feelings towards him or express how much the Society, as well as pharmacy in general, was indebted to him. Kind, sincere, and generous in all his dealings, he well deserved to be recognized in every meeting connected with pharmacy, and he felt most unwilling that this great meeting should separate without showing by a very hearty round of applause, how much and how truly they all appreciated the labour and the time both these gentlemen had for many years expended in forwarding the interests of pharmacy in this country. This was most enthusiastically responded to by the whole company joining in three hearty rounds of applause.

*** Through the pressure upon our space we are compelled to defer answering several correspondents until next week.

Communications, Letters, etc., have been received from Mr. Botham, Mr. Howie, Mr. Carr, Mr. Kingzett, Mr. Williams, Mr. Muir, Mr. Stoddart, Mr. Leay, Messrs. Fritz, Mr. Prebble, Litmus, A. M. M., J. H. L., A. W., C. J. S., G. and T., J. W. S. and Co.

NOTE ON ACETATE OF MORPHIA.*

BY M. MERCK.

Complaints are sometimes made as to the solubility of this salt, it being generally expected that this substance should be easily and completely soluble in water. But acetate of morphia only answers to this condition when it contains sufficient acetic acid for its saturation, which is the case only when it is freshly prepared. The combination of morphia and acetic acid, as is known, is not very stable. There is a continual, although slow, elimination of acetic acid from the preparation, which leads to the formation of a basic salt, and eventually of pure morphia, so that the salt that was at first soluble becomes thus insoluble. The acetic acid that separates accumulates under the stopper of the vessel containing the salt, its presence becoming manifest by the odour when the bottle is opened. This fact causes the preparation to be sometimes looked upon as being acid, and as at the same time the salt is found to be not completely soluble in water, it is considered to be a proof of a mechanical adulteration, or an alteration arising from foreign alkaloids. This cause of incomplete solubility is not generally taken into consideration; but in the testing of acetate of morphia, the precaution ought to be taken of judging the amount of acid by noting the behaviour of a solution to test paper. Afterwards the eventual residue should be examined for pure morphia before the preparation is condemned as impure.

Several pharmacopœias, the German, for instance, allow an acetate of morphia that contains a small quantity of basic salt or pure alkaloid, since they permit the addition of a few drops of acetic acid to obtain a complete solution. Besides, as the separation of acetic acid cannot be avoided during a prolonged keeping, it is recommended to employ the preparation as fresh as possible, and not to lay in too large a stock. The unjust reclamations which sometimes originate in the formation of an extractive substance, and the tendency of the salt to become yellow, or even brown after a time, would be thus avoided.

As the cause of this decomposition is inherent to acetate of morphia, it cannot be prevented even by the complete exclusion of air and light, but in the most favourable conditions it would be a little retarded.

Among the reactions for recognizing the purity of morphia the German Pharmacopœia mentions the colourless solution that this alkaloid should give with concentrated sulphuric acid and also utilizes this test for the salts of morphia. With respect to the application of this test to pure morphia, the author merely remarks that a solution after being allowed to stand for some time, and especially if it has been heated, always has a faint violet red colour. But when the test is applied to the acetate, according to the author's experience, it may, in certain cases, give false results.

A perfectly pure acetate of morphia, which shortly after its preparation is without reproach, will at the end of a few weeks give a faintly coloured solution, as has been proved by repeated experiments. The author concludes from this fact that the tendency of this salt to decompose is in close relation with the phenomenon of coloration. The colour does not become visible to the eye until after a long time, but in reality it exists much earlier. This is the reason why a preparation which is not fresh, but appears to be still colourless, cannot stand the delicate test with sulphuric acid. The author has arrived at the conviction, based upon numerous experiments, that commercial acetate of morphia will not dissolve without coloration in sulphuric acid, especially of the strength prescribed (sp. gr. 1·840).

Experience has shown that acetate of morphia undergoes no loss of its medicinal properties through the decomposition referred to, unless an intense yellow colour shows that the decomposition has proceeded too far. The author thinks that the test by means of sulphuric acid may be abandoned without disadvantage, and the more so as it may sometimes lead to the impression that narcotine is present.

* From the *Pharmaceutische Zeitung*.

ACTION OF HYDROGEN SULPHIDE ON ALKALOIDS.*

BY E. SCHMIDT.

Almost all the known vegetable bases are acted upon by hydrogen sulphide. The substances thereby formed, though in some cases definite compounds, appear for the most part to be mixtures which cannot be separated, owing to the facility with which they are decomposed. The author has examined more particularly the compounds formed with strychnine and brucine.

Strychnine.—When an alcoholic solution of strychnine is saturated with hydrogen sulphide and left at rest for some time, it gradually deposits fine orange-red needles of a substance to which Schmidt attributes the formula $2C_{21}H_{22}N_2O_2, 3H_2S_2$. This substance differs in colour and crystalline form from that which Hofmann obtained by the action of ammonium sulphide on strychnine, but cannot be distinguished therefrom by analysis. When kept for a day or two, it gives off hydrogen sulphide and slowly changes colour, whereas Hofmann's compound keeps for months without alteration. It was ascertained by direct experiment that this compound is formed only in presence of oxygen, not when the air is completely excluded. Its formation may be represented by the equation—

$$2\,C_{21}H_{22}N_2O_2 + 6\,H_2S + 3\,O = \begin{matrix} C_{21}H_{22}N_2O_2 \\ C_{21}H_{22}N_2O_2 \end{matrix} \left\{ \begin{matrix} H_2S_2 \\ H_2S_2 \\ H_2S_2 \end{matrix} \right. + 3H_2O$$

The compound is decomposed by mineral acids, with separation of oily drops of hydrogen bisulphide and formation of strychnine salts.

Brucine.—When hydrogen sulphide is passed into a strong solution of brucine in alcohol, freely exposed to the air, the liquid immediately assumes a yellow colour, and after a time deposits yellow needles, which, on prolonged standing, become covered with a yellowish-red layer of another sulphur compound. The yellow needles gave, on analysis, numbers agreeing with the formula $C_{23}H_{26}N_2O_4H_2S_2 + 2H_2O$, which is that of a compound of 1 mol. of brucine with 1 mol. of hydrogen bisulphide. This formula, however, is of no value, for the substance after drying possesses altered properties, and its composition is not represented by the formula $C_{23}H_{26}N_2O_4H_2S_2$. The crystals are prismatic, insoluble in the ordinary solvents, and undergo partial decomposition when kept. They are decomposed by mineral acids, with separation of hydrogen bisulphide and formation of brucine salts. The melting point is about 125°.

A second derivative of brucine is easily obtained by passing hydrogen sulphide into a dilute alcoholic solution of the alkaloid (1 in 100), till the liquid assumes a deep yellow colour and allowing it to stand in loosely-covered vessels.

* From the *Journal of the Chemical Society* for July. (Liebig's *Annalen*, clxxx., 287—304.)

In the course of twenty-four hours there is formed a deposit of ruby-red crystals, which, after washing with alcohol and ether, have the composition represented by the formula $C_{23}H_{26}N_2O_4{H_2S_2 \atop H_2S_2}$. The crystals belong to the triclinic system. In their behaviour they closely resemble the foregoing yellow compound.

The formation of these brucine compounds is dependent, like that of the strychnine compound, on the presence of oxygen, for if the air be perfectly excluded not a trace of them is produced. The following equations may, perhaps, represent their formation:—

$$C_{23}H_{26}N_2O_4+2H_2S+O = H_2O+C_{23}H_{26}N_2O_4H_2S_2;$$
$$C_{23}H_{26}N_2O_4+4H_2S+O_2=2H_2O+C_{23}H_{26}N_2O_4 \left\{ \begin{matrix} H_2S_2. \\ H_2S_2. \end{matrix} \right.$$

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

Meeting at Glasgow.

This Association met in the large hall of the Royal Hotel, George Square, Glasgow, on Friday, 8th Sept., at half-past ten a.m. There were about a hundred persons present, the principal towns in England and Scotland being represented. Mr. S. U. Jones, of Leamington, President of the Association, occupied the chair, and after a few introductory remarks, Mr. Barclay, of Birmingham, and Mr. Fairlie, of Glasgow, intimated that they had received a large number of letters from all parts of the country, from chemists and druggists, expressing regret at being unable to attend the meeting but heartily approving of the object of the Association.

The Honorary Secretary (Mr. Holdsworth, of Birmingham) was then called upon, and read a report of the meetings of the General Committee, of which the following is an abstract—

At a Committee Meeting held September 6th, 1876, in the Central Hall, Royal Hotel, Glasgow, the President, Mr. S. U. Jones, in the chair,—It was unanimously resolved—

"That the Honorary Secretary's and Honorary Treasurer's reports are hereby approved of, and that they be entered on the minutes and be read at the General Meeting on Friday."

"That Mr. T. W. Holdsworth be appointed Honorary Secretary for the present year."

"That Mr. W. F. Haydon be appointed Paid Secretary to the Association, security to be given to the satisfaction of the Committee."

"That Mr. H. Glaisyer, Bachelor of Laws of the University of London, Birmingham, be appointed Solicitor to the Association."

"That Professor Attfield be appointed Analytical Referee to the Association."

"That Messrs. Launday, Harrison and Harris, Accountants, Birmingham, be appointed Auditors to the Association."

"That Messrs. Lloyds' Banking Company (Limited), Birmingham, be the Bankers of the Association."

"That the Executive be authorized to take Offices in Birmingham, and to provide the requisite office furniture."

"That the Rules 1 to 12, now read, be and are hereby approved of, as the Constitution of the Association."

"That the scheme for organization now before the Committee be received and recommended to the General Meeting."

"That the following gentlemen form the Executive Committee for the present year:—Mr. S. U. Jones (Leamington), President; Mr. Thomas Barclay (Birmingham), Vice-President; Mr. W. Southall (Birmingham), Honorary Treasurer; T. W. Holdsworth (Birmingham), Honorary Secretary; Mr. F. W. Andrews (London); Mr. C. J. Arblaster (Birmingham); Mr. W. Y. Brevitt (Wolverhampton); Mr. W. J. Churchill (Birmingham); Mr. W. Cross (Shrewsbury); Mr. George Delves (Exeter); Mr. Francis Earle (Hull); Mr. J. M. Fairlie (Glasgow); Mr. A. Graves (Chesterfield); Mr. Thomas Greenish (London); Mr. Robert Hampson (London); Mr. W. Jervis (Sheffield); Mr. T. S. Johnson (Manchester); Mr. William Laird (Dundee); Mr. W. Matthews (London); Mr. J. McKenzie (Edinburgh); Mr. Richard Reynolds (Leeds); Mr. J. Shaw (Liverpool); Mr. G. Walker (Coventry); Mr. R. Walker (Birmingham)."

"That the following gentlemen be added to the General Committee:—Mr. A. P. Balkwill (Plymouth); Mr. F. B. Benger (Manchester); Mr. T. Blanchard (Edinburgh); Mr. T. Davison (Glasgow); Mr. T. G. Gibbons (Manchester); Mr. T. Glaisyer, (Brighton); Mr. W. Greig (Glasgow); Mr. T. Haffenden (Brighton); Mr. E. P. Hornby (Stockport); Mr. R. Howden (London); Mr. R. Humpage (London); Mr. Charles Kerr (Dundee); Mr. G. H. Laird (Edinburgh); Mr. A. McNaught (Greenock); Mr. J. Owen (London); Mr. George Passmore (Exeter); Mr. Tom Redfern (Penrith); Mr. J. Schweitzer (London); Mr. George Shepperley (Nottingham); Mr. G. F. Steele (Plymouth); Mr. A. Strachan (Aberdeen); Mr. W. W. Urwick (London); Mr. W. Woods (Plymouth)."

The Honorary Secretary's report stated that, in compliance with the request of the Birmingham Conference, he had forwarded on the 13th of July to the Secretary of the Pharmaceutical Society the resolution then passed, to the effect that the Conference of Chemists and Druggists urged upon the Pharmaceutical Society the necessity of testing the legality of cooperative traders selling and dispensing poisons. The receipt of the communication had been duly acknowledged by the Secretary, who promised that it should be submitted to the Council at its next meeting. Since then he had received another letter, saying that the resolution had been submitted to the Council at its last meeting and had been referred to the Law and Parliamentary Committee for consideration. A general circular had been issued to every chemist and druggist on the register, and the result had been gratifying. At the close of the Conference there were 377 members enrolled, and at the present time there were upwards of 1200 on the books, 150 of whom were London chemists. The amount of donations promised had risen from £260 at the close of the Conference to upwards of £620.

The Honorary Treasurer's report stated that at the close of the Birmingham Conference about £260 had been promised in donations; this included a number of subscribers of sums larger than 5s. In order to obtain the difference in donations a circular had been issued to these gentlemen asking them to allow the difference in the amounts to be placed as donations to the funds. The result was in nearly every case a ready compliance with the request. Mr. Churchill undertook to see the proprietors of the London wholesale houses and the result of his one day's canvass was most satisfactory. The general circular issued on the 24th ult. had proved financially a great success, as from the day it was issued till that time some £450 had been added to the funds, and every post continued to bring accessions of members and money.

Mr. Reynolds (Leeds) then moved the adoption of the reports. In the course of his remarks he said: I rather claim that this city should afford one illustration more of the utility of such an organization. Associations have been established by no fewer than two bodies with whom we are liable to be brought into conflict. The public analysts have their union; and on the other hand, a Medical Defence Association has been formed almost entirely to take from persons engaged in pharmacy some of their rights. It is quite possible that there are gross offenders and we should be very sorry to defend them, but on the other hand, we would far better trust to our sense of what is right and our own power to defend our actions if right than to the discretion and good feeling of an association about which we know nothing. If associations are found by these various bodies to be needed certainly a body which, like ours, is liable to encroachment from so many quarters, especially requires union. I believe the progress made the last two months has been very great. The work of organization has been as rapid as was possible, especially when it is considered that it is amongst persons far removed from one another. I now beg to move that the reports read be adopted.

Mr. Laird (Dundee) seconded the resolution, which was carried unanimously.

Mr. Greaves (Chesterfield): On the formation of the Birmingham Association we at once took steps at Chesterfield for the establishment of a local association, which we considered would be a great advantage and assistance to the general association as well as to the neighbourhood in which I reside. As a great many things arise locally which do affect the body generally, a good understanding is requisite to do away with the petty jealousies which cause such mischief to the trade. As we have experienced so great a benefit from our association, I was requested to bring the resolution of Chesterfield to be submitted to the consideration of the present meeting. It seems the scheme has been pretty well discussed at Birmingham by the committee. I mean the one propounded by Mr. Barclay. We purpose dividing our counties into hundreds, each district having an association. Our association embraces twenty members in a small area. We have no doubt we shall get every one in the districts, and we will have an organization which will assist very materially in collecting subscriptions, and making the duty of the secretary less costly to the general association, as well as doing ourselves a large amount of good. The resolution that is proposed by our committee is with respect to the desirability of forming local chemists' associations in each district throughout the country, and I have great pleasure in submitting the same.

Mr. Barclay said: The scheme we have the pleasure of presenting to you is very large and comprehensive. We think it is necessary that it should be so because this Association is not intended to embrace a few chemists here and there, but is intended to cover Great Britain. We hope that the Association will so commend itself to the sympathies of chemists generally that it will not be long before our highest expectations in that respect are thoroughly realized. We have confidence in going forward with this scheme from the progress that has already been made. We find wherever a canvass has been entered upon that the result has been most astounding. There were on all sides many jealousies, and previous efforts at union had failed. Reports have been given in by Mr. Cross, of Shrewsbury; Mr. Balls, Macclesfield; Mr. Dawson, York; Mr. March, Newark; Mr. Robinson, Dewsbury; Mr. Cooper, Leicester; Mr. Bell, Hull; Mr. Jones, Leamington; Mr. Prior, Oxford; Mr. Taylor, Leeds, etc. These gentlemen found almost without exception that all the chemists of their districts had been brought into the Association. Mr. Jones, of Leamington, gives an illustration of every chemist in a district having become member. I have a letter from Mr. Bell, of Hull, in which he writes: "I may just mention that my canvass was not a general one, or no doubt I would have been able to send you more names. But I can say this, that I had only one refusal to join the Defence Association, and the reason assigned to me was that the Pharmaceutical Society's bill of 1868 had done the trade no good, but made it worse for the chemists by reason of the grocers now selling so many drugs; that the privilege held by druggists of selling poisons did not pay for the trouble and care required in the sale of them, and that his son who had been in the trade for some time now would not follow it up." I could read many other letters, but the very fact that we have within two months 1200 gentlemen joining this Association, is sufficiently conclusive to warrant us in going forward with this large scheme. As to the need of organization, we all know that union is strength, and that if we are to have such a large number of members we must organize our forces to get the benefit of numbers. We have no organization that will touch the chemists of the country. The Pharmaceutical Society which we love so much only takes in the fringe of the trade, having only between 2000 and 3000 members, whereas there are 14,000 chemists on the register. Now, supposing there are parliamentary proceedings and that we had introduced during the past session, or have introduced, the bill of Sir W. Fraser, what should we have been able to do? I have endeavoured to ascertain his views. Mr. Mundy tried to see him, but he did not succeed. I wrote to one of Sir William's constituents, who has got a letter which may be of interest. It is in the following terms:—"In reply to your note received this evening, I have to say that before framing a bill on the subject of the sale of poisons and poisonous drugs, I shall consult many physicians, surgeons, druggists, and lawyers, and be able to do some good in a matter which calls for immediate attention.—W. Fraser." I think we may take encouragement from this letter that Sir W. Fraser's mind is at present a blank and that he is ready to receive impressions. If we go forward with our Association I think we shall be able to produce an effect in the direction in which chemists desire. The Pharmaceutical Council will give their greatest attention to this matter when it is introduced by Sir William. They will want help, for hitherto they never have had it in carrying forward any measure, the reason being that there was no organization. But if the proposed organization is put in force we shall be able in our various towns to bring pressure to bear upon our members of parliament and help the Council of the Pharmaceutical Society in carrying out their views. That is one of the objects we have in initiating this movement. We are not in antagonism to the Pharmaceutical Council or the Society. We think our movement is intended to benefit the Society to the greatest extent. We would not, I am sure, lift a finger to injure it in any way. I say this because it has been said we propose to do so. When we speak to some of our London, Glasgow, and Manchester friends with regard to the Adulteration Act, and the necessity of mutual protection, they say they can protect themselves, and state that they have their local organization, and can put their hands upon a local analyst and obtain his services. We say in reply, you have not a strong association with a large capital fund at your back and you cannot adequately protect yourselves as you would be able to do if you belonged not only to the local association, but were confederated with the great organization which we intend to form. But if the chemists in country places are considered, those in towns will see this is a selfish way of looking at the matter. How, again, are there to be local organizations in small towns or villages, and how can our brethren there engage a local analyst if they should be charged with selling a pennyworth of spirit of nitre, which, in consequence of evaporation, was not up to the standard? If an analyst wished to be crotchety, he could bring forward a prosecution in connection with the sale of such an article. In this way chemists in the country might, on account of their helpless position, be made to suffer. But if they belonged to this proposed organization there would be no chance of their suffering unjustly. We do not intend to defend cases of wilful adulteration. We would not soil our fingers by taking up cases which would in any way damage the reputation of the chemists of the country. I think our friends in Glasgow are capital illustrations of the necessity of a trade organization. Scotchmen are well known to be careful; this was shown within these few days, when it was tried to get them into this organization. I think their carefulness will lead them to join us. If they had been members they would have been told that Liebig's Liquid Extract of Meat would render them liable to the penalties of the excise, and they might not have been prosecuted. At any rate they would have been forewarned for the outlay of five shillings. It must have been extremely annoying to our Glasgow brethren to have been brought before the magistrates on the charge of acting as licensed victuallers. There is not only the annoyance, but there is also the fine, which might have been prevented if this Association had been in existence and those gentlemen members of it. Another result of this scheme would be the organization of the local association, which is of the greatest importance. We have had from Mr. Greaves a report from the Chesterfield Association. That association has resulted from the meeting at Birmingham. Indeed, when this large Association is fairly launched, we shall find associations springing up in all parts of the country, and we shall have instead of local jealousies gentlemen meeting in a united and friendly manner for their own protection. By the scheme it is intended that every county shall be divided into districts; that each district shall have one or more representatives on the general committee, that each representative shall *ex officio* be the local secretary in cases where there is only one. Where there is more than one representative appointed, then one of these shall be appointed local secretary. These local secretaries or representatives shall act for something like 120 districts. They shall form the general committee of this Association with not more than 30 others who shall be elected quarterly. It may be when the 120 gentlemen are assembled, they shall find there are some of the leading men of the trade that ought to be present. They shall look around and say so-and-so is not here, and ought to be upon this committee. They shall therefore proceed to add to that committee gentlemen who should be included, and so they shall bring up their number to not more than 150. Having sketched further what the committee might do, he said the secretary should be able to go on circuit when necessary, and deputations can be appointed to go to places where their services might be required. The general committee might meet within a week of the time when the annual general meeting of the Association will be held, and arrange the business to be considered. The railway expenses of the executive should be paid out of the funds of the Association. In that way, I think we should be able to get a representative executive, and bring pressure to bear upon Sir Wm. Fraser, and help the Pharmaceutical Council in promoting necessary legislation. There would thus be a power for good that was never possessed before. I move that the scheme for organization recommended by the general committee be adopted.

Mr. Greig (Glasgow): I have the greatest pleasure in seconding the motion. I am certain our brethren in the south will have a large measure of support from their brethren in the north. I come much into contact with the retail traders in Scotland, and know that the want of such an association is much felt ever since Mr. Freeland, of Bathgate, was hauled into the Court of Session and fined £12, not for any fault committed by him, but simply as a warning to druggists to keep proper assistants in their shops. This prosecution cost Mr. Freeland £100, which was defrayed by the druggists of England and Scotland. Again, in Glasgow, we are pounced upon by the excise. I suppose they think us better natured than people elsewhere, because they prosecute us for the thing manufactured in the south and not here. We should never have agreed to pay the penalty. The plea tendered by Mr. Davison was inadvertently done and misunderstood — Mr. Davison pleaded guilty to selling Liebig's Liquid Extract, but not to selling port wine—and the case was never tried on its merits as agreed upon. A case comes on at Hamilton, on Monday, and we have almost decided to have it tried. The thanks of the druggists of Glasgow are due to the editor of the *Mail* for the manner in which he has taken up this case. He is one of the Members of Parliament for Glasgow and has had two leaders favourable to our view of the case.

Mr. Preston (London): I hope it will not be considered intrusive if I, coming from London, should make a few remarks, especially as I feel a deep interest in the movement. I think this scheme at the present time is not put in print. I do not know whether it may occur to the gentlemen here, but I must confess that I could hardly take in exactly all the scheme that was placed before us by Mr. Barclay, although he spoke very clearly. But I think we should not pledge the executive or this meeting to the absolute scheme which that gentleman has indicated, but leave the resolutions so open that the executive may modify that scheme as may be found desirable. I have been connected with many associations and have very frequently found there has been great difficulty arising from first pledging the council to a definite scheme. You may indicate clearly what is desired, but as to details there should be considerable scope given. I heartily coincide with the desirability of forming some such association, because I know from my own experience that great hardship has been felt in various parts of the country in connection with the Adulteration Act. In London several cases have occurred of troublesome persecutions of chemists, and the practical effect is that generally speaking the retail chemist applies to the wholesale druggist as to what course he should pursue, and the latter feels in honour bound to protect, so far as he can, the chemist. I am sorry to say these prosecutions have arisen in a majority of instances with those who have been little able to defend themselves. I cannot say that analysts as a rule have carried out a generous policy with respect to this Adulteration Act. I hope it is not supposed I am starting anything in the shape of a defence of adulteration; but I think it is necessary to form an association, because various statements have been made in Parliament which affect the honour of the trade. I hope both the wholesale and the retail traders are as honourable men as those who sit in the House of Commons. I know a statement was made by the member for the Universities of Edinburgh and St. Andrews—Dr. Playfair—that it was customary to send a certain article to be ground up in the expectation that a larger quantity would be brought back. I do not know where the right hon. gentleman got his information. I know that Dr. Lyon Playfair was informed there was no truth in this statement, and that books were offered to him to show that nothing of the kind occurred. I spoke to one or two Members of Parliament, and urged them to bring this matter before the house, because, although it might be known to be false by the trade generally, still the statement goes before the public, who take little trouble to inquire into the accuracy of the statement. They only conclude that if such a man as Dr. Lyon Playfair says so it must be true. If an association were formed, pressure might be brought to bear upon the gentlemen who make in the House of Commons such random statements. I do not wish to cast any slur upon the Pharmaceutical Society for not having taken any action in this matter, but I feel that in the interests of the trade they might have done something. At all events, if they did not see their way clear to take some notice of it, it seems to me clear that it is the duty of the trade generally to form an association by which they might strengthen the hands of the Pharmaceutical Society to meet any false statements that may be made affecting the honour of the trade. Reverting to the fact that a chemist might be prosecuted for a liquid which had lost strength from the removal of the stopper, the conduct of the analysts reminds me of the fable of the boys and the frogs; it may be interesting to them to study this question, but it is anything but fun to those who have stones thrown at them. I think Birmingham is a proper place where a central organization of this kind may be formed. I think if formed it will be of material benefit to the trade.

