Schützenberger says Liebig's theory was borrowed from Willis and Stahl; possibly, but no one can dispute the right to it, the German chemist acquired by constructing through his own work the basis upon which he accepted and defended it. And after all there is remarkably little real difference between the theories of Pasteur and Liebig. Take that form of fermentation which is supposed by Bernard to cause the transformation of the glycogen of the liver into glucose; this effect of hydration is considered by Pasteur and his allies to be due to the influence of a special ferment in the blood, which, while it causes this change, reproduces itself from a part of the matter it influences. Well, Liebig would rather have viewed the change apart from a vital process; it was enough for him to perceive the conditions existing necessary for the starch to take up water and becomes sugar—he did not see the necessity for believing the result due to a form of life; all that was required was the presence, the contact, of a body itself in process of change. One of his favourite illustrations of the theory bearing his name, was the reaction which occurs between peroxide of hydrogen and argentic oxide, which, when mixed, produce metallic silver and give off free oxygen, $H_2O_2+Ag_2O=H_2O+Ag_2+O_2$. The peroxide of hydrogen being unstable, is constantly undergoing a change from the moment of its formation, which is attended with the liberation of oxygen, and immediately it is brought in contact with oxide of silver it gives to that body the same tendency; more, it causes its reduction to metal.

Brodie has explained this result on the hypothesis that the second oxygen in the peroxide of hydrogen is in a different polar condition to that of the oxygen in the silver compound, and that the two thus have an attraction for each other. However this may be, it deals rather with first causes of attraction, while the fact itself remains.

To conclude this digression, we may say that the only difference of note between the theories of Pasteur and Liebig is this, that while Pasteur cannot conceive an act of fermentation apart from life as a cause, Liebig would not admit this as a necessity while he recognized a cause; in both instances it will be seen that the direct cause is *something in change.*

Schützenberger then goes on to describe the life processes of yeast cells and their multiplication by budding and throwing off spores, after which he treats of their actual composition.

With regard to the inorganic side of this question, nothing can be more easily determined; it is known for instance that the ash of yeast consists essentially of phosphoric acid and potassium, together with a little magnesium and a trace of lime. And from this knowledge it is easy to make a medium in which yeast will flourish and reproduce itself, so far. But it is in regard to the nitrogenous substances in yeast that we know so little; even here, we can construct a solution containing nitrogen in various forms which is capable of being assimilated as food. Of the actual nature of the albuminous part of the yeast we know extremely little beyond that it is albuminous.

We cannot pause to consider with Schützenberger the various condition upon which the life, health, and disease of yeast and other cells depend, but one experiment that he describes is so beautiful that we state it. It must be understood that Pasteur has established the fact that yeast respires like the higher animals, and that when free oxygen is not available, it can derive it from sugar. This attraction, or rather necessity for oxygen, Schützenberger illustrates by causing red arterial blood to circulate through a sufficiently long system of hollow tubes constructed of goldbeaters' skin, and immersed in a mixture of yeast diffused in fresh serum, without globules, at a temperature of 35°C. (95°F). Under these conditions the blood gives up its oxygen to the yeast through the walls of the tubes, and then passes out black and venous at the other extremity.

Incidentally, Schützenberger introduces some researches of his, relative to the determination of dissolved oxygen, which tend to show that in contact with sodic hyposulphite, it is divided into two parts, one of which goes to oxidize the hyposulphite, and the other to form peroxide of hydrogen. This, however, is a subject to which we hope to return on a future occasion. After describing and discussing the various other forms of fermentation, *e.g.*, viscous or mannitic, lactic, ammoniacal, butyric, etc., he considers fermentation by oxidation, and finally comments upon the application of Pasteur's researches. In the second book he treats of the nature of albuminoid substances, or proteids with the view to understand the origin of ferments, and shows how impossible it is to do so, while our knowledge of the chemical constitution of albuminous substances is so meagre. He recapitulates the sum of our information on these headings and further gives the results of his own investigations made by decomposing various forms of albumin with baryta water, a method which as nearly as may be, when in conjunction with a mild form of oxidation, imitates the wear and tear processes of life, those processes which give rise in the body to decomposition products of the living principles. This employment of baryta water is not new; others have used it before and since, but Schützenberger has certainly extended the results obtained by this method of inquiry. Thus, after confirming what was previously known, he details evidence to show that the albuminoids are constructed upon an association of urea and amido-acid combinations of various series. Schützenberger rests his discovery of the presence of the urea group in the albuminoids upon the fact that he has obtained ammonia and carbonic acid from them in the proportions necessitated by this assumption. He has also recognized among the decomposition products of albuminoids, guanine, sarcine, and xanthine. In this latter respect, however, he is not alone; simultaneously Thudichum arrived at similar results and has even gone further in certain directions.

Schützenberger gives also a chapter on soluble ferments and indirect fermentation and concludes his book with a review of the various views and researches relative to the origin of ferments.

We cannot close our notice without saying how well the book we have reviewed repays reading.

Obituary.

Notice has been received of the death of the following:—

On the 10th of November, 1876, Mr. Richard Thompson, Chemist and Druggist, St. Helen's, Lancs. Aged 55 years.

On the 3rd of April, 1877, Mr. David Dandie, Pharmaceutical Chemist, Perth. Mr. Dandie had been a Member of the Pharmaceutical Society since 1852.

Notes and Queries.

[543]. GOUT PILLS.—Can any reader of the *Pharmaceutical Journal* inform me of a good recipe for Gout and Rheumatic Pills which will not run together after rolled?—T. G. C.

Correspondence.

Prescribing Chemists.

Sir,—In the Advertising Sheet to the Journal of the 24th ult., at page xvii,—"Assistants Wanted,"—I was pleased to see the following statement in one of the advertisements, viz., "The principal objecting to counter practice, a knowledge of prescribing is not required."

Now, surely this ought to be the rule among chemists, although it appears to be the exception in the trade. When I see in chemists' windows certificates of examination from the Pharmaceutical Society, I infer progress in knowledge; and if a chemist proceeds in his studies and obtains his diploma as M.D., I greatly admire his abilities.

But, if the prescribing chemist points to his pharmaceutical examination as his only authority for prescribing, he may choose three mallards for his trade mark, with the motto, Quack! Quack! Quack!

I am aware that there are occasions when the chemist is urged to prescribe, as I have been myself, on board ship, at sea, with no medical man to consult, but I trust the Pharmaceutical Society is not to be screwed down like a trades' union, and bound to support the prescribing chemist in his attempts to supersede the certificated medical man. The faculty may not be always infallible; but that is not our business.

JOSEPH LEAY.

Chilcompton, Bath.

Hydrobromic Acid by Fothergill's Process.

Sir,—I wish to supplement my letter printed in the *Pharmaceutical Journal* for March 17. I now find that the residue left on evaporation by hydrobromic acid made by Fothergill's process does not consist of acid tartrate of potassium, as a partial examination of it led me to suppose, but of bromide of potassium and free tartaric acid. Moreover, when acid tartrate of potassium (freshly precipitated and well washed) is suspended in water, and hydrobromic acid added drop by drop until complete solution is effected, the residue obtained by evaporating such solution is of the same composition as that obtained by evaporating Fothergill's acid, and, when ignited, yields not carbonate but bromide of potassium. It seems indeed likely that hydrobromic acid, even in the cold, decomposes acid tartrate of potassium, forming potassic bromide and tartaric acid, and that in Fothergill's process the further reaction of the last named substance, and precipitation of cream of tartar, is prevented when a certain quantity of hydrobromic acid has been generated. A sample just examined gives 9·3 per cent. hydrobromic acid, 8·11 per cent. tartaric acid, and 7·46 per cent. bromide potassium.

ALFRED N. PALMER.

69, Market Street, Manchester.
April 2, 1877.

EXAMINATION OF SOME COMMERCIAL SAMPLES OF CITRATE OF IRON AND QUININE.

BY B. H. PAUL.

The results obtained in the examination of some samples of citrate of iron and quinine which I have recently received from different sources are such as to show the necessity of exercising particular caution in regard to the scale preparations, and the desirability of obtaining a specific guarantee that they are not only what they ought to be, but also what they profess to be.

The particular preparation now referred to should contain 16 per cent. of quinine, and the test to which the Pharmacopœia directs that it should be submitted is one by no means severe, but rather likely to make any sample appear fully as good as it can claim to be. It is true that the precipitate obtained on adding ammonia to the solution of the citrate does not contain all of the quinine, and that some quinine is retained in solution in the ammoniacal filtrate, but the proportion of the alkaloid thus failing to be weighed is very small in all cases, and with reasonable precaution in operating it does not seriously affect the value of the result obtained, even when the precipitate is well washed and thoroughly dried.

There is, however, another circumstance connected with the Pharmacopœia test which operates so much in favour of the sample examined by that method, that it goes far to counterbalance any deficiency in the weight of the quinine precipitate resulting from the retention of some small proportion of the alkaloid in solution. I refer to the state of dryness, or rather of hydration, in which the quinine precipitate is directed to be weighed. Quinine thus precipitated and dried by exposure to the air, even in a moderately warm place, would probably consist of the trihydrate of the alkaloid, which contains upwards of 14 per cent. of water, and the weight of the precipitate would therefore indicate a proportionately greater amount of quinine than is really present in the preparation tested.

It may be in some cases that the amount of water retained by the quinine precipitate is not so large, and that the somewhat uncertain conversion of trihydrate into monohydrate may take place while the precipitate is being washed and exposed to the air; but even in that case it would still retain upwards of 5 per cent. of water, an amount which exceeds that of the quinine held in solution in the filtrate.

Consequently, the precipitate obtained according to the directions of the Pharmacopœia from fifty grains of citrate of iron and quinine ought not to weigh less than eight grains, if the preparation has been made in such a way as to be entitled to rank as a Pharmacopœia preparation.

It is a common thing to hear the statement that although in making citrate of iron and quinine the proper proportion of alkaloid is used, it is impossible to obtain from the finished product the same quantity of quinine. I am disposed to think that this opinion rests solely upon misconception, either in regard to the proportion of citrate scales obtained from a given quantity of quinine being greater than it should be, or some analogous circumstance. Judging from various experiments that I have made with the object of ascertaining whether quinine experiences any alteration when the citrate is prepared, I am decidedly inclined to think that it does not change, but that any discrepancy between the amount of alkaloid in the finished preparation and the proportion used in making it must be due to some unobserved augmentation in the quantity of the product.

Having thus pointed out that the results to be obtained by the application of the Pharmacopœia test to samples of citrate of iron and quinine are likely to be rather in favour of the quality of the article than otherwise, I will now give the results furnished by three samples lately tested.

Sample No. 1 was contained in a one-ounce bottle, bearing the label of a wholesale druggist in London, with the name and address of the firm, and describing the preparation as "Citrate of Iron and Quinine, British Pharmacopœia." The bottle was sealed with a seal, on which were the words, "Citrate of Iron and Quina." On testing this sample, according to the directions of the Pharmacopœia, it gave a precipitate amounting to 9·3 per cent. instead of 16 per cent., or little more than one half as much as it should be. On testing this sample by another method, and carefully extracting the alkaloid by means of ether the total amount of dry alkaloid was 8·96 per cent. A further examination of this alkaloid showed that it was not entirely quinine, but that nearly one fourth of it consisted of cinchonidine with some amorphous alkaloid and cinchonine. The actual proportions were as follows:—

Quinine	6·80
Other alkaloids	2·16
	8·96

Sample No. 2 was also in a one-ounce bottle; it bore a label describing it as "Citrate of Iron and Quinia, British Pharmacopœia," and the seal on the cork bore the words "Citrate of Iron and Quina."

By the Pharmacopœia test this sample gave a precipitate amounting to 11·7 per cent.

When tested with ether, the dry alkaloid extracted in this way amounted to 9·7 per cent., and on further examination of this alkaloid it proved to contain, as in the previous instance, other alkaloids besides quinine; the actual figures being as follow:

Quinine	7·08
Other alkaloids	2·62
	9·70

Sample No. 3 was received in a paper packet, and had already become somewhat damp. When tested by the Pharmacopœia method it gave a precipitate which in drying gave indications that it was not quinine. This precipitate amounted to 8·87 per cent. The alkaloids extracted from this sample by treatment with ether and drying thoroughly amounted to 6·96 per cent., and this consisted chiefly of amorphous alkaloid; the actual figures being as follow:

Quinine	1·69
Other alkaloids	5·36
	6·96

The fact that in two cases the preparations here referred to professed to be in accord with the requirements of the British Pharmacopœia renders these facts especially noteworthy. There is here evidently no room for the excuse sometimes made with justice that manufacturers of scale preparations are required to make them of inferior quality, since there is no conceivable justification for labelling such articles "British Pharmacopœia."

GLYCEROLE OF NITRATE OF BISMUTH.

BY W. WILLMOTT.

A few weeks since Mr. Balmanno Squire introduced to the readers of the *Pharmaceutical Journal* a preparation of nitrate of bismuth in glycerine to which he gave the name, "Glycerole of Nitrate of Bismuth." After an able comment on its great probable value, and the expression of an opinion that the nitrate should be kept by every chemist in the kingdom, he wrote as follows:—

"I accordingly lay the results of my investigation before the pharmaceutical body in the confidence that they will soon develop its capabilities (*i.e.*, the capabilities of the glycerole) in a very considerable degree."

This invitation was promptly responded to, and at a meeting of the Society held on the evening of December 9th, 1876, the preparation received due consideration. Some exceedingly interesting reactions were shown by the President, and it was pointed out by him that, in order to avoid precipitation of the bismuth, the preparation should be made without heat. He stated, however, that, notwithstanding this precaution, the glycerole seemed to acquire the condition necessary to cause precipitation when diluted with water after about three weeks keeping. The exact nature of this compound was then fully discussed, and it was left in considerable doubt as to how far it really represented the preparation which Mr. Squire intended it should be. The following remarks are offered with a view to throw some light on the subject, and, in point of fact, if possible, to answer the question, What *is* glycerole of nitrate of bismuth? In the first place I would direct attention to the ready solubility of the nitrate in mixtures of glycerine and water, or, as I should prefer to put it, in glycerine when diluted with water. And I may say at once that I do not think this ready solubility arises from any solvent power which such mixtures may possess *per se*, but that the glycerine by being spread out, so to speak, or thinned down, or by having its density lessened, is brought into the best condition to exercise its solvent action; and in the present instance it does this in a rather remarkable manner. For instance, a mixture of glycerine and water containing only 15 per cent. of the former, or a little more than a drachm to the ounce, readily takes up double its own weight of the salt; so that the glycerine in this thin or attenuated condition dissolves, without the slightest difficulty, no less a quantity than from 12 to 14 times its own weight of the crystals of nitrate of bismuth. In this proportion the bismuth is subsequently thrown down and a gas resembling one of the lower oxides of nitrogen is disengaged. Contrary to what might be expected the solvent action of the mixtures referred to decreases in proportion as the glycerine increases, until, in glycerine itself, in its pure and undiluted form, weight for weight dissolves only with difficulty and after some considerable time. The whole of the solutions so prepared, as will be readily understood, throw down the bismuth on the addition of water in certain proportions according to the quantity of glycerine contained in them. This, however, will be rendered clearer if we take smaller quantities of the nitrate as shown in the table below. The precipitate occurs in more or less time when the water is added in certain proportions only, and not when it is added in either small or large quantities. The following are approximately the proportions as attained by experiment:—

Strength of Glycerole.			Proportions of Glycerole to water within which precipitate occurs.*				
Nitrate.		Glycerine.		Glycerole.	Water.	Glycerole.	Water.
1 oz.	in	1 fl. oz.	= from	1	× 4 to	1	× 384
½ oz.	„	1 „	= „	1	× 4 „	1	× 192
2 drs.	„	1 „	= „	1	× 4 „	1	× 96
1 dr.	„	1 „	= „	1	× 4 „	1	× 48
40 grs.	„	1 „	= „	1	× 4 „	1	× 32
20 grs.	„	1 „	=	No appreciable precipitate in any proportion.			

It will be seen from this table that when the glycerine is present in the water in the proportion of 20 per cent., or when the glycerole is diluted to that extent (1 to 4), the whole of the nitrate in each case is retained. At this point the basic properties of the water come into play and precipitation goes on, slowly or otherwise, until the water itself, by repeated additions, becomes the solvent, assisted to some slight extent by the glycerine which, as regards time, plays the part of a modifier of the whole process. I do not say that this solvent property of the water, small though it be, is retained indefinitely; but it exists for a considerable time, nevertheless, and cannot be altogether overlooked. The smaller the proportionate quantity of nitrate present in the glycerole, the longer the glycerine retains its hold, or exerts its protective influence, and the sooner of course the solvent action of the water becomes apparent. In this process, as shown in the table given, we have, in fact, glycerine working at one end and water at the other.

The solvent properties of the water and glycerine respectively may be clearly determined by the following simple experiments:—

1. (*Water*).—To ten minims of the glycerole prepared by dissolving 1 dr. of nitrate of bismuth in 1 fl. dr. each of Aq. Dest. and glycerine previously mixed together, add water *very carefully* (about ʒj) until a precipitate is thrown down. Then continue *at once* the addition of the water up to 2 fluid ounces or more, and the precipitate will be re-dissolved.

Note.—This reaction is liable to vary somewhat from very slight causes.

2. (*Glycerine*).—To the clear solution thus obtained add caustic potash. The precipitate will not be dissolved in excess of the potash, but will be readily taken up by the addition and admixture of glycerine.

It will be observed that in the glycerole of 20 grs. to the ounce there is no appreciable precipitate, *i.e.*, for a considerable length of time, in any proportion of water that may be added to it, because, before the glycerine loses its hold on the nitrate the water grips it—if I may be allowed the expression—and prevents it from falling. As this proportion would no doubt be considered too weak for a glycerole for ordinary use, the 40 grs. strength would probably be unobjectionable as regards the precipitation, and upon this hypothesis I venture to suggest the following formula:—

℞ Nitrate of Bismuth . . . . . ℥ss.
Distilled Water . . . . . ʒij.
Price's Glycerine . . . . ad ℥vj.