The Chairman: The resolution has been amended, in consequence of the suggestion of Mr. Preston, to the satisfaction of the mover and seconder. The motion is "that the scheme for organization recommended by the General Committee be adopted subject to such modifications as the executive may deem desirable."

The resolution was then unanimously adopted.

The Secretary then read the following rules as suggested by the General Committee:—

RULES.

1. This Society shall be called the Chemists and Druggists' Trade Association.

2. Its objects shall be the protection of the legitimate interests of chemists and druggists from unfair attacks and encroachments, and the promotion of their common welfare.

3. The annual subscription shall be five shillings, due in advance on the 1st day of July in each year. Members whose subscriptions are in arrear will be disqualified from voting at any General Meeting.

4. The Annual General Meeting shall be held at some time within the months from May to September inclusive, at such place and time as the Executive Committee may determine. Notice shall be sent to each member by the Secretary not less than ten days previous.

5. The General Committee shall consist of representatives to be elected from the various districts throughout the country in accordance with the scheme and resolution which have been adopted. In the event of a district failing to elect a representative the Executive Committee shall fill the vacancy.

6. The Executive Committee shall consist of a president, a vice-president, a treasurer, an honorary secretary, and twenty other members, to be elected by ballot at each annual meeting. Five members to form a quorum. It shall be the duty of the General Committee to prepare and recommend to the annual meeting a list of the names of members to serve on the executive committee for the ensuing year.

7. The votes at all meetings, where not otherwise provided for, shall be taken by a show of hands, but any two members may demand that the votes be taken by ballot, and, in case of the numbers being equal, the chairman shall have a second or casting vote.

8. The railway expenses of the Members of the Executive Committee shall be repaid by the Association.

9. The duties of the paid secretary shall be determined by the Executive Committee, who shall control them unreservedly.

10. The Association will retain, within the discretion of the Executive Committee, the right of determining whether action shall be taken in any cases that may be suggested to it either for prosecution or defence, but it will consider its members to have superior claims to those of chemists and druggists who are not members. When it is desirable that information shall be promptly given to members upon any question affecting trade interests, a private circular shall be issued to each.

11. The Rules shall not be altered or rescinded, nor shall any new ones be added excepting at an Annual General Meeting, or at a special one called for the purpose. At least ten days' notice of such meeting must be given, and also of the alteration proposed.

12. A Special General Meeting may be called either by the Executive Committee or on the demand in writing of any twenty-one Members of the General Committee.

Mr. Matthews (London): I move that you adopt the rules from one to twelve as the constitution of this Association.

Mr. McKenzie (Edinburgh), in seconding the motion, was glad that the scheme had been extended to North Britain, where there was no union. The strength of their friends in the south would materially encourage chemists in the north. The recent prosecutions showed there was a necessity for union, which rubbed off angular corners and removed all causes of jealousy. He confessed he looked upon the Poisons Act as being but half of what they ought to get for the annoyance they were put to in registering the sale of poisons; and they were not remunerated by the profit obtained by the transaction, and they ought to have more than what the Act gave them. In prosecuting measures in Parliament, and in obtaining amendments, a Parliamentary Committee of the Executive would always be in readiness to proceed to the lobby of the House of Commons; as much could be done in this way as by individual members of the Association writing to their Members of Parliament in London. He had had experience of this in the past, and the senior member for Edinburgh had told him that deputations had as great weight with their Members of Parliament as with the Government, whoever they might be.

The motion was then put to the meeting and carried unanimously.

Mr. James M. Fairlie (Glasgow) then read the following memorial, signed by upwards of twenty-five Scotch chemists who were present at the meeting.

SCOTCH MEMORIAL.

"To the President and Members of the Chemists and Druggists' Trade Association.

"Gentlemen,—The undersigned Pharmaceutical Chemists and Chemists and Druggists of Glasgow and other towns in Scotland, approving as we do, the formation of a Chemists and Druggists' Trade Association, the objects of which shall in no way conflict with the operations of the Pharmaceutical Society of Great Britain, desire to enrol ourselves as members of such an organization, but as the trade in Scotland differs in many respects from that in England, and as we believe the arrangement will be of benefit to the Association generally, we respectfully request that the Executive consider the propriety of establishing a Branch Association for Scotland, and would suggest that the Scottish Executive might consist of the Members of the General Committee residing in Scotland, with powers relegated to them by the Executive Council of the Association."

(25 *Signatures.*)

Mr. Fairlie said that no programme of the business having been issued, they in Glasgow were not aware what was to be the order of procedure that day, and it was only late the night before that they had been able to decide as to what action should be taken by the Scotch members of the Association present. The memorial had, therefore, only been drafted that morning; hence the small number of names attached to it. He could safely say, however, that it represented several hundred chemists in Scotland. During the past few weeks he had had a great deal of correspondence with chemists in Scotland in reference to this meeting and the trade association, and with a single exception, every one had expressed himself as thoroughly in favour of some such organization. That one declined to take any action in the matter. He (Mr. Fairlie) had then written another gentleman on the subject; that gentleman had called on a number of chemists in the town, and he had found all he had spoken to in favour of the Association. Every town in Scotland had taken some action with regard to this matter, and there were representatives present from the far north, and the east, and he could confidently assure their English friends that they would have able support from Scotland. In nearly all the letters he had received, however, there was one thing indicated, and that was that Scotland should be specially recognized by the Association. There were some arguments which our English friends might make in opposition to this, as for instance, that we sent our M.P's to a common Parliament, that not only would Scotland be largely represented on the General Committee, but also on the Executive. On the other hand, some Scotchmen say, why not have an organization of our own in Scotland? It appeared, therefore, that a compromise between these two opinions must be made, and if the Executive can see their way to comply with the petition of the memorial, they will find that the arrangement will greatly strengthen them, and that any Scotch business will be greatly facilitated. It is but a carrying out of the principle of the scheme sketched out by Mr. Barclay—namely, to localize organization, and at the same time have a central head to operate from. The principle had already been carried out by the Pharmaceutical Society in establishing the North British Branch. He could see, for instance, that in the drafting of this scheme a Scotch committee would do much to make it complete, in so far as Scotland was concerned. Thus, in regard to Scotch legal cases, they would require to be watched by a Scotch committee, as the law in nearly every case operated differently in Scotland from what it did in England. Then, again, very often Scotland received a separate Act of Parliament, and in such cases attention would be paid more readily to a Scotch committee than otherwise. He must not say anything regarding the necessity for a strong union of chemists and druggists; they had had several examples of it of late there. He was strongly of opinion that the recent excise prosecution would never have taken place had this organization been in operation six months sooner. In London some time ago there was what was known as the citrate of magnesia case; there was no one to help the druggist who was prosecuted on that occasion, and he lost his case. They had a similar case at Greenock; the Glasgow chemists united with their Greenock brethren, and they defended successfully that prosecution. Had it been every man for his own hand at Greenock, as it was in London, the probability is that that case would have been lost too—another druggist ruined in business and in character, and the whole trade stigmatized as deceivers of the public. Mr. Fairlie concluded by expressing his opinion that both England and Scotland have much to gain and nothing to lose by the plan suggested in the memorial.

The Chairman said that this important memorial would strengthen the movement very much, and he was sure that their best thanks were due to Mr. Fairlie for the trouble he had taken. He might say to that gentleman that it was a good morning's work, indeed.

Mr. Andrews (London), moved—

"That the memorial of the members of the Association resident in Scotland be received and referred to the Executive for its best consideration."

Mr. Gibbons seconded the motion.

Mr. Kerr (Dundee) said that he signed the memorial in some doubt, but after hearing the reports which had been read and the speeches that had been made at the meeting, he was quite pleased at what he had done. He was glad that this trade association was not in opposition to the Pharmaceutical Society. From the discussions that had taken place he believed that this movement would be a great help to that Society, for it would gather in more members. He did not see why the members of this Association should not be members of the Pharmaceutical Society as well. He was convinced himself that even in the matter of trade grievances the Pharmaceutical Society had done much and deserved credit for what it had done. It, however, required encouragement and support, and he could see it would get much from this Association.

Mr. Kinninmont (Glasgow) said he thought he was one of the cautious men Mr. Barclay had referred to. He was quite prepared to concede that if the organization kept within its proper limits it would do great good. He believed they would never take action to defend adulteration. He quite knew the importance of union and he was surprised Mr. Fairlie had omitted to refer to the fight they had over the Poisons Bill in 1871, one of the most obnoxious attempts at legislation he had ever known. It was their pulling together at that time that saved them from the terrors of the policeman as their inspector, and he hoped that the objects indicated by the promotors of this organization would be fully realized. He had signed the memorial after some consideration and he believed that their friends from the south would find their hands greatly strengthened by carrying Scotland with them in their plans.

The Chairman said—We are no friends of adulteration, but we don't want a chemist who sells a genuine article to be pulled up for adulteration; neither have we any hostile feelings towards the Pharmaceutical Society, but we feel as a trade organization that we can take up matters which the Pharmaceutical Society cannot.

Mr. Anderson (Musselburgh) said that the whole of the chemists in the town he had come from had agreed to join the Association, and as stated by Mr. Fairlie, had expressed the opinion that Scotland would require an executive to manage Scotch affairs. He was glad there was a likelihood of such being carried out. The Association had his hearty support, and he knew that in most small towns it was just some such association that was required to bring the members of the trade more together, that they might work for each others' welfare.

After some remarks from others present, the motion was put from the chair and carried unanimously.

Mr. Jones (Leamington) then moved that the best thanks of the meeting be given to Mr. Fairlie and the local committee for the admirable manner in which they had arranged this meeting, which was seconded by Mr. Mason of Liverpool, and agreed to with acclamation.

Mr. Fairlie, in reply, said their work had been very light in so far as the Trade Association was concerned, but taken in connection with the British Pharmaceutical Conference meetings, they had been amply repaid for their labours in witnessing the happy faces of their friends from England. They had wrought for this end, and their object had been obtained without a single hitch. Personally he had experienced the hospitality of their friends from the south in their own country, and to his brother Scots he would say, go next year and see whether you have done anything more than your duty.

On the motion of Mr. Brown, Manchester, seconded by Mr. Jaap, Glasgow, a most cordial vote of thanks was passed to Mr. S. U. Jones for his conduct in the chair.

Mr. Jones, in reply, expressed his gratification at the manner in which the business has been gone through, especially at the excellent arrangements that had been made for them by the local committee.

At the request of the local committee the members present afterwards partook of luncheon in the Royal Hotel, at the close of which Mr. Greig, on behalf of the local committee, thanked the English members of the Association for their presence at the meeting, and wished the Association just started every success.

Mr. Barclay proposed the health of the Local Committee, coupled with the name of Mr. Fairlie, and expressed his personal appreciation of the efforts that had been made to make their meeting a success. This having been enthusiastically responded to, Mr. Fairlie briefly replied and the meeting broke up.

Test for Sugar.—Vidau has observed that a mixture of equal parts of hydrochloric acid and oil of benne (*Ol. Sesami*), either in the cold, or when slightly heated, assumes a distinct rose-colour in the presence of cane or grape sugar, provided not less than 0·001 gm. ($\frac{1}{64}$ gr.) of sugar is present for every cc. (16·3 min.) of mixture.—*Journ. de Ph. et d. Chim.*

THE SALE OF LAUDANUM.

IT might have been thought, after upwards of seven years' experience, that there was little probability of a fresh reading of the 17th section of the Pharmacy Act being set up which would materially differ from the construction hitherto unexceptionally put upon it. But the report on p. 247 shows that the expectation would not have been warranted. A gentleman holding the responsible position of a Coroner, belonging also, we believe, to the legal profession, has construed the law as to the sale of laudanum and other poisons contained in Part 2 of the poison schedule in a sense that, if it proved to be correct, would probably make dealing in these articles impracticable.

Many extraordinary statements, betraying profound ignorance of the subject, have before now been made respecting the Pharmacy Act by similar functionaries, but hitherto these have done little harm, and we should have thought it only necessary to put this fresh opinion on record, were it not that it has received a quasi-professional endorsement, and we have been informed that there is a probability that an attempt will be made to enforce it by the police authorities of the locality. We therefore at once enter a protest against any hasty proceedings being taken in the matter.

It will be seen by the report that a witness having stated that it was not necessary to register sales of laudanum, the Coroner interposed with the remark that he was clearly of opinion that it was necessary to register the sale of all poisons specified in both Schedules A. and B. [so reported, but no doubt meaning Parts 1 and 2 of Schedule A.]; and further, that if there was a sale of poison to any stranger, it must be made only after an introduction by some person known to the chemist, and after obtaining the signatures of both parties. To enable our readers to guess as to how the Coroner came to this conclusion, by which he applies the more stringent regulations as to registration and signatures to the whole of the poisons in the schedule, we reproduce the commencement of the 17th Section of the Act:—

"It shall be unlawful to sell any poison either by wholesale or retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained, be distinctly labelled with the name of the article and the word poison, and with the name and address of the seller of the poison; and it shall be unlawful to sell any poison of those which are in the first part of schedule (A) to this Act, or may hereafter be added thereto under section II. of this Act, to any person unknown to the seller, unless introduced by some person known to the seller; and on every sale of *any such article* the seller shall, before delivery, make or cause to be made an entry in a book to be kept for that purpose," etc.

It will be seen that the first clause of the sentence, applies to "*any poison*" under the Act. The second clause then goes on to say respecting poisons included in the first part of the schedule *only* that they must not be sold to a person unknown to the seller without an introduction, and that the sale of any such article shall be registered. The Coroner for Spalding appears to wish to apply the words, "*any such article*," in the second clause of the sentence, to all that has gone before, although the construction of the sentence evidently limits their application to the latter clause of the sentence in which they occur. Moreover, if this point were doubtful, there is no doubt as to what has been the custom, and the custom has been in accordance with the tabulated schedule drawn up some time since by the Council of the Pharmaceutical Society, a copy of which was sent to every chemist and druggist for his guidance. That schedule, which no doubt represents the intentions of the legislature respecting the conditions under which poisons are to be sold, interpreted by the body to whom Parliament has entrusted the carrying out of those intentions, limits, and we believe correctly, the provisions as to knowledge of buyer and registration of sale to the poisons in the first part of the schedule. In fact, were it otherwise, there does not appear any sufficient reason for the division of the schedule into two parts.

Still we are free to confess that Mr. CALTHORP has found an endorsement of his opinion. The question seems to have been submitted by some one to the editors (three barristers) of the *Justice of the Peace*, a professional paper of good standing, and in the issue for last Saturday they give their opinion that the words "sale of any such article" apply to the whole of the previous part of the 17th section.

We understand that steps are being taken to bring the matter before the Council at its next meeting, and meanwhile we hope that local officials will be restrained from commencing vexatious proceedings against unoffending chemists and druggists.

PATENT MEDICINES IN THE STATES.

IN this country one "crying evil" in connection with so-called patent medicines is that some retailers supply them to their customers at a considerable discount from the advertised prices. In the United

States this bad habit appears to have extended to the manufacturers. In the words of a speaker at a meeting of wholesale druggists, recently called together in New York to consider the subject, the branch of the business known as proprietary medicines has become demoralized by excessive and unbusiness-like competition extending through many years, and has finally become a source of positive loss to jobbers. The wholesale druggists have therefore resolved to "impress" upon manufacturers of proprietary goods the necessity of maintaining regular prices, and that even when a parcel is supplied on special terms it is the duty of the parties to the bargain to maintain schedule prices. The practice of delivering proprietary goods throughout the country without freight or other charges has also been condemned as not in accordance with sound commercial usage or good business principles. A committee of wholesale druggists has been appointed to confer with the manufacturers upon the subject.

PRESERVATION OF SYRUPS BY SALICYLIC ACID.

M. Lajoux, a Paris pharmacien, has been making some experiments with the object of ascertaining the minimum quantity of salicylic acid by which the fermentation of syrups can be prevented during the summer. The syrups experimented upon were red-currant, cherry, mulberry, capillaire, gentian and compound ipecacuanha. It was found necessary to add a quantity of salicylic acid equal to one thousandth part of the weight of the sugar in the syrup. Syrups thus prepared were kept simply covered with a sheet of paper at a mean temperature of about 17°C. At the end of two months they were intact, whilst the same syrups, placed in the same conditions, but without salicylic acid, were completely altered.

MANCHESTER SCHOOL OF PHARMACY.

A programme of the arrangement for the session 1876 7, of the Manchester School of Pharmacy in connection with the Manchester Chemists' Association has just been issued. From it we learn that three courses of lectures, to be delivered by Mr. Louis Siebold, are to commence early next month. Chemistry, including the elements of Physics, is to be dealt with in a course of thirty lectures, illustrated fully by experiments, on Friday evenings, from 7·30 to 9 o'clock. The Materia Medica course is to consist of twenty-five lectures, to be delivered on Tuesday evening, from 7·30 to 8·45 o'clock. The Analytical Chemistry course is to consist of twenty lectures, delivered on Tuesday evenings, from 8·45 to 9·45. It is also announced that a course of lectures on Botany will be commenced by Mr. Leo H. Grindon early after Christmas. Students attending these courses must be Associates of the Manchester Chemists' Association. Further particulars respecting fees, etc., may be obtained from the Honorary Secretary to the Association, Mr. F. Baden Benger, 7, Exchange Street, Manchester.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE

Tuesday, September 5, 1876.

After the close of the President's address the reading of papers was proceeded with. The first paper read was a—

Note on Liquid Extract of Pareira.

BY B. S. PROCTOR.

I make no pretension of having such knowledge or experience of this preparation as would justify me in assuming any tone of authority in what I am about to say.

I recently had application for liquid extract of pareira, and not having any in stock procured some from one of my neighbours; it struck me as being very weak, but there was not another sample to be had in Newcastle for comparison, so I commenced making some, and at the same time sent to two makers in London for samples.

The first point of interest is the great disparity in the strength of the four. I do not wish to mention the names of makers so have indicated the samples by letters. It is only fair, however, to remark that they all came from large firms of good repute.

The first (which had struck me as weak) is marked R; those from London are indicated as M and D; and my own as Proctor's No 1 and No 2.

Judging by the quantity of Proctor's No. 1 which was required to be added to a given volume of water to make mixtures equal in taste to that of each of the other samples, it would appear that D is nearly double the strength of R, Proctor's No. 2 just double, and M nearly thrice the strength, while Proctor's No. 1 is six times the strength. It is very unsatisfactory that so great a disparity should occur in cases where we have no reason to suppose that in any of the four there had been any intention but to carry out the instructions of the Pharmacopœia.

It suggests the consideration, what is the actual intention of the instructions, and what change would be desirable to make in them with the view to uniformity?

The Pharmacopœia directs us to take a pound of *coarse powder* of pareira root, *digest* it in a pint of boiling water for twenty-four hours, pack it in a percolator, and adding more of the water, allow the liquor to pass *slowly* until a gallon has been collected, or the pareira is *exhausted*, etc.

I think we may assume that the intention is that the pareira should be exhausted as nearly as practicable, and that if this be accomplished, the degree to which comminution and percolation is carried, is comparatively of little moment. But if this be the intention, the expression is not so precise as it should be, for the words used imply that percolation is to cease when a gallon is obtained, whether exhaustion be complete or not, and that percolation may cease before a gallon is obtained if exhaustion be accomplished with a smaller quantity.

If exhaustion could be completely effected with any moderate quantity of water, the formula might be improved by omitting the limit of one gallon and simply defining that percolation should be continued till water ceased to extract anything, but we know that this is not practicable with ordinary vegetable powders; the degrees of exhaustion are only comparative, and the judgment of the operator is the only guide as to when the process should be considered complete; and from the evidence quoted it is clear that this judgment is a blind guide.

The quantity of water requisite for obtaining a given degree of extraction must vary with the degree to which comminution has been carried, and if we were to adopt fine powder, as directed in the U.S. Pharmacopœia, probably no great discrepancy would occur. The powder which I used in making my experiment was almost what would be called a very fine powder, and was ordered and supplied to me simply as "Powdered Pareira Root"* (for when I order rough powders I always find the wholesale druggists supply the materials in much too coarse a condition for satisfactory work). The 1lb. of powder was mixed with 1 pint of boiling water but not digested, *i.e.*, it was allowed to become cold, it was then packed in a wide conical percolator, and a pint of boiling water put upon it: percolation was slow and the liquor came through loaded with extractive matter. The first ten ounces, mixed with three ounces of rectified spirit, were kept separate from the subsequent portions of percolate. When a pint of percolate had been obtained percolation became more rapid and the liquor evidently weaker, so much so that when a total of three pints was obtained it was considered that a fair approximate exhaustion had been obtained, consequently this second portion was evaporated down to three ounces so as to make up 16 fluid ounces with the first percolate and spirit. This total is what I have indicated as Proctor's No. 1.

Percolation was then continued as before, with the view of ascertaining if much more extract would be obtained by using the whole of the gallon as named in the Pharmacopœia. The percolate became very weak towards the end though not by any means either tasteless or colourless. The five pints thus obtained were evaporated down to 6½ fluid ounces and 1½ fluid ounce of rectified spirit added. This constitutes what I have marked Proctor's No. 2.

A comparison of the series by taste was made as follows:—

℥i water required the addition of,—

12 minims	of Proctor's No. 1 to equal	R
25	" " " "	D
30	" " " "	P.'s 2
45	" " " "	M

Or estimating the strength of each compared with P.'s No. 1 from the above calculation.—

R	is equal	16·6 per cent.
D	" "	29·4
M	" "	42·8
P.'s 2	" "	33·3

A further comparison by weighing the dry residue of 100 grains of each of the five is subjoined, together with their specific gravities.

R	sp. gr. 0·9888†	left 3 gr.
D	" " 1·0108	" 6 gr.
M	" " 1·0226	" 10 gr.
P.'s 1	" " 1·0504	" 15·5 gr.
P.'s 2	" " 0·9930	" 3·5 gr.

These residues exposed to the air absorbed moisture, and, what is noteworthy, the hygroscopic quality was in inverse order to the quantity of the residue, except in the case of P.'s 2, which continued powdery while P.'s 1 and M became pilular (M the softer of the two), and the others became semifluid. These residues were all much alike in taste.

This comparison suggests that in the commercial samples the process has only been carried so far as to extract those portions of matter most soluble, and to leave large portions of extractive matters equally sapid and probably equally active. No doubt the coarse comminution is the root of the evil, as it would readily allow a gallon to pass through (we could scarcely say to percolate), but to wash through, simply superficially washing from off the particles the liquor and extractive matter loosened by the first pint of water, and the weakness of the last pint or two of liquor thus produced might lead the operator to the conclusion that exhaustion has been nearly perfect. Thus it has the double disadvantage of being difficult to exhaust and liable to deceive.

To keep up a digesting heat may be advantageous, but certainly adds something to the trouble, and is probably not important. In my experiment the liquor ceased to be hot long before it passed through.

If it were found necessary to add a further security against imperfect work, it might be desirable, instead of defining the quantity of liquor to be obtained from a pound of root, to define the *density* to which it should be raised by evaporation, before adding the spirit, as adopted in the case of liquid extract of cinchona; or as another alternative to direct evaporation to a pilular consistence, and then solution of a given weight of the extract thus obtained in spirit and water, as now adopted in the case of liquid extract of opium. I incline to the latter mode as there is less probability of any great error.