Dissolve the nitrate of bismuth in 2 fluid drachms of the glycerine previously mixed with the distilled water; then add the solution to the remainder of the glycerine and mix well together.

This is prepared *at once* and without the slightest

* Temperature 50° to 60° Fahr. Time indefinite.

difficulty. It contains five grs. of the active ingredient in each fluid drachm, and is most convenient for prescribing. Even therapeutically the addition of the water is an advantage, since, as in the cases of tannin and borax, the density of the undiluted glycerine prevents the action of the remedy from coming readily into play. It is better in each case to dilute with a little water before using. This addition in the formula given may or may not affect the result as regards stability, but the difference in this respect (if any) with so small a proportion will be comparatively trifling.

Effect of heat.—The effect of heat on the glycerole appears to be this. A portion of the nitric acid is separated and retained *pro tem.* by the glycerine. If the process be stopped here, we have a glycerole which smells strongly of nitrous acid, and which no doubt soon acquires the condition in which a precipitate is thrown down directly on the addition of water. Other combinations of nitrogen and oxygen are possibly formed, as the case is one in which different conditions very readily produce different results. But if the heat be continued or increased, nitrous acid fumes are disengaged with violent ebullition, and there is left in the dish a soft pasty mass consisting for the most part of oxide of bismuth and glycerine. By carrying the process still further in a higher degree, we arrive at the phenomena so graphically described by Mr. Postans on a former occasion. It is clear, therefore, as pointed out by the President, that heat should not be employed in the preparation of the glycerole of nitrate of bismuth.

Reactions.—The reactions exhibited by this compound resolve themselves to a great extent into a question of proportions. If we take a concentrated glycerole and precipitate it from its solution in water by caustic potash, the precipitate is not re-dissolved in excess of the potash, the glycerine being proportionally too small, but if we employ a weaker glycerole (one dr. or two drs. to the oz.) the precipitate is re-dissolved immediately under similar circumstances. This, however, does not occur in the absence of the glycerine. A precipitate thrown down by potash from a solution of the nitrate in water, is not taken up by excess of the alkali; but the addition of a small quantity of glycerine immediately dissolves it. The glycerine appears here to act as a solvent in the presence of a slight excess of potash. No such effect as this follows the employment of ammonia. Glycerine is powerless in the presence of this reagent, probably because the ammonia more completely withdraws the nitric acid from its combination with the bismuth; but whether the precipitate be thrown down by ammonia, or by potash, or by a glycerole of long keeping, it is at once restored by the free addition of nitric acid. From this it may fairly be inferred that the glycerine in this preparation is simply acting the part of a solvent, similar to water, and that its protective influence, due possibly to its great density, is a question of time only. The reactions are complicated and sometimes obscure, but, bearing in mind the nature of the substance with which we are dealing, this is precisely what we should expect.

As the result of the attention I have given to the subject (limited it is true), I think it more than probable that the glycerole is what Mr. Squire intended it to be, namely, "a simple solution of the salt in glycerine." At the same time, all my experiments tend to corroborate the opinion of Professor Redwood, that "the nitrate of bismuth being an acid salt, in which the greater part of the nitric acid is held by an affinity so weak that water itself is capable of removing it, the glycerole is rarely likely to be uniform in its composition."* To this Mr. Squire replies (*Pharm. Journ.*, Dec. 16, 1876), "If the preparation will not keep for many weeks unchanged, no more will any of the infusions which are so largely prescribed, and no more will sulphurous acid solution."

Whether, therapeutically, this new compound will justify the sanguine anticipations with which it was introduced, I am not prepared to say, but there can scarcely be a doubt that all will welcome any addition to the deservedly recognized value, which, in the practice of medicine, the preparations of bismuth most indisputably possess.

King's College Hospital.

AN EASTER HOLIDAY IN LIGURIA.†

BY PROFESSOR FLÜCKIGER.

The strip of land that extends round the Gulf of Genoa from Spezzia to Nizza, is rightly called simply "The Shore" (*Riviera*). But where again is there such a diversified abundance of landscape beauty poured out? Perhaps the double gulf of Naples and Salerno outbids the Genoese coast in soft grandeur, but not in loveliness of form of mountain and sea, or in the variety and fulness of its flora. Not till four degrees further south does the plant-world again find itself under equally favourable conditions for the unfolding of the southern characteristics that so much attract the Northerner, and doubly fetter him if privileged to shelter himself upon that sunny coast from the last wild storms of winter.

By the end of March, or beginning of April, the umbrageous westerly and south-westerly portions of the Lombardy plains are already rejoicing in a fresh, if not a varied green, which in a very short time reaches the sea by the Turin and Savona road. The Ligurian Alps are still covered with snow, and from ravines and valleys turbid streams rush southward, and, conducted through widely ramified artificial channels, fill numberless reservoirs from which in summer time the olive and lemon gardens are refreshed. The snow covering becomes thinner and thinner; the bare chestnuts and miserable pines are replaced by olive thickets and the glossy foliage of the *agrumi*, where aromatic lemons, mandarins and oranges make their appearance in thousands. Savona is more than superficially connected with these, for a burgher of that pleasant city, Georg Gallesio, cannot remain unmentioned when speaking of our botanical knowledge of those noble economic plants, since he contributed to it a still valuable book, 'Traité du Citrus' (Paris, 1811). Gallesio rightly traced back their numerous cultural varieties to the few principal species of *Citrus;* for instance, in his opinion the bergamot is a hybrid between the orange and the lemon. According to him, also, lemons and citrons were cultivated in Savona in the middle of the fifteenth century.

Charming as is this locality, the beauty of the coastline and the mountains westward increases considerably. The stages between San Remo and Bordighera to Nizza may be described as the most magnificent portion of the whole Riviera; and if one single point is to be preferred, it is the district of Monaco. But it would be a fastidious undertaking to attempt to separate the most beautiful from the perfectly lovely. In respect to climate, however,

---

* The case, probably, may be stated thus. The glycerine being a powerful solvent and of great density, is slow to bring about those changes which, with the difference due to rapidity of action, are effected by water alone.

† From the *N. Repertorium f. Pharmacie*, vol. xxv. 1876.

a sharp boundary can be drawn. The mildest portion is the strip between Ventimiglia and Beaulieu, or Villafranca, in which, near Monaco and Mentone, landscape beauty and softness attain their most complete expression. Only rarely are a few snow-flakes seen at Mentone, and the number of days upon which rain falls (not rainy days) is about sixty; but at Nizza it is at least eighty. These figures illustrate clearly the considerable difference between Mentone and Nizza. At Nizza the sheltering mountains recede, the back ground is more open, and the outlook extends to the lofty summits of the Maritime Alps; the district is therefore more accessible to wind and weather.

Between Ventimiglia and Villafranca the country is level only where the rivers have broken their banks and left deposits of detritus. The mountains consist of hard Jurassic limestone, soft marly deposits, and much distorted strata of crumbling numulitic limestone, presenting a sufficiently large surface to the attack of water to form excavations, which sometimes recall—as in the Val di Latte—the famous "Karrenfelder" of the Alps, and impart to the coast a wild craggy formation. The principal action of the water probably occurred far back in prehistoric times, and it stands out in striking contrast to the present poverty of water in the district.

As in many southern lands, so also in the Riviera, the heights put off their forest adornments for the longest time; only isolated patches of pine, consisting mostly of weakly trees, are to be seen on the upper mountain slopes. Somewhat denser and more stately clumps here and there adorn the shady sides of the more craggy valleys, which are not suited to cultivation. The magnificent *Pinus Pinea*, L., is absent from the western half of the coast, the Riviera di Ponente; on the eastern half, the Riviera di Levante, as at Sestri, beautiful groups of this species occur; but not until considerably farther south, as at Viareggio, near Pisa, is there an opportunity of admiring its full effect as a forest tree. By far the most prevailing conifer in the Riviera is the *Pinus halepensis*, Mill., much less picturesque than the mighty *Pinus Pinea*, though always affording a beautiful prospect, from the light green of its soft, thin, outspreading tufts of needles. Even the smallest trees bear comparatively numerous cones, which are at first very slender and acutely conical, but after the falling out of the seed, through shrinking, come to look shortened and rounded, and remain on the weather-beaten trees. They are always sharply recurved, the scales broad and not pointed. This maritime pine is distinguished from other species by its less rigid growth; the stems and branches often assume the most fantastic contortions from the direction given to the south-west wind by rocky angles exposed to it. *Pinus Pinaster*, Solander, generally known under the name of *Pinus maritima*, Poiret, occurring more isolated in the Riviera di Ponente, is of more regular growth and rigid appearance, to which the stiff divergent spines, 3 millimetres thick and 25 centimetres long, especially contribute. In no part of the country do these coniferæ occur in such number or of such size as to favour their use in the production of resin or turpentine.

The northern juniper is in these sunny climes replaced by the far more handsome *Juniperus Oxycedrus*, L. Its somewhat broader and shorter needle-leaves do not differ very much from those of the *Juniperus communis*, but from the greater prominence of the white bands on the under side they produce a different impression. Moreover, the much more plentifully developed ramifications of this tree do not tend upwards, but form dense rounded crowns of vigorous appearance; consequently it differs essentially from the compact pyramidal growth of the *Juniperus communis*. The berries of *J. Oxycedrus* attain a size of 17 millimetres by 15 millimetres, but are sometimes much smaller; they are red-brown when ripe, and usually proceed from three carpels like those of *J. communis*. Göppert has described a variety of the latter as *J. duplicata*, in which two whorls of three leaves grow adherent to the fruit. This condition occurs frequently in the cones of *J. Oxycedrus*, and the grey-blue hoary sutures of the carpels contrast strongly with the brown epidermis. The fruit encloses only three seeds, which, as in *J. communis*, are supported by the sides and back of the hollow resin vessel. Opinions may differ as to the delicacy of the smell, but it is undeniable that this southern conifer is much less aromatic than its northern sister. The epicarp is also tougher, and the light yellow fleshy portion of the fruit is drier and coarsely fibrous. The undoubtedly smaller proportion of oil present in the berries of *J. Oxycedrus* allows their sweetness to become more manifest, although they may contain less sugar. The contents of the resin vessels are nearly solid and tasteless, and consist just as little as in *J. communis* of volatile oil. The reply to an oft-repeated inquiry whether the juniper or its berries were in any way used in this district, was always positively negative. If the Pharmacopœa Germanica derives its oleum juniperi empyreumaticum (oil of cade) from the wood of *Juniperus Oxycedrus*, it cannot, at any rate, be drawn from the Riviera, and it is probable that the tree does not occur commonly anywhere else.

The mastic tree (*Pistacia Lentiscus*, L.) in this district no longer merits the name of tree, since as a mere bush it forms the chief constituent of the underwood, and its glossy evergreen leaves cling to the dryest rocks. One exception is the magnificent mastic tree of the Villa Giribaldi, in Bordighera, probably one of the largest specimens at present in existence; for throughout the Mediterranean district the scarcity of fuel has pressed hardly upon this tree. The mastic tree at the above villa stands upon a rather elevated spot, it appears as if the earth is heaped up round about the stem, so that only the strong boughs, bare underneath, are visible, these are much branched, and form a beautiful leafy shade, about 10 metres in diameter. The smooth branches are prettily bent, and form an elegant crown, adorned even on the 8th of April with racemes of male flowers. From the slow growth of this species an age of several decades may be ascribed to the Bordighera tree. Even the owner was not exactly informed upon the subject, but gave the promise henceforth to pay more attention to it. In Chios, which island is famed for mastic resin, many of these trees were killed in 1850 by frost; the tree at Bordighera, although standing in a position by no means particularly sheltered, remained uninjured, which is a striking testimony to the mildness of this strip of coast.

A very usual companion of the mastic bush is the myrtle (*Myrtus communis*, L.), the ornamental flowers of which do not appear until late in summer. At present the plant has not a specially cheerful look, as it only bears a few shrivelled berries, and the evergreen leaves present no fresh colour at the commencement of April. A somewhat less massive, but not quite dissimilar form of bush appears in the slender *Daphne Gnidium*, L., the flowering time of which is already past. Its bark is used in Italy, France, and the north, like that of *Daphne Mezereum*. Both plants are distinguished, amongst other characteristics, by a very remarkable growth. *D. Gnidium* occurs frequently with a stem more than a metre long; at the end only of which are a number of nearly whorled compressed branchlets; but the true leathery leaves are arranged at wide intervals nearly throughout its height. Gnidium bark is therefore easily recognized by the arrangement of its leaf scars, and moreover it is never so broad as Mezereum bark, since the stems seldom exceed a centimetre in diameter, which in the knotty *Daphne Mezereum* is frequently the case.

Buxus sempervirens, L., is entirely absent from the coast, but grows beautifully in the cool well-watered valleys. Thorns and prickles prosper in this country better than in the north. In this respect the *Smilax aspera*, L., is guarded in a prominent manner, and is of unparalleled importunity, being a disagreeable evil throughout all the Mediterranean. On the rocks it forms, with its prickly leaves and stems, a dangerous thicket, but an *Oxycedrus juniper* ensnared and overgrown by *Smilax* is unapproachable. It costs considerable trouble to obtain for the herbarium good specimens in which the tough tendrils, the elegant drooping bunches of red-black insipid berries, and the many-shaped leaves can be shown uninjured. More difficult still is it to obtain the root-stock, which does not resemble sarsaparilla. The part above ground, however, does so very much, recalling the *Smilax officinalis*, and giving a very good idea of the appearance of the sarsaparilla plants. Of course, the leaves of *S. aspera* are much smaller; but in good soil and rather moist spots they attain a diameter of 10 centimetres and a length of 12 centimetres, and might very well then be compared with the leaves of the South American species, the obtusely cordate outline of which they completely share. *Smilax aspera* possesses a tolerably elongated woody root-stock, which is absent from the corresponding roots of the officinal Radix Sarsaparillæ. It has not been demonstrated whether these root-stocks contain the same frothing substance (parillin, smilacin) as is present in sarsaparilla. "Radix Sarsaparillæ, Smilacis asperæ, Peruvianæ," which occurs in the medicine tariffs of the seventeenth century, as, for instance, in that of Nordhausen (1657), shows that already this similarity had been noticed. It is more remarkable perhaps to find in a Nuremberg tariff of 1652, "Baccæ Smilacis asperæ." This plant, in respect to the number and form of its leaves, stalks and runners, shows as many variations as our blackberry, and was doubtless specially favourable to the setting up of a good number of species and varieties.

Smilax forms the most formidable bulwark of thorn-bush when it is combined with *Spartium spinosum*, L. (*Cytisus spinosus*, Lamk.), and *Sp. junceum.* The golden blossoms of these two even now adorn the uncultivated slopes and crags, just as in South Germany they are covered at Easter by the nearly allied *Sarothamnus scoparius*, Koch. (*S. vulgaris*, Wimmer). The representative of the elastic pliable stems of the latter are in the *Spartium spinosum* shorter and more woody, and hence more offensively rigid; their points of similarity can however usually be detected.

Beautiful as are the above-mentioned Papilionaceæ, and some other bushes of ths same family that also make their appearance at this time, they are far excelled by the perhaps less plentiful *Euphorbia dendroides*, L., an indescribably elegant bush when in full bloom. All the German euphorbias, even the *Euphorbia palustris*, have only a simple herbaceous stalk; but the stem of this species, which at the base is some centimetres thick, is quite woody, and rises in most elegant three-forked branches to a most beautiful light false umbel, at the height of a man. The bark and the herbaceous portions are full of milky juice, and it would not be difficult to collect sufficient for comparison with that of the official euphorbium. In the summer all its magnificence is dried up and withered, and the arid branches of the *Euphorbium dendroides* then no longer attract notice.

Among the indigenous shrubs the *Coriaria myrtifolia*, L. also takes a prominent position. Its long, and generally bowed and nodding stems, are usually almost smooth at the end of March, but in the first days of April the succulent light green leaflets and insignificant blossoms shoot forth very rapidly into luxuriant fulness. The crystallizable bitter principle of this plant (coriamyrtin) possesses poisonous properties, recalling to some extent those of picrotoxin. Coriaria blends the form of the bramble, as *Smilax* and *Rubus*, with the marked rigidity of *Spartium.*

The most generally diffiused shrub is the *Rosmarinus officinalis*, L., which is everywhere distributed in masses from the coast to the hilltops. The rosemary has peculiar claims to be considered the distinguishing plant of the western Mediterranean countries, as it is not even wanting in the Sahara. The Northerner sees with interest the carefully protected and poetically celebrated acquaintance of his native land, here growing luxuriantly and in perfect riot as vigorous underwood to a height of $1\frac{1}{2}$ metres. Nevertheless, the woody stems of the rosemary are neither truly erect nor truly bent, the flowers are neither blue nor white, the leaves are neither grey nor green; in short, it is difficult to recognize in this plant, peculiarly deficient in features noteworthy to the eye, one held in high esteem from ancient times, and possessing also chemical interest. The stearoptene of rosemary oil appears to consist of two varieties of camphor rotating a beam of polarized light in opposite directions.

Rosemary cannot be mentioned without the thoughts reverting to *Thymus vulgaris*, which on this coast occupies a similar place, although not so conspicuous on account of its small size, it only attaining a height of about four decimetres. But thyme is a much more spreading plant, its knotted stems are singularly bent; from the dull grey of the leaves the beautiful reddish flowers stand out brightly; and the aroma of the little shrub is as peculiar as it is powerful. The name *Rosmarinus* is indicative of the preference of this plant for the immediate neighbourhood of the coast; the *Thymus vulgaris*, on the other hand, rises in this, as in the Aragon districts, to an elevation of upwards of 1000 metres in the mountain regions, and makes a most lovely appearance in the valleys of the Maritime Alps, where the rosemary no longer occurs, although in the Balearic isles it attains an elevation of 1300 feet. With this is connected the greater power of resistance possessed by the thyme. The far more vigorous rosemary cannot endure the German winter; but the little thyme is not injured by the winter of Christiania, and as an annual garden plant flourishes at a latitude of 65° to 70° in Sweden, in Iceland, on the mild Norwegian coast even at 70°, and at the other extreme in Morocco. So extremely differently do these two labiates behave that in the Riviera grow in the closest association, though singularly enough almost entirely wanting in Greece. The insignificant thyme remained a stranger to the Romans and in the middle ages, whilst the rosemary was distinguished in many places in Latin literature as a popular plant, and was also esteemed by the Arabs. This explains how Charles the Great, in the year 812, included "ros marinum" in the list of South European economic plants, the cultivation of which should be attempted on this side of the Alps, but did not include thyme, which probably first obtained its position as an aromatic kitchen herb since the middle ages.

With the thymol generated by the chemical activity of the *Thymus vulgaris* money might be made, as probably it possesses antiseptic properties similar to those of other allied substances. But nobody thinks of such a thing here; nowhere throughout the Riviera is the distillation of essential oils energetically carried on as in Mentone. In the Val di Latte, near Ventimiglia, rosemary, lavender, and thyme are occasionally distilled in a very crude fashion, but in inconsiderable quantities; the production of oil of neroli, however, in the Riviera di Levante does not fall off.

Lavandula vera, DC. (*Lavandula officinalis*, Chaix, *L. angustifolia*, Mönch.), has in March and April only old rosettes of leaves and flower-stalks to show. It is much less frequent and does not occur so plentifully as rosemary and thyme. *Lavandula* shuns the sea-coast here decidedly, and appears first on the borders of the olive region, at an altitude of 500 or 600 metres; it cannot therefore be taken into consideration in picturing the spring vegetation of the Riviera.

Besides the plants already mentioned, the shore is chiefly enlivened by the *Zostera oceanica* (?), the ligulate leaves and strong rhizomes of which tossed upon the beach by the breakers become bleached and weather-beaten. Further, there are the two Cruciferæ, *Moricandia arvensis*, DC., and *Crambe maritima;* also *Crithmum maritimum*, L., *Thelygonum Cynocrambe*, L., some species of *Statice* and *Atriplex*, the *Galactites tomentosa*, with white besprinkled leaves, and the beautiful *Lavatera maritima*. Of Algæ there are not many to be found here; the larger fucoids especially are wanting.

(*To be continued.*)

THE DISTRIBUTION OF CARDIAC POISONS IN THE VEGETABLE KINGDOM.*

BY PROFESSOR T. HUSEMANN.

3. Ranunculaceæ.

(*Concluded from page* 796.)

The only known cardiac poison existing in this family is helleboreïn, occurring in *Helleborus viridis*, L., *H. niger*, L., and *H. fœtidus*, L., and accompanied by the narcotic glucoside helleborin.† According to Schroff's investigations, the same glucosides, or at least very similar bodies, appear to exist in many other species of *Helleborus*. A closer examination of the latter would be highly interesting, as it might throw some light upon the history and action of *Helleborus orientalis*, Lam., which was the cardinal remedy for psychical affections among the Greeks, and the reputed brilliant effects of which are unattainable with the ordinary species mentioned above.

Nearest related to *Helleborus* is the genus *Eranthis*, the sole representative of which, *Eranthis hiemalis*, Sal., was included in the genus *Helleborus* by Linné. Vauquelin found in it a soft resin, which he called helleborin, but it remains very doubtful whether this plant contains any glucosides analogous to those of *Helleborus*.

There is hardly occasion to suspect any cardiac poisons in other members of the sub-class Helleboreæ, although some of them are decidely poisonous, as for instance, *Caltha palustris*, L., which contains, according to Spiritus (1827), an acrid poison acting upon kidneys and skin, while other species of Caltha, as *C. Cadua*, Ham., and *C. Bishma*, Ham., are more probably to be referred to the genus Aconitum.

4. Leguminosæ.

Only quite recently has there been found a cardiac poison among this family. It is a proximate principle contained in the bark of *Erythrophlœum Guineense*, G. Don. (*E. judiciale*, Procter), growing near Cape Palmas and in Sierra Leone, and used by the natives as an arrow-poison and in ordeals. It is also known as Mancona bark or Teli. Gallois and Hardy discovered in it an alkaloid‡ acting similarly to digitalis. Their physiological experiments, however, were not made with the pure principle, but with the extract, and an exhaustive chemical analysis of mancona bark has not yet been made. Although the sub-order Papilionaceæ, which is so rich in esculent plants, contains more poisonous individuals than is generally supposed, we have no reason to suspect in it the presence of any cardiac poisons. Erythrophlæum is included in the third sub-order of the Leguminosæ, the Mimoseæ, and is nearest related to the genus *Parkia*, species of which furnish the so-called Sudan Coffee. A few Mimoseæ are emetic; so the root of *Adenanthera Pavonina*, L., growing upon Hayti. The bark of *Pithecolobium salutare*, Benth., of Columbia, is diuretic; and *Malvia judicialis*, of Mozambique, is used, like mancona bark and calabar bean, in ordeals.

Of domestic Leguminosæ, only a few deserve investigation. *Ononis spicata*, L., is known as a diuretic, and contains a glucoside, ononin,§ which, however, does not appear to have any cardiac effects. The same may be said of scoparin, the supposed active diuretic principle of broom, which contains besides an alkaloid, spartein, certainly not a cardiac poison.

5. Artocarpeæ.

From this family* we have to mention only one representative, the *poison-tree* of Macassar, *Antiaris toxicaria*, Lessh., containing a glusoside, antiarin, which is the active principle of the well-known Asiatic arrow-poison, *antiar*, and forms probably also the main constituent of the arrow-poison "dayaksh," used by the Orangdayas or Dyaks, and of some other similar poisons used by the Yatruns and Mintras of Malacca.† *Antiaris toxicaria* appears to be the only Artocarpea which produces remote poisonous effects. Rumph, who first described the tree, mentions besides an "Arbor toxicaria femina" occurring upon Timor, which was named *Antiaris innoxia* by Bluhme, because it is said to be much less poisonous.

These five families of dicotyledonous plants are the only ones containing cardiac poisons, and if we were to judge from the great superiority in numbers of poisonous dicotyledonous over monocotyledonous plants, we would hardly expect any cardiac poisons among the latter. But we know with certainty two families furnishing representatives.

6. Smilaceæ (Asparagus).

The cardiac poison belonging to this family is convallaramin, existing in *Convallaria majalis*, L., lily of the valley, alongside of the drastic purgative glucoside convallarin‡. Whether other species of Linné's genus of Convallaria contain the same glucosides remains to be investigated, but it is quite probable. The flowers and berries of *Convallaria Polygonatum*, L., the root of which was used for a long time as medicine under the appellation "Radix Sigilli Salomonis," are emetic and cathartic; and the same is probably the case with *Convallaria multiflora*, L.§ Another poisonous plant belonging to this family, and known from olden times, is *Paris quadrifolia* L., one berry, or true love, the berries of which were called in ancient medical works "baccæ *Solani* quadrifolii," showing that they were considered very active and efficacious. Our knowledge of the toxic action of this plant is, however, very limited, and the only reasons for suspecting it to contain a cardiac poison are its emetic effects, and the discovery therein by Walz of two glucosides, paridin and paristyphinn,|| possibly analogous to those in Convallaria.

Two other species of Paris, growing in northern Asia, namely *P. obovata*, Led., and *P. polyphylla*, Sm., said to contain an acrid narcotic principle, are likewise deserving of investigation. To these must be added some North American Smilaceæ, related to the genus Paris, namely *Medeola Virginica*, L., which, on account of its reputed emetic and diuretic effects, may possibly contain a cardiac poison, and certain species of Trillium, as *T. erectum*, L., and *T. grandiflorum*, Sal., possessing emetic properties, although in the latter the *acridity* of root and berries is mentioned as principal characteristic.

7. Liliaceæ.

According to Professor Husemann's own investigations, made with the Extractum Scillæ of the German pharmacopœia, this family contains an exquisite cardiac poison in *Scilla maritima*, L., well known to be an active emetic. The cardiac principle is chiefly contained in the alcoholic extract, and is not identical with the commercial sub-

---

* Abstract of a paper in *Archiv der Pharmacie*, Nov., 1876.

† See *Pflanzenstoffe*, pp. 796-800.

‡ Professor Husemann is somewhat astonished at the discovery of an *alkaloid* in this plant by Gallois and Hardy. He should have expected, and even yet suspects, *glucosides*.

§ *Pflanzenstoffe*, 675.

* Often counted as a sub-order (II.) of Urticaceæ.

§ This is actually the case. See King's 'Dispensatory.'—Ed. N. R.

|| *Pflanzenstoffe*, 1042.

stance scillitin, which was found to exert no toxic action on rabbits, nor to affect the cardiac functions of the frog.

The family of Liliaceæ is known to contain a large number of congeners or surrogates of squill, principally belonging to the sub-order Asphodeleæ, and mostly included in the genera Scilla and Ornithogalum. Such are the East Indian *Scilla Indica*, Roxb., the South African (Cape) *Ornithogalum Lassoni*, Gm., and *O. scilloides*, Jacq.; besides *Drimia altissima*, Ker., which is used as a substitute for squills at the Cape; the South European *Agraphis nutans*, Lk., and finally *Muscari moschatum* and other species of Muscari. The analogous therapeutic use permits the conclusion of analogous physiological action; in other words, to assume the presence in these plants of a principle augmenting the blood-pressure, and possibly also accounting for the diuretic action of *Anthericum ramosum*, L., *A. Liliago* L., and *A. Liliastrum*, L.

Still more weighty are the reasons for assuming the presence of a cardiac poison in the bulbs of *Fritillaria imperialis*, L., belonging to the sub-order of Tulipaceæ, which appears certainly to belong to the acrid narcotics, as it is reported to produce emesis as well as trembling and subsultus in animals, and phenomena resembling conium-poisoning in man. Orfila has shown that the bulb of this plant produces no *local* effects, but that its action is altogether remote. The bulbs of *Tulipa silvestris*, L., and *T. Gesneriana*, L., act likewise as emetics, and *Erythronium flavum*, Smith, is said to have the same property. But it is not unlikely that in these last named plants the effect may be due to local irritation, as we are tolerably certain is the case with the best known poisonous liliaceous plant, *Gloriosa superba*, S., superb lily, native of Ceylon and Malabar.

Although these two monocotyledonous families are the only ones which certainly contain cardiac poisons, Professor Husemann, is inclined to suspect the presence of others in the family of Amaryllidaceæ. Several exotic species of the genus Amaryllis have long been known as violent poisons, although our information is rather vague and uncertain. One of these is *Amaryllis disticha*, L. (*Hæmanthus toxicarius*, Ait.), growing at the Cape, the juice of which, inspissated by exposure to the sun, is said to be used by the Hottentots as an arrow-poison, and the bulb of which is used as a drastic cathartic, according to Rosenthal. The same uses and properties are ascribed to the Brazilian and West Indian *Amaryllis Reginæ*, L., and *A. princeps*, Vell. *A. Belladonna* L., another native of the West Indies, is said to be an emetic, and in larger doses an active poison, three gm. of the dried bulb having been known to produce death in three hours. *A. Sarniensis* L., the so-called Jersey lily, growing at the Cape, *A. equestris*, Ait., the South American funnel lily, and *A. pudica*, L., the red Cayenne lily, appear to have similar properties.

More probable yet is the presence of a cardiac poison in various species of the genus *Crinum*, as *C. Zeilanicum*, L., and *C. Asiaticum* L., the latter being known under the name bakoun, as a Malay antidote against intoxication by poisonous fish, crabs and serpents, or poisoned arrows. Both are held to be emetics, and *C. Zeylanicum* is used in China and Cochin China exactly like our squills. Several species of *Hymenocallis* and *Pancratium* partake of the same properties; of the latter particularly the Mediterranean *P. maritimum*, L., the bulb of which has now and then been used as a regular substitute for squill, and was even known as "Radix scillæ minoris."

Of European Amaryllidaceæ, the most likely to contain a cardiac poison is *Narcissus pseudonarcissus*, L., or daffodil, if we may draw a conclusion from the effects obtained by Orfila upon dogs, namely repeated emesis, intoxication with consciousness, deep inspirations, falling upon the side, dyspnœa, and death free from convulsions. The same effect is probably inherent in *N. poeticus*, L., cases of poisoning by which are on record; and possibly also in *Leucojum æstivum*, L., *L. vernum*, L., and *Galanthus nivalis*, L.

All these facts make it probable that among the hitherto known, but unstudied, poisonous plants, there are many which must be classed with the cardiac poisons. At the same time, we see how fragmentary is our knowledge of the physiological action of plants, and how large a material for pharmacodynamic investigations remains to us for study. In conclusion, Professor Husemann hopes that some of the problematical plants mentioned may be made the subject of closer investigation.

EMULSIONS.*

BY EDMUND GREGORY.

There exists so much difference of opinion as to the comparative success of various methods for producing emulsions, that it gives rise to a suspicion there may be an equal difference in the estimate of what qualities are essential to the constitution of a perfect emulsion. Hence the necessity of a fixed standard of excellence. Such a standard we find in the milk of the cow. An emulsion, then, should be white as milk, and should have its fat-globules too small to be visible to the unassisted eye, and so well suspended that, although on standing a cream-like layer may rise to the top, it will readily reunite on shaking. Adopting this standard the writer will endeavour to enumerate the various methods proposed for making emulsions, and to give the results of actual experiment. Considering oil of turpentine as a fair type of the volatile oils, and that they are the most difficult class of substances to operate with, researches have been mostly confined to that drug. Premising these remarks, I proceed to consider:

1. The method which directs that equal parts of mucilage of acacia and oil should be put into a bottle and well shaken together, the requisite quantity of water being gradually added. If the mucilage be fresh, the bottle only partially full, and the shaking very vigorous, tolerable results can be obtained with castor oil, moderate results with balsam copaiba, and with oil of turpentine a total failure. But in all cases the oil-globules are distinctly visible to the naked eye.

2. Equal parts of oil and mucilage are put into a mortar together, and briskly triturated.

This gives barely tolerable results with the balsams and thicker oils, but with oil of turpentine it is a total failure, no amount of labour producing the slightest effect.

3. Equal parts of oil and mucilage, the oil to be gradually added, triturating briskly after each addition until the portion added is emulsified.

A fair result can be obtained by this process if the operator have plenty of patience and a liberal supply of muscle, but the product is too dark in colour. The oil-globules are not visible to the naked eye, but can be easily seen with a magnifying power of three diameters. It separates into two layers in two and a half hours, the lower layer being dark but not watery.

4. The next process is that wherein equal parts of mucilage, water, and oil are put into a suitable vessel, and agitated with an egg-beater until emulsionized.

This yields a tolerable result, is simple, and requires no skill, but is rather laborious, and yields a product very dark in colour. The oil-globules are not visible to the naked eye, but quite distinctly under a power of three diameters. It separates into two layers in three hours, the lower layer being very watery.

5. The next process tried was that of Mr. Charles F. Hartwig (published in the *Pharmacist*, October, 1875), in which one part of mucilage and one part of water are put into a suitable vessel, thoroughly mixed by being drawn up into and ejected from a small vaginal syringe, and one part of oil having been added, the emulsion is produced by the use of the syringe alone in the same way.

* Read before the American Pharmaceutical Association, in reply to a query, How much acacia is needed to emulsify perfectly the fixed or volatile oils and balsams?

This process yields excellent results, but the emulsion is not quite as white as it should be; the process is rather tedious and the after-cleaning very troublesome. It is the best of the processes in which officinal mucilage is employed. The oil-globules are invisible to the naked eye, but are distinctly seen with a power of three diameters. It separates into two layers in twenty hours, the lower layer being milky in appearance.

6. A process, published in the *Journal of Pharmacy*, in February, 1872, by Mr. J. Winchell Forbes, and apparently designed more especially for oil of turpentine, in which he directs that one part of oil shall be put into a bottle and shaken, then one eighth part of pulverized acacia, and after thorough agitation half a part of water added, the whole to be then vigorously shaken until emulsified.

The resulting emulsion is deficient in whiteness. The oil-globules are distinctly visible, as a multitude of gem-like points, under a magnifying power of three diameters, and are also visible to the naked eye if a drop be placed on a plate of glass and held up between the eye and the light. It separates into two distinct layers in fifteen minutes, the lower layer being quite watery, but it easily reunites on shaking.

7. If, however, in the preceding process, three eighths of a part of pulverized acacia be used instead of one eighth, a very good result is obtained, the product being much whiter, the oil-globules about half the size, and quite invisible to the naked eye. It now takes twelve hours to separate into two layers, the lower layer, however, being still watery.

8. The next process for consideration is described on page 343 of Mohr and Redwood's 'Pharmacy,' English edition of 1849, in which one part of pulverized acacia and one and a half parts of water are put into a mortar, and after thorough trituration three parts of oil are added gradually, each separate portion being emulsified before another is added.

The results are admirable, the product being white as milk. The oil-globules are not visible to the naked eye, but slightly so under a power of three diameters, and it does not separate into two layers under twenty-four hours, the lower layer having the appearance of milk.

9. The last process which will be referred to is recommended by Mr. Hans M. Wilder, in the *Druggists' Circular* for December, 1874. One part of pulverized acacia and two parts of oil are put into a mortar and rubbed together; one and a half parts of water are then added at once, and with a few revolutions of the pestle the whole is emulsified.

It has yielded in my hands the very best results. The emulsion is beautifully white, scarcely to be distinguished from milk, and the necessary manipulations are very speedy and simple. The oil-globules are totally invisible to the naked eye, and not very perceptible with a power of three diameters. It separates into two layers in twenty-four hours, the lower layer being quite like milk, whilst the upper would pass for cream, and at the time of writing this, four days after making, retains the same appearance, and is by far the best out of six samples that are standing undisturbed before the writer.