The root when well exhausted yields about 17 per cent. of *dry* extract or about 25 per cent. of a soft pilular consistence. Four ounces of this pilular extract with three fluid ounces of rectified spirit and water sufficient to make up 16 fluid ounces would make a satisfactory preparation, little liable to vary in strength, and corresponding pretty closely with the best that can be prepared by the present official process. To confirm this, a portion of Proctor's No. 1 was evaporated to an extract, and then dissolved again in spirit and water, and made up to its original bulk. Though it had deposited a brown precipitate, the clear liquor had the same intensity of colour and taste as the original sample.

In conclusion I would again urge the importance in a future Pharmacopœia of adopting some system of indicating in all cases the degree of comminution to which vegetables and other substances are to be reduced when used in making preparations. The system adopted in the U. S. Pharmacopœia appears to be worthy of imitation.

The PRESIDENT said he was sure all present were desirous to express their thanks to Mr. Proctor for the very practical and useful communication that gentleman had just made. He himself entirely concurred in the last paragraph of the paper, where reference was made to the importance of indicating in the Pharmacopœia the degrees of comminution to which vegetable and other substances were to be reduced in making preparations. He did not at present entirely go with Mr. Proctor in the earlier part of his remarks, namely, that in the process given in the Pharmacopœia the indication of the quantity of water to be used in exhausting the pareira might with advantage be omitted. He thought there was an advantage in having an average quantity mentioned, whilst it was clearly indicated that if the pareira could be exhausted with less than a gallon, the process should be stopped, or if the gallon was not sufficient, something more should be used. But there was an advantage in giving an indication of the quantity that should be used, as it suggested to the operator that he must so arrange his conditions as to cause exhaustion to be effected as nearly as possible with the gallon, and this was an indirect indication to him of what the degree of comminution should be, and of the packing of the material in the percolator. However, that was a trifling matter as compared with other points that Mr. Proctor had brought forward in his paper. He was quite sure that the known experience and skill which Mr. Proctor possessed and had been accustomed to exercise in pharmaceutical operations would engender confidence in the results obtained, and would place the paper among those to which he had alluded as greatly aiding hereafter in the preparation of a new edition of our Pharmacopœia.

* It could be almost entirely passed through a sieve having 120 wires to the linear inch.

† As the sp. gr. of the mixture of spirit and water used in the preparation of this liquid extract is about ·980 there is probably an excess of spirit as well as a deficiency of extractive in the sample R. In the other samples the relation between the density and the residue is nearly concordant.

Mr. H. B. BRADY (Newcastle) said that the paper was a very important one, not only for its matter, but also for the manner in which the subject had been treated. But there was one important point to which the author had not called attention. A man might be perfectly honest in intention and work with what looked like pareira brava but was not, and even with a knowledge of what pareira root should be, there was a difficulty in obtaining it. The wood and the old roots did not yield the same proportion of extract as the younger roots did. One got sometimes a batch of roots running from one inch to an inch and a half in thickness, and from these a tolerably uniform product could be obtained. The liquid extract might thus be well made, pharmaceutically speaking, and still not give the quantity of extractive which the preparation should contain. He wished Mr. Proctor had powdered the roots himself, because he thought that although the matter of comminution was no doubt a very important element in the success of the process it was by no means the only one. With regard to what Professor Redwood had said, it was certainly important that a sort of maximum volume of fluid should be stated; it not only affected the mode of exhaustion, but in reality the amount of heat to which the material was subjected in the subsequent evaporation.

Mr. PROCTOR said he agreed with Professor Redwood as to the quantity of water. There must be a limit and the smaller that limit the better. He would rather use three pints if with that quantity the roots could be satisfactorily exhausted. He thought that three pints almost effected a satisfactory exhaustion of the root.

Mr. KINNINMONT said he thought Mr. Brady had touched the real point; it was necessary for the operator to make sure he had got hold of the right stuff. Knowing that Mr. Proctor was coming forward with his paper he had brought with him some specimens. (Mr. Kinninmont then proceeded to describe these.) Having got into difficulties with the pareira brava, he welcomed Mr. Hanbury's paper on the subject with great pleasure; for in getting various samples he found not one was right. He did not think any great quantity of the true pareira root could be got. He had found that the true root gave a thick decoction having a bitter and liquorice taste, and that in proportion as it possessed this taste, so it was efficacious as a medicine. Were any one to take the root in commerce he would condemn the product as Mr. Proctor has done.

Mr. PROCTOR said he always looked upon the use of the true root as of primary importance; but on this occasion he had simply prepared a short note upon the pharmacy side of the question.

Mr. GREENISH asked Mr. Proctor whether he had ascertained how long the preparations he had compared with his own had been kept. He had observed in this liquid extract, a great tendency in the preparation to become deteriorated by age.

Professor ATTFIELD said, that the paper referred to the question of the introduction of definitions of fine and coarse powder into the Pharmacopœia, and he drew attention to the important remarks in connection with this subject of the President, who, it would be remembered, was not only the President of the Conference, but the editor of the British Pharmacopœia. The President had agreed with the author of this paper. and the author of many other papers, that it would be desirable to introduce into the next Pharmacopœia some indication of the relative degrees of fineness into which vegetable substances should be powdered. Mr. Proctor had referred to what was given in the United States Pharmacopœia, and suggested that similar definitions should be introduced into the British Pharmacopœia. That definition in the American Pharmacopœia, under the head of "fineness of powder," was as follows:—

"As different degrees of fineness are necessary in powders, according to their nature and mode of treatment, the special degree required is designated in the several formulas. For this purpose the terms very fine, fine, moderately fine, moderately coarse, and coarse are used;—the powder passed through a sieve of eighty or more meshes to the linear inch being designated as *very fine;* through one of sixty meshes, *fine;* through one of fifty meshes, *moderately fine;* through one of forty meshes, *moderately coarse;* and through one of twenty meshes, *coarse.*"

In reply to Mr. Greenish, Mr. Proctor said he had no information as to when the preparations were made. He presumed they were not very old.

NOTES ON THE COLOURING MATTER OF CROCUS SATIVUS.

BY W. W. STODDART, F.C.S., ETC.

The well-known colouring matter of the saffron is no less interesting than puzzling. In many physical and chemical characters it differs from all the other yellow dyes, and when present in very minute quantity is somewhat difficult in its identification. Comparatively little is known of its composition and very little has been done towards the solution, so that it behoves the experimentalist to bring forward any matter of detail however trifling.

A short time ago I had some confectionery brought for analysis which was suspected of being coloured with orpiment or chromate of lead. The comfits in question were white, globular and composed entirely of sugar. Each had a nucleus about the size of a pea having a canary yellow colour. It was during this examination that I noticed what I think promises to be a good and delicate test for the colouring matter of saffron (*Crocus sativus*).

A small piece of the sugarplum was put into a test tube and dilute hydrochloric acid added. Instantly all the colour vanished, strongly resembling the reaction of a metallic salt. I then inserted a small piece of copper foil suspended by a platinum wire in the usual way for Reinsch's test, and boiled. To my surprise the yellow colour returned with a bright and extremely beautiful red fluorescence. This was especially noticeable because the yellow matter present in the comfit must have been infinitesimal.

This was repeated several times with the same result, so that it may be used as a safe and easy test. It is imperative that a weak solution of saffron be used for its proper working. Turmeric behaves in a somewhat similar manner, but is easily distiuguished by the powerful action of alkalies which do not affect the colour of saffron.

Of course this singular experiment led me to make an examination of the colour given by the stigmata of the crocus but the subject soon showed so many and unexpected difficulties that I have not been able to get ready the requisite number of analyses that must be performed before its nature can be fully explained.

The experiment was next repeated with a plain infusion of the stigmata, but utterly failed. The liquid was decolorized but remained obstinately colourless when boiled, nor could I get the fluorescent reaction in the slightest degree. At length the thought occurred that the original experiment was on a saccharine material, and a single crystal was dropped into the test tube, when to my great satisfaction the colour and fluorescence were instantly developed, so that the sugar had evidently something to do with their production.

The test is used by putting into a test tube a *very dilute* infusion of saffron on a suspected yellow colour. If no sugar be present add a crystal and as much dilute hydrochloric acid as will completely decolorize it. Bring the whole to the boil, and if the colour be due to saffron, the yellow tint will be restored in a few seconds and the beautiful fluorescence make its appearance on the surface of the liquid. To give some idea of the extreme delicacy of this reaction, an infusion was made containing only

$\frac{1}{3}\frac{1}{3}$nd part of its weight of the stigmata, when the characteristic appearances were shewn in the most decided manner.

The natural colouring matter of the leaves is called polychroite, but is evidently a compound of two colouring principles, a red and a yellow. It is very soluble in water, but insoluble in ether and absolute alcohol. Its aqueous solution is completely decolorized by chlorine, nitric and hydrochloric acids. A large quantity of the last is required. The colouring matter dissolved from the third of a grain of the stigmata requiring about thirty minims of strong hydrochloric acid for complete decolorization.

The stigmata of *Crocus sativus* are divided into three linear divisions joined together at the summit of the long style. When properly prepared they make good microscopic objects, showing their cellular structure in a most interesting manner.

In addition to the polychroite the stigmata contain both cane and grape sugars, with gum and a volatile oil, to which the peculiar odour of saffron is due.

The following is the mean result of several analyses :—

Colouring matter (Polychroite)	62·31
Volatile oil	1·32
Sucrose	·43
Glucose	·11
Gum and allied substances	7·50
Cellulose	9·64
Ash	6·82
Moisture	10·87
	100·00

The volatile oil is a bright yellow, and is said by Weiss (*J. pr. Chem.* 101, 65) to be isomeric with carvol ($C_{10}H_{14}O$) which is so universally present in most of the essential oils. It is worthy of remark that when this oil has been kept some time, it becomes changed into a white solid having the same elementary composition and resembling thymol.

When an infusion of saffron is boiled with hydrochloric acid it is decomposed and a copious flocculent red precipitate of crocin ($C_{16}H_{18}O_6$) separates. When dried it forms a bright red powder which is tolerably soluble in alcohol but quite insoluble in water, thus having exactly the opposite qualities than when it existed in combination as polychroite. One hundred grains of the stigmata yield from 9 to 10 grains of crocin. Crocin is extremely soluble in very dilute solutions of the various alkalies, forming a very pure and brilliantly yellow liquid, from which it may be reprecipitated by acids.

The liquid filtered from the crocin contains the yellow colour with a large quantity of glucose, and the same yellow volatile oil as previously found in the plant.

Weiss in his paper before mentioned gives the following formula for the decomposition of polychroite by acids :—

$$\underset{\text{Polychroite.}}{C_{48}H_{60}O_{18}} + H_2O = \underset{\text{Crocin.}}{2\,C_{16}H_{18}O_6} + \underset{\text{Carvol.}}{C_{10}H_{14}O} + \underset{\text{Glucose.}}{C_6H_{12}O_6}$$

But in all probability it is not quite correct, because he has not allowed for the colouring matter left after the separation of crocin, nor does it explain the action produced by the addition of a little more sugar than that existing in the stigma.

Moreover, according to the formula we ought to get more crocin than is found to be the case in practice.

The presence of more sugar than is naturally present appears to be necessary for the complete decomposition of polychroite, so that probably the following would be the more perfect rendering of Weiss's formula :—

$$\underset{\text{Polychroite.}}{C_{48}H_{60}O_{18}} + \underset{\text{Sucrose.}}{C_{12}H_{22}O_{11}} + 2H_2O =$$
$$\underset{\text{Crocin.}}{2C_{16}H_{18}O_6} + \underset{\text{Carvol}}{C_{10}H_{14}O} + \underset{\text{Glucose.}}{3\,C_6H_{12}O_6}$$

When crocin is precipitated by acids from an alkaline solution it is a dark brown instead of a bright red. It seems to be hydrated $2(C_{16}H_{18}O_6), 3\,H_2O$.

The determination of the percentage composition of perfectly dry crocin gave the following results of three trials which agree very closely with Weiss's formula of $C_{16}H_{18}O_6$:—

0·63 grm. gave 1·4469 grm. of CO_2 and 0·3384 grm. of H_2O
0·41 „ „ ·9416 „ „ 0·2203 „
0·44 „ „ 1·011 „ „ 0·2352 „

which would yield –

	I.	II.	III.
C	·3946	·2568	·2757
H	·0376	·0244	·0261
O	·1978	·1288	·1382
	·6300	·41	·44

The percentage of these would therefore be :—

	I.	II.	III.	Calculated.
C	62·64	62·63	62·67	62·745
H	5·97	5·97	5·94	5·882
O	31·39	31·40	31·39	31·373
	100·00	100·00	100·00	100·000

When polychroite is dissolved and mixed with sugar, it easily ferments and the crocin precipitates. This is often seen in the shops, forming the red deposit so troublesome at the bottom of the syrupus croci bottle when kept a long time, especially in warm weather. The ready solution of crocin in alkalies explains the reason why many pharmacists add a little potash to prevent the thickening of the syrup.

The very limited time at my disposal has prevented my pursuing the subject any further at present, but I am now engaged in more fully examining the subject both chemically and optically, so that at some future time I may have the pleasure of bringing before you more detailed results.

After a vote of thanks had been accorded to Mr. Stoddart for his paper, an adjournment was made till the afternoon.

Upon the Conference reassembling at two o'clock, the following communications upon the subject of opium were read :—

The Variation in Strength of the Opium Preparations.

BY D. B. DOTT.

In the following communication, the subject of which is one of those suggested for investigation by the Conference, I give the results of an examination of a number of the official opium preparations. It was not thought necessary to test samples of all these preparations, but only of the tincture, extract, and liquid extract; the morphia-strength of which will probably afford a sufficiently accurate idea of the quality of the opium preparations at present supplied to the public. All the samples examined were procured from druggists of good standing in London, Dublin, and Edinburgh.

In the first place I give the assays of a variety of opiums, with the amount of extract obtained from each. The percentage of extract was not found directly but by subtracting the percentages of water and insoluble residue from 100, the difference being the percentage of dry extract. The proportion of the morphia in the extract is calculated from the result of the opium assay.

It will be seen from this table that the richest extract obtained would contain 34·4 per cent. of morphia, while the poorest would contain 13·7 per cent. Whence it is manifest that two chemists, starting with opiums perfectly answering the Pharmacopœia tests, and strictly following the officinal process, might succeed in preparing extracts, one of which would be more than twice the strength of the other.

Description of Opium used.	Morphia per cent.	Water per cent.	Aqueous extract per cent.	Residue insoluble in water per cent	Morphia in extract per cent.

In the next table I give the estimation of several samples of *Extractum Opii.*

	Water per cent.	Morphia per cent.		Morphia per cent.
No. 1	19·2	19·4	No. 7	22·8
No. 2	21·2	19·7	No. 8	19·3
No. 3	26·8	16·2	No. 9	20·5
No. 4	18·4	19·6	No. 10	15·4
No. 5	23·2	19·7	No. 11	20·4
No. 6	22·0	18·2		

The difference between the maximum 22·8 and the minimum 15·4, is equal to a variation in the morphia-strength of about 3 to 4½. The average percentage is 19·7.

I next give a list of the samples of Extractum Opii Liquidum examined, with their specific gravities and the amount of morphia in the fluid ounce.

No.	Spec. Grav.	Grs. Morphia in fl. oz.			No.	Spec. Grav.	Grs. Morphia in fl. oz.		
		I.	II.	mean			I.	II.	mean
1	0·987	3·82	4·08	3·95	9	0·985	4·68	4·34	4·51
2	0·992	4·02	3·95	3·98	10	1·000	4·17	4·01	4·09
3	0·986	2·66	2·87	2·76	11	0·989	3·68	3·75	3·76
4	0·993	3·04	3·89	3·46	12		3·71		
5	0·996	3·73	3·12	3·42	13		2·28		
6	0·995	2·26	2·06	2·16	14		0·61		
7	0·992	1·78	1·63	1·66	15		2·22		
8	0·996	4·33	4·34	4·33					

It will be observed that in these fifteen samples the grains of morphia in the fluid ounce varied from 0·6 to 4·5, the average being 3·12. Only one estimation of the last four was made as these were examined some months ago, without any intention of publishing the results. In one or two cases it would have been advisable to repeat the determination of the morphia, but the quantity of each sample admitted of only two estimations being made.

In the following table I give the assays of eighteen samples of the Tinctura Opii, with their specific gravities.

No.	Spec. Grav.	Grs. Morphia in the fl. oz.			No.	Spec. Grav.	Grs. Morphia in the fl. oz.		
		I.	II.	mean			I.	II.	mean
1	·922	3·30	3·50	3·40	10	·960	3·50	3·57	3·53
2	·938	2·80	2·70	2·75	11	·953	3·04		
3	·955	2·10	2·10	2·10	12	·936	3·90		
4	·940	2·90	3·70	3·30	13		3·71		
5	·956	2·05	2·10	2·07	14		4·37		
6	·937	2·08	2·23	2·15	15		2·02		
7	·929	3·12	3·28	3·20	16		0·83		
8	·957	3·62	3·45	3·53	17		1·91		
9	·962	1·40	1·59	1·49	18		0·55		

In this, the most important of the opium preparations, the variation in morphia strength extends from 4·37 to 0·55 grs. in the fluid ounce; the average being 2·66.

The method employed in all the above noted assays, is a modification of that recommended in the British Pharmacopœia. I find that the precipitate of crude morphia obtained in that process is equal on an average to $\frac{7}{10}$ths of its weight of the pure base. It is a process, which, I have every reason to believe, gives at least as accurate results as those obtainable by any of the recognized methods.

I think the most obvious conclusion to be arrived at from the foregoing experiments, and from those of other observers, is that the opium preparations are not remedies to be relied on. When one considers that a physician who prescribes for his patient one drachm of laudanum, intending that the latter should receive thereby $\frac{1}{3}$ of a grain of morphia, may in reality be only giving him $\frac{1}{10}$ of a grain; it is manifest that this indicates a condition of things demanding amendment. It has been proposed by Dr. Squibb (reported in the 'Year-Book for 1870') to prepare a strong tincture, assay it, and then dilute to the proper strength, or at least to prepare the tincture, etc., from assayed opium. I am afraid, however, that there would be great, if not insuperable, difficulty, in getting this system brought into general use. The trouble involved in following such a plan would deter the majority of pharmacists from adopting it. For my own part, I believe the ultimate solution of the difficulty will be the abolition of all the galenical preparations of opium from the Pharmacopœia. Indeed,, unless opium possesses therapeutical properties which are not possessed by its alkaloids, there can be no reason for retaining it. That is a question, of course, to be decided by medical men. Still, I venture to think that our knowledge of the physiological effects of opium and its constituents is sufficiently complete to enable us to affirm that all the objects for which opium is prescribed can be attained equally well by the use of its alkaloids. Among these only three can be said to have any practical importance, viz., morphia, codeia and narceine, which are all hypnotics, and seem to differ from one another mainly in the amount required to produce the desired effect. The other bases are either inert in ordinary doses, or exist in such minute quantities that the proportion of them in a large dose of laudanum could only produce a physiological effect in the imagination of a homœopathist.

I believe that the chief work of pharmaceutical chemistry for a long time to come will consist in the perfecting of processes for the isolation of the active principles of the vegetable remedies, so that in due time all the mediæval tinctures and decoctions of the Pharmacopœia will become obsolete, and be superseded by preparations of definite and invariable strength. It is my sincere hope, that this paper, meagre and imperfect though it is, may in some small measure be the means of hastening such a desirable consummation.

Report on the Assay of Opium for Morphia.

BY EDWARD LAWRANCE CLEAVER, F.C.S.

In order to thoroughly criticize the different processes in present use for the estimation of morphia in opium it is necessary to have a thorough knowledge of the following points:—

1. What are the constituents of opium?
2. In what state of combination do they exist?
3. The action of solvents and reagents on these principles.
4. The action of solvents on opium.
5. The action of alkalies on solutions of opium.
6. The action of heat, acids, etc., on morphia.

This paper will therefore be divided into two parts. The first consists of remarks on the foregoing heads; the second of the application of these remarks to point out the advantages and disadvantages of the existing processes used for opium analysis.

PART I.

The principal constituents of opium are as follows:—morphine, narcotine, narceine, codeine, thebaine, papaverine, a substance resembling caoutchouc, probably two resins, meconic acid and calcium salts, and a substance we will designate by the name of extractive.

Of these the morphine in all probability exists combined with the meconic acid to form soluble meconate of morphine.

The narcotine is either entirely free or partly combined with acid.

The remaining alkaloids are probably in a state of combination.

The meconic acid is partly free and partly combined.

The action of different solvents and reagents on the principles of opium are as follows.

Water (distilled).—Morphine is soluble to the extent of one part in 1000; narcotine in 10,000; narceine is sparingly soluble though more so than morphine; the meconic acid is freely soluble; the resin, caoutchouc, etc., are insoluble.

Alcohol.—Morphine is sparingly soluble in cold alcohol, freely in boiling. The remaining alkaloids, resin, and caoutchouc are soluble.

Fusel oil.—All the alkaloids are freely soluble in fusel oil. The resin is also slightly soluble.

Ether, Benzol, Bisulphide of Carbon.—Morphine is soluble to the extent of one part in 2000; the remaining alkaloids are freely soluble. The resin is insoluble; caoutchouc soluble.

Acids—The whole of the alkaloids and resins are soluble in acids.

Fixed Alkalies.—Morphine is freely soluble in solutions of fixed alkalies, narcotine is insoluble. In the presence of morphine narcotine is dissolved by lime water; narceine is soluble. The remaining alkaloids are insoluble. The resin is partly soluble.

Ammonia.—Morphine is sparingly soluble in ammonia, a 1 per cent. solution dissolving five parts in 1000. The narceine and codeine are soluble. The remaining alkaloids and resin are insoluble.

Action of Solvents on Opium.

It follows from the foregoing remarks that when opium is treated with water the solution contains meconate of morphine, salts of narcotine and other alkaloids; resin, taken into solution by the free acid present; calcium salts, meconic acid and extractive.

An alcoholic solution will, in addition to the above, contain more narcotine, caoutchouc, fat and resin.

The question here arises as to whether water will thoroughly exhaust the opium of its morphine. Opinions on this point are divided, but I believe that, provided the solution produced be acid, water will effectually exhaust the marc.

It may be said that opium after prolonged treatment with water has a bitter taste, thus proving some constituent to be present; but that this bitterness is not due to morphine may be proved by treating the marc with benzol, ether, or bisulphide of carbon, when the bitterness is entirely removed. Preliminary treatment with one of the above mentioned solvents is recommended by some authors, and this plan has the advantage that the quantity of water required for the after treatment of the opium is much less than if the preliminary exhaustion be omitted, and also that the narcotine being nearly all removed, the point of exhaustion is more easily noticed by the solution dropping through devoid of bitterness. It must, however, be remembered that a slight loss of morphine is entailed by the preliminary treatment, but the amount may be calculated by adding ·005 gr. for every 10 c.c. of solvent used to the amount of morphine afterwards found.

Hot water is also recommended by some, but I do not think much advantage is gained by its use, as the following experiment will prove.

No. 1. 100 grains of dried powdered opium were treated with hot water. It yielded 69 per cent. of extract and 12·2 per cent. of brown crystalline morphine.

No. 2. 100 grains of the same opium were treated with cold water by percolators; five fluid ounces of water were used and then the solution had a very bitter taste. It yielded 54·3 per cent. extract and 11·9 per cent. of coloured crystalline morphine.

No. 3. 100 grains were treated first with boiling benzine and afterwards percolated with water. It required under 3 ounces of liquid to render the marc tasteless, whilst in the previous experiment 5 fluid ounces were required, and even then the solution obtained was slightly better. The liquid yielded 54·7 per cent. of extract and 12·2 of coloured crystalline morphine.

It will be seen from these experiments that although hot water dissolves more from opium than cold water yet the yield of morphine is not greater. The effect, however, of first using benzine is more marked and the increased yield of morphia I believe to be due to the fact that less water being used; less time was required to evaporate the solution, and thus destruction of the morphia by heat is avoided. I also tried the effect of mixing opium with chalk, and then adding water, and percolating.