In summing up results, the conclusion must be arrived at that those who desire an unexceptionable emulsion must abandon those processes in which officinal mucilage is used, and adopt one which calls for pulverized acacia. Any inquirer, who will take the pains to prepare a series of emulsions according to the formulas given above, and will set the bottles in a row before him, will in a few hours receive a very striking lesson. Of these, the process No. 9, of Hager and Mohr, noticed by Mr. Hans M. Wilder, is the quickest, is simple, demands no apparatus that does not exist in every pharmacy, and yields unexceptionable results. Next to this comes process No. 8, taken from Mohr and Redwood's 'Pharmacy,' which yields an admirable product, but is a little more tedious than the preceding. No. 7, Mr. Winchell's process improved, is admissible when a pestle and mortar cannot readily be obtained from any accidental cause, but it will scarcely succeed with the more viscid oils or balsams, such as castor oil or balsam copaiba. Of the processes using officinal mucilage, the only one yielding a good result is that of Hartwig, No. 5, in which the vaginal syringe is used.

In answer, then, to the query at the head of this paper, the writer would say, that three drachms of acacia in fine powder are necessary to emulsify one ounce of any of the volatile oils, and that a little less (about two drachms) will answer for the fixed oils and balsams. And that to this quantity of gum four drachms and a half of water must be added (no more and no less), and that either the water or the oil may be added first to the gum, but it is quickest to add the oil first, and well triturate before adding the water. Less gum can be made to yield a good result by a careful operator, but as a general practical working rule it may be said that three drachms are necessary for one ounce of oil.

INDIAN HEMP AND ITS ACTIVE PRINCIPLE.*

The home of hemp is Persia and the high plateau of Northern India, whence it has gradually spread to other countries, so as to be domesticated at present everywhere. Its narcotic properties, however, are only developed fully in its native home in Asia, and in certain parts of Africa, where it is used as a narcotic stimulant and intoxicant by nearly 300,000,000 of inhabitants.

A preparation, called Madjoun is sold in Algiers, which is powdered *Cannabis sativa* boiled with honey for a longer or shorter time, according to the desired consistence. Usually it is kept mixed with a certain portion of *Ras-el-hanout*, a spice-compound, containing nutmeg, cinnamon, cloves, various peppers, ginger, galangal and Guinea grains. This mixture is also called *Kif*. The dose varies from the size of a hazel to that of a walnut, according to the age, sex, and tolerance of the person using it. Most eaters of hashish also smoke the dried leaves of the plant, either alone or mixed with the so-called "tobacco of the desert," which, according to Dr. Guyon, is a species of hyoscyamus.

Dr. Preobraschensky, who accompanied the expedition to Chiwa in 1873, furnishes the following information on the hashish of Central Asia. "This article occurs in the bazaars of large cities of Middle Asia in the form of plates, or cakes of various shapes, mostly five to fifteen inches long, five to ten inches broad, and one to three inches thick; externally they are dark brown, internally greenish or brownish, of firm consistence, very tough, and almost incapable of being broken, but easily cut into fine shavings. They are prepared as follows: The resinous juice from the fresh unripe flower-tops is collected during spring, mixed with sand and water to a doughy mass, which is spread upon a surface of clay and dried until it can be cut with a knife into plates. In a few days more the excess of water has evaporated, and the substance is ready for use. It is called hashish by the Russians, Nascha by the natives, Bang and Gunjah by the Persians, and is exported from Bochara to Chiwa, Tashkend, Kokant (Chokand) and other places.

The active principle of hashish has been supposed to be resin. Dr. Preobraschensky has, however, lately subjected hashish to a chemical analysis, and has found an alkaloidal body—not only in the commercial substance, but also in the flower-tops of hemp itself, and the pure extract prepared from it—which was recognized as *nicotine*. 150 gm. of the herb, distilled with water, furnished 25·4 mgm. of nicotine; 50 gm. of the herb, distilled with caustic lime and potassa, yielded 335·28 mgm.; 5 gm. of the extract of *Cannabis Indica*, dissolved in alcohol and distilled, yielded a distillate containing 91·14 mgm. of nicotine, and 2 gm. of the extract, distilled with caustic lime and potassa, furnished 63·5 mgm. of the same alkaloid

The Pharmaceutical Journal

SATURDAY, APRIL 14, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DECEPTIVE SCALE PREPARATIONS.

THE importance of the results obtained in the examination of some specimens of so-called citrate of iron and quinine, which are recorded on another page, will not be ignored by the careful pharmacist. Of course we know that there is no novelty in the suggestion that citrate of iron and quinine as sent in by a manufacturer may not contain 16 per cent. of alkaloid; still, an approximate check for this is provided in the Pharmacopœia test. But there is the additional danger that a considerable part of the alkaloid precipitate yielded by that test, and even the greater part, may not be quinine, but may consist of one or more of the other cinchona alkaloids. It is obvious that should such a specimen fall into the hands of a competent public analyst, and result in proceedings under the Sale of Food and Drugs Act, there might be some difficulty in proving that it was of the nature, substance, and quality of the article demanded, although it might pass the Pharmacopœia test; and the great difference in the money value of the several alkaloids would, if stated in evidence, be liable to create in the mind of the magistrate an ugly prejudice against the defendant.

It must not be forgotten that the law as it stands not only applies to the wilfully fraudulent, but also to the negligent dealer. As a matter of convenience, many pharmacists buy their scale preparations from the wholesale manufacturer; but with this convenience there is associated a fresh responsibility, that of ensuring that they are getting what they ask for. Some will be content to trust to the manufacturer in this respect, and we are glad to believe that if they are prepared to pay a fair price and go to a respectable house they may do so with comparative safety. But, especially now that quinine fetches such an enormous price, it having trebled in value during the last three months, it will be well to remember that a low-priced article may not be the cheapest, and to take precautions accordingly.

In connection with this subjct we notice a statement made by Dr. DUPRÉ in *The Analyst* for the present month, that as public analyst he has analysed a certain number of drugs and found 43 per cent. more or less adulterated. We repeat here what we have said before, that such statements are very unfair when made by a public official in the absence of any proceedings that would appear to be demanded if those statements are well founded, for they justly raise the inquiry whether there has been excessive officiousness on the part of the analyst or remissness on the part of the local authority since these cases have not been carried into Court. Such sweeping statements ought not to be made without giving a fair opportunity of testing them, and we would remind Dr. DUPRÉ that a public analyst's evidence in the witness box does not always bear the test of a cross-examination. We note also that at the last meeting of the Society of Public Analysts it was announced that the Council had ceased to have any proprietary right in *The Analyst*, and, in fact, it is now edited by Mr. G. W. WIGNER and Dr. MUTER, and published by Mr. BAXTER. We hope that this change of proprietors is not to be synchronous with the starting of a policy of sensational attacks on chemists and druggists or any other class.

THE BENEVOLENT FUND DINNER.

IN our Advertising Sheet this week will be found an announcement concerning the Dinner in aid of the Benevolent Fund which is to take place on Tuesday, the 15th of May, together with a First List of Stewards. We think that the fact of the list including nearly two hundred and fifty names of gentlemen more or less connected with pharmacy, who have come forward to show their sympathy with this effort on behalf of distressed chemists and druggists, their widows and orphans, augurs well for the length of the list of donations to be read by the President after the Dinner. It will be noticed that gentlemen unable to attend the Dinner may send to the Secretary, 17, Bloomsbury Square, their donations for the President's list any time before the 15th of May.

EARLIER CLOSING.

WE are glad to learn that MR. GEORGE WEBB SANDFORD has consented to preside at the meeting in respect to earlier closing that is to be held in the theatre of the Society's House, 17, Bloomsbury Square, on Wednesday evening next. The hours of business for pharmacists, notwithstanding some improvement has taken place during the last few years, are still so unreasonably long, and this involves so much overwork both of mind and body, that we hope this favourable opportunity of discussion as to the best way of mitigating the evil will be utilized by a large number of chemists and druggists from all parts of the metropolis. We need hardly add that the meeting is not to be one of the members of the Pharmaceutical Society specially, but will be open to every member of the trade who chooses to attend. The chair will be taken at half-past eight o'clock precisely.

QUICKSILVER HOARDING.

THE *Public Ledger* last week quoted some curious evidence which tends to show that the well-known passion of the Asiatic for converting his surplus wealth into gems and the precious metals, and hoarding it up with a characteristic contempt for interest, has manifested a considerable development in investments in quicksilver. It is stated, apparently upon good authority, that the stock of this metal in the warehouses of Hong Kong on the 1st of February was 11,000 flasks, and that subsequent shipments from San Francisco to that port have raised that amount to 19,500 flasks. As the most careful estimates give the total consumption of quicksilver in all China at 100 flasks per month, it is clear that the stock in hand in February, without the subsequent shipments, would have been sufficient to provide for the Chinese consumption during several years. What then is to become of all this quicksilver, for it is to be presumed that the San Francisco merchants have some idea of what they are about in sending so much across the Pacific? Is this metal destined to play a *rôle* similar to that of its sister silver, which for so long was poured into the Asiatic continent without an apparent return? This theory finds some support from an assertion, which however requires further confirmation, that 16,000 flasks of quicksilver were recently uncovered in "one of the towns in India."

THE ROYAL INSTITUTION.

THE "probable arrangements" for the Friday evening meetings for the remainder of the session are announced to be as follows:—April 13th, "Experiments with a Great Induction Coil," by W. SPOTTISWOODE, LL.D., F.R.S.; April 20th, "Spinoza," by F. POLLOCK, M.A.; April 27th, "The Physical Causes of Indian Famines," by Lieut., General RICHARD STRACHEY, R.E., F.R.S.; May 4th, "Researches on the Origin and Development of Minute and Low Forms of Life," by the Rev. W. H. DALLINGER; May 11, "The Intellectual Movements and Secret Societies in Russia," by D. MACKENZIE WALLACE, M.A.; May 25th, "The Evolution of Nerves and Nervo-Systems," by G. J. ROMANES; June 1st, "The History of Education," by OSCAR BROWNING; and June 8th, a Lecture by Professor TYNDALL.

YORKSHIRE COLLEGE OF SCIENCE.

THE Council of this College have received a communication from the Worshipful Company of Clothworkers to the effect that the Court of that Company has decided upon expending a sum of £10,000 in providing adequate and permanent accomodation for the textile industries department in the College. The conditions attached to the grant will be laid before the Board of Governors at its annual meeting on Monday next.

APPOINTMENT OF ANALYSTS.

AT the Quarterly Meeting of the West Riding Magistrates, held at Wakefield on April 2nd, Mr. A. H. ALLEN, of Sheffield, was appointed Analyst for the West Riding, at a salary of £250 per annum, and 6*s.* for each analysis. At the same meeting the appointment of Mr. WILLIAM BAKER as Analyst for the division of upper Strafforth and Tickhill was revoked.

ERRATUM.—p. 657, col. 2, line 1, *for* Abergele *read* Liverpool.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eleventh general meeting was held at the Royal Institution, March 15th, 1877. The President, Mr. A. H. Mason, F.C.S., in the chair.

The minutes of the previous meeting were read and signed.

The following queries were found in the question box. No. 1. "Among the tests for liq. am. fort. given in the British Pharmacopœia is the following—Dilute with four times its volume of water it does not give a precipitate with lime water. This test was applied to a sample of ammonia and no precipitate was produced. Air was then blown through the ammonia from the lungs with the expectation that sufficient carbonic acid would be absorbed to give the reaction with the lime water. This was not the case as no precipitate was produced. Upon warming the mixture, however, the precipitate appeared. Can anyone explain this?"

Mr. E. Davies, F.C.S., said that time, very probably, was an element operating in this reaction, and heat also had an effect in inducing the change, giving as instances the precipitation of strontium sulphate, calcium oxalate, and other reactions that similarly depend on the conditions mentioned.

No. 2. "In the report of the recent prosecutions at Salford of the sale of adulterated balsam copaiba it is stated that all the tests applied by the analyst were fallacious. As the published authorities recommend several of these processes, what is a reliable test for balsam copaiba?" A lengthy discussion took place on this question in which the President, Messrs. Abraham, Davies, Tanner, Dr. Brown, Dr. Symes and others took part.

Mr. Michael Conroy, F.C.S., said that most of the tests given in text books and works on materia medica, especially those known as the magnesium carbonate and ammonia tests are entirely misleading from the fact that copaiba naturally varies in composition, the amount of resin ranging from 20 to above 70 per cent. in samples from different sources. The magnesium carbonate test is that genuine copaiba dissolves one-fourth of its weight of carbonate of magnesia by heat and remains transparent. The resulting compound being copaivate of magnesium dissolved in the essential oil, but since the resin of copaiba consists almost entirely of copaivic acid it is evident that a sample of copaiba containing say 30 per cent. of resin will not dissolve as much magnesium as a sample containing 70 per cent., therefore this test only proves that the copaiba does or does not contain a large amount of acid resin and in no way proves the sample to be adulterated. The ammonia test for similar reasons cannot be applied indiscriminately to all samples of copaiba. The tests given in the British Pharmacopœia are almost useless, for a sample would pass as genuine which contained almost any amount of fixed oil. The heat test is evidently intended to distinguish between gurgun balsam and copaiba but a sample of the latter containing from 10 to 20 per ent. of gurgun balsam does not gelatinize. He agreed with Dr. Campbell Brown that it is absurd to attempt to prove the genuineness of copaiba by the application of empirical tests and that the only plan of operation should consist in looking for all possible adulterants. The adulterants known to be used are, fixed oils, crude turpentine, oil of turpentine and gurgun balsam. The presence of a fixed oil can readily be found by heating a drachm or so on a watch glass or in a small porcelain dish so as to drive off the whole of the volatile oil, when a brittle and pulverizable resin will remain if the sample be free from fixed oil. A sample containing 5 per cent. of oil leaves a soft "birdlimy" substance. Even with 1 per cent. a brittle but *not a pulverizable* resin is obtained. A good plan to adopt is to place a drop of the melted resin on a piece of well glazed writing paper, and allow to cool when, if the sample is perfectly free from fixed oils the spot of hard resin can be rubbed into a very fine powder with the finger.

During the evaporation of the volatile oil in conducting the above experiment, the presence of turpentine can be detected by the odour if the sample is adulterated with that article. The same applies to the oil of turps. As the odour of turpentine is so totally distinct from that of oil of copaiba, the presence of 1 per cent. can be detected. The presence of gurgun balsam may be detected by the almost entire *insolubility* of this substance in *alcohol*, whereas copaiba is almost entirely soluble. Absolute alcohol only is that which can be used for this test, and the appearance of a slight milkness may be disregarded as most samples of old balsam do not dissolve perfectly clear in alcohol. He was indebted to Mr. Siebold for the following which is also an excellent test for gurgon balsam, viz. :—Its slight solubility in rectified petroleum spirit, or what is commonly known as benzoline. As copaiba is almost completely soluble in this menstruum, the presence of a very small percentage of gurgun balsam is easily detected. In reply to Mr. Tanner, Mr. Conroy said most samples of copaiba are fluorescent, and that about 96 per cent. of the resin found in copaiba consists of copaivic acid. The other resin found in copaiba he considered was formed by the oxidation of the volatile oil, for he found that old samples contain more of this particular resin than new ones. He stated that it was through using *rectified* spirit instead of alcohol, that the Salford analyst reported the samples in question to be adulterated with what he supposed to be a foreign volatile oil.

Dr. J. Campbell Brown, D.Sc., F.C.S., etc., exhibited and explained the "Geisler's Vaporimeter," and demonstrated the practical application of the same in the estimation of dilute spirit by taking the vapour tension of the mixture, after which he exhibited Duboscq's New Polariscope, "Saccharimètre à Pénombres," upon which he read the following notes:

Duboscq's New Polariscope.—"Saccharimetre a Pénombres."

BY DR. J. CAMPBELL BROWN, D.SC., F.C.S., ETC.

The polariscope for saccharimetric and similar purposes is founded on the property which sugar and some other substances possess of turning the plane of polarization of a polarized ray of light passing through them, either to the right or left, through a certain angle, depending on the nature of the substance and its quantity.

The usefulness of the instrument depends on the degree of precision with which you can measure the angle of rotation of the plane of polarization.

The first polariscopes were the same in arrangement as those used attached to microscopes. The substance was placed between the polarizing and analysing prisms when they were so placed as to produce darkness without the object; and the rotation of the analysing Nicol's prism necessary to restore darkness was taken as the indication of the quantity or thickness of the substance when its specific rotatory power was known.

But it was extremely difficult to know when the point of maximum darkness was reached, even when monochromatic light was used, obtained by placing red copper glass behind the polarizer.

Those who are accustomed to use the instrument of Soleil will only require to be reminded of the means employed for rendering the observation more accurate.

(1) He fixed upon a certain purple tint, which is not only most remarkable, but which changes most rapidly, when the analyser is revolved, to red on one side and to violet on the other. This tint is called "sensitive tint" or "transition tint," and is produced by placing a plate of quartz, 3·75 mm. thick, between the polarizing prism and the analysing prism, set with their principal sections parallel.

The interposition of the sugar solution causes this tint to change and the rotation is measured by the number of degrees through which the prism must be turned to restore the transition tint.

2. Greater exactness still was obtained by using a double plate of quartz, 3·75 mm. thick, one half being composed of left-handed and the other of right handed quartz. This plate exhibits the transition tint on both halves when the polarizing and analysing prisms are placed with their principal sections parallel, but when the analyser is revolved or the sugar is introduced, the one semi-disk appears red and the other violet, so that on inserting the sugar solution the analyser must be rotated to restore the transition tint to both halves.

When the rotation is great an error arises from the different angles of rotation imparted to different coloured rays, and the consequent interference with the transition tint.

3. The third improvement, which is peculiarly Soleil's, obviates this difficulty. Instead of rotating the analyser, he adjusts and fixes it before inserting the sugar solution, and after inserting the sugar solution he restores the transition tint by introducing what he calls a compensator, that is two quartz prisms of small angle set perpendicularly to the axis, and which can move over one another in contrary directions so as to vary the thickness through which the modified light has to pass. They are moved by a toothed pinion to which the vernice and scale is attached: so that the rotation caused by the sugar is measured by the thickness of quartz required to compensate it.

This is a beautifully and ingeniously complicated instrument. First, the light passes through a polarizer consisting of an achromatized calc spar Nicol's prism then through a double plate of quartz 3·75 mm. thick, one half of which is dextro- and the other lævo-rotatory; then through the sugar tube; then through a quartz plate cut perpendicularly to its axis and the compensator of quartz prisms of contrary rotation to the plate and of maximum thickness equal to that of the plate; then through the analysing Nicol's prism, and finally through a telescope.

For coloured solutions another quartz plate and Nicol's prism are made to revolve so as to neutralize the colour of the solution.

The defects are—

(1) The interference which coloured liquids introduce.

(2) The fact that different substances affect the rotation of different rays in different ratios renders it useless for any other than one kind of substance.

(3) The fact that the eye cannot distinguish differences of colour so delicately as differences of depth of shadow, especially when the eye is tired; and colour-blind persons cannot use the instrument at all safely.

(4) The less degree of movement in the compensator as compared with the revolving analyser.

Duboscq's Saccharimètre à Pénombres is beautiful for its simplicity; it is a partial return to the original form:—

Description extempore—

(1) Monochromatic light.

(2) Double quartz plate of right and left-headed quartz retained.

(3) Compensator discarded, and the rotation measured by actual rotation of the analyser.

If the substance contains only cane sugar and no other substance which acts upon light, dissolve 16·35 or 16·2 grams in water and make up to 100 c.c.; place the solution in the 20 c.m. long tube.

Turbid or gummy solutions may be mixed with one tenth volume of isinglass solution, and then one and a half volume alcohol, and filtered; or add two or three c.m. of saturated solution of acetate of lead, and filter. If coloured decolorize by charcoal, rejecting first fourth.

If the substance contains any other sugar as well as cane sugar, the rotatory power is observed before and after the inversion.

(1) Observe before inversion in the usual manner, then take 50 c.c. of the same solution, add 5 c.c. of pure fuming hydrochloric acid, warm in a water-bath to 68° then remove and cool the solution, filter if necessary, and observe in a tube 22 c.m. long, lined with glass, and bearing a thermometer; the index must now be turned to the right instead of to the left as before inversion.

Since the rotatory power of the solution cooled to the original temperature (the observations being made in a tube one-tenth longer than the former), remains unaltered in so far as it was due to glucose or other substance, whereas the cane sugar has been replaced by inverted sugar $\left(\begin{matrix}\text{dextrose and} & \text{lævulose}\\ +56^\circ & -106^\circ\end{matrix}\right)$ the amount of cane sugar may be calculated from the rotatory power peculiar to invert sugar.

The rotatory power (a) observed first was made up of the molecular rotatory power (c) of the cane sugar (C) and that (g) of the grape sugar or other substance (G).

$$a = cC + gG.$$

The rotatory power observed after is made up of the unaltered rotatory power of the grape sugar and that of the inverted sugar.

$$a' = iC + gG.$$

hence

$$a - a' \text{ the difference} = cC - iG.$$

$$\text{or } C = \frac{a - a'}{c - i} \quad i\,c = \frac{a - a'}{73{\cdot}8 + 25}$$

because i is 25 at 15° C., but varies with the temperature, hence the tables of Clerget.

In general, when ordinary sugar solutions are to be estimated (a) is a + quantity, and (a') is a — quantity; so that the cane sugar is found by adding the two observations together and looking up the sum in Clerget's table under the column corresponding to the temperature of the second observation.

In default of tables:—

T = temperature.
S = the sum or difference of the two observations.
P = the rotatory power.
R = the quantity of sugar per litre of solution.

$$P = \frac{200\ S}{288 - T}$$

$$R = \frac{P \times 16{\cdot}2}{10} = P \times 1{\cdot}62$$

Diabetic Sugar.

Diabetic sugar : Cane sugar :: 73 : 100. Hence each 1° on scale must be multiplied by 2·243 to give parts per litre.

Various queries asked by members at the conclusion as to the instruments were answered by the Lecturer. And on the motion of Mr. J. T. Armstrong, F.C.S., seconded by Mr. E. Davies, F.C.S., a cordial vote of thanks to Dr. Brown for his very interesting and instructive lecture was carried by acclamation.

PLYMOUTH, DEVONPORT, AND STONEHOUSE CHEMISTS' ASSOCIATION.

A general meeting of the members of the above Association was held at the Exmouth Hall, Stonehouse, on Wednesday evening, April 4th, the President, Mr. F. Codd, in the chair, for the purpose of considering the position of the trade with reference to the recent prosecutions, and to appoint a local committee to make arrangements for receiving the Pharmaceutical Conference.

The minutes of the previous meeting having been read and approved, the following resolutions were unanimously passed:

Moved by Mr. A. P. Balkwill, seconded by Mr. J. Allen, and resolved—That this meeting is of opinion that any prosecution of chemists and druggists for ordinary counter prescribing is contraryto the spirit and intention of the Apothecaries' Act, and the enforcement of such restrictions would be an unjust interference with the rights of the public, and the privileges of the trade.

Moved by Mr. H. T. Netten, seconded by Mr. S. B. Turney, and resolved—That this meeting desires to express its approval of the action now being taken by the Chemists and Druggists' Defence Association, and earnestly recommends all members of the trade to join the Association at once, and thus assist in strengthening its efforts to protect the interests of the trade.

Moved by Mr. G. Breeze, seconded by Mr. J. Allen, and resolved—That the secretary be instructed to forward copies of these resolutions to the Birmingham Trade Defence Association, the Council of the Pharmaceutical Society, and to each of the trade journals.

Moved by Mr. J. Allen, seconded by Mr. H. T. Netten, and resolved—That as the coming annual meeting of the Pharmaceutical Conference will be held in Plymouth, it is desirable that every effort be made to receive its members in a cordial and enthusiastic manner, and that this meeting pledges itself to render every assistance to that end.

Moved by Mr. S. B. Turney, seconded by Mr. J. Dampney, and resolved—That with a view to carry out the foregoing resolution, a local committee of the following gentleman be formed with power to add to their number, viz.:—Allen, Plymouth; Balkwill, Plymouth; Breeze, Devonport; Burdwood, Plymouth; Clark, Plymouth; Codd, Devonport; Coker, Plymouth; Elliott, Plymouth; Geldard, St. Austell; Guyer, Torquay; Hearder, Torquay; Hearder, Plymouth; Hemmings, Penzance; Netten, Stonehouse; Percy, Truro; Riches, Torquay; Rowe, Devonport; Rowe, Redruth; Smith, Torquay; Snell, Stonehouse; Turney, Plymouth; Woods, Plymouth.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this society was held on April 5th, Professor Odling, F.R.S., in the chair. After the announcement of visitors, the minutes of the previous, the anniversary, and the extraordinary general meetings were read and confirmed. The names of the following candidates for election to the fellowship of the society were read for the first time:—H. R. Hind, A. Watt, G. A. Milne and Dr. A. E. M. Franchimont. A lecture

On the Discrimination of Crystals by their Optical Characters.

BY PROFESSOR N. S. MASKELYNE, F.R.S.,

was then delivered:—

The methods of investigation, the description of which is the purpose of the discourse, are in their more practical aspect *qualitative* methods. The practical application of them being that of determining the kind of symmetry which a crystal obeys, *i.e.*, the system to which it belongs. An attempt is being made, by the introduction of *quantitative* measurements into these methods, to get some insight into the nature of molecular structure. Thus far the physical and morphological properties of crystals have not been brought into very distinct correlation and if, as is probable, the *intro*-molecular co-ordination of atoms and of groups of atoms within the unit molecule of the crystal may have to be invoked to unravel what a purely symmetrical *inter*-molecular distribution of the centres of mass of the unit molecules themselves may not be competent to explain, the result cannot fail to be of interest to the chemist, to whom the function discharged by special atom-groups in his compound molecules is becoming every day a more important question.

Reverting, however, to the practical side of the methods to be discussed, it will be seen that by a judicious use of the aid which, polarized light affords, the chemist, who is continually forming crystals of new and remarkable substances, will be enabled to obtain rapidly valuable information about these crystals without having previously to become an adept in crystallography. The different systems of crystallography are distinguished by the character of their symmetries. For the purposes of optical comparison, as a cubical crystal acts on light as an isotropic body we may omit the *cubical* system. The *tetragonal* and *hexagonal* systems may be grouped together. The *prismatic* or orthorhombic, the *oblique* or clinorhombic and the *anorthic* systems will be treated of separately. The *orthorhombic* system, which may be termed the orthosymmetrical system, has three perpendicular planes of symmetry which are not congruent, *i.e.*, with respect to which the morphological and physical characters are dissimilarly distributed. The perpendicular axes in which these three planes intersect are the morphological axes of the crystal and are coincident in direction with the three principal axes of the ellipsoids which represent optical, thermic or magnetic properties. The *oblique* or monosymmetric system has a single plane of symmetry, its normal is one of the axes of the different ellipsoids which represent physical characters and it is also that crystallographic axis which is perpendicular to the other two. The *anorthic* or centrosymmetrical system presents the smallest amount of symmetry possible, viz., that to a centre; the repetition of any morphological element is therefore simply that of the feature presenting itself on opposite sides of the crystal.

The influence of the crystalline arrangement of the ponderable matter upon the luminiferous ether results in the elasticity of this medium varying in different directions or in its degree of condensation being different, or in both; and it also results that the directions of elastic strain and stress only act upon the same line when that line is parallel to one of the three perpendicular directions which are called the axes of optical elasticity. While in ordinary media the direction of a ray is normal to the tangent to the front of the wave to which the ray belongs, in the general case within the crystal the ray is oblique to the wave normal. The cases in which it is not so being those of the axes of elasticity and certain other exceptional directions of the optic axes. As the result of the peculiar distribution of optical strains in a crystal, an ideal wave of light would, in the general case move forward with two velocities and would present two wave-fronts, one lagging behind the other. If we consider the path of a ray belonging to any point of one of these wave-fronts, it will be seen, that it must have bifurcated, one branch of it meeting the other wave surface; but the normals to the wave surface at the two corresponding points are connected by the fact of their being parallel to each other. The swings of the vibrations at these two points are perpendicular to each other and to the wave normal. Wire models were exhibited in which the intersections of this wave surface with the principal sections (*i.e.*, with the intersecting planes perpendicular to each axis) were seen to compose in two cases a kind of ring, formed by a concentric circle and ellipse in the third case, the figure produced was that formed by the intersection of a circle and an ellipse, the principal axes of the ellipse being in the ratios of the greatest and of the least, while the radius of the circle represented the intermediate parameter of the three velocities along the several axes. A tangent drawn to the circle and ellipse near their point of intersection meets in the case of the circle a ray, which is coincident with the wave-normal, and the lip or margin of a conoidal depression in this part of the wave surface is circular in form and touched by the same tangent plane, which contains the tangent to the circle and ellipse. To every point of this circle there belongs a portion of a ray and if a section be cut in a crystal parallel to this tangent plane, these rays will emerge with a common wave front, the normal of which will now be coincident with the rays as they emerge into an isotropic medium, while the oscillations are performed in the case of each ray in a plane passing through the wave normal and the centre of the margin-circle. The light thus emerging has therefore lost its polarized character, and the direction of the wave normal is a primary optic axis of the crystal. The radius of the circle at the point of intersection with the ellipse where the two figures have a ray in common, is a secondary optic axis. From the symmetry of the figures there are two primary axes, differing in the angles which they enclose, according to the ratios of the three constants representing the velocities along the three axes. These three axes will now be called the two mean lines and the normal; the *first mean line* bisects the acute angle between the optic axes; the *second mean line* bisects the obtuse angle; the *normal line* is that axis which is perpendicular to the other two. The orientation of the mean lines, *i.e.*, their relative situations in parallellism to one or another crystallographic axis, is the first problem in the study of the optical characters in a crystal. Next, we have to determine the angle between the optic axes, and here the dispersion, *i.e.*, the difference of angle for different colours has to be taken into account. In connection with the first of these problems we have to contemplate the cases in which the angle between the optic axes becomes *nil*—the axes themselves coinciding with the first mean line. Let, for instance, $a=b$ (where a, b, c, are the three velocities represented in the order of magnitude). In this case, then, the ellipse has b and c for the ratios of its principal axes, the radius of the circle being represented by b; the wave surface then becomes defined by a sphere, and a prolate spheroid touching the sphere internally, the common axis of the two figures being on the axis of least velocity. This then would be a uniaxal crystal, positive in optical character, the ordinary ray being the quicker and represented by the (external) sphere. Where $c=b$ the crystal is negative; the common axis is that representing the greatest wave velocity; the ellipse is external to the sphere and the ordinary becomes the slower wave. So, too, a biaxal crystal will be conventionally termed positive or negative, according as its first mean line coincides with the axis of least or greatest elasticity.

Returning to the subject of dispersion it was shown that this character presented itself under two conditions, one in which the directions of the axes of wave velocity were the same for all colours, the other in which the directions of those axes were not coincident. Without entering upon an explanation of the beautiful isochromatic curves and the black cross or black hyperbolas intersecting the optic "eyes" of a crystal when examined in a polarizing apparatus, it was shown that whereas in the case of the plane containing the optic axes lying in or being perpendicular to the plane of polarization, the figure for any one colour, say red, would be black at the point if emergence of an optic axis but red around it, and then rings alternately *black* and *red*; in the case of the plane being at an angle of 45°, the axial point would be red surrounded by a black ring, and then rings alternately *red* and *black*. The result of this last case is that if the blue "eyes" were external to the red, the "eye" which is black, as far as the red is concerned, would be illuminated by the first blue ray, etc. Whence the character of the dispersion may be predicated as being in the inverse order of the colours which fringe the hyperbolas on their inner and outer edges as they traverse the "eye" of the section.

As to the kind of symmetry which crystals may present, it will be obvious that in the orthorhombic system, dispersion of the optic axes is alone possible, the mean lines necessarily coinciding in direction with the crystallographic axes. Thus sections of crystals of cerussite arragonite, and barytes were exhibited on the screen by means of the electric light and polarizing apparatus, the first illustrating the case where the red rays are more dispersed than the blue, whilst in the second and third the blue rays are more dispersed than the red. Sections of brokite and ammonio-magnesic-chromate were shown to illustrate the case of crystals in which the first mean line for red coincided with one axis, that for blue with an axis perpendicular to it. In the oblique system with its single plane and single axis of symmetry, the conditions for dispersion are more widely varied; in this system besides the dispersion of the optic axes we have three kinds of dispersive distribution of one or other of the mean lines. 1. The first mean line may coincide with the axis of symmetry, the second mean line and normal line lying in the plane of symmetry, in which they may be distributed. This is the *crossed dispersion* of Des Cloizeaux; it was illustrated by a section of a crystal of borax; the isochromatic figures in this case are centro-symmetrical. This may be termed *centro-symmetrical dispersion.* 2. The second mean line coincides with the axis of symmetry; the first mean line being distributed in the plane of symmetry. In this case, the figures presented are symmetrical to a line perpendicular to the line that would join the optic axis for any particular colour. It is the *horizontal dispersion* of Des Cloizeaux. It was illustrated by Adularia. It might perhaps be more correctly called *perpendicular dispersion.* 3. The first and second mean lines are distributed in the plane of symmetry; the figures are in this case symmetrical to the line passing through the centres of all the "eyes," which is the trace of the plane of symmetry, this is the *inclined dispersion* of Des Cloizeaux, and might be called *euthy-symmetrical dispersion.* This variety was illustrated by a section of gypsum, and the effect of heat in changing the character of the dispersion into a dispersion of the horizontal kind was most beautifully shown, the optic axis closing in upon the centre of the figure, but unsymmetrically, by reason of the axial dispersion, and then opened out again along a line perpendicular to their former direction. In the anorthic system where there is no coincidence of the mean lines with any crystallographic axis, either of the kinds of dispersion last described may concur together with axial dispersion.

The Lecturer then proceeded to discuss the mode of determining the symmetry or system of a crystal by finding the directions in it or in sections cut from it in, and perpendicular to, which light vibrations will be performed, *i. e.*, the determination of the directions of maximum darkness, when the crystal or the section is turned round between crossed Nicols. The first thing to know is the plane of polarization of the entering light, which we will suppose to be indicated by a vertical spider-line in the eye-piece of a microscope, a minute crystal or crystals may now be placed on the stage of the microscope, and the stage revolved until the light ceases to pass through one or other of the crystals. With the aid of a rotating spider-line and a graduated circle, the direction of any of the edges of the crystal may now be determined in respect to the vertical spider-line, *i. e.*, in respect to the directions of the principal sections of the particular section of the crystal. By comparing the results obtained in this way from the various crystals with the kinds of symmetry which prevail in different systems it is often possible to determine the system to which the crystals belong. Where we are dealing with crystals in which the optical characters have been determined, it is generally possible to identify the substance, provided its crystallography and optical characters have been well studied. A beautiful application of this principle, in the latter form, is that by which Des Cloizeaux discriminated between the felspars, by determining the angle in which the trace of the plane of the optic axes intersects with the edge formed by the planes of cleavage. Sections of the felspars were exhibited on the screen, including some of microline, the felspar in which Des Cloizeaux has recently recognized a potash isomorph of albite, so that the potassium felspar is now known to be dimorphous. The method of determining the exact position of maximum darkness in a section or a crystal has recently been greatly enhanced in delicacy by M. Emile Bertrand, by means of a quadrant biquartz plate, with the aid of which the slightest deviation to right or left of the crystal from its true position imparts tint to the little plate which is placed in the focus of the eye-piece. This instrument was exhibited on the lecture table.

Professor Odling, in proposing a vote of thanks (which was carried by acclamation), said that the Fellows must feel greatly obliged to Professor Maskelyne for his endeavours to reassociate chemistry and crystallography, and all must have appreciated the lucid and earnest lecture, as well as the novel and beautiful illustrations.