100 grains of opium, as before, yielded 45 per cent. of extract, which gave 11·9 per cent. of brown crystalline morphine.

The difference in extract yielded by the plan is due to the fact that the free acid being neutralized by the chalk, the meconic acid, part of resin, the whole of the meconate of calcium, and part of narcotine are removed from solution and so diminish the weight of extract obtained. The results obtained by this process compared with others will be given further on.

Action of Alkalies on Infusion and Tincture of Opium.

Ammonia.—If excess of solution of ammonia be added to infusion of opium a precipitate is obtained, which consists chiefly of morphine, but contains small quantities of narcotine and other alkaloids, meconate of calcium, and resin. This precipitate is either crystalline or amorphous, accordingly as the solution was hot or cold when precipitated. If the solution be concentrated until about equal to twice the weight of opium employed, and ammonia added to the boiling liquid, with constant stirring, the resin is precipitated, melts and adheres firmly to the sides of the containing vessel or to the glass rod used for stirring. The liquid can then be poured off immediately, when the morphine, etc., will begin to be precipitated owing to the change of temperature. The crystals so obtained are free from the resin and light brown in colour. The morphine is not entirely precipitated by ammonia from infusion of opium, owing to the solubility of morphine in water and in ammonia. If the ammonia be added in slight excess only, and the liquid allowed to stand until the smell of the ammonia has disappeared, then the amount of morphine left in solution should correspond to the amount of liquid used, unless there be any constituent in the infusion of opium which prevents the complete precipitation of morphine. This, according to Professor Dragendorff, is the case. The following experiments, however, tend to prove that, provided the excess of ammonia be nearly driven off, the amount of morphine left in solution is in direct accordance with its solubility in water.

6·48 grams of dried Turkey opium were exhausted with water, and concentrated to 35 c.c. It yielded ·800 gram of of morphine. The solution, which with the wash water measured 70 c.c., was shaken repeatedly with fusel oil; fusel oil removed and evaporated. The residue was treated with dilute acid and precipitated with ammonia. This last operation was performed entirely with about 10 c.c. of liquid. It yielded ·067 gram of morphine, which with ·010 to be added for loss of morphine in the 10 c.c. of liquid gave ·077 or only ·005 gram in excess of the theoretical quantity, which may be accounted for, as the morphine was not quite free from colour.

Five grams of Persian opium treated as above yielded ·460 gram of morphine, and 50 c.c. of liquid was used. This treated by amylic alcohol gave ·053 gram of morphine.

6·480 grams of a very rich sample of Persian opium gave ·907 of morphine, 6·80 c c. of wash water were used. This by treatment with amylic alcohol yielded ·087 gram of morphine.

There is, however, one point in connection with the precipitation of morphine by ammonia to which special attention must be paid. It is that solutions of opium from which the morphine has been precipitated by slight excess of ammonia, if left to stand until the smell of ammonia has disappeared, redissolve a large quantity of the precipitate, so that care must be taken that the liquid should always have a *slight excess* of ammonia present. It is, I believe, to the neglect of this fact that Professor Dragendorff has made the statement that opium contains some ingredient which hinders the precipitation of the morphine.

When, however, ammonia in strong excess was allowed to remain in the liquid, the amount of morphine extracted by amylic alcohol was much greater, in one case as much as 3 per cent.

If the opium before treating with water has been mixed with chalk, then the precipitate obtained by ammonia consists of morphine, narcotine, and resin, the meconate of calcium being entirely got rid of. If the opium has been treated with boiling benzine, bisulphide of carbon or ether, previous to infusion, then the precipitate consists of morphine, meconate of calcium, resin, and minute quantities of other alkaloids. The following experiment will illustrate the difference in composition of the precipitate under these different circumstances.

No 1. 6·480 grams of dried opium treated with cold water, the solution evaporated to half an ounce, ammonia added in slight excess, and allowed to stand twenty-four hours, gave 1·695 gram of precipitate; of this 1·506 was soluble in boiling alcohol. The alcoholic residue, etc., treated with bisulphide of carbon lost ·358 gram. The remainder dissolved in dilute acid, and treated with slight excess of ammonia, yielded ·870 gram of morphine.

No. 2. 6·480 grams mixed with chalk, and treated as above gave 1·258 of precipitate by ammonia. Of this 1·200 was soluble in alcohol, ·267 soluble in bisulphide of carbon, and ·858 of morphine.

No. 3. 6·480 grams treated with bisulphide of carbon and afterwards exhausted with water yielded 1·332 gram of precipitate by ammonia, of which 1·137 was soluble in alcohol, and ·008 in bisulphide of carbon and yielded ·880 of morphine.

From this it will be seen--

	1	2	3	4
Precipitate by Ammonia .	26·06	19·6	20·5	18·3

" " $C.S_2$ . .	5·5	4·1	0·1	
Morphine contained in precipitate	13·28	13·25	13·59	13·7

That a large quantity of morphine escapes precipitation by ammonia is a point strongly to be remembered, as in the case of a bad opium containing only from 2 to 4 per cent. of morphine, more morphine might remain in the liquid than was precipitated.

It has been proposed to take the weight of the precipitate given by ammonia as a criterion of the goodness of opium, and good opium should certainly not give less than 14 to 15 per cent. of it, but it should be borne in mind that it does not contain more than half its weight of morphine.

If ammonia be added to infusion of opium (which has been acidified with hydrochloric acid) until exactly neutral, the resin and meconate of calcium are precipitated, whilst soluble hydrochlorate of morphine remains in solution; the precipitate can then be filtered off and then ammonia be added to the filtrate in slight excess; a light coloured precipitate is obtained, which consists of morphine and narcotine in a very pure form.

Potash, soda, and lime, added to infusion of opium, cause a precipitate of narcotine, and resin, and meconate of calcium, but the morphine is dissolved by the excess of alkali present. If the solution be filtered quickly the morphine soon separates out, and is in a very pure form, but there is some loss in the process, as I have never been able to recover by this means as much morphine as by other processes. Lime water also dissolves narcotine to some extent, provided morphia be present.

Action of Heat on Morphia.—If morphine or its salts be boiled with water for some time, the solution becomes coloured; if acids in excess be present the action is more marked, whilst with alkalies the action is stronger still, and a flocculent brown precipitate is soon formed. The following experiments may prove useful as showing that, provided allowance be made for the solubility of morphine in water, the precipitate is complete:—

I took ·583 gr. of pure morphine, dissolved in acid and treated with slight excess of ammonia. After twenty-four hours the precipitate was collected, dried and weighed; it gave ·552 gr. of morphine; the wash water was 30 c.c. equivalent to ·030 of morphine, thus making the total ·582 gr.

·113 gr. of pure morphine, treated as above, gave ·100 gr. of precipitate and 13 c.c. of liquid, which would correspond to ·013 gr. of morphine, thus making the total ·113.

Ammonia added to tincture of opium, or to an alcoholic solution of the precipitate produced by ammonia, produces a precipitate of part of the morphine and part of the narcotine present, the amount remaining in solution depending on the strength and quantity of the alcoholic liquid; if the liquid be tincture of opium, then the precipitate contains meconate of calcium.

PART II.

In commencing my criticisms on the processes in use I will begin with the most simple, and then proceed to describe others more complicated.

Arnoldi's process (*Journ. Chem. Soc.*, 1874). Opium is exhausted with water, the solution treated with animal charcoal, concentrated and precipitated by ammonia. The precipitate is collected, dried, and weighed as impure morphine. The author states that good opium should yield above 14 per cent.

The objections are—

1. That the morphine is not entirely precipitated by ammonia.

2. That the precipitate, though called impure morphine, does not contain much more than half its weight of morphine.

3. The use of animal charcoal ensures loss of alkaloid, as the undermentioned experiment will prove:—

2·435 grams of pure morphia were dissolved in acid and boiled with animal charcoal. The morphine was precipitated, and the amount obtained, allowing for loss by solubility, was 2·405 gr., thus indicating a loss of over 1 per cent.

A second experiment showed even a higher loss.

The process given by Professor Flückiger in the 'Pharmacographia' is better, but far from perfect. It is as follows:—Opium is exhausted by boiling ether, the residue dried, treated with water, and precipitated by ammonia. This precipitate recrystallized from boiling alcohol.

Professor Flückiger himself describes the process as imperfect, and gives his reasons. He is one of the very few who seem to have taken notice of the loss of morphine by virtue of its solubility and of its destruction by heat. The chief objections to the process are—

1. The long continued boiling with ether (twenty or thirty times repeated with fresh quantities) takes away some of the morphia, and care must be taken that the ether employed is free from alcohol and water.

2. The loss of morphia by virtue of its solubility.

3. In crystallizing from alcohol much morphia remains in solution, but the crystals deposited are very pure.

The small proportions of morphine found by Professor Flückiger tend to prove the correctness of these statements.

Guibourt's process (*Journal de Pharmacie et Chimie*) consists in exhausting opium with water, precipitating by ammonia, and washing the precipitate first with dilute alcohol to remove narcotine and colouring matter, and afterwards dissolving the morphine by means of strong alcohol. The alcoholic solution is evaporated, dried and weighed.

The objections to this process are loss of morphine by washing the precipitate with dilute alcohol, and in the precipitation with ammonia.

The residue obtained by the evaporation of the alcoholic solution is not pure morphine but contains narcotine and resin.

Schacht's process (*Archiv der Pharmacie*, 1863).—The process is an improvement on the last mentioned. It consists in exhausting opium with water by two or three macerations, treating with animal charcoal, concentrating, and adding ammonia. The precipitate is weighed, treated with ether and the ethereal solution evaporated and weighed. The portion insoluble in ether is treated with strong alcohol, the alcoholic solution evaporated, dried and weighed; or it is washed with water and dilute alcohol and again weighed, the weight being taken as pure morphia.

This process has the following objections:—

1. The amount of water used by macerating three successive times necessitates long applications of heat for evaporating, which tends to destroy the morphia. The meconic acid present is also split up and forms other coloured matters, which help to make the morphine impure.

2. The animal charcoal used retains alkaloid.

3. If the alcoholic solution be evaporated, the results are high, as it contains colouring matter and resin.

4. If washed with alcohol (dilute) and water, morphine is dissolved away.

5. No mention is made of the morphine lost in precipitating.

It is, however, the best of those processes in which water is used alone as a solvent, and by slightly modifying, as follows, can be made to produce very good results.

The solution from which the morphine has been precipitated by ammonia should either be measured and allowance made for the morphia dissolved, or it should be treated with amylic alcohol as before described.

1. The opium should be first treated with benzine, as by that means less water is required for exhaustion, and the marc should be percolated, not macerated.

2. The use of animal charcoal should be precluded, the morphia being purified by being dissolved in acid, made neutral, filtered, and then adding ammonia.

The process devised by Merck, consists in exhausting with water, and precipitating by means of carbonate of soda and heat. The precipitate is dissolved in acetic acid and made neutral, filtered, and excess of ammonia added.

This process has the following objections:—

1. The alkali and heat cause destruction of the morphine.

2. No account is taken of the loss by precipitation. It has the advantage that the method of purification proposed avoids loss of morphine.

Guillermond's process consists in treating opium with alcohol, and adding ammonia to the alcoholic solution. The morphine so produced is very pure, but as a large quantity remains dissolved in the alcohol, it is only a comparative method. The precipitate also contains meconate of calcium.

The process of Staples, which consists in adding alcohol to concentrated infusion of opium, then after filtration mixing more alcohol and ammonia, is also open to the same objections as the last.

The process of Mohr which has been adopted, with slight modifications, by the compilers of the B. P., consists in exhausting opium with water, mixing with milk of lime and boiling; the filtered liquid is mixed with hydrochloric acid and concentrated. It is then made exactly neutral with ammonia, filtered, and mixed with excess of ammonia. The precipitate dried and weighed. This process if properly and carefully carried out is one of the best, as, by the use of lime, the resin and meconate of calcium, also meconic acid, is removed from solution. The objections to it are—

1. That the large quantity of water used and the subsequent evaporations cause loss of morphine.

2. That no account is taken of the loss of morphia by non-precipitation.

The modifications I would introduce are as follows:—

1. The opium should be first treated with bisulphide of carbon or benzine.

2. The dried residue should then be mixed with its own weight of lime and two or three times its bulk of some inert powder, such as pumice or glass. It is then to be percolated with water, the first part of percolate being returned as fast as it runs through. By this means much less water will be required to exhaust the opium than would otherwise be the case. After the opium is exhausted, which will be known by the liquid dropping through devoid of taste, the solution should be exactly neutralized with dilute sulphuric acid and filtered and the precipitate washed. The clear solution is then to be evaporated over a water-bath until its bulk is about half an ounce, and again filtered if requisite; then ammonia is to be added in slight excess, and the liquid allowed to stand twenty-four hours. The precipitate can then be collected, washed with ether, and dried, and to the amount found must be added the amount corresponding to the quantity of water used in precipitating and washing. The morphia obtained by this process is of a dull white colour, crystalline, perfectly soluble in alcohol, acids, and alkalies.

In concluding these few remarks, which I hope may prove useful as indicating which methods are most likely to give correct results, I beg to state that I do not consider the subject in any way exhausted, and that I still intend to work upon opium analysis, and hope to communicate further results at another meeting of the Conference.

Note on the Assay of Opium.

BY B. S. PROCTOR.

During the last six years I have had the estimation of morphia in opium pretty frequently under my consideration, and have accumulated numerous disjointed facts, which I have looked forward to bringing under the notice of this Conference so soon as I had arrived at a satisfactory conclusion. This I have not yet accomplished, and I should not now presume upon troubling you with a record of inconclusive experiments were it not that the announcement of Mr. Cleaver's report upon the same subject suggests the propriety of my putting on record a few experimental results and theoretical deductions while the subject is before you.

Experience soon taught me that me that it was useless to trust to any reaction, or series of reactions, based only upon a knowledge of the behaviour of the proximate constituents of opium in the separate state; and a more extended experience added the conclusion that a process acting satisfactorily with one sample of opium may not give results equally good with another.

Narcotine, we are taught to believe is not soluble in aqueous liquors free from acid reaction, but experiment shows that aqueous solutions of opium, having no acid reaction, contain it in notable quantity. We are also taught that narcotine is not soluble in lime water, yet experiment shows that this is not to be trusted to for separating morphia from narcotine when thrown down together. In like manner I find my record of experiments furnishes me with many statements apparently in contradiction to the teachings of the handbooks. I say apparently in contradiction, for we cannot say that there is any real contradiction, so long as the circumstances do not precisely coincide. Here lies the index to the whole difficulty. No two samples of opium are precisely alike, consequently in no two assays are the alkaloids presented under circumstances which precisely coincide; and any process contrived with the view of eliminating uncertainty can only be accepted as satisfactory when it has been proved by trial, upon every variety of opium, to give results as good in each case as can be obtained by any other process. If we multiply the number of processes worthy of trial by the number of samples of opium notably different we should form an estimate of the number of assays from which we might draw a conclusion. I have endeavoured to simplify this elaborate subject by dividing the process into sections, the first being the extraction, the obtaining of the morphia in solution together with more or less of the other constituents of the opium; the less the better, provided the thorough extraction of the morphia be assured. I have not met with any instance in which a thorough extraction was not easily and speedily obtained by the method which I published in 1873* (*i.e.*, reducing the opium to a pulp with a little warm water, adding spirit and percolating with spirit). I never found a sample of opium which did not give an acid reaction, but it is stated that some samples, being destitute of free acid, require the addition of an acid to insure their exhaustion. I will quote one experiment illustrating the exhausting of the opium.

200 grains of lump opium with half an ounce of water rubbed to a pulp in a warm mortar, 1½ ounce of methylated spirit gradually added, the whole put into a percolator. The percolation was slow. More spirit was added as required, and the percolate was fractionated; the first portion of 2 ounces yielded 18·8 of pure morphia, the second portion of 2 ounces yielded 4·6 of morphia nearly pure, and the third portion consisting of 3 ounces yielded 1·0 of morphia. In this instance we find 200 grams of opium exhausted with 7 ounces of methylated spirit. In practice for the sake of safety I habitually use at least double this proportion.

The next stage is to separate the alkaloid from the other matters held in solution.

I have seen less reason to fear the partial precipitation of the alkaloids—morphia especially—by reagents not supposed to precipitate them than I have seen to fear their imperfect precipitation when intentionally thrown down from solutions containing the extractive matters of opium; besides which these colloid bodies detract from the crystalline conditions of the alkaloids, which is of some importance in the third stage of the process. Guided by these considerations I aimed at separating the bulk of amorphous matter before acting on the crystalloids. With this view I evaporate the solution to a syrupy condition, adding a little water towards the end of the evaporation to insure the spirit being got rid of without making the residue thicker than syrup. This syrupy liquid, though devoid of spirit, holds in solution sundry matters reputedly insoluble in water, but which increase the solubility of one another, while their proportion to that of the water is considerable, but which do not retain that mutually solvent action when diluted; I therefore add two ounces of water (in the treatment of 100 gr. opium), by which means there is thrown down a considerable quantity of caoutchouc, fat, resin, colouring matter, narcotine, etc. These sometimes adhere into a soft, plastic mass, which may remain attached to the bottom of the dish, or be collected in a lump on the end of a stirring rod. I have repeatedly tested this clot and found it devoid of morphia. In physical qualities it varies with different samples of opium. The liquor when decanted, or if necessary filtered, contains all the opium constituents which are freely soluble in both water and spirit, and the treatment has rejected the great bulk but not the whole of those constituents which are reputedly insoluble in these two menstrua. It is to be evaporated to two fluid-drachms, an equal bulk of methylated spirit added, and then ammonia added in slight excess.

If the spirit added exceeds the water present, mucilaginous matter is frequently deposited; if, on the other hand, there be a deficiency of spirit, the ammonia throws down much colour with the alkaloids. The alkaloids are sometimes thrown down immediately, and in powder, but in many cases slowly, in crystals and contaminated with but little colour. Twelve to eighteen hours are allowed for the deposition of the alkaloids, which concludes the second stage of the process. The third stage consists in the treatment of this precipitate. It is collected on a filter, washed with a mixture of equal parts of methylated spirit and water till the washings are almost colourless, about an ounce of the dilute spirit being usually sufficient, then washed with water till a drop on evaporation leaves an insignificant residue.

The precipitate is then dried and contains morphia in yellow or brown crystals, and narcotine, usually silky white. Without removing the precipitate from the filter, benzine is washed through so long as a drop evaporated on a slip of glass leaves any conspicuous residue. Half an ounce to an ounce of benzine usually suffices.

As soon as the benzine evaporates the morphia is in condition for weighing. I believe the process as now described will be found an improvement upon that of the Pharmacopœia, or many others which have been recommended, but it is not yet perfect. The morphia is not quite pure and I have not yet been able to vary the process so as to insure a satisfactory approximation to purity in all cases, without having recourse to redissolving and reprecipitating the morphia. The precipitate however is so nearly pure morphia that its behaviour with solvents and precipitants can be depended upon. It may be dissolved with lime and water,—filtered,—acidulated with hydrochloric acid,—evaporated to small bulk—and precipitated by ammonia. Or it may be dissolved with acid and water, then spirit added, and finally ammonia. I have with me a sample of well crystallized morphia

* 'Lectures on Practical Pharmacy,' p. 352.

obtained by this latter method. The use of spirit and water as the solvents from which to precipitate the morphia involves a small loss amounting to about ¼ grain in the original precipitation and as much more if a second solution and precipitation is necessary; but this is a trifle compared to the large and uncertain proportion of impurity contained in the precipitates yielded by many of the published modes of assay.

I think there has been too much stress laid upon avoiding a free excess of ammonia in the precipitation of morphia—a 5 per cent. solution of ammonia only retains about 0·4 per cent. of morphia. And I have repeatedly found liquors, which had had ammonia added till a faint odour was perceptible, lost that odour on standing a day, and deposited a further crop on the addition of more ammonia.

Since writing this note, having an assay in hand, I took the opportunity of recording a little more precisely the results in this respect. To the liquor prepared from 100 grains of opium, in the manner before described, ammonia was added till the odour was perceptible though not powerful; on standing eighteen hours the precipitate was collected on a filter, and though the liquid was still feebly evolving ammonia, as indicated by red litmus paper slowly becoming blue when suspended over it, no further precipitation took place on standing six hours; but on the addition of three drops more of strong solution of ammonia a second crop of morphia was obtained; after standing eighteen hours this was collected separately. This treatment repeated again gave no further precipitation of morphia, only dark brown sticky matter being thrown down. The first precipitate after washing weighed 6·6, the second 2·5. The first, as it was thrown down, contained narcotine, morphia, and colour; the second contained morphia and colour, and the third colour only. The first when purified yielded 5·1 and the second 2·0 of pure morphia.

It has been recommended to add ammonia freely and drive off the excess by evaporation, a proceeding which I likewise think objectionable. It is stated that morphia is not soluble in ammonium chloride, but if morphia be added to a solution of ammonium chloride, ammonia is liberated and by the repeated evaporations the whole of the morphia may be dissolved and will be re-precipitated on the addition of free ammonia. I might add many observations having more or less bearing upon the subject, but at the present time they could only be fragmentary and ill digested. And though I do not deny the importance of recording unsuccessful researches the value of negative results depends much upon their being so arranged as to afford positive information.

I have said I consider the process of extraction satisfactory. I may now add in conclusion that I think the treatment of the liquor satisfactory as far as it goes; that is, that evaporation and precipitation by water, followed by the addition of spirit before precipitation is advantageous, but that some further intermediate treatment, such, for example, as boiling with lime, might be beneficial.

The treatment of the precipitate when formed is satisfactory as regards washing with weak spirit, then with water, and finally, after drying, with benzine. I consider it desirable to avoid the necessity for redissolving and again precipitating the morphia on account of the time and loss of material. I therefore advise that the precipitate should be weighed after treatment with benzine, and only subjected to purification if on treatment with lime water it is found to be contaminated with much colour or a palpable amount of insoluble matter, and finally, I advise no one to trust very much to my recommendations.

So far as the subject has yet been investigated it appears to me, no method or selection of methods would give infallible results, even in the hands of an intelligent operator unless supplemented by some considerable experience.

I usually make two assays of a sample by different methods, and whether they agree or differ they are a check upon one another and a lesson on the applicability of the processes.

New Derivatives from the Opium Alkaloids.

BY C. R. ALDER WRIGHT, D.SC. LOND.,

Lecturer on Chemistry in St. Mary's Hospital Medical School.

Since the last meeting of the Conference the following results have been obtained in continuation of the author's researches on the subject, and in conjunction with Mr. G. H. Beckett.

A community of "structure" between the alkaloids narceine and narcotine has been established, and both have been found to be closely related to a new alkaloid, *oxynarcotine*, recently separated from the crude narceine obtained from the mother-liquors of the Robertson-Gregory morphine extraction process by Messrs. Macfarlan, of Edinburgh, and sent to the author for further purification and examination. To these three bodies the following formulæ are found respectively to apply:—

Narceine,	Narcotine,	Oxynarcotine,
$(C_{13}H_{20}NO_4)$	$\left\{ C_{11}H_{11}(CH_3)NO_3 \right\}$	$\left\{ C_{11}H_{11}(CH_3)NO_3 \right\}$
$\vert$	$\vert$	$\vert$
CO	CO	CO
$\vert$	$\vert$	$\vert$
$C_6H_2 \begin{cases} CO.OH \\ O.CH_3 \\ O.CH_3 \end{cases}$	$C_6H_2 \begin{cases} COH \\ O.CH_3 \\ O.CH_3 \end{cases}$	$C_6H_2 \begin{cases} CO.OH \\ O.CH_3 \\ O.CH_3 \end{cases}$

From each of the three bases, by appropriate means, the bibasic acid *hemipinic acid*—

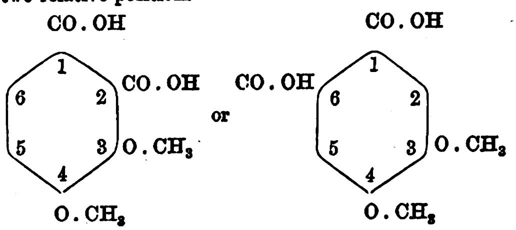
$$C_6H_2 \begin{cases} CO.OH \\ CO.OH \\ O.CH_3 \\ O.CH_3 \end{cases}$$

can be prepared, narcotine giving rise to the nearly correlated *opianic acid*—

$$C_6H_2 \begin{cases} COH \\ CO.OH \\ O.CH_3 \\ O.CH_3 \end{cases}$$

by an intermediate reaction; this latter, however, as indicated by the above formulæ, is not producible from either of the other two alkaloids.

In pursuance of this subject a lengthy research has been made on the nature of the reactions undergone and the products furnished by hemipinic acid, with the result of completely establishing that this acid is a benzene derivative, as expressed by the above "structural formula;" and that, moreover, it is a carboxylated protocatechuic acid, the four lateral chains being in one of the two relative positions—



The CO.OH which represents the linking—CO—radical in the formulæ of narcotine, narceine, and oxynarcotine being in one of the two positions (2) or (6), with reference to the other three lateral chains, the two oxymethyl groups being in the positions 3 and 4, and the other remaining group in the positions 1.

In the course of this research it has been demonstrated that *vanillin* the odorous principle of vanilla, can be manufactured from narcotine; the small yield, however, has prevented this practical application of the hitherto almost waste product in morphine-extraction, narcotine. The steps in this operation are as follow:—

(1) By cautious oxidation with manganese dioxide and sulphuric acid narcotine furnishes, as is well known, opianic acid.

(2) Opianic acid, when converted into sodium salt and cautiously heated with an intimate admixture of dry sodalime, furnishes a distillate from which, by fractional distillation, a crystalline body melting at 41° and boiling at 283° can be separated; this body is *methyl-vanillin* (dimethyl protocatechuic aldehyde), formed thus from the opianic acid—

$$C_6H_2\left\{\begin{matrix}CO.OH\\CO\ \ H\\O.CH_3\\O.CH_3\end{matrix}\right. = CO_2 + C_6H_3\left\{\begin{matrix}COH\\O.CH_3\\O.CH_3\end{matrix}\right.$$

(3) By heating methyl vanillin with hydrochloric acid, methyl chloride is evolved and *vanillin* (monomethyl protocatechuic aldehyde) is formed thus—

$$C_6H_3\left\{\begin{matrix}COH\\O.CH_3\\O.CH_3\end{matrix}\right. + HCl = CH_3Cl + C_6H_3\left\{\begin{matrix}COH\\OCH_3\\OH\end{matrix}\right.$$

A large number of other derivatives from opianic acid have also been obtained; some of these were previously known, and have been re-investigated for the purpose of establishing their "structural" relations to one another and to bodies well known as derived from other sources, but not hitherto recognized as being in any way connected with any of the natural alkaloids. (For the details of these experiments the reader is referred to the *Chem. Soc. Journ.*, 1876, February, March and April numbers.) It is hoped that the knowledge thus gained may ultimately lead to the synthesis of one or other of these alkaloids, and thus pave the way to the artificial manufacture of the more valuable alkaloids, such as morphine and quinine; as yet, however, this prospect is still far off.

Narcotine, oxynarcotine, and narceine, besides having a considerable amount of community of "structure," resemble one another, and differ from most other alkaloids in the ease with which these compounds with acids break up in presence of water into free acid and a basic salt; the amount of acid retained in these basic salts seems solely to be influenced by the amount of water present relatively to the acid, no definite basic compounds being obtainable. Curiously, however, narceine exhibits an extraordinary attraction for small quantities of hydrochloric acid, it being extremely difficult (even by precipitation with excess of an alkali) to obtain narceine perfectly free from hydrochloric acid associated as a highly basic salt.

No derivatives of opianic acid have hitherto been obtained from morphine or codeine, although carefully sought for, whence it would seem that these two bases, although of closely similar "structure," are nevertheless very different in constitution from narcotine and its congeners narceine and oxynarcotine. These latter bases, moreover, are physiologically possessed of but little activity; that this is due to the influence of the copulated benzene radical is rendered highly probable from the circumstance that hydrocotarnine is (as mentioned in the paper read before the Conference last year) a tolerably active alkaloid, this base being readily formed from narcotine by the reaction—

$$\underset{\text{Narcotine.}}{C_{22}H_{23}NO_7} + H_2O = \underset{\text{Hydrocotarnine.}}{C_{12}H_{15}NO_3} + \underset{\text{Opianic Acid,}}{C_{10}H_{10}O_5}$$

With a view to completing the history of the "constitution" of narcotine and its congeners experiments are being carried on with hydrocotarnine and its derivatives. The results of these experiments (if not entirely negative) will in due course be brought before the Conference.

Note on the Presence of Free Acetic Acid in Opium.

BY DAVID BROWN.

It does not appear to be generally known that free acetic acid exists in opium and that it can be obtained from it by submitting an aqueous extract to distillation, neutralizing the distillate, evaporating to dryness, and decomposing the residue with sulphuric acid. Traces of butyric acid were observed in the crude acid. The silver salt of the pure acid gave 64·13 per cent. Ag; theory requires 64·67.

The quantity found in opium is small; I have, however, been able to extract it from a sample of genuine Turkey opium as well as from all grades of that drug, until I came to an article which bore the name opium, but which certainly had nothing in its composition to entitle it to such a designation.

From the frequency with which I have observed the presence of this acid in opium I think it may, with all safety, be set down as a constituent of that drug.

I have much pleasure in confirming the statement made in 1869 by Dr. Flückiger regarding the presence of a member of the pectin series in opium. In 1864 I roughly examined a quantity of crude pectate of lime obtained from opium, but a pressure of other work prevented me at that time going more fully into the subject. In 1871, without any knowledge of Dr. Flückiger's work, the subject was again taken up, and the result of a careful examination of various opium samples enables me to confirm his results.

The President said the first duty of the Conference was to express its thanks for these very valuable communications, and he had also to invite discussion upon them. Those papers which were first brought under notice were in particular of considerable interest for all practical men. He certainly considered that if this Conference had produced nothing more than these papers it would have added greatly to the indebtedness of pharmacists to it for having brought under their notice matters of such importance. The questions affecting the strength of the preparations of opium are very important. He conceived, however, that in the consideration of the subject, it would have been desirable to give attention in the first place to the means of ascertaining the strength of opium, that is, to testing or titrating the different samples of opium that were used. If druggists were more in the habit of applying the test of the Pharmacopœia, or any improvement upon that test which could be devised, it would no doubt obviate to a very great extent, in fact, practically, it might entirely remove the objection that had been taken, founded upon the great variation observed by practical men in the preparations of opium. These variations were referable chiefly to the differences in the samples of opium used, and it was known, in fact the statements made by Mr. Cleaver and Mr. Proctor indicated, that there were very considerable variations in that respect. Then with reference to the processes which have been suggested for testing the strength of opium, he confessed he had been considerably gratified in finding that so decided a testimony was borne to the value of the process now given in the Pharmacopœia. He did not consider that process to be by any means perfect. In fact he had long considered it to be a process which called for some modification. Whether the modifications that have been suggested by Mr. Cleaver would be sufficient to meet the requirements of the case, he was not prepared to say. He had been himself rather disposed for sometime past to look more to a process analogous, or very similar, to that recommended by Mr. Proctor. At all events the question was an important one, and it was just one of those questions which he should like to see referred to such a committee of the Conference as he had alluded to in his opening address, with power to have a sufficient number of experiments carried out by an operator employed by such Committee, with the view of determining which process should be considered the most reliable and best.

Mr. CHIPPERFIELD said it had struck him in making tincture of opium as well as other tinctures by the formulæ of the British Pharmacopœia that the results were more uncertain than if they were prepared by the old method of the London Pharmacopœia, for this reason, that the London Pharmacopœia directed that maceration should take place, and that the marc should be pressed. No matter what loss there might be by the imperfection of the pressing, the strength of the tincture would remain the same whether a great or a small loss took place. By the present method, however,—that of the British Pharmacopœia—a very great loss in strength might result. If tincture of opium were made in large quantities and pressed by hydraulic power, then there would be little waste. If it were made in smaller quantities and very imperfectly pressed there would be a very considerable percentage of loss, which loss being made up with additional menstruum, to that extent the tincture would be reduced in strength, and could not contain "1 in 13½." In that respect the old method of making the tinctures by the London Pharmacopœia was superior to that of the B. P.—insuring a uniform result.

Mr. GERRARD said he was able to confirm Mr. Cleaver's statement with reference to the use of benzole in the assay of opium, more especially in the Persian variety, which sometimes contained a large quantity of oil.

Mr. CLEAVER said his investigation was made more especially with the object of devising the process in which the whole of the morphia in opium could be obtained. In the ordinary processes the precipitate weighed as morphia was not all morphia—in fact, it contained 10 to 20 per cent. of colouring matter. He tried, therefore, to purify the morphia and prevent loss in the purification. He thought the method he had given would do so. As to the difference between his and Mr. Proctor's modes of operation for the extraction of morphia, he thought that Mr. Proctor would not get any more by his process, for the simple reason that he washed with dilute spirit, by which means there was a certain loss of morphia. Then, again, he did not take account of the loss owing to the solubility of morphia in water.

Mr. PROCTOR said he had used the method he had proposed for extracting Persian opium. He thought the main thing was the comparative purity of the different samples of morphia as obtained by the two processes, and he produced samples as giving indications of the actual superiority to be obtained by the process advocated by him. He thought the main thing to be aimed at was getting the alkaloid in a pure state, not in a state of proximate purity, which the Pharmacopœia and other formulæ give.

Professor ATTFIELD remarked that it would be obvious the specimens in the upper part of the box submitted by Mr. Proctor were much lighter in colour than those in the lower, which he understood were samples given to Mr. Proctor by a friend who had adopted some other process. He should like to ask Mr. Proctor or Mr. Cleaver whether they could hold out any hope that pharmacists would ever have any one particular process for the extraction of morphia in opium which would answer for all opiums, and whether also much must not depend upon the experience of the operator, in judging by preliminary experiment and the appearance of the opium as to which of the one, two or three modifications of processes he would adopt.

Mr. CLEAVER said he would not say the process he had described was applicable to every sample of opium that was to be met with, but it was applicable to the greater part, and he thought the judgment of the operator must be the best guide. He should also make a preliminary test of the opium in order to see whether its acqueous infusion was freely acid. If so every trace of morphia would be extracted by the method described.

Mr. PROCTOR pointed out that one of the last remarks in his paper was that no system whatever would be perfect without very considerable experience on the part of the operator.

(To be continued.)

Parliamentary and Law Proceedings.

THE SALE OF LAUDANUM.

An inquest was held at Spalding on Thursday, August 24, before Mr. J. G. Calthorpe, coroner, touching the death of Thomas Kirby. The deceased had been found by his wife in a heavy sleep, with a bottle labelled "Laudanum" close by. Medical assistance was obtained, and by the stomach pump the contents of his stomach, smelling strongly of opium, were removed. Under medical treatment the deceased appeared to recover from the effects of the poison, but died four days afterwards from inflammation of the lungs, which the medical witnesses could not say had not been aggravated by the treatment necessary to recovery from the effects of the laudanum. Deceased, who was a volunteer, had received a slight hurt whilst exercising, and had attracted the attention of his comrades by his strange behaviour.

The following is the evidence respecting the sale of laudanum to the deceased, and the coroner's remarks thereon:—

Frederick Arch, apprentice to Mr. Gibson, chemist, saw the deceased on the Friday previous about 4 o'clock. He came into the shop for some laudanum, and witness supplied him with one ounce. He said he had fallen and hurt his ribs at Bolton, and witness supposed he required the laudanum for external application. He knew deceased quite well, and he noticed nothing peculiar in his manner. He did not enter the sale in his book; Mr. Gibson kept a register for the sale of poisons. He did not consider it necessary to enter the sale of laudanum in any case. He had been at Mr. Gibson's four years, and during that time he had sold a great deal of laudanum without entry.

Alfred Lunn, apprentice to Mr. Asling, chemist, said Kirby went to his master's shop just before 5 o'clock on the previous Friday for three pennyworth of laudanum. Witness supplied him; deceased did not say for what he required it. Witness knew him well, but he did not recollect supplying him with laudanum before. Mr. Asling kept a register of the sale of poisons, but this was not entered, as it was not required by law. It was not Mr. Asling's practice to register the sale of laudanum. Unless they knew the person purchasing, they did not usually supply it without a good reason from the purchaser. He did not recollect that Mr. Asling had given him any instruction as to the sale of laudanum, or any preparation of opium. His practice was to sell any quantity up to half-a pint to a known customer. A stranger did not require an introduction if his explanation was satisfactory when purchasing laudanum. Witness had been at Mr. Asling's a little over four years.

Henry Atkin Gibson, chemist, said he had sold laudanum to Kirby on the previous Friday night; it would be between 5 and 6 o'clock. Kirby asked for two ounces of laudanum in a bottle, and he supplied him with it. He told him he had an ounce from his young man before on that afternoon, and he had used it all for his arm, on which he had had a fall on some ice. He appeared in the same state and manner as usual. Three ounces was not a large quantity to sell in one day to one person. They did not register laudanum; any one could get it at his shop, and without any explanation, except in a special case. Practically, he made no restriction on the sale of laudanum. He was acquainted with the Sale of Poisons Act, and it was not necessary to register laudanum; that was the general opinion of chemists.

The Coroner here remarked that, for the information of witness and all other chemists, he might say he was clearly of opinion that it was necessary to register the sale of all poisons specified both in Schedule A and B. And furthermore, if there was a sale of any poison to any stranger, it must be only after the introduction by some person known to the chemist, and after obtaining the signature of both the parties.

The jury returned a verdict in accordance with the medical evidence.

Poisoning by Laudanum.

On Friday September 8, an inquest was held at Lower Broughton Road, Broughton, near Manchester, by Mr. F. Price, district coroner, on the body of Maud Aramina, aged seven days. The child was in the care of a monthly nurse, named Margaret Johnson, who on the previous Monday morning compounded a mixture, consisting of three or four drops of brandy, one drop of laudanum, and about a dessert-spoonful of water, and gave the infant a teaspoonful to alleviate pain in its stomach. The next night the child was again troubled with the pain, and the nurse about midnight gave it a similar dose. This caused the child to sleep until about eight o'clock on Wednesday morning, and when it awoke its father observed that it presented a peculiar appearance. He drew the attention of Johnson to it, who said she thought it had "caught cold," but made no reference to the mixture which she had administered. Mr. Winterbottom, surgeon, was summoned, and, on seeing the child, he said it was suffering from the effects of some narcotic poison. The nurse said she had not given it anything, but afterwards admitted that she had "given it a drop of laudanum to quieten it." The child became convulsed, and died during the day.—The woman Johnson, in her evidence, said that so far as she knew she did not put more than one drop of laudanum into the mixture which she compounded on Tuesday night, but she might have put a little more than one drop into it, and have administered more than a teaspoonful of the compound to the infant. A medical man had once recommended her to give children the mixture, and she had been in the habit of administering it regularly to infants which she nursed.—Mr. Winterbottom said there was no doubt the child had died from the effects of narcotic poison. The jury were of opinion that the mixture had been administered solely with the object of relieving pain, and, there being no suspicion against the nurse, returned a verdict of "Death by misadventure." At the request of the jury the coroner censured Johnson for her carelessness.

Obituary.

Notice has been received of the death of the following:—

On the 20th of June, 1876, Mr. William Woods, Pharmaceutical Chemist, Worcester. Aged 60 years. Mr. Woods had been a Member of the Pharmaceutical Society since 1842, and at the time of his death was the Local Secretary of the Society for Worcester.

On the 30th of July, 1876, Mr. Robert Carr, Chemist and Druggist, Berwick-on-Tweed. Aged 47 years.

On the 19th of August, 1876, Mr. John Legge Newcombe, Chemist and Druggist, Okehampton, Devon. Aged 60 years.

On the 20th of August, 1876, Mr. Joseph William Gowing, Chemist and Druggist, Snettisham, Norfolk. Aged 55 years.

On the 21st of August, 1876, Mr. James Agnew, Chemist and Druggist, Great Homer Street, Liverpool. Aged 41 years. Mr. Agnew had been a Member of the Pharmaceutical Society since 1869.

On the 4th of September, 1876, Mr. Joseph Moore, Chemist and Druggist, Pembroke Dock. Aged 45 years.

On the 5th of September, 1876, Mr. Joseph Bower Williams, Chemist and Druggist, late of Kingswinford, Staffordshire. Age 26 years. Mr. Williams had been an Associate of the Pharmaceutical Society since 1869.

On the 7th of September, 1876, Mr. Henry Clement Heard, Chemist and Druggist, Bridgewater. Aged 58 years.

On the 9th of September, 1876, Mr. Joseph Fairs, Rye Hill, Newcastle. Aged 76 years. Mr. Fairs was formerly in business as a Chemist and Druggist in Newcastle, but retired from business a few years ago.

Notes and Queries.

[524]. GLYCERINE AND COLLODION OINTMENT.—Can any reader oblige us with formula for making Glycerine and Collodion Ointment.—G. and T.

Correspondence.

NOTE ON THE PRINCIPLES OF ERGOT.

BY M. TANRET.

In a note read before the French Academy in the latter part of last year, and reproduced in this Journal,* M. Tanret published his discovery in ergot of what he considered to be a new alkaloid, to which he gave the name of "ergotinine." Subsequently, Professor Dragendorff published in this Journal† the results of his investigation of ergot in conjunction with Herr Padwissotzky. In this paper Professor Dragendorff stated that Tanret's ergotinine had been prepared by himself and his colleague and that they were of opinion that it did not represent a chemically distinct substance, but that it contained, among other substances, an admixture of sclererythrin, to which its activity was to be attributed. This statement has evoked from M. Tanret the following rejoinder, which appears in the *Journal de Pharmacie* for September:—

"In the course of my researches upon ergot of rye I have isolated a colouring matter which is found to be the sclererythrin of MM. Dragendorff and Padwissotzki. It was prepared by treating with an acid the alcoholic extract of ergot from which the fatty matter and resin had been separated. The precipitated sclererythrin was collected and purified by solution in ether. The study which thus enabled me to prepare this substance has also permitted me to demonstrate by numerous proofs that my ergotinine cannot contain the least trace of sclererythrin. I will limit myself to some in which the evidence is clear, and depends upon properties that M. Dragendorff has attributed to sclererythrin.

"Sclererythrin is a red substance. Its alcoholic or ethereal solutions are of an intense reddish yellow colour. A trace of it is sufficient to give with dilute alkalies 'a beautiful murexid colour.' Now ergotinine is nearly colourless, and does not give any colour reaction with alkalies.

"If an alkaline solution of sclererythrin is treated with an acid and shaken with ether the colouring matter passes into the ether. The contrary takes place with ergotinine; acids remove it from its solution in ether.

"As to the violet colour which sulphuric acid produces with scleroiodin, it cannot be confounded with that characteristic of ergotinine. Sulphuric acid alone gives with the latter only a greenish blue colour; in order that the red yellow colour followed by a magnificent violet blue may be manifested it is necessary that the acid should not be too concentrated, but diluted with about one eighth water, and, what is indispensable, with sulphuric ether, though of this there might not be more than a trace. Further ergotinine is soluble in alcohol, chloroform and ether, whilst scleroiodin is not.

"As M. Dragendorff has not named the other substances that he says are mixed with sclererythrin to constitute ergotinine I am not at present able to deal with them. But might it not be with them as with sclererythrin?

"In conclusion, I would express a regret, and one that is shared by all who are interested in the study of ergot of rye, that M. Dragendorff has not given more explicit details as to the preparation and properties of the bodies that he has represented as being the active principles of ergot, scleromucin and sclerotic acid."

PRELIMINARY NOTE ON XANTHIUM SPINOSUM.*

BY M. GUICHARD.

The author presents the following contribution to the chemical and pharmaceutical history of this new medicament, which has recently been recommended as a remedy for hydrophobia.†

The drug is met with in the form of stalks bearing leaves and numerous spines. There is room therefore for the study of the picked and unpicked drug, and to ascertain which of the two should be employed, as probably the activity of all the parts is not the same. Their yield in extract is very different, 20 grams of cleaned leaves gave with alcohol 5 grams, or 25 per cent., of green extract containing much chlorophyll. 150 grams of the uncleaned drug treated in the same way yielded also a green extract, but in less quantity, the yield being only 12 grams, or 7½ per cent. The difference was due to chlorophyll.

The two extracts were prepared by coarsely powdering the plant, and treating it after twelve hours' maceration by displacement, first with 90 per cent. and then with 60 per cent. alcohol.

128 grams of the unpicked plant were treated by infusion, then pressed, and treated a second time. The product was evaporated in a water-bath, and gave 50 grams, or 39 per cent. of extract.

The alcoholic extracts were very bitter; the aqueous extract scarcely so. The author therefore thinks that probably the alcoholic extract is the most active, and this appears to be borne out by the following preliminary experiments:—

The alcoholic extract redissolved in water was precipitated by iodized iodide of potassium, but not by cadmi-potassic iodide. The alkalies precipitated iron and alumina. When dried with calcined magnesia and treated with ether, an extract was obtained which, if redissolved in water acidulated with few drops of hydrochloric acid, gave with the iodized iodide an abundant kermes-coloured precipitate, and with cadmi-potassic iodide a dirty grey precipitate that separated rapidly like curdled milk. Ammonia precipitated the solution slightly.

If the above aqueous solution be allowed to evaporate upon the object glass of a microscope crystals are obtained of various forms, such as needles grouped in crosses, or three branched stars and granular crystals; also some green colouring matter. The hydrochloric solution gives large square or rectangular tables as well as acicular crystals. The liquid precipitated by ammonia contains a large number of amorphous points and numerous bundles of fine needles.

The aqueous extract treated in the same manner gives no results. But the author considers that the preceding experiments demonstrate the presence of an alkaloid which he hopes soon to be in a position to isolate.

The mode of employment of the drug previously indicated was to administer 60 centigrams of the plant, finely pulverized, several times a day.

† See before p. 80.

PEPTONE.*

The term "Peptone †" is used to denote those albumin-, or proteïn-bodies, which have been altered by the gastric juice, or in other words, the result of the action of pepsin upon fibrin or albumin. Peptones, introduced into the digestive organs, are directly absorbed into the blood, without having to undergo previous digestion, and are converted into albumin-bodies. As there are various diseases in which the secretion of normal gastric juice is more or less diminished or entirely suppressed—preventing, therefore, the assimilation of the protein compounds —the nutrition of the system may still be accomplished by introducing peptones into the digestive canal. The importance of this mode of administering nourishment in typhous and gastric diseases is fully recognized by physicians.

The German peptone is sold in round tin cans weighing 340 gm. (12 ozs. avoird.), and containing 250 gm. (9 ozs. avoird.) of material. Dr. Hermann Hager suggests the following method of examining it: 10 vol. of the peptone are slightly warmed, mixed in a large test-tube with 60 vol. of a concentrated solution of sodium chloride, and the mixture set aside. After the lapse of thirty minutes the peptone has collected at the bottom of the liquid, and occupies 8 to 9 volumes, after thirty minutes more 7 to 8 volumes and after twelve hours not less than 3·3 volumes. Peptone, in a thin layer, is a clear liquid of the consistence of thin syrup, has a faintly bitter aste, somewhat resembling that of extract of beef or extract of mushrooms. A peptone-chocolate is also manufactured; this is of dark brown colour, has the consistence of a soft extract, and is sold in the same kind of tin boxes as the peptone itself.

Hager quotes the following extract from a report of Dr. H. Sanders in Amsterdam (who is also a manufacturer of peptone): It is well known that the albuminoid substances are the most important nourishing agents of the animal body. From them the muscles and nerves draw the necessary material for their constant recontruction during the process of life. But before these albuminoids can become of any use to the body, they must be digested; and this is done by being converted into peptone in the stomach and intestinal canal; as peptone, it is taken up by the blood, and there reconverted to albumin. As soon as any peptone as been formed, it is very rapidly absorbed. Whenever digestion is defective, or the gastric juice is of abnormal character, it is readily understood that the conversion of albumin or fibrin into peptone, and hence nutrition in general, must become impaired.