In his reply to the unanimous vote of thanks, Professor Maskelyne mentioned that a Crystallological Society had been formed to carry out some of the objects which he had mentioned in his lecture; it consisted of chemists to make suitable groups of crystals and of crystallographers to examine the crystals when made.

The society then adjourned to Thursday, April 19th, when the following papers will be read:—

"On the Estimation of Manganese in Spiegeleisen and of Manganese and Iron in Manganiferous Iron Ores," by E. Riley.

"On Certain Bismuth Compounds, Part V.," and "On a Method for detecting small quantities of Bismuth," by M. M. Pattison Muir.

SOCIETY OF ARTS.

Certain Relations between Plants and Insects.*

BY SIR JOHN LUBBOCK.

(*Concluded from page* 825.)

The genus *Sitaris* (a small beetle allied to *Cantharis*, the blister-fly, and to the oil-beetle) is parasitic to a kind of bee (*Anthophora*), which excavates subterranean galleries, each leading to a cell. The eggs of the sitaris, which are deposited at the entrance of the galleries, are hatched at the end of September or beginning of October, and M. Fabre not unaturally expected that the young larvæ, which are active little creatures with six serviceable legs, would at once eat their way into the cells of the anthophora. No such thing: till the month of April following they remain without leaving their birthplace, and consequently without food; nor do they in this long time change either in form or size. M. Fabre ascertained this, not only by examining the burrow of the anthophoras, but also by direct observations of some young larvæ kept in captivity. In April, however, his captives at last awoke from their long lethargy, and hurried anxiously about their prisons. Naturally inferring that they were in search of food, M. Fabre supposed that this would consist either of the larvæ or pupæ of the anthophora, or of the honey with which it stores its cell. All three were tried without success. The first two were neglected, and the larvæ, when placed on the latter, either hurried away or perished in the attempt, being evidently unable to deal with the sticky substance. M. Fabre was in despair: "Jamais expérience," he says, "n'a éprouvé pareille déconfiture. Larves, nymphes, cellulles, miel, je vous ai tous offert; que voulez-vous, donc, bestioles maudites!" The first ray of light came to him from our countryman, Newport, who ascertained that a small parasite found by Leon Dufour on one of the wild bees, was, in fact, the larva of the oil beetle. The larvæ of sitaris much resembled Dufour's larvæ. Acting on this hint, M. Fabre examined many specimens of anthophora, and found on them at last the larvæ of his sitaris. The males of anthophora emerge from the pupæ sooner than the females, and M. Fabre ascertained that, as they come out of their galleries, the little sitaris larvæ fasten upon them. Not,

* From the *Journal of the Society of Arts*, February 23, 1877.

however, for long: instinct teaches them that they are not yet in the straight paths of development; and, watching their opportunity, they pass from the male to the female bee. Guided hy these indications, M. Fabre examined several cells of the anthophora; in some, the egg of the anthophora floated by itself on the surface of the honey, in others, on the eggs as on a raft, sat the still more minute larva of the sitaris. The mystery was solved. At the moment when the egg is laid, the sitaris larva springs upon it. Even while the poor mother is carefully fastening up her cell, her mortal enemy is beginning to devour her offspring; for the egg of the anthophora serves not only as a raft, but as a repast. The honey which is enough for either, would be too little for both; and the sitaris, therefore, at its first meal, relieves itself from its only rival. After eight days the egg is consumed, and on the empty shell the sitaris undergoes its first transformation, and makes its appearance in a very different form.

The honey, which was fatal before, is now necessary; the activity, which before was necessary, is now useless; consequently, with the change of skin, the active, slim larva changes into a white, fleshy grub, so organized as to float on the surface of the honey, with the mouth beneath and the spiracles above the surface: "grâce à l'ebonpoint du ventre," says M. Fabre, "la larve est à l'abre de l'asphyxie." In this state it remains until the honey is consumed; then the animal contracts, and detaches itself from its skin, within which the further transformations take place. In the next stage, which M. Fabre calls the pseudo-chrysalis, the larva has a solid corneous envelope and an oval shape, and in its colour, consistency, and immobility reminds one of a *Dipterous pupa*. The time passed in this condition varies much. When it has elapsed, the animal moulds again, again changes its form; after this it becomes a pupa, without any remarkable peculiarities. Finally, after these wonderful changes and adventures, in the month of August the perfect sitaris makes its appearance.

In fact, whenever in any group we find differences in form, or colour, we shall always find them associated with differences in habit.

To return, however, to my principal subject, the sphinx caterpillars. For such an inquiry as this, the larvæ of Lepidoptera are particularly suitable, because they live an exposed life; the different species even of the same genus often feed on different plants, and are therefore exposed to different conditions; and last, not least, because we know more about the larvæ of the Lepidoptera than of any other insects. The larvæ of ants all live in the wet; they are fed by the perfect ants, and being therefore all subject to very similar conditions are all very much alike. It would puzzle even a good naturalist to determine the species of an ant larva, while, as we all know, the caterpillars of butterflies and moths are as easy to distinguish as the butterflies and moths; they differ from one another as much as, sometimes more, than the perfect insect.

There are five principal types of colouring among caterpillars. Those which live inside wood, or leaves, or underground, are generally of a uniform pale hue; the small leaf-eating caterpillars are green, like the leaves on which they feed. The other three types may, *si parva licet componere magnis*, be compared with the three types of colouring among cats. There are the ground cats, such as the lion or puma, which are brownish or sand colour, like the open places they frequent. So also caterpillars which conceal themselves by day at the roots of their food-plant tend, as we have seen, even if originally green, to assume the colour of earth. The spotted or eyed cats, such as the leopard, live among trees; and their peculiar colouring renders them less conspicuous by mimicking spots of light which penetrate through foliage. Lastly, there are the jungle cats, of which the tiger is the typical species, and which have stripes, rendering them very difficult to see among the brown grass which they frequent. It may, perhaps, be said that this comparison fails, because the stripes of tigers are perpendicular, while those of caterpillars are either longitudinal or oblique. This, however, so far from constituting a real difference, confirms the explanation, because in each case the direction of the lines follows those of the foliage. The tiger that walks horizontally on the ground, has transverse bars; the caterpillar, which clings to the grass in a vertical position, has longitudinal lines, while those which live on large veined leaves have oblique lines like the oblique ribs of the leaves.

Thus then, I think, we see reasons for many at any rate of the variations of colour and markings in caterpillars which at first sight seem so fantastic and inexplicable. I should, however, produce an impression very different from that which I wish to convey, were I to lead you to suppose that all these varieties have been explained or are understood. Far from it, they still offer a large field for study; nevertheless I venture to think the evidence brought before you to-day, however imperfectly, is at least sufficient to justify the conclusion that there is not a hair, or a line, not a spot or a colour, for which there is not a reason, which has not a purpose and a function in the economy of Nature.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, W.C., on Thursday evening, March 22, 1877, when a paper was read by Mr. A. P. Luff, F.C.S., "On the Common Metals, and their Chief Uses," of which the following is a short abstract:

The substances to which the term metal is applied all belong to the class of bodies known as elements. All elements, however, are not metals, but they consist of two classes—metals and non-metals. Of the sixty-six elements fifty-two are metals; of these fifty-two metals only about twenty-four have received any practical applications. Generally when a metal unites with a non-metal, the product does not possess any metallic characters; to this there are some noteworthy exceptions. Steel consists of iron united with about one per cent. of the non-metal carbon; phosphor bronze consists of brass united with a small percentage of the non-metal phosphorus, yet they both possess metallic characters to a high degree. The metals which are found in nature in the free state are bismuth, copper, gold, iron, mercury, platinum, and silver: three of these, viz., gold, platinum, and silver are "noble metals," that is, they possess only a feeble affinity for oxygen. Whenever a metal displaces another metal from one of its compounds, evolution of heat takes place. For instance, copper will displace mercury from a solution of mercuric chloride, because the copper in uniting with the chlorine evolves more heat than mercury does in uniting with chlorine. One property possessed by metals when in a compact state is that of lustre, or the power of reflecting light. Metals, however, in a fine state of division do not possess lustre; for instance, platinum black, which consists of finely divided platinum, is quite black. Another example is found in Faraday's ruby gold, where very fine particles of gold suspended in water communicate to the liquid a ruby colour. Most metals are white, but copper possesses a reddish colour, and gold a yellow colour. Metals are generally opaque, but gold when beaten into leaf the $\frac{1}{200000}$th of an inch in thickness, transmits light, and this transmitted light is of a green colour. Metals vary very much in their density. Of the common metals, aluminum is a very light one, and on account of this property it is frequently used in the construction of the tubes of telescopes. Perhaps the most valuable quality possessed by any metal is that which steel possesses of acquiring and retaining magnetism, for by this means the magnet, so invaluable to man, can be constructed.

Experiments were shown, and reference was made, to the squirting of metals into wires and pipes, the conduction of heat and electricity by metals, the Davy lamp, the sonority of metals, the founding of metals, the formation of alloys and the separation of their constituents, fluid-pressed steel, annealing, hardening, tempering, electro-gilding, electro-silvering, use of metals in coinage, pewter, britannia-metal, and tin-lined lead tubes.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE MOLECULE AND THE ATOM.*

BY PROFESSOR G. F. BARKER.

(*Continued from p.* 805.)

The fourth and last method is one based by Thomson,† and subsequently by Maxwell,‡ on the phenomena of gaseous diffusion. It is well known that if one gas be placed in presence of another, the lighter being uppermost, after a time, longer or shorter according to the density of the individual gases mixed together, they will be found thoroughly intermingled. Loschmidt, in 1865,§ from his experiments, and subsequently Clausius,‖ on theoretical grounds based on the theory of molecular motion in gases, which we shall presently refer to, has proved that "the average length of the free path of a particle from collision to collision bears to the diameter of each molecule the ratio of the whole space in which the molecules move, to eight times the sum of the volumes of the molecules." Hence the number of molecules in the unit of volume is equal to the square of this ratio, divided by the volume of a sphere whose radius is equal to the average length of free path. If we assume with Maxwell, that in a liquid the volume of any substance is nearly that occupied by the molecules themselves in contact, we see that, since experiment renders doubtful the condensation of any known gas to one forty-thousandth of its volume without reducing it to a liquid, the ratio of the volume of a gas to the combined volume of all the molecules contained in it is as 40,000 to 8 or as 5000 to 1. But this, by the statement of Clausius above given, is the ratio which the length of the free path of a molecule of gas bears to the diameter of this molecule. If then we accept one ten-thousandth of a millimeter as the length of a free path, which is the value given by Joule and Maxwell, it follows that as this length is five thousand times that of the diameter of the molecule, the diameter of the molecule must be one fifty-millionth of a millimeter.¶

Moreover, the number of molecules in a cubic centimeter of any gas, being the quotient of the square of the above ratio $(5000)^2=25,000,000$, divided by the volume of a sphere whose radius is one hundred-thousandth of a centimeter, cannot be greater than six thousand million million million (6×10^{21}). In the case of liquids and solids, which vary in density from five hundred to sixteen thousand times that of atmospheric air, the number of molecules in a cubic centimeter may vary from three million million million million to a hundred million million million million (3×10^{24} to 10^{26}). And the distances from centre to centre of these molecules, assuming that they are arranged in the form of a cube, would be from one fourteenth-million to one forty-six-millionth of a millimeter.

From the rather remarkable coincidence of the results which have just been obtained from independent and widely different data, it may be concluded with a high degree of probability that in ordinary liquids or solids the diameter of the molecule is less than the ten-millionth and greater than the two hundred-millionth of a millimeter.

The next point of interest concerning the molecule is its weight. The relative weight of molecules is readily determined, and is frequently used in the fixing of rational formulæ. From the deduction from Avogadro's law already given, that equal volumes of all gases contain the same number of molecules, it necessarily follows that the weight ratios of equal volumes of all gases must be also the weight ratios of their molecules, which is Gay Lussac's law.* Because, for example, a liter of hydrogen weighs ·0896 gram and one of oxygen weighs 1·4298 gram—the weight ratios here being 1 : 16—it follows that the molecule of oxygen must be sixteen times as heavy as the molecule of hydrogen. If the hydrogen molecule be assumed as a standard, the molecular weight of any gas will be represented by its weight-ratio. Since, for reasons presently to be given, the molecular weight of hydrogen is called two, the molecular weight of any other substance in the state of gas will be twice the weight-ratio; *i.e.*, twice the density. As the molecule does not lose or gain matter when the physical state is changed, the molecular weight of a body in the liquid or solid state is the same as in the gaseous. As to the absolute weight of a molecule, it may be readily obtained, of course, by dividing the weight of a cubic centimeter of the substance in the gaseous state by the number of molecules contained in that volume of hydrogen, as already given. This has been done for several gases by Professor Maxwell.†

There is one circumstance connected with the question of molecular weight which deserves some attention. I refer to physical isomerism. Several years ago, in his excellent researches on radiant heat, Tyndall observed discrepancies between the absorptive power of gases for heat as obtained by experiment, and that which would have been predicted on the theory of molecular structure thus far assumed.‡ If it be true, as the modern theory supposes, that radiation is but the communication of molecular vibrations to the ether, and absorption, which is its precise correlate, only the reception of motion from it, then it is obvious that radiating and absorbing power should be increased by molecular complication. And this in general is what Tyndall's experiments showed to be true, olefiant gas being a better absorber than marsh gas, marsh gas than carbon dioxide, and carbon dioxide than nitrogen or any simple gas. But there are exceptions to the rule; thus, the absorption of hydrogen being unity, that of chlorine is 60, that of bromine is 160, and that of hydrobromic acid is 1005, although the molecular structure of all these bodies is commonly regarded as similar. A consistent application of the theory of molecular complication would require us to suppose aggregations of simple molecules which exist and act as the absorbing and radiating particles. This opens the question at once: Is the chemical molecule, which is defined as the least collection of atoms which can exist in the free state, identical with the physical molecule? Or are there varieties of the latter made up of several of them united into one? The assumption that there are such varieties is the basis of the theory of physical isomerism. It has been invoked to account for the different rotatory action on polarized light of chemically identical forms

of amyl alcohol and other bodies.* But the most remarkable instance of it, and one which, it must be admitted, goes far to establish the hypothesis, is the recent discovery by Laubenheimer† of four forms of nitrometa-chlornitrobenzene, three of which are solid and one liquid. All these forms are chemically identical, and indeed are capable of conversion by very simple means the one into the other. But physically they are entirely distinct. Of the solid forms, two crystallize in the monoclinic system, though with different axis ratios and different angles of inclination; the other crystallizes in the orthorhombic system. The α form fuses at 36°·3, the β form at 37°·1, and the γ form at 38°·6. The discoverer explains these phenomena very properly upon the hypothesis of Naumann,‡ that the crystal molecule of the more stable modification is formed from a greater, the less stable from a smaller number of chemical molecules.

A final question remains to be asked concerning molecules: Are they at rest, or have they relative motions among themselves? Just at the close of the last century, Rumford§ proved most conclusively that work could be converted into heat. And as the conversion seemed perpetual, he argued most acutely that heat was not matter, but motion. It is entirely unnecessary for us to stop here to give the proofs of the dynamic theory of heat. The magnificence of the science of thermo-dynamics which rests upon it is the best evidence of its truth. But there is one phenomenon worth considering for a moment, because it furnishes direct proof of this motion. This is the phenomenon of diffusion. The interpenetration of one gas by another, even through a porous partition, is due, according to the kinetic theory of gases of Clausius,‖ to the actual passage of molecules from one into the other in virtue of their actual velocities. In gases all molecules move in straight lines, and hence impinge against each other, and against the walls of the containing vessel. The pressure, then, which a given volume of gas exerts upon a given surface is a function both of the number and of the velocity of the molecules. If we increase the number of molecules in a given volume, *i.e.*, the density, we increase the pressure proportionately. This is the law of Boyle.¶ If we increase the velocity of the molecules, *i.e.*, the temperature, we cause expansion, since the number of impacts is increased. Moreover, since all gases have the same number of molecules in equal volumes, they all expand equally for an equal increase of temperature. This is the law of Charles.** In liquids as well as in gases, we have the phenomenon of diffusion due to the same cause. But since the molecular motion is very much restricted, the diffusion takes place with corresponding slowness.

Granted now the motion, what are its quantitative relations? How fast do molecules move? The first answer to this question was given by Joule,†† who sought to ascertain, by calculation, what the molecular velocity must be in hydrogen to produce in a given volume the pressure observed. The result showed that in this gas, at the ordinary temperature and pressure, the velocity of mean square of the hydrogen molecules was 6097 feet per second, or about seventy miles a minute. As they move in straight lines, and as the length of the free path between two successive encounters is only from one twelve-thousandth to one twenty-thousandth of a millimeter, it may easily be calculated that the number of collisions made by each hydrogen molecule in a single second is seventeen thousand seven hundred million. Maxwell has calculated these values for oxygen, carbonic oxide, and carbonic dioxide.* Calling the velocity of hydrogen 1859 meters per second, that of oxygen is 465 meters, that of carbonic oxide 497, and that of carbonic dioxide 396. The number of collisions made by each molecule per second is, for oxygen 7646, for carbonic oxide 9489, and for carbonic dioxide 9720 millions. In air, the number of collisions made by each molecule is only one half of that above given for hydrogen, and the average molecular velocity one fourth as great as for the latter gas.