This defect may be removed by introducing ready-made peptone, which is rapidly and completely absorbed by the body, and which requires no further digestion. For this reason, it is just as effective if administered by the rectum, as if introduced into the stomach, and in many cases the former way is alone practicable.

The only disagreeable point about peptone is its taste; and if given by the mouth, this may require correction. In the case of nursing infants, it is sufficient to add it to the milk, about one to two tablespoonfuls to the quart. By beginning with small quantities, say one teaspoonful, they become easily accustomed to it. Adults may take it in milk, or diluted with water, or beef-tea. Or it may be mixed with equal parts of sherry, madeira, or some other generous wine. The most agreeable mode of administration, however, is the following:

Peptone-chocolate: 250 gm. (9 ozs. avoird.) of peptone are gently heated, and 200 gm. (7 oz.) of white sugar dissolved in it; to the warm solution are added, under constant stirring, 100 to 125 gm. ($3\frac{1}{2}$ to $4\frac{1}{4}$ ozs.) of pure pulverized chocolate (free from oil), until there is produced a homogeneous syrupy mass, which may be flavoured with vanilla, essence of orange, or of lemons. On cooling this mixture may be kept for a long time without spoiling, and a portion may be dissolved in hot water or milk. When administering it per rectum, it should be diluted with four to six parts of warm water.

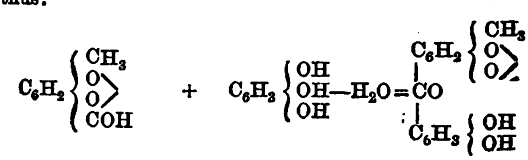
† Πεπτός, όν, digested, digestible.

GENTISIN.*

BY H. HLASIWETZ AND J. HABERMANN.

A previous paper on this subject appeared in abstract in this Journal.† Further research has shown that pyrogentisic acid is identical with hydroquinone. Of the various melting-points of the latter body hitherto given none are correct; the true melting-point is 169° (uncorr.). Gentisic acid has been found to be identical with oxysalicylic acid, which melts when pure at 196°—197°.

Gentisin, when treated with sodium-amalgam, yields a compound having the formula $C_{13}H_{10}O_4$, which differs from that of gentisin ($C_{14}H_{10}O_5$) by CO; and when fused gentisin is treated with dry hydrochloric acid, it yields methyl chloride. Hence gentisin contains the radicle methyl. In the former paper a diacetyl-gentisin was described, showing that gentisin contains two hydroxyl-groups. These facts admit of explanation on the assumption that gentisin is formed by the combination of phloroglucin with a body isomeric with piperonal, thus:



Piperonal isomer, Phloroglucin, Gentisin.

CAMPHIC ACID.‡

BY J. DE MONGOLIFIER.

This acid, which Berthelot obtained by treating camphor with alcoholic potash, is also formed by the action of oxygen on sodium camphor.

$$C_{10}H_{15}NaO + O = C_{10}H_{15}NaO_2.$$

Thus on heating a solution of the sodium-compound in benzene to 100° in a tube filled with oxygen, the gas was completely absorbed in a few hours, while at the common temperature it took two days. To prepare camphic acid, the product of the action of sodium on camphor is dissolved in coal-tar naphtha boiling at 125° C., and a current of air is passed to the gently boiling liquid. After the reaction is finished, the naphtha is distilled off, the residue exhausted with water, and the solution fractionally precipitated with an acid. First a resin is precipitated carrying down camphoric acid, which is also formed, and then camphic acid is thrown out, while some camphoric acid remains in solution.

Camphic acid yields, by double decomposition, the salt $(C_{10}H_{15}O_2)_2Cu$ as a green powder, which is partly soluble in ether, benzene, chloroform, and strong alcohol. The green alcoholic solution deposits a viscid almost black mass, drying up to a dark-green brittle substance consisting of $C_{10}H_{16}O_2 + (C_{10}H_{15}O_2)_2Cu$.

By oxidizing camphic acid with potassium permanganate, it is converted into oxycamphic acid, $C_{10}H_{16}O_3$, which does not crystallize, and resembles camphic acid, but is more liquid. At the same time some acetic acid and camphoric acid are formed, as well as an acid which appears to be toluic acid.

THE IGNOBLE ARMY OF GRUMBLERS.

THE letter which appears in our correspondence columns this week, under the title of "Pharmaceutical Politics," expresses some wholesome views in regard to several of the subjects which have recently agitated the pharmaceutical community, with the result that another effort is being made to bring about united action of the trade for purposes of internal self-government. Without entering into the merits of the objections referred to by our correspondent as being urged against the Council of the Pharmaceutical Society on the ground that it has not secured for every individual in the trade that particular condition of affairs which would be deemed satisfactory by himself, we will merely direct attention to the concluding paragraphs of the letter as being especially worth considering.

The opinions there put forward are by no means novel; in fact they have been in various ways repeatedly urged, but hitherto they have been to a great extent disregarded. We are not aware of any attempt having ever been made to prove that they are unfounded, neither do we believe that such an attempt would be at all successful. On the contrary, we regard the recent endeavour to form a Trade Association as evidence that the greatest need of the trade and the chief obstacle to its improvement is want of unity. It has been inferred by some that the comments we have made on the slow increase in the numbers of the Trade Association were instigated by a spirit of antagonism, or a desire to discountenance the enterprise. We entirely repudiate such motives, and far from being disposed to sneer at the disproportion between the members of the Association and those upon the 'Register,' we are rather moved with regret at being the unwilling witness of another indication that there is amongst the great mass of the trade a radical unfitness for participating in or even recognizing the value of any effort to improve.

Even the very form of the complaints that reach us from time to time give evidence of the grave deficiency we refer to. "What do we get for our guinea a year?" writes a Norwood chemist *à propos* of the correspondence which lately appeared in the *Echo* on the subject of dispensing charges, and if the question has any meaning we must infer that he supposes the Council of the Pharmaceutical Society ought to impose a tariff of dispensing charges for the whole of the country. It is true that in the particular case referred to the difference in the charge made for the medicine dispensed was between a Registered Chemist and a Co-operative Store, and our correspondent must be credited with the belief that the Stores carry on a piratical trade which the Council of the Pharmaceutical Society ought to oppose. We are aware that many hold this view; but it is not represented in the Council to such an extent as to command its being acted upon, and, therefore, the charge of neglect of duty falls to the ground.

But the cry, "What do we get for our money?" betrays a further and a more serious evil in the state of feeling among certain sections of the trade. There is nothing but the selfish regard of individual interest, without any consideration of the benefit conferred on the trade at large by giving support to an organization which has, at least, for its object the advancement of those engaged in this pursuit, which has already done much in this direction, and has unquestionably been restricted in its beneficial action by the fact that it does not even now represent more than one half the trade.

We, therefore, commend to the thoughtful consideration of the dissatisfied portion of the trade the letter in which MR. MEE deals with this subject.

SALE OF POISONS.

IT is scarcely possible to believe that the provisions of an Act of Parliament which was passed mainly out of consideration for the safety of the public should be so generally misunderstood as it appears is the case in regard to the sale of poisonous drugs. Last week we had occasion to comment on the unaccountable misinterpretation of the Pharmacy Act, by which it was held to be necessary to register the sale of laudanum, and on previous occasions we have had to record equally unjustified proceedings on the part of magistrates and coroners.

But it is still more remarkable to find that in regard to an Act dealing specially with the sale and supply of drugs, a vast amount of ignorance prevails among medical men. Only last week the *Lancet* in reporting the facts of the Spalding case, commented upon the sale of the laudanum in the following terms:—

"The gravest aspect of the case is the facility with which a large quantity of opium was and can be obtained. Laudanum was sold in large quantities to the man by two chemists: by one, first one ounce was given, and afterwards two ounces more. No entry was made of the sale in the register for the sale of poisons, and it was stated by the chemists in question that the sale of laudanum is never so registered by them. Any quantity is sold on a pretext being given for its use, without any of the restrictive regulations prescribed by the Sale of Poisons Act. This is reducing the statute to a dead letter, for it is disregarding it where it is most needed."

Here the assumption that the Act requires registration of the sale of laudanum is manifestly the basis upon which these opinions are expressed. The fact that such an assumption is totally inconsistent with the provisions of the Act, would be sufficiently clear to most of our readers, but to the public generally, and even to medical men, this would not be the case. The result is, that an unmerited opprobium is cast not only upon the actual vendors of the laudanum in the Spalding case, but also upon chemists and druggists in general, who are represented as being in the constant habit of disregarding the regulations of the Act. With the same injustice they are indirectly charged with aiding the deleterious practice of opium eating. In point of fact, however, there is nothing in the Pharmacy Act which would enable the druggist to influence that practice one way or the other, and we venture to add that it is no part of his business to attempt doing so.

If our contemporary be desirous of attacking one of the illegal modes in which narcotics are supplied for consumption by the rural population in some parts of the country we recommend to his attention the sale of laudanum and opium under the guise of patent medicines, that is to say with a 1½*d.* Government stamp on the packet containing them, so as to evade the provisions of the Pharmacy Act. This is an abuse which not only facilitates the pernicious habit of opium eating, but also does harm in other ways. We shall be glad to see the influence of the *Lancet* brought to bear for its suppression.

TESTIMONIAL TO A PHARMACIST.

We learn from the *Cape Mercury* that a very handsome testimonial was recently presented to Mr. Thomas Daines, Pharmaceutical Chemist, and a member of the Pharmaceutical Society of Great Britain, of King William's Town, Kaffraria. The testimonial consisted of an address, illuminated and engrossed on vellum, together with a highly finished binocular microscope and accessories, and was in recognition of Mr. Daines' services as Secretary to the King William's Town Temperance Society.

FRENCH PHARMACEUTICAL STATISTICS.

According to recent statistics, quoted in the last issue of the *Bulletin Commercial*, there are at the present time in France 2,121 pharmaciens of the first class and 4,089 of the second class, being a total of 6,210 pharmaciens. Ten years since, in 1866, there were 2,457 of the first class, and 3,346 of the second, or altogether, 5,803 pharmaciens. Next to the department of the Seine, in which alone there are 820 pharmaciens (495 first class and 325 second), the departments having the highest number of pharmacists are the Bouches-du-Rhone, Gironde, Nord, Seine-Inferieure, Seine-et-Oise, Var, and Haute-Garonne. Between the 1st of January, 1803, and the 1st of January, 1876, the superior schools, the medical juries, and the preparatory schools of pharmacy have conferred no less than 16,650 degrees of pharmacien, of which 6,462 have been of the first class and 10,188 of the second. On the average, there is now in France one pharmacy to 10,000 inhabitants and a territorial area of 2,000 hectares.

ONTARIO NOTES

At the last half-yearly meeting of the Ontario College of Pharmacy, an application from a Government detective to be appointed Public Prosecutor under the Provincial Pharmacy Act of 1871 was agreed to. The new official, who holds a similar appointment from the Dental Association and the College of Physicians and Surgeons for Ontario, is to act as the authorized agent of the College, but it is provided that the College shall not incur any expense by his operations.

At the same meeting a person applied for registration under the local Pharmacy Act, without submitting to examination, producing as proof that he had been in business on his own account before 1871 a receipt given by the Pharmaceutical Society of Great Britain. The application was, however, rejected, on the ground that the provision in the Act applies to the province of Ontario only.

There appears to be a very general desire amongst the members of the Ontario College of Pharmacy that the American Pharmaceutical Association should meet in Toronto next year. A delegate has been authorized to attend the meeting of the Association at Philadelphia with an invitation to that effect, and a numerous and influential committee has been appointed to carry out the necessary arrangements should the invitation be accepted.

ARTIFICIAL COLOURING OF WINES.

Since the vintage of 1875, the artificial colouring of wines in France has attained such a development as to raise fears not only for the good name of French wines, but also for the public health. The Syndicate of wine merchants of Paris has taken the matter up and urged it upon the attention of the French Government in a vigorously written memorial, in which it is roundly asserted that the sole object of the colouring is so to treat a wine, at an insignificant cost, that it may be sold considerably above its real value. Formerly colouring was only done to a small extent and with vegetable and comparatively inoffensive matters, but now, it is stated, hundreds of kilograms of arsenical fuchsine and other equally poisonous substances are used for the purpose and the sale of such preparations is openly advertised. The Syndicate urges that it is useless to discuss in chemical laboratories whether fuchsine itself, or arsenical fuchsine when diluted to a certain extent, is poisonous or not, there being no guarantee against the greediness of the wine colourer. One result of the agitation has been that the officers of *octroi* have been ordered to take samples, for analysis, of all red wines coming into Paris.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

At the Annual General Meeting of this Association, held at the Bristol Museum and Library, on Thursday, August 31st, the following gentlemen were elected to serve on the Council for the ensuing year:—Mr. C. Boorne, President; Mr. J. Stroud, Vice-President and Treasurer; Mr. R. L. Tucker, Honorary Secretary; Mr. W. Berry; Mr. J. Boucher; Mr. J. Pitman; Mr. J. G. Plumley; Mr. G. F. Schacht; Mr. W. W. Stoddart; Mr. A. Towerzey; Mr. C. Townsend; and Mr. J. W. White.

The next paper read was on—

A New Excipient for some of the Official and other Pill Masses.

BY G. WELBORN.

One of the subjects for investigation in the list compiled by the British Pharmaceutical Conference relates to the unsatisfactory condition which some of the pill masses of the Pharmacopœia acquire by long keeping.

It has doubtless been observed by every pharmacist who has had an extended experience in the preparation and dispensing of the official pill masses, that, as far as regards the keeping qualities of several of the masses in question, there is still much to be desired.

Deterioration is marked by widely different phases, and is dependent upon a variety of causes. In some instances, the masses are hygroscopic and become soft or sticky, *e.g.*, "pil. saponis comp.," "pil. scillæ comp.," and "pil. ipecac. c. scillâ." Others become dry through evaporation,—as "pil. colocynth. comp.," or, extremely hard and vitreous, as "pil. assafœtidæ comp.," or granular, as in "pil. aloes et ferri."

Having noticed the various altered conditions developed by age in the above mentioned preparations, it becomes of some importance to consider whether those changes can be prevented by the use of some more suitable excipient.

With the view of obtaining such a substance, glycerine was selected as a basis, since it has been found to prevent the damaging effects caused by evaporation. It cannot, however, be used by itself for this purpose, as it is open to the objection of causing pills thus prepared to "fall," and, in some cases, to run into a mass.

This tendency may be obviated by the addition of tragacanth mucilage in the following proportions:—

Gum tragacanth, in powder .	½ oz.
Glycerine	
Water, of each	2¼ oz.
Oil of Pimento	gtt. v.

Mix.

The above product will keep good for several years in an ordinary covered pot.

The weight of "tragacanth excipient" required for the following official pill masses and the Pharmacopœia quantities, is approximately as follows:—

	Tragacanth excipient		Conf. of Roses.
Pil. aloes et ferri	2½ oz	may be substituted for	4 oz.
Pil. aloes et myrrhæ	1 oz	"	2½ oz. Treacle.
Pil. rhei comp.	2 oz	"	4 oz.

ʒj of Howard's sulphate of quinine, and ℈j of the tragacanth excipient make a nice mass; while only gr. vij of it are required to form a tough, plastic mass with ʒj of compound ipecacuanha powder.

When this excipient is used there is but rarely the slightest tendency to adhesion between the mass and the pill mortar,—consequently there is no loss of materials.

Another point of some importance is, that the use of pill-powder in the operation of pill making is usually unnecessary.

The advantages as an excipient possessed by the substance just described, may be summarized as follows:—the small quantity necessary to effect the desired purpose; the facility with which it mixes with dry powders; its cleanliness; and its efficacy as a preservative.

The thanks of the Conference having been awarded to the author,

Mr. Greenish observed that tragacanth and glycerine as an excipient for pills was by no means new, and he considered the addition of oil of pimento unnecessary and a bar to its general employment.

The next paper read was a—

Note on Phosphorus Pills and Pill Coatings.

BY THOMAS HAFFENDEN.

My mode of dispensing phosphorus in pills is by means of a water-bath. The one I use is a small porcelain kind of cup and saucer, the cup holding four or five ounces and the saucer a proportionate amount of water. This, with a tripod stand and ordinary spirit lamp, is all the apparatus that is needful in addition to the usual pill making requisites. The bath is filled up with nearly cold water, and then inside the cup a small quantity of B.P. mucilage and the phosphorus; in a few minutes, as soon as the proper degree of heat is attained, the phosphorus melts, and on being stirred forms quite an emulsion with the mucilage. Now is the time. The cup containing the emulsion is removed from the saucer and the powder to form the pills rapidly but carefully stirred in with a small spatula. Care is required in doing this to keep the mass together, otherwise if spread on the warm sides of the cup the phosphorus is apt to catch. When well mixed together they may be put in a mortar and worked up in the usual way. By this method, without using any greasy or oily preparation, we get a pill containing phosphorus in a free state and exactly in the condition required by the profession. Dr. Corfe and Mr. Eugene Hart, for whom I have frequently prepared them, speak most highly of them. This simple and expeditious method seems to obviate the necessity of keeping them in stock, or being obliged to limit prescribers to one or two formulæ. They take but a few minutes longer in the making than any ordinary pill. I have also dispensed the emulsion of phosphorus in a mixture and it combined quite readily. I found the emulsion did not keep by itself for more than a few days, a deposit of some kind making its appearance. I have, however, kept pills for months, made of phosphorus, quinine, iron, tragacanth, and mucilage, by simply varnishing them with tolu and ether. To make them more presentable it is my custom to coat also with French chalk. The secret of successfully coating pills is to varnish, first rendering them partially waterproof; then it is simply a question of manipulation to get a pearl-like covering with mucilage and French chalk. I have succeeded very well with albumen, freshly prepared in the way recommended for albumenized paper for photography, substituted for mucilage.

The President said there was in the Pharmacopœia a process for the preparation of phosphorus pills which had been a good deal criticized by some members of the trade. It was one which originated with himself, although he did not originally suggest it. The first suggestion came from Mr. Abraham, who found that phosphorus was very readily dissolved or diffused through tolu balsam when the latter was heated. The resinous substance having a greater specific gravity than water could be melted at the bottom of hot water and the phosphorus could then be mixed with it without any possibility of oxidation taking place from contact with the atmospheric air. Certainly it did appear to him that this process was a perfectly good and valuable one, and as far as he had been able to judge by comparison with other processes to the present time, he believed that it was the best process for administering phosphorus in the form of a pill, or rather he should say the best form for keeping phosphorus in a pilular condition available for dispensing. It had, however, been stated by a gentleman who was present, and confirmed by others, that this phosphorus pill, when taken in this form would pass through the intestinal canal without the phosphorus getting into action. But that was very easily obviated by the admixture of a little soap. The great advantage which he considered this pill to possess, was, that it afforded a perfect facility for dissolving or entirely diffusing in a very minute state of comminution the phosphorus through the tolu balsam without oxidation of the phosphorus taking place. This product, when the wax had been added to it, could be kept beneath the surface of cold water for a great length of time without any change occurring. He had kept the mass for more than twelve months and found the free phosphorus present at the end of that time just as it was at the commencement. This he held to be a great advantage. When this pill was prescribed the physician ought to order that in dispensing it a small portion of soap should be added, which was easily done with a drop or two of spirit, and one grain of Castile soap to three grains of the pill mass rendered the pill perfectly miscible in water, and therefore its action would take place without difficulty. There was one other form for the administration of phosphorus in a pillular form that he consider was also a good one, although in some respects he did not consider it equal to the one he had just described. It was first to dissolve the phosphorus in some kind of grease, tallow for instance, and then to add to it powdered phosphate of lime, which possessed in a very remarkable manner the property of giving a greasy substance, such as lard or mercurial ointment, a good pilular consistency when added in a comparatively small quantity. If phosphate of lime were added to the fat or tallow in which the phosphorus had been melted by the aid of heat, the mass could be kept beneath the surface of water, because the addition of the phosphate of lime gave the mass a greater specific gravity than the water. A pill mass of that description could be kept beneath cold water, just as phosphorus was kept, for any length of time without sign of a change, and a pill of that kind diffused in the contents of the stomach more readily than the resinous mass which was at present ordered by the Pharmacopœia. These were the two forms which, as far as he knew, appeared to be most advantageous for administering phosphorus in a pill.

Mr. Martindale said he felt inclined to take objection to the mode of making phosphorus pills directed by Mr. Haffenden on this score, that the pill would be merely in a state of emulsion, minutely divided, not perfectly dissolved. He thought phosphorus was much better administered in a state of solution. For making phosphorus into a pill mass he had with great advantage for several years adopted the plan of dissolving it the extent of one per cent. in cacao butter. He objected to Mr. Haffenden's method because the pill would only reach a state of minute division, and much of it would be scarcely acted upon in its passage through the human body, as it required a higher temperature than that of the body to liquefy it. On that account a much larger dose would be required to produce the same action than if it was in the state of perfect solution. With regard to the use of resin as a basis one member of the medical profession who used phosphorus largely said decidedly that he could not get any definite effect from phosphorus given in a state of pill as described by Mr. Gerrard. It was well known that among other things common turpentine neutralizes the effect of phosphorus and renders it non-poisonous if a sufficient quantity be given to act as an antidote. Common resin being so nearly allied to it one might assume that it may have a similar action. Other resins, such as balsam of tolu, may also have the same effect and thus be objectionable. The formula first published by Messrs. Bell and Co., Oxford Street, was that of using suet as a solvent for phosphorus, and rolling it in pills. Cacao butter would make a harder pill with a little dexterity, but there was at first a little difficulty in rolling it out. He had tried the President's process of adding a little phosphate of lime. He did not think that with it the cacao butter was more plastic or easily rolled, so he left off using it. But such a mass might be kept, under water, as the President said, without much difficulty. It could, however, be better kept in a bottle with a well greased stopper, by which means there was an entire prevention of the access of air; and there was an objection to keeping the pill mass under water in that it became saturated with moisture, and pills made from such a basis would not take a varnish well. Mr. Proctor recommended a solution of sandarach in ether—he preferred in absolute alcohol— as a varnish. This gave the pills a nice coating, and they were as a rule much liked if they were made by a careful manipulator.

Mr. Proctor said he thought there was one point in which the Pharmacopœia formula for these pills was defective. It did not contain sufficient phosphorus. Sometimes he could scarcely get the dose prescribed into an ordinary pill if he used the pill mass of the Pharmacopœia. If the formula were increased in strength it would be a fairly satisfactory one when used in connection with the soap. He knew of one case in which a quarter-grain of phosphorus was prescribed in a dose, but according to Mr. Martindale's form 25 grains would be required—rather a large dose to swallow. In such cases he worked by a formula which he published in the *Pharmaceutical Journal* for November 1, 1873, p. 359, in which the phosphorus was dissolved in sulphide of carbon, and a drop of oil of cloves was used to reduce the tendency of the phosphorus to inflame. He varnished the pills with sandarach dissolved in ether, not in alcohol, and they kept in good condition, so much so, that when manipulated between the finger and thumb they could be almost made to ignite after being kept for six months in an ordinary pill box.

Mr. Greenish stated that he considered bisulphide of carbon as a solvent for phosphorus quite unexceptionable; he had long used it in preference to any other. With regard to the vehicle for a pilular form, cacao butter was perhaps one of the best; but he had found that the addition of a little balsam of Canada rendered the mass more plastic, and this addition would also have a tendency to retard the too rapid solution of the pills in the stomach. There was, however, one great objection to cacao butter alone as a vehicle for phosphorus which he should like to mention, and that was, the too ready solubility of the pills in the stomach, giving rise to the unpleasant eructations peculiar to phosphorus, on account of which some persons had been obliged to discontinue taking it. He had taken the pills himself and considered that the objection was well grounded. To remedy this inconvenience, he would suggest that the cacao butter be combined with some other and less soluble substance, so that the pills should pass lower down the stomach before being dissolved, and he considered that the addition of balsam of Canada to the pill mass was a step in this direction.

Mr. Borland said he had for some time past had experience in the preparation of phosphorus pills, both with theobroma butter and with the process given in the Pharmacopœia, and he most distinctly gave his preference to the one as stated in the Pharmacopœia, for the reason that he had found it to keep much better. In the locality from which he came some medical gentlemen were in the habit of prescribing it as a compound pill. The difficulty that had presented itself in compounding such a pill was how to get a butter made pill to take as good a shape in pill mass. When they had to take half-a-grain of extract of nux vomica and one grain of ferrum redactum, with three grains of phosphorus pill, if they used the cacao made pill they could not get a mass at all. It was with great difficulty they could get a five-grain pill made unless they employed the mass according to the Pharmacopœia formula, and by introducing a very small portion of Castile soap they found no difficulty whatever.

Mr. Ekin said that in his opinion, resin answered best. The objection to Mr. Martindale's formula was that it was very difficult to varnish, and it made far too bulky a pill with a large dose of phosphorus. To him resin seemed to answer every possible purpose. The solution took place very readily under hot water, and the product, as he had proved, kept perfectly well under cold water for ten or twelve months without any apparent loss of phosphorus. With resin such a strength of solution could be made as would be convenient for dispensing, it being possible to give a full dose of phosphorus, combined with 3 or 4 grains of other matter, such as quinine and reduced iron, without making too large a pill. The mass also powdered very readily, and could be worked up easily and rapidly. Phosphorus combined in this way had been prescribed very largely and with excellent effect, especially in cases of acute neuralgia, so that the activity of the phosphorus was evidently not impaired by the solvent used.

Mr. Taylor said there were some practical difficulties in the way of preparation that were rather against the use of tolu balsam. The B. P. phosphorus pill, in his opinion required to be modified in some way so that a soluble instead of an insoluble substance like wax could be introduced.

The President said: The object of adding the wax was to give better pilular consistency to the mass. Long ago he urged upon medical men in prescribing this pill that it should always be prescribed in combination with soap.

In answer to a question from the President, Mr. Ekin said that he used the common yellow resin, which yielded a mass having a greater specific gravity than water.

The next paper read was on—

Some Salts of Pilocarpine.

BY A. W. GERRARD,

Teacher of Pharmacy at University College Hospital.

The only described compounds of the alkaloid pilocarpine known to the present time are the nitrate, chloride, and platino-chloride. The two former, I, a year since, prepared and briefly described; the latter has since been made by Kingzett as a crystalline salt, and was used by him in making an elementary analysis of the alkaloid, to which, after several experiments, he assigned the formula—

$$C_{23}H_{34}N_4O_4+4H_2O$$

In the early part of this year I succeeded in obtaining some almost pure and colourless alkaloid (its purification having been hitherto a matter of difficulty) by means of the property I found the nitrate of pilocarpine to possess of being soluble in boiling alcohol, from which it separates on cooling in tufts of white shining crystals. By three crystallizations it can be obtained in an almost perfect state of purity. The alcohol from which it is crystallized should be retained for further treatment, as it still holds in solution a small portion of the salt. The crystals thus obtained dissolve in water and the solution made alkaline with potassic hydrate, shaken with chloroform, the chloroform separated and removed by distillation yields as a residue the purified pilocarpine. Portions of alkaloid prepared by this method were dissolved in water and neutralized respectively with nitric, hydrochloric, sulphuric, acetic, phosphoric, and hydrobromic acids; the quantities of each being small, they were allowed to evaporate spontaneously. In three days they had all become crystalline, the nitrate, phosphate, and hydrobromide were best defined, the remaining salts were very deliquescent, especially the sulphate and acetate; when in the crystalline state the acetate formed a block of pretty looking crystals with plumose markings.

I made some experiments on the effect of various solvents on the above salts, excluding the sulphate, as its crystals were imbedded in a viscous mass and difficult to separate. Nitrate of pilocarpine is soluble in water, sparingly in cold, but freely in boiling alcohol; it is insoluble in ether, chloroform, benzole, and carbon bisulphide. Hydrochlorate of pilocarpine is soluble in water, alcohol, and chloroform; insoluble in ether, benzole, and carbon bisulphide. Phosphate of pilocarpine is soluble in water, sparingly in cold, but more freely in boiling alcohol, from which it crystallizes on cooling, in lustrous tables; it is insoluble in ether, chloroform, benzole, and carbon bisulphide. Acetate of pilocarpine is soluble in water, alcohol, chloroform, benzole, and ether; insoluble in carbon bisulphide. Hydrobromide of pilocarpine is soluble in water, alcohol, and chloroform; insoluble in ether and carbon bisulphide. The form of the crystals of all these salts are, I believe, tabular and of the oblique system; the nitrate and phosphate, by reason of their stability and definite character, recommend themselves most for general purposes.

Mr. Kingzett said he wished to correct some errors committed by Mr. Gerrard in referring to his researches. He was the first to attach, on analytical evidence, a formula to pilocarpine, and he did this not only on the analysis of the free alkaloid, but also on that of the dihydrochloride platinic chloride compound, which he was the first to prepare and in a crystalline form. Mr. Gerrard had alluded to it as the platinic chloride salt; this it was not, and it was important to recognize the fact. Mr. Kingzett contended that his researches left no doubt of the true composition of the alkaloid. Its formula was $C_{23}H_{34}N_4O_4 (4H_2O)$ and that of the salt he had discovered $C_{23}H_{34}N_4O_4, 2HCl\ PtCl_4$. Although he had failed to get a crystalline hydrochlorate of the base, there yet could be no doubt that there was in jaborandi only one alkaloid. This fact would become evident when his research was seen by them in printed form. The suggestion made by Mr. Gerrard to the effect that his (Mr. Kingzett's) preparation may have been a mixture admitted of no support; it could not be. He had isolated the alkaloid by various methods, but most readily by means of the phosphomolybdic acid method, and it was from the analysed free base that the platinic compound had been prepared. He had, moreover, reconstructed the base from the platinum salt. He had seen Mr. Gerrard's preparations, and of course did not doubt their existence, but before all things it was necessary that they should be submitted to analysis; this, however, had not been done. He should feel extremely grateful for any preparations that Mr. Gerrard or others might be pleased to make over to him, and in that case he would examine and analyse them. He moreover, trusted to be able at the next meeting of the Conference to supply some knowledge regarding the physiological action of pilocarpine, a matter which a medical friend of his intended to study. Mr. Kingzett added further, that it was his opinion that the difference exhibited in the compounds of his preparation and that of Mr. Gerrard was probably to be explained on the ground of isomerism.

The President said he thought it should be understood that Mr. Gerrard only undertook to extract from the jaborandi some crystalline salts, and to get at the pharmacy rather than the chemistry of the matter.

In response to the President's request, Mr. Kingzett promised to carry on his researches in this direction.

Second Report on the Chemistry of the Aconite Alkaloids.

BY C. R. ALDER WRIGHT, D.SC. LOND.,

Lecturer on Chemistry in St. Mary's Hospital Medical School.

The results described in the first report (made to the Conference last year) on the chemical composition of the alkaloids extracted by Mr. Groves from *Aconitum Ferox* and *A. Napellus*, whilst rendering it probable that the principal active constituents of the two roots are not identical, were yet not completely satisfactory on the point, inasmuch as the methods of extraction adopted by Mr. Groves were in each case extremely liable to induce changes and decomposition of the alkaloids originally present; and that such changes were actually produced in the product from *A. Napellus* is rendered almost certain by the circumstances that the majority of the mixture of bases yielding crystallizable salts obtained by him consisted of an almost inert bitter base closely akin to the "crystallizable aconite" of Duquesnel, but differing therefrom not only in physiological potency but also in facility of crystallization from ether; whilst by a different method of proceeding, Duquesnel obtained a considerable yield of a highly active, well crystallized body.*

The circumstance observed by all who have worked with the aconite alkaloids that these bodies are very readily alterable; the fact that the commercial drug called "aconitine" is for the most part amorphous and not of constant physiological power; and the very different characters ascribed to the alkaloid isolated from *A. Napellus* by different observers; all appear to point to the conclusion that the use of alcohol acidulated with a *mineral* acid to percolate the ground root, and the subsequent boiling down of the extract thus rendered acid, as usually practised, cause alteration in the alkaloid originally present; whilst the use of tartaric acid and a low evaporating temperature, as recommended by Duquesnel, appears, from the crystallizable nature of the base thus obtained, to produce less change, or perhaps none at all. Inasmuch as nearly all the observers who have worked on the aconite alkaloids have employed mineral acids as extracting agents in the first instance, it seems to be not impossible that the bodies described by Hübschmann, Groves, and others as Napelline, Lycoctonine, Acolyctine, Pseudaconitine, etc., may really be different alteration products, or mixtures of such products, of some one parent alkaloid common to all the species of aconites.

A thorough revision of all that has been done on the subject seems therefore essential in order to reconcile conflicting statements and to clear up the true character of the active principles contained in these roots: with this object in view experiments were first commenced with *A. Napellus*, the extraction method of Duquesnel being employed; the results of these experiments being as yet far from complete, the following must only be taken as an interim report on the subject.

Messrs. Hopkin and Williams kindly carried out the first part of the operation, viz., grinding 2 cwt. of *A. Napellus* root, percolating with alcohol acidulated with tartaric acid (about one pound of tartaric acid and about 60 gallons of alcohol being used), and concentration of the extract at as low a temperature as possible. Two percolates were thus obtained (No. 1 and No. 2), but as these did not appear to exhibit any essential differences in character, they were finally worked up together. The concentrated extracts jointly amounting to some 5 gallons were sent to the reporter, and consisted of a clear brown red aqueous solution and a resinous viscid mass insoluble in water. The whole was exposed to the air in shallow pans for about ten days to dissipate as far as practicable remaining alcohol, and was then diluted with its own bulk of water and filtered from the resinous mass. The filtrate and washings were agitated with benzoline (light petroleum distillate) whereby some further amount of resin was removed, and the aqueous liquid was then precipitated by means of potassium carbonate; flakes were thus thrown down which became indistinctly crystalline on standing, whilst the alkaline liquor retained some alkaloid in solution. The whole was filtered through calico and the precipitate washed two or three times; the filtrate was precipitated by mercuric iodide dissolved in potassium iodide solution; a copious precipitate was thus thrown down which was collected, washed, and suspended in alcohol and decomposed by sulphuretted hydrogen. The base ultimately obtained from this liquid has not yet been completely examined; it appears to be non-crystalline and completely different from the crystalline alkaloid described below, which is almost absolutely insoluble in sodium and potassium carbonate solutions.

On agitation with a large bulk of ether of the precipitate thrown down by the potassium carbonate, it dissolved with the exception of some humus-like flakes; the ethereal solution was agitated with aqueous tartaric acid, and the ether thus deprived of alkaloid used over again, and so on seven or eight times; finally the ethereal liquid left after agitation with tartaric acid retained in solution a small amount of a clear yellow resin. The acid tartrate solution thus obtained was precipitated by a slight excess of sodium carbonate, and the precipitate agitated successively with small bulks of ether. Much was thus dissolved, but finally, a considerable quantity of snow-white crystalline flakes, comparatively sparingly soluble in ether, were left. A portion of these was well washed and dissolved in hydrochloric acid; with auric chloride it threw down a pale yellow amorphous gold-salt of which

0·8045 gram dried over H_2SO_4 and finally at 100° gave 0·1640 Au = 20·38 per cent.
0·9210 " " 0·1875 " = 20·36 "

These crystalline flakes were then agitated with ether so as to dissolve about one-third; on spontaneous evaporation, the ethereal solutions deposited crystals (No 1) which were converted into gold salt, of which 0·4825 gram gave 0·0980 Au = 20·31 per cent. The insoluble residue was again similarly treated with ether, and two gold salts made, one from the crystals from this second ethereal solution (No 2), the other from the crystals finally left undissolved by the ether (No. 3).

From ethereal solution (No. 2) 0·5730 gram gave 0·1165 Au = 20·33 per cent.
Left undissolved (No. 3) 0·6760 gram gave 0·1375 Au = 20·34 per cent.

The percentage of gold in these different gold salts being practically identical, it would seem that the portion of the original potassium carbonate precipitate which was left undissolved by successive treatments with ether, consisted of one single base; a conclusion corroborated by the results obtained on combustion of the different samples thus prepared, and by the similarity in their general properties.

No. 1	0·2615 gave	0·5840 CO_2 and	0·1600 H_2O.	
No. 2	0·3545 "	0·7880 "	0·2200 "	
	0·2720 "	0·6060 "	0·1670 "	
No. 3	0·2830 "	0·6380 "	0·1730 "	
	0·2880 "	0·6475 "	0·1800 "

Gold in gold salt 20·38 20·36	20·31	20·33		20·34		20·34

* *Comptes rendus*, lxxiii., p. 207.

Notwithstanding the tolerably close agreement between these different specimens, however, it seems that no one of them was absolutely pure, though each one was very nearly so; for on mixing about equal quantities of Nos. 1, 2 and 3, dissolving in slightly warm dilute hydrobromic acid, and precipitation by sodium carbonate of the drained and washed snow-white crystals of hydrobromide that separated on cooling and standing, a quantity of base was obtained which after solution in ether gave by spontaneous evaporation crystals much better defined and larger than any of the above described specimens; from these the following numbers were obtained (purified base, specimen "A"):—

0·2660 gram of base dried at 100 gave 0·5955 CO_2 and 0·160 H_2O
0·3445 gram of gold salt dried at 100 gave 0·1690 Au.

These numbers agree best with the formula $C_{33}H_{43}NO_{12}$ which requires the following values:—

Calculated.			Found. Purified Base. Specimen "A."	Mean of Nos. 1, 2 and 3.
C_{33}	396	61·39	61·06	61·02
H_{43}	43	6·67	6·68	6·84
N	14	2·17		
O_{12}	192	29·77		
$C_{33}H_{43}NO_{12}$	645	100·00		
Gold in Au Salt— $C_{33}H_{43}NO_{12}$ H Cl, Au Cl_3		= 19·92	20·01	20·34

Similar numbers have also been obtained with other specimens of purified base (*vide infra*); from which it may be concluded that two or three recrystallizations from ether are not sufficient to free aconitine completely from another base of lower molecular weight which accompanies it, whilst, however, a greater degree of purity is attained by crystallization of a salt of the base, *e.g.*, the hydrobromide.

The ethereal solutions obtained as above described, by agitating with successive small bulks of ether the precipitate thrown down by sodium carbonate from the crude acid tartrate, were mixed and allowed to evaporate spontaneously to a small bulk; a large crop of slightly coloured crystals was thus obtained, which were drained with the filter-pump and slightly washed with ether; the remaining crystals were then dissolved in benzene, in which they were very soluble, most of the colouring matter being retained by a small aqueous layer, which formed under the benzene solution. On adding light petroleum distillates (benzoline of commerce) to the benzene solution a large crop of nearly white crystals was thrown down (No. 4). These crystals appeared identical with the substance constituting specimens Nos. 1, 2 and 3, but were less pure. They gave the following numbers:—

No. 4.—0·2330 gram gave 0·5360 CO_2 and 0·1470 H_2O.
0·3965 gram of gold salt gave 0·1850 Au.
0·9215 " " " 0·1905 "

After recrystallization from ether somewhat different numbers were obtained, almost identical with those given by specimens Nos. 1 and 2.

No. 5.—0·2700 gram gave 0·5980 CO_2 and 0·1620 H_2O.
0·5630 gram of gold salt gave 0·1140 Au.

Finally, these recrystallized crystals were converted into hydrobromide, and the base regenerated from the drained and washed crystals of the salt, and crystallized from ether. This sample ("Purified Base Specimen B") gave numbers almost identical with those obtained with "Purified Base Specimen A."

0·2440 gram gave 0·5500 CO_2 and 0·1520 H_2O.
0·5725 gram of gold salt gave 0·1145 Au.

Calculated for $C_{33}H_{43}NO_{12}$.		Found.			
		Purified Base Specimen B.	No. 5.	No. 4.	
Carbon in Base . . .	61·39	61·47	60·40		62·74
Hydrogen " . .	6·67	6·92	6·67		7·01
Gold in Gold-Salt . . .	19·92	20·00	20·25	20·63	20·67

Hence the base contained in the crystals obtained from the portion of crude bases first taken up by a quantity of ether insufficient to dissolve the whole was identical with that left in the portion not taken up by the ether so employed, both giving numbers agreeing with the formula $C_{33}H_{43}NO_{12}$. To this base it is proposed to restrict the name *aconitine* in future.

In last year's report numbers were given, obtained by the analysis of a base derived from the products obtained by Mr. Groves from *A. Napellus*, closely resembling this aconitine, but somewhat different from those required for the above formula. These numbers, however, are very close to those obtained with specimen No. 4. Thus—

Impure Aconitine. No. 4.			Base from Mr. Groves' Products.*		
			From Specimen marked "B" in First Report.	From Specimen marked "C" in First Report.	
Carbon in Base		62·74	62·90	62·90	62·75
Hydrogen "		7·01	7·45	7·24	7·30
Gold in Gold-Salt . . .	20·63	20·69	20·32		20·71

From this it would seem very probable that the physiologically active crystalline base extracted from Mr. Groves' products really was aconitine in an impure state. In order to make sure that this is so, the crystalline base from the specimen marked "B" in first report was converted into hydrobromide, and the base regenerated from the well drained and washed crystals of the salt. The following numbers were then obtained, agreeing perfectly with the above formula for aconitine:—

0·2245 gram gave 0·5080 CO_2 and 0·1370 H_2O.
0·4630 gram of gold salt gave 0·0925 Au.

Calculated for $C_{33}H_{43}NO_{12}$.		Found.
Carbon in Base.	61·39	61·71
Hydrogen "	6·67	6·78
Gold in Gold-Salt.	19·92	19·98

The hydrochloride examined last year gave numbers agreeing better with this formula than with those considered probable last year from the analyses of the impure base.

Per Cent.
Chlorine in anhydrous salt—$C_{33}H_{43}NO_{12}$, HCl = 5·21
Found . . . . 5·18

Water of crystallization, calculated for—
$C_{33}H_{43}NO_{12}$, HCl, 3 H_2O = 7·34
Found . . . . 7·59

Hence it is clear that the crystalline physiologically active base obtained from Mr. Groves' products really was aconitine $C_{33}H_{43}NO_{12}$ in a state of imperfect purity.

The various mother liquors obtained in the preceding crystallizations of the two batches of aconitine were worked up in the hope of isolating some second crystallizable alkaloid from them, but without success, nothing but the above described aconitine in a state of greater or

* 'Year-Book,' 1875, p. 514.

less purity being obtainable from them. Thus from the mother liquors of crop No. 5, a crop of crystals was obtained which gave a gold salt containing 20·68 per cent. of Au. Other similar crops were obtained by evaporating down the ether-petroleum liquors from which No. 4 had separated, together with the syrupy ethereal liquors drained from the first crop of crystals from which No. 4 was obtained by solution in benzene and precipitation by petroleum distillate; the residues thus obtained were dissolved in dilute acetic acid, whereby a little resin was left insoluble, and were then slightly precipitated by a small addition of sodium carbonate; the filtrate from this precipitate (which contained much tar and colouring matter) was then wholly precipitated by sodium carbonate, and dissolved in ether. By spontaneous evaporation crystals were obtained of which the gold salt contained Au = 20·88 per cent. The mother liquors of these dried up to a resinous mass containing a few crystals; these were extracted by thinning the resinous mass with a little ether, and filter-pumping. After recrystallization from ether they exactly resembled the other crops, and gave a gold salt containing Au = 20·71. The viscid liquid which drained from these crystals dried up to a varnish; on solution in acids it gave no crystalline salts whatever; the gold salt darkened slightly at 100°, and appeared to be slightly decomposed. The following numbers were obtained.

0·2210 gram gave 0·5380 CO_2 and 0·1580 H_2O
0·2990 of gold salt dried at 100 gave 0·0715 Au.

These numbers are not very far removed from those required for the formula, $C_{30}H_{47}NO_7$, assigned by Von Planta to the amorphous alkaloid which he isolated from *A. Napellus*, and considered to be the active principle thereof.

	Calculated	Found
Carbon in base	67·54	66·39
Hydrogen „	8·79	7·94
Gold in gold salt . . .	22·48	23·91

Whence it would seem not at all improbable that the body examined by Von Planta consisted of a mixture of this noncrystalline substance (napelline?) with more or less aconitine, and the products of its alteration, with probably more or less adherent resinous matter.

This amorphous alkaloid has a strong tendency to become mechanically adherent to or enclosed in the crystals of aconitine that form from ether; and in all probability the slightly higher percentages of gold found in the gold salts from the crystals thus prepared were due to the adherence of this other body. The hydrobromide of this amorphous base is readily soluble in water, however, and does not appear to stick mechanically to aconitine hydrobromide.

The different batches of impure aconitine thus extracted from the mother liquors were united and crystallized from ether. The crystals (No. 6) gave the following values.

0·2525 gram gave 0·5705 CO_2 and 0·1520 H_2O
0·5615 „ gold salt gave 0·1135 Au.
0·5190 „ „ „ 0·1050 „

To make sure that they really were aconitine identical with the former samples, they were converted into hydrobromide; the regenerated alkaloid then gave the following numbers (purified base specimen "C").

0·3005 gram gave 0·6800 CO_2 and 0·1850 H_2O.
0·6210 „ gold salt gave 0·1240 Au.

Hydrogen „ ...	6·67	6·84	6 69
Gold in Gold Salt	19·92	19·97	20·23 20·21

The total quantity of crystallized aconitine in a state of either approximate or absolute purity obtained from the 2 cwts of roots employed amounted to somewhat upwards of an ounce, representing about 0·03 per cent. of the roots used, whilst the total yield of alkaloids crystalline and non-crystalline, and including the mother liquors of the crystalline base which still retained aconitine, was fully 2½ oz., or 0·07 per cent. Probably in the extraction of crystallized aconitine on a large scale, where mother liquors could be methodically worked up, a yield of 0·04 per cent. of pure crystals of aconitine would have been obtained with the quality of roots experimented with; say ¾oz. per cwt. It would be of considerable pharmaceutical interest to determine on the large scale the relative quantities of *pure* aconitine obtainable from *A. Napellus* roots grown in different soils, and under different conditions of climate, etc. The values obtained by Zinoffski, Dragendorff and others, by the use of a standard mercuric iodide solution represent the *total quantities* of alkaloids present, and give no clue to the amounts of crystalline active base, *aconitine*, actually present in the different samples and different portions of the plants examined by them at various times; and similar remarks apply to the results obtained by Proctor (*Chemical News*, ix., 87), who found a total percentage of alkaloids amounting to 0·42 in American roots, and 0·2 in roots of European origin. The foregoing results clearly show that *Aconitum Napellus* contains only one crystallizable physiologically active base, and that this body when pure, possesses the formula $C_{33}H_{43}NO_{12}$. Duquesnel, who first obtained this crystallizable body, does not appear to have succeeded in getting it quite pure, to judge from his analytical figures; whilst apparently no other experimenter has succeeded hitherto in obtaining it even in a state of approximate purity. The following table gives the results of the preceding analyses of the pure and nearly pure specimens examined.

Specimens purified simply by crystallization of free base from ether, etc:—

Calculated for $C_{33}H_{43}NO_{12}$ . .	61·39	6·67	19·92

All these samples of pure base were perfectly anhydrous after crystallization from ether; they exhibited exactly the same physical and chemical properties and produced the same tongue-prickling and irritation characteristic of the aconites. Experiments on the physiological action of the pure base are contemplated but have not yet been proceeded with; involuntary experiments in the laboratory, however, show that the base is extremely active. The gold salts when dried for several days over sulphuric acid lost no weight and suffered no change whatever on heating to 100° for a few hours; several hours' heating at 100° causes no alteration in the pure alkaloid; at a higher temperature it becomes yellowish and fuses with decomposition and blackening. It is proposed to examine some of the salts of the alkaloid, and more particularly to investigate the action of acids and other reagents upon it, with a view to obtaining information as to whether the inert bitter alkaloid obtained by Mr. Groves, and examined in the first report (base A.), which gave numbers leading to one of the formulæ $C_{30}H_{43}NO_{10}$ or $C_{31}H_{45}NO_{10}$, can be prepared by its decomposition; and generally to endeavour to obtain a clue to its relationships to other series of chemical substances.