Having now discussed pretty fully the molecule, we come to ask of it as we did before of the mass—Is it divisible? In the case of the salt, to use our previous illustration, we observed that so soon as the molecule was reached, further subdivision produced particles of matter entirely unlike salt, called chlorine and sodium. The evidence that these particles are really smaller than molecules, is found in Hofmann's argument for the composition of hydrochloric acid.† Suppose a certain volume of hydrogen to contain 1000 molecules, then the same volume of chlorine will contain 1000 molecules also. If now these two volumes be mixed and then caused to combine, there will result two volumes of hydrochloric acid gas containing 2000 molecules. If now the new gas be analysed, each molecule of it will be found to contain both hydrogen and chlorine. The particles of chlorine and the particles of hydrogen must therefore be less than the molecules of which they are parts. As each molecule of the compound gas contains one atom of chlorine and one of hydrogen, the 2000 molecules must contain 2000 of each. But the 2000 atoms of hydrogen came from the 1000 molecules, and the same is true of the chlorine; hence, a molecule of hydrogen is composed of two atoms. An atom, then, is the smallest portion of matter which can be reached by nature's processes of subdivision. It is generally defined as the smallest particle of simple matter which can enter into the composition of a molecule.

Let us pause here a moment to say that no metaphysical conception at all attaches to the modern idea of atom. With the question whether it can be divided, chemistry does not concern itself. The word atom came into use to express a universally conceded fact expressed in the law of definite proportions, namely, that a certain definite quantity of matter by weight combines with a similar definite quantity of some other matter. The smallest quantity of any substance which is found ever to enter into combination is called an atom. No real objection, it would seem, can lie against the idea of atom when defined in this way. If we concede that the molecule has as real an existence as a mass, I see no reason for not conceding the same to the atom.

The first point of chemical interest about an atom is its weight. The relative weight of an atom referred to that of hydrogen as the unit is called its atomic weight, and is one of the most important of chemical constants. To ascertain the atomic weight of an element, two distinct processes are required: First, the ratio in which it combines with some other substance whose atomic weight is known, is necessary; and second, the molecular weight of the compound analysed must be obtained. Thus, given marsh gas to fix the atomic weight of carbon: Analysis shows that in 100 parts of marsh gas, there are 75 parts of carbon, and 25 of hydrogen, which is in the ratio of 3·1. Three parts of carbon then unite with one of hydrogen. By the balance, one liter of marsh gas

† 'Einleitung in die moderne Chemie.' Fifth ed., 238.

weighs 0·716 gram, or eight times as much as a liter of hydrogen. Hence, its molecule must be eight times as heavy; and as the hydrogen molecule weighs two, the molecular weight of marsh gas is sixteen. Now, of these sixteen parts, we have shown above that three fourths is carbon and one fourth hydrogen. One molecule of marsh gas contains, therefore, twelve parts of carbon, and four parts of hydrogen. On comparing this quantity of carbon with that contained in other single molecules into which carbon enters, it is found to be the smallest. By our definition therefore, twelve, being the smallest quantity by weight in which carbon enters into the formation of a molecule, is its atomic weight.

The absolute weight of an atom is a datum of no practical value at present in chemistry. Yet as a matter of curiosity as showing the minuteness of the quantities with which we are dealing, it may be worth while to calculate it from the data already given concerning molecules. If we take Thomson's estimate, a cubic centimeter of hydrogen cannot contain more than six thousand million million million molecules. As now this cubic centimeter weighs ·0896 milligram, it is obvious that the weight of one molecule of hydrogen is ·0896 divided by $(6 \times 10_{21})$ milligrams. This is equal to $·015 \times 10_{21} = ·000,000,000,000,000,000,000,015$. As a hydrogen atom weighs one half as much as its molecule, we infer that its weight cannot be less than ·000,000,000,000,-000,000,000,0075 milligram, being seventy-five ten-million-million-million-millionths of a milligram. On Maxwell's hypothesis,* that a cubic centimeter of hydrogen contains but nineteen million million million molecules, the weight of an atom would be considerably more, namely, two hundred and thirty-five hundred-thousand-million million-millionths of a milligram, or about three hundred times as great.

Parliamentary and Law Proceedings.

Illegal Sale of Poison at Sutton-in-Ashfield.

At the Mansfield Petty Sessions, on Thursday, Mar. 29, before Colonel Salmond and Captain Need, R.N., Henry Slack, described as a shopkeeper, was summoned for that on the 13th of February, 1877, he did unlawfully sell a certain poison, to wit, "laudanum," which poison when sold was contained in a bottle, and which bottle was not distinctly labelled with the name of the article and the word "poison," and that the name of the said Henry Slack, the seller of such poison, was not placed upon the bottle.

This was a case which arose from an inquest held upon a child, in which the mother had given it a dose of laudanum, mistaking it for cordial, there being no label on the bottle, which was procured from defendant's shop, and the present proceedings were instituted at the suggestion of the Coroner (Mr. Heath).

Mr. Hibbert, of Mansfield, appeared for the defence, and said he pleaded guilty on behalf of the defendant to save the trouble of going at length into the case. Colonel Salmond asked if he were going to say anything in defence. —Hr. Hibbert: I shall wish to make a few remarks.

Mary Ann Bilton, a married woman, living at Sutton-in-Ashfield, was then called, and said on the 13th February, she asked a Mrs. Turner if she would let her little boy fetch her a pennyworth of cordial and some butter. In about an hour after the boy brought what she supposed to be the cordial, and during the night she gave it her child, which afterwards died. Was sure she sent for cordial.

Superintendent Bexon: Was there anything on the bottle; any label of any description?—Witness: No, sir. (The bottle was here produced.)

George Turner, a little lad, aged nine years, spoke to going for the cordial, and in reply to Mr. Hibbert said he was quite sure he did not ask for laudanum.

Superintendent Hallam produced two bottles, which he received from Dr. Harding. He had shown them Mrs. Bilton, and she identified one as that from which she gave the laudanum. The other was a bottle containing poison, and which he took possession of. It was labelled with the words "Laudanum—Poison."

Mr. Hibbert, in addressing the bench, said he did not wish to take exception to anything that had been said, although there was nothing to show that the compound was absolutely laudanum. The defendant regretted that this accident should have happened, and as they had it in evidence that it was sold by the daughter and not by himself, he asked them to be as lenient as they possibly could. Defendant was not at home, and he had assured him (Mr. Hibbert) that the laudanum was kept there for his own use, as he was troubled very much with rheumatics, and he had kindly sold it to colliers and others when they had been injured. Defendant also assured him that he had given instructions that it should not be sold, but the daughter had been away from home and did not know. She was also under the impression that laudanum was asked for, but if her father had been at home he would not have allowed the sale. He desired him (Mr. Hibbert) to express his deep regret for what had happened, and that it was not his intention to keep any more laudanum in his house.

Colonel Salmond said it made no earthly difference who it was sold by, whether daughter, son, or servant, as he was quite as responsible as a publican was for the order of his house, and he would have to pay £3 and costs. The money was paid.—*Nottinghamshire Guardian.*

Suicide with Prussic Acid.

On the 28th ult. an inquest was held by Mr. Heath at Mansfield Woodhouse, touching the death of Rebecca Bowler, aged 39 years. It appeared that the deceased, who lived as housekeeper to Dr. Curran, had on the previous Sunday had some angry words with her employer, and afterwards was found dead in her bed with a bottle containing prussic acid, which had been taken from the surgery, close by her. The medical evidence left no doubt that prussic acid had been the cause of death. The jury returned a verdict that deceased died from a dose of prussic acid, but that there was not sufficient evidence to prove her state of mind when she took it.

Review.

Year Book of Pharmacy: Comprising Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foregn Journals, from July 1, 1875, to June 30, 1876. With the Transections of the British Pharmaceutical Conference at the Thirteenth Annual Meeting, held in Glasgow, September, 1876. London: J. and A. Churchill.

At last the 'Year Book' for 1876 is ready, and we hope that now its prompt delivery, together with the Editor's apology for the delay in its appearance, will be successful in smoothing the sadly ruffled feelings of at least those of the many members of the Conference who have confided to us their distress because of its non-reception.

As is known, the volume supplied annually to the members of the Conference consists of two principal sections, the 'Year Book' proper, which this year is the work of Mr. Louis Siebold, and the 'Transactions,' for which the honorary secretary, Professor Attfield, is responsible.

So far as we are able to judge from a rather hasty inspection, the new volume in both its sections will be a worthy companion of its predecessors as a record of the progress of pharmacy, and as a handy-book of reference on the pharmacist's book shelf.

The first section contains 380 pages, or about 24 pages less than last year, and includes an "Introduction" and a large number of well-prepared abstracts of British and Foreign papers on a wide variety of subjects allied to pharmacy. These we consider to be very thoroughly representative of the literature of the twelve months ending June, 1876. Of course, considering that this includes a period now a year and three quarters distant, whilst the most recent papers date nine months back, many of these abstracts will suggest "auld lang syne," but to a very considerable extent this is unavoidable under the conditions of the case. One of them, however (Méhu on Iodized Cotton, p. 361), proved to be a very "auld acquaintance," having appeared in this Journal in September, 1871, and subsequently in the 'Year Book' for 1872 (p. 375). But, French in its origin, it has recently become rejuvenescent in a German medium, through which it is now quoted. This, however, is only one of numberless similar traps that lie round the feet of an editor of a Year Book, and the wonder is that he is not caught more frequently.

Although we consider the work to be very creditable to all who have taken part in it, we shall venture, as the book is placed in our hands for criticism, to make one or two queries and suggestions which may be taken for what they are worth. First, is an "Introduction" desirable, and if so, what should be its nature? In our opinion, it is, but it should not—even in part—be a mere recapitulation of the principal facts recorded during the year; this story would be sufficiently, and, indeed, better told by the abstracts themselves, were they systematically arranged. If, however, it were limited to the linking of current investigations or reports with work done in former years, and the discussion of their mutual bearings, and the record of the personal experience of the editor in respect to some of them, such as occur here and there in the present volume, it would, we think, become more useful and interesting. For an indication of what we mean, we would refer to the Introduction to the Yearbook for 1872. We recently alluded to this question, when noticing the American volume, and pointed out how such recapitulations might degenerate into cataloguing and involve repetitions, and in the present case it allows us to be told twice in twenty lines, that M. Comaille has made out the solubility and fusing-point of caffeine, and suggested a method for its detection.

Again, would it not be better to drop the title "Pharmaceutical Chemistry" for one of the divisions in favour of the simple one of "Chemistry," placing such portions as have a specially pharmaceutical bearing under the existing head of "Pharmacy?" Of course, there are reasons why this should not be; but we confess we do not quite understand why a note on Gallium should be classed under "Pharmaceutical Chemistry," one on the Poisonous Properties of the Alkali Metals under "Pharmacy," and one on the Reaction of Hydrocyanic Acid with Calomel under "Notes and Formulæ."

With respect to the 'Transactions' we have little to say. The papers read at Glasgow have already appeared in this Journal, and they have evidently been carefully seen through the press. But as a final query, we would ask whether it is worth while to print the names of the members twice over, or whether the space occupied by one list might not be more usefully devoted to the bibliography of the year, or even saved altogether.

Obituary.

Notice has been received of the death of the following:—

On the 16th of March, 1877, Mr. James Nichols, Chemist and Druggist, Tideswell. Aged 76 years.

On the 2nd of April, 1877, Mr. Charles Edward Bishop, Chemist and Druggist, Oxford Street, London. Aged 23 years. Mr. Bishop had been an Associate of the Pharmaceutical Society since 1871.

On the 10th of April, 1877, Mr. Francis Thomas Atkins, Pharmaceutical Chemist, Lewisham High Road. Aged 87 years. Mr. Atkins had been a Member of the Pharmaceutical Society since 1842.

On the 6th of April, 1877, Mr. Stephen Carr Sagar, Chemist and Druggist, Sevinton. Aged 66 years.

Correspondence.

Medicine Measures.

Sir,—I trust it will not be considered an unprofitable occupation of your space if I reply to some of the criticisms passed upon the note on medicine measures, which, in my absence, Professor Attfield was so good as to read for me at the late Pharmaceutical Meeting.

If I were to consider myself only in the matter I would be content with my own experience and the satisfaction I have felt in the actual use of the measures which I had begun to experience before I wrote the note, and which is participated in by many of my customers. But so long as Mr. Martindale and Mr. Plowman advocate a change in the official value of the terms teaspoon and tablespoon, and so many others advocate a retention of the use of these terms, to express their old value, I feel that a further effort is still called for to clear away the difficulties—principally imaginary—which attend the little change which I have advocated.

There is so strong a tendency to magnify the difficulties of a prospective change, and to overlook the incongruities of an old custom, that I am by no means surprised at the hesitation expressed regarding the desirability of the suggested change, while at the same time I am satisfied that it only requires trial to prove its very great superiority to the present custom.

Mr. Greenish's difficulty—that we should require so many sizes, and that a graduated glass will eventually have to be used—does not interfere at all with my custom; those who will buy glass measures and understand them will not be put to any disadvantage by a new form of measure being at their disposal. There will be no more difficulty in using a graduated glass or a wine-glass, as a measure, consequent upon the substitution of a half-ounce measure for a tablespoon, but there will be inextricable confusion and difficulty if graduated glasses continue in use indicating half an ounce by the term tablespoonful, and medical men adopt the same term to mean 6 drachms, as Mr. Martindale and Mr. Plowman think should result from hospital experience, or if dessertspoon were to be the translation of ℥ss, as I before stated, was the custom with one of our local practitioners.

Mr. Bland's objection that so long as medical men prescribe by spoonsfuls the pharmacist would be obliged so to label does not militate against the suggestion I made that the label should be written "a tablespoonful (half an ounce) thrice a day."

He also objects to the expense of supplying measures *gratuitously*, which is not part of my suggestion. My custom in dispensing is to give, but if I found the giving too burdensome, I would prefer in most cases still to supply a measure, but to regard it as part of the cost of the dispensing, and to charge accordingly, and in any case I should think a simple and cheap measure a less serious outlay than the careful graduation of the bottle with a diamond, which Mr. Bland says he adopts. Mr. Long, on the other hand objects to entertaining the consideration of cheapness, and seems to think the form of measure I have adopted will be wanting in accuracy.

Though I have adopted a particular form with the view to cheapness and accuracy, if that form were unsuccessful, it would militate against a point of detail in my working, but not against the general principle advocated; but at the same time, I must suppose that Mr. Long spoke without full knowledge, for the measures I had made were produced by a method which secures greater uniformity than it has been my fortune to observe in graduated glasses The clay being turned down by a template produces a vessel in the first place more accurately uniform than could be produced by almost any other mechanical operation, but the clay in drying and burning contracts, and the contraction varies a little according to the temperature of the furnace. The thickness of the glaze will also vary to a small extent, but so far as my examination has gone, these sources of error are too small ever to be a serious objection to the use of earthenware measures if turned under a template.

Professor Redwood suggests that in a household where medicine is much in use, the measure-cups would accumulate and become nice playthings for the children; if so, they will learn in the infant school or nursery the meaning of ounce and drachm, a species of knowledge which the pharmacist often finds great difficulty in instilling into the understanding of his adult customers who have to use graduated glasses and the coming generation would thus be better prepared for any form of measure for small quantities of fluids. I regard Professor Redwood's suggestion to have graduated glasses marked by ounces on one side and spoonfuls on the other as very desirable for adoption during a transition period, provided he can come to terms with Mr. Martindale and Mr. Plowman as to where the spoonful graduations are to stand, whether the teaspoon is to be ʒi or ʒiss and the tablespoon ʒiv or ʒvi. I have advocated the discontinuance of the terms teaspoon and tablespoon, and I do not know that any more effectual mode of effecting their disuse could be adopted than the change advocated by Messrs. Martindale and Plowman.

I thank Professor Redwood for his suggestion, which I think really suited to the circumstances of the times, and likely to be useful to such patients as will pay for graduated glasses and learn to use them. Perhaps before long I may have to thank also Messrs. Martindale and Plowman for the beautiful confusion which will expunge spoonful graduations altogether.

Newcastle. BARNARD S. PROCTOR.

Sir,—The subject of medicine measures brought forward by Mr. Proctor at the evening meeting on Wednesday last, is one of considerable importance, alike to the prescriber, the compounder, and the patient. As far as we, the compounders, are concerned, it is our duty to make the directions of the prescriber as intelligible as possible, so that the exact quantity ordered shall be taken. I am of opinion that the measures introduced by Mr. Proctor would have the effect of complicating rather than simplifying the matter.

Mr. Martindale's suggestion that because spoons have much increased in size of late years a teaspoonful should be regarded as 1½ drachm and a tablespoonful 6 drachms would lead to much confusion. The question is not as to what is meant when a tea, dessert, or tablespoonful is ordered, as it is well understood to mean respectively ʒi, ʒii, ʒiv, but as to the best way of putting it so that the patient shall take the proper dose. Undoubtedly the use of the spoon should be abandoned in measuring medicines; as to whether prescribers use the term spoonfuls on the symbols is of little importance.

Graduated bottles of sufficient accuracy are easily obtained, and answer well; when greater accuracy is needed, as in the case of concentrated medicines, we have graduated glasses. As to the prescribing of concentrated medicines, it is often done as a matter of convenience to the patient, and should be charged for according to the number of doses contained in the bottle. We have no right to dictate to prescribers how they shall order medicines, neither does it lie in our power to insist upon the use of measuring glasses, as propounded by Mr. Long.

51, *Judd Street.* FELIX STEVENS.

COUNTER PRESCRIBING.

Sir,—It is the opinion of Mr. J. Leay, who I presume has, by means of the pharmaceutical ladder, attained to the position of M.D. or M.R.C.S., that all chemists should discourage prescribing and counter practice, and that the Pharmaceutical Society ought not to be "bound to support the prescribing chemist in his attempts to supersede the certificated medical man." If he knows anything of the policy or antecedents of that Society he must be aware that there is no probability of its being bound to support anything of the kind, and as for chemists generally, I am not aware that they are at all desirous of "superseding" the doctor.