The practical conclusions that may be drawn from the above experiments, incomplete though they are as regards the "constitution" and chemical relationships of aconitine, appear to be as follows:

(1) When *A. Napellus* is treated by Duquesnel's process there are extracted (*a*) a crystallizable alkaloid, insoluble in potassium carbonate solution, which is difficult to purify by simple crystallization from ether, but which after conversion into a crystalline salt and regeneration therefrom gives numbers agreeing with the formula $C_{33}H_{43}NO_{12}$*; and (*b*) a second alkaloid or mixture of bases which does not crystallize itself, and does not yield crystalline salts, and which has a lower molecular weight than aconitine, and contains more carbon and hydrogen: (*c*) a non-crystalline base or mixture of bases soluble in dilute potassium carbonate solution, and possibly identical with (*b*).

(2) The formula assigned to "crystallizable aconitine," viz., $C_{27}H_{40}NO_{10}$, by Duquesnel, who first isolated the substance in a state of moderate purity does not exactly represent the compesition of the pure base, the difference in Duquesnel's results being apparently due to imperfect purity of the substance isolated and examined by him.

(3) The amorphous substance examined by Von Planta, to which he assigned the formula $C_{30}H_{47}NO_7$, was probably a mixture of aconitine, more or less altered during the extractive process, and the amorphous bases above mentioned. Whether this amorphous body pre-exists in the fresh roots, or whether it is formed in drying or during the extraction process it is at present impossible to say. Probably "Napelline" is identical with or closely allied to this body.

(4) Although when alcoholic hydrochloric acid is used to extract the alkaloids from *A. Napellus* a considerable quantity of a comparatively inert base (base A. of First Report) appears to be formed, and largely dilutes the crystalline nitrate of the active base, $C_{33}H_{43}NO_{12}$, yet no appreciable amount of this substance appears to be produced by Duquesnel's tartaric acid method.

(5) The method that ought to be adopted for the preparation of a pharmaceutical product of constant composition and properties is: 1st, percolation by alcoholic tartaric acid and evaporation to a small bulk of the percolate at as low a temperature as possible (probably in a vacuum pan would be best): 2nd, crystallization from ether of the base separated by sodium or potassium carbonate from the aqueous solutions of the extract (after separation of resin, etc.); in this way "base A." if present would be separated: and 3rd, further purification by conversion into a crystalline salt, for which purpose the hydrobromide is well fitted; in this way small quantities of another base which obstinately adheres to aconitine when crystallized from ether are separated. The base obtained in this way is a simple body, expressed by the formula $C_{33}H_{43}NO_{12}$, in a state of great purity and possessing high physiological activity.

* It has been pointed out by Hesse and corroborated by the author and Mr. G. H. Beckett (*Chemical Society's Journal*, 1876, May), that *papaverine* is characterized by a precisely similar behaviour; a large number of crystallizations from various solvents of the free base itself do not suffice to give the body more than an approximate degree of purity; whilst a pure alkaloid is readily obtained by converting the partly purified substance into a crystallizable *salt* (the acid oxalate) and regenerating the base therefrom.

The PRESIDENT said, the importance of this inquiry could hardly be overrated. Up to the present time the results obtained had principally borne a pharmaceutical aspect. It had been shown that what had been hitherto met with in commerce, or prepared by the Pharmacopœia process, as amorphous aconitine, could not be depended upon as the active principle of aconite in its unmixed and most active condition. There was now no doubt that it could be obtained in a pure state as a crystalline alkaloid, and that was the only condition in which it ought to be used medicinally. He was glad to find also that there was a prospect of having the subject still further worked out in its chemical as well as its pharmaceutical aspects.

Mr. WILLIAMS said that it might be worth mentioning that upon one occasion, in operating upon aconite for the extraction of aconitine, the roots were divided into two equal quantities, and one was treated with alcohol and tartaric acid and the other with alcohol and hydrochloric acid, and it was a curious fact that the alcohol containing the tartaric acid only yielded half the weight of crude alkaloid that the tartaric alcohol did.

The next paper read was on—

CAPSAICIN: THE ACTIVE PRINCIPLE OF CAPSICUM FRUIT.

BY J. C. THRESH, F.C.S.

Soon after the last Conference I had occasion to examine a very suspicious sample of cayenne pepper; it was of an unusually red colour, and almost immediately stained the paper in which it was wrapped. Referring to Hassall's work on the 'Adulteration of Food,' I found that he considered this a certain indication of the presence of common salt. Upon incinerating a portion and examining the ash, I could detect only a trace of chlorine, therefore it could not be adulterated with sodium chloride. A microscopical examination of it revealed nothing abnormal, consequently in order to continue my investigation it was necessary to look up the published analyses of this pepper, but the results obtained by the few chemists who had examined it differed so widely that they were totally useless for my purpose, and I was thus left to my own resources.

The result of this investigation, so far as I have yet pursued it, I do not intend troubling you with at present, excepting so far as it may relate to the subject of my paper.

The active principle which I have been so fortunate as to isolate, and which I have named capsaicin occurs only in the pericarp of the fruit, and is intimately associated with a red fat or mixture of fats, the whole together forming 20 per cent. of the weight of the pericarp. The process by which I first isolated this crystalline substance, and which is published in the *Pharmaceutical Journal* of the 8th of July last, answered very well when employed on a small scale, but when I began to work with 7lbs. of the pepper, I found that it would be requisite to use very large quantities of almond oil and spirit (and as the former cannot be recovered, the process is very costly) in proportion to the small quantity of capsaicin obtained.

Experiments made with the small quantity of this substance at disposal led me to substitute petroleum for almond oil, which besides being much cheaper, answers very much better.

The residue obtained by this first part of the process is a pale red waxy substance, and from this the crystalline capsaicin can be obtained by three methods. Before relating in detail these processes, let me say that unfortunately pressure of business has prevented me preparing a sufficient quantity of the crystals in a state of absolute purity for the purpose of effecting their ultimate analysis, I hope, however, during the coming winter to be able to do this, and to communicate the results in due course.

The first method of crystallizing the capsaicin is the one by which I originally obtained it, namely by dissolving the fatty or waxy residue in dilute solution of caustic potash, and adding thereto excess of ammonium chloride solution; a milky fluid results which is not affected by filtration, but if this is put aside for a number of hours, the capsaicin settles in well defined crystals, and the supernatant liquid becomes quite clear. In the second process the residue is dissolved in warm liquor potassæ, then diluted and set aside. The milky liquid deposits crystals much more rapidly than in the former process, but since capsaicin is freely soluble in dilute solutions of the fixed alkalies, a considerable quantity remains in the mother liquor.

The third plan consists in dissolving the residue in dilute liquor potassæ, and passing carbonic acid through the solution, when the capsaicin is immediately precipitated in minute crystals, which can be entirely removed by filtration. This method not only yields the principle with greater facility but also in a state more approaching that of purity. The first plan yields the finest crystals, but there is great difficulty in freeing them from traces of ammonia and colouring matter, and besides it does not yield the whole of the capsaicin. From the mother liquors I attempted to obtain it by adding excess of acid, and treating the oily matter thus separated with petroleum and spirit, as the original fat was treated, but I was not successful, since the fatty acid is as soluble as the active principle in the spirit, and consequently the spirit removes both from the petroleum, leaving the latter colourless.

The few characteristics, etc., of this substance which in the limited time at my disposal I have been able to ascertain are as follows:

The action of heat. Carefully heated capsaicin melts at 138°F. to a transparent oily fluid, and if then allowed to cool it rapidly solidifies, and assumes a crystalline condition. A portion melted on a watch glass and left to cool rapidly crystallizes, but if a portion is heated in a melted narrow tube a few degrees above its melting point, it does not upon cooling return to its crystalline condition but remains semi-fluid and transparent for 24 or 30 hours, solidification then commencing at the surface and slowly extending through the whole mass.

Capsaicin can be volatilized without suffering decomposition. A small portion was placed on a watch glass, covered accurately with another, and the pair laid on a hot plate, and a thermometer placed near. At 240°F. the capsaicin began to volatilize, and at 248° it began to change colour, becoming brownish black. On removing the upper watch glass it was found to be covered with minute oily globules which have since become crystalline.

The specific gravity is 1060, as ascertained by taking the specific gravity of a solution of sodium chloride, in which a cylindrical piece of the fused substance floated indefinitely in any portion.

Strong nitric acid acts energetically upon it, decomposing and dissolving it. The resulting solution is of a bright red colour, which when heated evolves ruddy fumes and changes in colour to a straw yellow. The addition of water causes no precipitate, but the addition of an alkali in excess strikes a rich golden yellow colour, which is perceptible even when the fluid is largely diluted.

Dilute nitric acid, though acting more slowly upon it than the strong acid, appears to decompose it with formation of the same products. The solution thus formed when neutralized is quite tasteless.

Strong cold sulphuric acid readily dissolves it without decomposition, but if heat is applied or a little water added the fluid becomes first red and ultimately purple black.

In dilute sulphuric acid capsaicin is not soluble, therefore it is precipitated when the strong acid solution is poured into a considerable volume of water.

The sulphuric acid and bichromate test applied to this substance gives rise only to the green colour resulting from the reduction of the bichromate.

Strong solution of hydrochloric acid dissolves only a trace, which is deposited when the solution is diluted.

Glacial acetic acid readily dissolves it, but from this solution water precipitates it.

As previously stated strong solutions of the fixed alkali readily dissolve it and deposit a portion when diluted, if the alkali is not in excess.

Strong liquor ammoniæ takes up but a mere trace, and retains it when diluted, but a current of carbonic acid passed through the liquid renders it opalescent.

In solutions of carbonates of the fixed alkalies and of ammonia it appears to be totally insoluble; hence carbonic acid precipitates it from its solution in alkali.

Alcohol, rectified and proof spirit, dissolve the crystals instantaneously; ether, amyl alcohol, acetic ether, benzine, and fixed oils dissolve it very readily; turpentine and carbon bisulphide much more slowly; and in petroleum oil it is soluble with great difficulty. Even when heated, petroleum does not readily dissolve it, and upon cooling the greater part is deposited in a crystalline form upon the sides and bottom of the containing vessel. The addition of a little fixed oil or of the red capsicum fat greatly increases the solvent power of the petroleum. I have not yet attempted to form any substitution products from capsaicin, but I have noted that after it has been acted upon by chlorine, either by passing the gas over the crystals or by sending a current of the gas through water in which the crystals are suspended, whilst the appearance of the substance remains unchanged, it is no longer freely soluble in alkaline solutions.

Boiling dilute sulphuric acid, even after a length of time, does not affect it, and the acid liquor remains free from glucose.

My physiological experiments with this powerful substance have been confined to the application of a solution to the arm, and the administration of one-eighth of a grain in a coated pill.

The application consisted of one part of capsaicin to forty of spirit and glycerine. In this I dipped a piece of lint and laid it on my arm. I very shortly began to experience a sensation of warmth, which gradually increased until it became unbearable and I had to remove the lint. A great part of the arm appeared much inflamed, but there was no blistering, and in two hours from the time when the lint was removed the skin had assumed its normal appearance and the pain had ceased.

The one-eighth of a grain dose I took after breakfast (at about 9 a.m.), and felt nothing of it until 11 o'clock, when I was seized with violent burning pain in the stomach, which I was glad to assuage with copious draughts of demulcents. A similar dose taken next day produced exactly the same effects. In conclusion, I may state that I have also tasted it. The result is an agonizing sensation of burning throughout the whole mouth, accompanied by a copious flow of saliva, of tears, and of mucus from the nose. This continues for about a quarter of an hour and then rapidly abates.

A vote of thanks to the author having been passed the Conference adjourned until the next morning.

The Conference was resumed on Wednesday, the 6th inst. Professor Redwood, President, in the chair. The first paper read was a—

Report of the Limited Oxidation of Essential Oils. Part IV.

Containing a Preliminary Report on the Ethers.

BY CHARLES T. KINGZETT, F.C.S.

A. Oxidation of Turpentine.—Since my last publication on terpenes and the products of their limited oxidation, I have had the opportunity of repeating the whole of my observations upon the aqueous solution that results when turpentine is oxidized by a current of air in the presence of water. This opportunity has been afforded me while experimenting upon no less than fifty gallons of turpentine; and while in no one particular have I to withdraw or alter any of my original statements, certain matters have come more strongly before my observation which are worthy of some notice. Before proceeding to summarize these, it will be well to recapitulate the main products of the oxidation. My past researches then have established that turpentine yields when oxidized by air in the way I have described, peroxide of hydrogen, and camphoric acid (both of which may result from the action of water upon camphoric peroxide $C_{10}H_{14}O_4$), acetic acid, camphor, and certain other less defined substances. The oil itself increases in specific gravity and contains, after this treatment, certain oxidized bodies among which is a further quantity of this camphoric peroxide.

I have been able to indicate the rate at which this oxidation takes place, and to investigate more fully the nature and uses of the solution I have described. And in doing so I have experimented with large earthenware vessels arranged in a series like so many Wolffe's bottles, each of about twenty gallons capacity.

The oxidation proceeds very slowly at first, the rate being indicated by the estimation from hour to hour of the peroxide of hydrogen which is formed; but when once the oxidation has fairly set in, it proceeds more rapidly with increasing production of peroxide of hydrogen and the other products, the amounts of which are simply limited by that of the turpentine itself. Now, assuming the operation to be started with a given quantity of turpentine in the presence of a given quantity of water at, we will say, 60° C., the turpentine begins slowly to oxidize and produce the bodies named, which then pass into solution, while the oil itself increases gradually in specific gravity, a phenomenon which is accompanied by a gradual rise in its boiling point. Now if no fresh turpentine be added to that already in operation there will come a time when the percentage of peroxide of hydrogen is at a maximum and then if the blowing be continued after that time it slowly diminishes, in fact at about the same rate that it forms. If, on the other hand, the turpentine which is blown away as vapour be condensed and returned to the oxidizer, or what amounts to the same thing, if fresh turpentine be added, the oxidation proceeds as rapidly as ever, while there is no limit to the amount of peroxide of hydrogen which is formed.

It is remarkable that turpentine in the act of being oxidized is capable of imparting to fresh turpentine the same and equal facility to absorb oxygen.

The slow rate at which the oxidation of fresh turpentine proceeds, and the greater rate attained after the molecules have undergone the change which induces a rapid oxidation is seen by the following figures which relate to an experiment conducted on some gallons of turpentine and water,

Hours.	Grms. of H_2O_2 in 100 c.c. solution.
After 37 hours	·0651 grammes H_2O_2
„ 41 „	·2000 „ „
„ 54 „	·3000 „ „
„ 58 „	·4500 „ „

The increase that takes place in the specific gravity of the oil of turpentine as the oxidation proceeds is exemplified by the following figures which relate to another experiment:—

	·864 originally
After 24 hours the sp. gr. of the oil	= ·8[illegible]0
„ 28 „ „	= ·881
„ 32 „ „	= ·888
„ 44 „ „	= ·949
Again—	
After 16 „ „	= ·8886
„ 20 „ „	= ·8996
„ 26 „ „	= ·9060
„ 39 „ „	= ·9136
„ 46 „ „	= ·9366
„ 48 „ „	= ·9476

The increase in the boiling point of the oil as the oxidation proceeds is illustrated by the following determinations which relate also to a different experiment.

The turpentine used in this experiment boiled as indicated in column (1).

(1) Original Oil.	(2) Oil after 24 hours Oxidation.	(3) After 27 hours Oxidation.
10 p. c. over at 157°C	162°C	165°C
20 „ „ 159	165·5°C	166
30 „ „ 160	168	170
40 „ „ 160	171	171
50 „ „ 160·5	174	174
60 „ „ 161	181	185
70 „ „ 162	193	206
80 „ „ 164	210	
90 „ „ 166		

In regard to these boiling point determinations I should remark that in each case 100 c.c. were subjected to distillation in the way that is usual in these matters, and the temperature recorded after each 10 c.c. was collected. It is necessary also to point out that the oil, although it has been oxidized in the presence of water, is yet so full of the organic peroxide I have discovered and described in my previous researches, that when it has once reached a temperature of 160° C. or less, a violent effervescence sets in from the escape of oxygen, and much heat is eliminated, as indicated by the rise in the thermometer after the lamp has been removed. I shall conclude this part of my paper by stating that having been led by the value of the solution as an antiseptic and disinfectant to attempt the manufacture of it and the residual oil I have described, on a commercial scale, I have devoted a great deal of time to the study of those conditions which are calculated to lead to the most desirable results. In this attempt I have received much help from Mr. J. Brown, F.C.S., which I have the pleasure to acknowledge. I have been so far successful as to obtain, readily, under certain conditions, from an inconsiderable amount of turpentine, water, and air, a solution containing such large quantities of peroxide of hydrogen and the other substances above named, as to qualify it for purposes and uses upon which I propose to dwell in section B. of my report. I find that a solution containing so much peroxide of hydrogen as to be capable of evolving from 1 litre either 1531 c.c. oxygen or 3062 c.c. oxygen, according as one or both molecules of oxygen (in H_2O_2) are affected, has all the properties which I propose to describe; but before doing this I must add that these properties are far from being entirely dependent upon the peroxide of hydrogen contained. They are related also to the camphoric acid and other constituents, for they are not seriously impaired by the total destruction of the peroxide of hydrogen. This I have substantiated in an experimental way, and shall now proceed to describe the experiments themselves. These I shall only preface by stating that a solution which contains 323 grains of peroxide of hydrogen to the gallon also contains 367 grains of camphoric and acetic acids. But the percentage of each constituent and the strength of the whole mixture are matters to a great extent under control in the method of preparation.

B. Antiseptic and disinfecting powers of the solution.—In studying the properties of the solution I have described

I discovered that it possessed great power as an antiseptic and disinfectant, and I was led to investigate this matter somewhat fully, also to inquire into similar properties possessed by the known constituents of my solution, and in comparison with those of salicylic acid.

In the following experiments the solution employed was of that general strength I have indicated above and contained 2·5 grms. H_2O_2 per litre.

Article experimented upon.	Antiseptics Used.	Result.	With equal vols. of water and no Antiseptic.
Egg Albumen. 50 c.c. containing 10 c.c. white of egg in each case.	5 c.c. neutralized by soda = 10 per cnt.	Observed 24 days. Still fresh as at first.	Began to stink on 2nd day after.
Must from Muscatel Grapes, 50 c.c. taken in each experiment.	10 c.c. neutral antiseptic = 20 per cent.	No fermentation even after days.	Soon fermented at 40° c., giving alcohol.
Milk. 200c.c. in each case.	10 c.c. Neutral antiseptic = 5 per cent.	Faintly acid on 5th day after. Solid on 7th day.	Solid and sour on 3rd day after.
Urine. 60c.c. in each case.	10 c.c. Antiseptic = 16 per cent.	Unchanged after 7 days. No longer observed.	Bad smell 2nd day. Stunk on 3rd day.
Brain matter. 10 grms. in each case.	10 c.c. Antiseptic.	Kept fresh 15 days. No longer observed.	Stunk on 3rd day after.
Milk. 100 c.c. in each case.	10 c.c. Antiseptic = 10 per cent.	Liquid, and sweet for 9 days.	Sour and solid on the 2nd day after.
Flour paste. 100 c.c. in each case.	10 c.c. Antiseptic = 10 per cent.	Fresh after 19 days. No longer observed.	Stunk on the 3rd day.
Milk. 160c.c. in each case.	10 c.c. Antiseptic = 6 per cent.	Solid and sour after 7 days.	Bad on the 2nd day. Very bad on 3rd day.
Bitter Beer. 160 c.c. in each case.	10 c.c. Antiseptic = 6 per cent.	Still good and unchanged on 7th day. No longer tested.	Thin films on 2nd day. Fungus over surface on the 3rd day.

All the foregoing experiments were made during October and November, 1875.

Those now to be given were made during June, July, and August, 1876. The antiseptic solution employed was not so strong as that used above.

	With 3·5 c.c. Antiseptic = 10 per cent.	With 1·75 c.c. Antiseptic = 5 per cent.	With 4 c.c. neutral. Antiseptics = 11 per cent.
White of egg. 35 c.c. in each case.	Kept fresh for 35 days; then mould appeared. No stink.	Fresh for 21 days; then mould appeared. No smell.	Fresh for 35 days, then mould appeared. No smell.

The only other alteration in each case was a slight darkening to brown in the colour of the albumen. But after each experiment the albumen had still its coaguable character and was not otherwise changed.

After dipping in the same solution, brain matter also kept fresh for several days, whereas without such treatment it stunk on the next day.

Milk was also preserved for a much longer period than without, but not for so long a period as in the winter months.

Beer was also thoroughly preserved for a number of days, as long as observed; so also was blood serum. Stinking water recovered and remained good with it for months.

In conclusion I would only add that I have never examined seriously the influence of less percentages than those detailed, but there can be no doubt that much less quantities could be used in many cases with the same effects as those described. In fact this would be necessary with articles of food on account of the aromatic odour and peculiar taste of the solution.

The experiments that follow next were conducted in order to ascertain to which constituents of my solution the antiseptic and disinfecting character is to be ascribed. They are as follows:—

Camphoric Acid experiments.

0·3 grm. of the acid in water was sufficient to preserve 400 c.c. milk unaltered for seven days. After that a skin appeared and a cheesy taste. But it did not go solid and sour till the eleventh day.

0·1 grm. camphoric acid kept 50 c.c. of flour paste fresh for eleven days. On the twelfth day it became sour.

0·1 grm. camphoric acid preserved 50 c.c. grape juice in a warm oven from fermentation permanently so far as could be observed.

0·1 grm. camphoric acid kept 15 c.c. egg albumen and 10 c.c. water fresh for twenty-one days. Became mouldy afterwards.

0·1 grm. camphoric acid preserved 200 c.c. bitter beer unaltered for eleven days in an open vessel. It afterwards became covered with fungus.

Peroxide of Hydrogen experiments.

The strength of the solution used was that of Robbin's 10 volume solution.

10 c.c. preserved 400 c.c. milk for six days, meanwhile oxygen was slowly evolved; thick and sour on the eleventh day.

5 c.c. preserved 47 c.c. grape must from fermentation for some twenty-four hours, then bubbles of oxygen were liberated; finally it had an odour like apples.

5 c.c. preserved 15 c.c. albumen (egg)+10 c.c. water fresh for very many days.

5 c.c. preserved 400 c.c. bitter beer unaltered for twenty-six days; then sour; fungus did not appear.

5 c.c. preserved 30 c.c. flour paste for six days; afterwards went bad.

Experiments with Salicylic Acid.

0·1 grm. preserved 100 c.c. bitter beer for twenty-five days, but gave to it a most peculiar taste—spirituous, bitter sweet. No longer observed.

0·1 grm. preserved 100 c.c. milk for four days. On the fifth it was sour and cheesy, and on the seventh it stunk.

0·1 grm. preserved 50 c.c. flour paste for a number of days, but acquired even on the fourth day a very stale odour.

0·1 grm. preserved 23 c.c. egg albumen, and 12 c.c. water fresh for four days. On the fifth it stunk.

These experiments, as also those with camphoric acid and peroxide of hydrogen, were all conducted during October, November, December, 1875.

I will conclude these remarks by pointing out that the solution whose properties have been described has a somewhat bitter but not unpleasant taste; it is non-poisonous, and harmless to clothing and furniture. While its antiseptic power is distributed between the peroxide of hydrogen and camphoric acid, the former of these is able to evolve large quantities of oxygen, which in this state is nascent and of a powerful oxidizing character. Finally, I desire to express my thanks to my friend Dr. H. W. Hake, for having rendered me much help during the prosecution of this part of my investigation.

C. I now propose to resume the thread of my original researches, and by way of introduction, I may be allowed to state that by them it has been established that all the members of the terpene family represented by the formula $C_{10}H_{16}$ give peroxide of hydrogen by atmospheric oxidation, and I have further pointed out that this property is undoubtedly related to cymene ($C_{10}H_{14}$) which, as obtained from various sources, also yields peroxide of hydrogen, so that any hydrocarbon containing cymene as a proximate nucleus would presumably give peroxide of hydrogen under suitable treatment.

Since my last publication, I have been able through the kindness of Dr. Wright, who placed a small quantity of menthene ($C_{10}H_{18}$) at my disposal, to investigate that body according to the method instituted by me.