With regard to counter prescribing, I differ entirely from Mr. J. Leay, and consider that an assistant, otherwise competent, who can prescribe, is more valuable than one ignorant of that art. I, without adopting "three mallards" for my crest, or "Quack! Quack! Quack!" as my motto, hold that it is the duty of every man to make himself as useful as he can to his fellow men in that sphere of life in which his lot is cast, and if a chemist, botanist, eclectic, allopath, or any other "path," has a knowledge, acquired by study, observation and experience, of drugs and their action in the cure or alleviation of suffering, it is his right and duty to use it. The knowledge that quinine is a remedy for neuralgia, opium for pain, sulphur for the itch, etc., is not the exclusive property of the "certificated medical man," and he who possesses it and uses it as occasions arise is not (Mr. Leay notwithstanding) to be branded as a "quack." With encroachments on our business, daily increasing in all directions, let not our foes be they of our own household; let us not stultify ourselves by rejecting counter prescribing, the right to which we have acquired by long years of usage, and which judiciously cultivated is a lawful source of profit to ourselves and of advantage to the public.

Harrow Road, W. WM. YOUNG, M.P.S.

EARLIER CLOSING.

Sir,—It was with great pleasure that I read in the Journal of Feb. 24th, that the chemists and druggists of Bayswater and Notting Hill have been roused from their lethargy by the Early Closing Association, and that they have at last found out that "the hours of business which have hitherto prevailed amongst chemists and druggists are unnecessarily prolonged and beyond what the public convenience requires."

It is with still greater pleasure that I read in the Journal of to-day that a meeting of the chemists and druggists of London is to be held for the purpose of discussing what steps can be taken to shorten the hours of business. I trust it will meet with the support it deserves and that every master and assistant who is fortunate enough to be off duty will be present.

My object in writing to you, however, is to suggest that some decision should be arrived at with regard to the supply of medicine, etc., after the shop is closed. I think it will be admitted by all that at least three-fourths of the prescriptions brought after business hours might be brought sooner, and would be if the invalid (real or imiginary) knew the medicine could not be procured, or that a higher price must be paid. The practice of bringing prescriptions late I attribute chiefly to two causes,—first, neglect of servants,—second, forgetting to take the prescription to the stores to be dispensed when the other goods were purchased in the day time. The remedy I suggest is this, that chemists should take down their present brass-door plates on which are usually engraved the inviting words—"Medicines may be obtained at any time by ringing the bell," and substitute plates with words something like the following—"Medicines urgently required may be obtained by ringing the bell, an additional charge of 50 per cent being made on usual prices. This would no doubt have the effect of curing the neglect of servants—the supporters of cooperative stores no chemist would sympathize with, and in cases of sudden illness the public would not grudge the extra charge.

A WEST END ASSISTANT.

"*Juvenis.*"—(1) We cannot answer your question, since we do not know what construction you would put upon the words "whole holidays." Certainly you would not be entitled to absent yourself from business on some so-called holidays without the permission of your master. (2) The publishing office of the *Lancet* is No. 423, Strand, W.C.

"*Quærens.*"—Bichromate of potash in no doubt poisonous, death has been known to follow in five hours after the taking of two drachms. According to Taylor the treatment consists in the administration of emetics, and a paste of carbonate of magnesia or chalk with milk, albumen or water.

M. P. S.—The chemical formula for sodium salicylate is $NaC_7H_5O_3$.

"*Omega.*"—It would be impossible to say without having some knowledge of the nature of the colouring matter.

COMMUNICATIONS, LETTERS, etc., have been received from Professor Dymock, Mr. Clayton, Dr. Davy, Mr. Horton, Mr. Summers, Mr. Hayden, Mr. Postans, Mr. Bostock, Syrupus, A. Y. Z., J. N. B.

THE PRESENCE OF AMMONIA IN BISMUTHI SUBNITRAS.

BY W. G. PIPER.

Sometime ago my attention was called to a prescription containing bismuthi subnitras, sodæ bicarb. and borax. When these were rubbed together a decided smell of ammonia was given off and as I could find no explanation of the circumstance in books, I determined to try and find out where the ammonia came from and how it got there.

I found from experiments detailed below (*a*) that the ammonia noticed was evolved from the bismuthi subnit.; (*b*) that it was present in most samples of that substance to a small but variable extent; (*c*) that the ammonia was formed by the action of the bismuth on the nitric acid during solution.

The formation of ammonia during the solution of metals in nitric acid was first noticed in connection with zinc and has since been found to take place with many other metals. I have never up to the present heard of its formation during the solution of bismuth in HNO_3. The following equation or some similar one would probably represent the reaction.

$$2Bi_2+15HNO_3=4Bi3NO_3+6H_2O+NH_3+N_2O_3$$

Bismuth and nitric acid give bismuth nitrate, water, ammonia, and nitrogen trioxide.

To the presence of nitrogen trioxide (N_2O_3) in solution, I attribute the green colour seen in unboiled solutions of bismuth in nitric acid, for although N_2O_3 is decomposed by contact with water, yet, it is, I believe, more permanent in the presence of nitric acid. The green colour referred to might easily be mistaken for that caused by the presence of copper, did it not entirely disappear on boiling.

Even though ammonia were formed in considerable quantities, yet it might be supposed that the subsequent precipitation and washing with water would remove every trace of it. We may explain the fact of its remaining in one of two ways. Either the ammonia is retained by the well known mechanical action of powders, which enables the soil to retain for the use of plants the traces of ammonia carried into it by the rain and which makes it next to impossible to remove every trace of ammonia from ferric hydrate or other substances precipitated by its aid. The chief objection to this explanation is that the quantity of ammonia formed in the act of solution is so small as almost to be lost on the precipitation of the bismuth. alb. with water. Or on the other hand we may imagine that a difficultly soluble ammonio-nitrate of bismuth is formed, which is only partially removed by subsequent washings. The tendency of bismuth to form double salts supports this suggestion, but the fact that no such double salt is known militates against it.

My aim in conducting the following experiments, was simply to prove the presence of ammonia in commercial samples of $BiONO_3$, to determine comparatively the quantity present, and to trace it to its source. My experiments therefore were not conducted with the minute accuracy and excessive care necessary in determining atomic weights or molecular composition.

Sample A. referred to below, was purchased at a good retail shop in Norwich, price 10*d*. an ounce.

B., a sample from a similar house, price 6*d*. an ounce.

C., from one of the best shops in the city: Howard's manufacture; 4*d*. an ounce.

D., from a London wholesale house, which bears a better reputation for cheapness than for quality or honesty.

The method by which the ammonia was finally estimated was a modification of that of Wanklyn and Chapman for the estimation of free ammonia in potable waters. Though this method does not give strictly accurate results, yet they are reliable for comparison, and are sufficiently delicate for my purpose. Half a gram of $BiONO_3$ was added (with 25 c.c. of saturated solution of carbonate of sodium) to a quantity of water free from ammonia in a retort connected with a Liebig's condenser. Heat was applied and the distillate collected 50 c.c. at a time in suitable jars. The ammonia was then estimated, as in water analysis, by comparing the colour in the distillate and in 50 c.c. of a solution of ammonia of known strength given by 1½ c.c. of Nessler's reagent.

Starting from the mixed "Bismuth Powders," I had to determine which constituent yielded the ammonia. The borax and bicarbonate of soda yielded no ammonia on heating with caustic potash, but the bismuthi subnit. yielded it distinctly though not freely.

To determine the quantity present, one gram of the bismuth subnitrate was placed in a suitable flask, so arranged that all ammonia given off would be absorbed by a known quantity of normal sulphuric acid (*i. e.*, a solution containing the molecular weight in grams of univalent H_2SO_4 in a litre of water; 49 grams real H_2SO_4 in one litre). Caustic soda was then added in excess from a pipette fixed in the cork, and the whole boiled to drive off every trace of NH_3. Twenty-five c.c. of normal acid were taken, and it was found that they required 25 c.c. normal ammonia to neutralize them, showing that the ammonia present in one gram $BiONO_3$ was not appreciable by ordinary volumetric methods of analysis.

A weighed quantity (about 5 grams) was then treated in the same way, and yielded NH_3=·04 per cent.

To determine the ammonia present, more accurately, the method above described was resorted to.

½ gram A treated by distillation yielded in the

1st 50 c.c. of distillate	·18	milligrams NH_3
2nd „ „	·085	„ „
3rd „ „	·035	„ „

½ gram $BiONO_3$ yields: ·3 milligrams NH_3 =·06 per cent.

½ gram B gave in—

1st 50 c.c. . .	·2	mgm. NH_3
2nd „ . .	·04	„
3rd „ . .	·01	„

½ gram yields: ·25 mgm. NH_3=·05 per cent. NH_3

½ gram C gave in—

1st 50 c.c. . .	·03	mgm. NH_3
2nd „ . .	·01	„
3rd „ . .	—	
	·04 „	=·008 per cent. NH_3

½ gram D gave in—

1st 50 c.c. .	·31	mgm. NH_3
2nd „ .	·06	„
3rd „ .	·31	„
4th „ .	—	

½ gram yields ·38 „ =·076 per cent. NH_3

The above results sufficiently prove the frequent presence of ammonia in commercial samples of white bismuth.

To discover how the ammonia came there bismuth was dissolved in nitric acid and water as directed in the Pharmacopœia and the solution decanted from the scanty black flaky precipitate. Ten c.c. were taken, neutralized by carbonate of sodium, and distilled as before.

1st 50 c.c. yielded	·05 mgm.	NH_3	
2nd " "	·01	"	
	·06	"	= ·6 per cent. NH_3

in the solution before precipitation with water.

It follows from this that much of the ammonia formed is removed by the wash-waters, but at the same time the bismuth retains an undue proportion. The better the sample is washed the less ammonia it retains (compare for this the history of C and D).

The presence of ammonia in this substance can only be regarded as an accidental impurity, and it is never present in sufficient quantities to excite the ire of a public analyst. My only object in bringing it before the pharmaceutical world is to add my mite to the history of drugs.

ADULTERATED DRUGS.

BY PROFESSOR ATTFIELD.

I think it desirable to strengthen the warning given to pharmacists in the last number of the *Pharmaceutical Journal,* respecting some unprincipled manufacturer who is endeavouring to palm off Citrate of Iron and Quinine of half the official strength by labelling it "British Pharmacopœia." Samples sent to me for analysis by different dealers during the past few weeks have each yielded quinine of what may be termed average commercial quality, but in only half the official proportion, namely, little more than eight per cent. instead of sixteen. Now, although I am not aware that there is a demand at the present time for any other than the official article, it is just conceivable that a medical practitioner might desire a weaker preparation; hence I have nothing to say just now against such a compound *per se,* if its label correctly describes its character. But distinctly to label parcels of half the official strength with the words "British Pharmacopœia" as was done in these cases, and to sell under such false colours, is simply to commit fraud. The bottles were sealed over with reddish-brown wax, impressed with the words "Citrate of Iron and Quina," while the label bore the words "Citrate of Iron and Quinia. British Pharmacopœia." The maker's name was not given. In one case the label was absent; but any use of an official name for an article of unofficial strength, at all events unless the strength is stated on the label, is, in my opinion, *suppressio veri* tantamount to *suggestio falsi.*

Attention having been drawn to the presence amongst us of an enemy to the public welfare and to the prosperity of British pharmacy, for such is the character of the drug adulterator, of course he will at once retreat. But it is more than ever necessary that British pharmacists, wholesale and retail, should exercise that vigilance which has hitherto characterized them, in themselves detecting and exposing any tampering with medicinal substances. For although it would perhaps have been unwise and impolitic to object to and resent the indignity of being placed under an Adulteration Act, no just man can expect that pharmacists will long continue to submit to the insult to their good faith and to the liability to vexatious annoyance which are involved in this position. Up to the present time they have well stood the ordeal. They have only to maintain that denunciation of adulteration and all such malpractices which they have hitherto carried on, more especially since the Pharmaceutical Society and Pharmaceutical Conference were instituted, and then application sooner or later for a repeal of the Food and Drugs Act, so far as they are concerned, will be irresistible.*

NOTE ON GLYCEROLE OF SALICIN AND GLYCEROLE OF PEPSINE AND SALICIN.

BY A. W. POSTANS, F.C.S.

A few years ago salicin (which has the chemical formula $C_{13}H_{18}O_7$ and, as is known, may be obtained from various species of *Salix,* especially the *Salix alba*) was but little used by the medical profession, and it was every now and then found as an adulterant of quinine.

In Phillips's translation of the Pharmacopœia Londinensis for 1851, the following method is given for its detection: Dissolve half a drachm of the salt in three drachms of sulphuric acid; if it strikes a red or red-brown colour salicin may be suspected; dilute this solution with six fluid drachms of water, which will precipitate the salicin, and this, slightly washed with water, may be recognized by the bright red colour it produces with concentrated sulphuric acid.

Twenty-six years ago, Phillips recorded this test for salicin as a common adulterant of quinine. Now, however, the scene has changed and we find this white crystalline substance amongst the fashions of physic holding a foremost place, and, having recently been asked to prepare some of it in the liquid form, I am induced to bring before your readers my result, which affords another instance of the wonderful power of glycerine as an almost universal solvent.

The solution I made was of the strength of five grains to one fluid drachm.

The salicin and glycerine were first rubbed together in a glass mortar, then transferred to a porcelain dish and a gentle heat applied until complete solution was effected. It was found that one drachm would not take up ten grains, or rather that about one-half of it separated again on cooling, whereas the five grains remain in perfect solution.

This I have called glycerole of salicin. I am desirous, however, of suggesting the formula for a combination of this salicin solution with glycerinized pepsine. To obtain this solution of pepsine the fresh stomach of the pig is washed in water until all particles of food are removed, and, the cardiac end being rejected, it is cut into slips and digested for a week in as much glycerine as will entirely cover it, then strained and filtered. The solution is about the consistence of simple syrup, of a pale sherry colour; it has a sweet taste, with the characteristic flavour of pepsine. This process was given by Mr.

* Even "lac sulphuris" should either be placed in the Pharmacopœia or its sale be gradually discountenanced altogether. The *bona fides* of the pharmacist must not only be beyond attack but beyond suspicion.—J. A.

Edward Long, L.A.H., Dublin, in the *Medical Press and Circular*, vol. viii., p. 300, and the digestive power of the preparation is considerable. One drachm of it mixed with one ounce of water acidulated with 15 minims of muriatic acid dissolves 700 grains of moist fibrin at 100° F.

If equal proportions of these two solutions are mixed together a most valuable and excellent preparation results, possessing those tonic and digestive properties which in many cases are so much desired by physicians, and this I have called glycerole of pepsine and salicin.

35, *Baker Street, W.*

AN EASTER HOLIDAY IN LIGURIA.*

BY PROFESSOR FLÜCKIGER.

(*Continued from p.* 834.)

But the plant which above all other determines the appearance of the entire country is the olive tree (*Olea europœa*, L.). At this time of the year its fresh young blossoms begin to unfold; its thick evergreen leaves cover the landscape with their solemn grey, which accords so well with the cloudless sky, the bare mountain tops, and the blue-green sea. The cheerful light green of northern more delicately foliaged trees would be far less suitable than these mighty trunks, endowed with such tenacious power of life, which almost alone lift on high their far extending branches. It is in such a landscape as this especially in the lower valleys, that the olive tree must be seen to be properly valued. Neither age nor injury from axe or from storm appears to be capable of extinguishing its vital forces. So long as the trunk exists it sends out its knotted branches, or emits shoots from its wide extending roots which with wonderful power insinuate themselves into the wildest rocks as soon as they bear the slightest covering of fertile soil. In fact, the olive trees of the Riviera have attained a size that is not met with again in Central Italy, but only in the south, as at Sorrento. The pleasant semi-shadow of the olive groves calls to memory the German fruit gardens, or the dense foliage of the German forests, the peculiar charms of each only gaining by the comparison. Where the ground is too steep and bare, the industrious Italian cultivates terrace above terrace in order to provide space for the olive, vine, and fig tree. These artificially graded walls (*muricciuoli*) allow the most favourable devolopment of the peculiarities of the olive tree. The planting of the olive is easy, as every one of the numerous spreading rootlets has the power of development. The *Olea europœa* may take quite another from, or, rather, revert to its original form; the trunks and boughs grow straight; the leaves remain shorter; and the branches run out into thorny points. These degenerated bushes, *Olea oleaster*, are improved by grafting. For the completion of the picture is wanted the oil mill, which is always constructed in the simplest fashion, and so placed that at the proper time the requisite quantity of water can be conducted to its overshot wheel; for which cause the number of these mills is rather limited. They do not serve as dwelling places, but contain only the two millstones and the rude screw press. The crushed fruit is packed into sacks, and yields first the finest and thinnest oil; the press residues are then worked with hot water to obtain the inferior oil. "Fex olei seu amurca, Baumölhefen," mentioned in a Frankfort tariff of 1612, referred to such a very impure oil, which in olden times found many applications. In front of the larger oil mills are to be seen a number of open quadrangular receptacles, constructed of rude brickwork, which serve to hold the residues from the first or second pressings, belonging to different proprietors, until separated for further working. The entirely exhausted mass, consisting principally of kernels, is used for manure, and most probably exercises a very long continued influence, since the olive stones being only incompletely crushed by the millstones, open up slowly in the dry soil. The olive stones also render good service as fuel.

The produce of the olive tree fluctuates considerably both as to the quality and the quantity of the oil; even the variety of the tree has its influence. The wild tree, or that which has been allowed to return to a wild state, distinguished as *olivastro*, produces a small, oblong, very bitter fruit; its shoots are therefore improved by grafting when it is only two years old. The particularly large delicate olives of a variety distinguished by their long willow-like leaves, called in this country *punginaire*, are principally used for preserving. The ripest fruits yield the finest oil. In the Riviera district, between Nizza and Ventimiglia, the full devolopment of the olive can be peacefully awaited, but on the coast lying farther westwards the French are frequently compelled to commence the harvest prematurely, in order to prevent the olive being spoilt by the cold winds (*mistral*) of the latter part of the year. Upon the same ground, the olive trees there are supported by props, in order to produce a somewhat denser and better shelter of foliage. In the Riviera nothing of this is known, and certainly it adds not a little to the beauty, or at least to the peculiarity of the tree, that it is left to attain a perfectly natural development. However, here it is not quite safe from insects; on the coast frequently a large quantity of fruit is spoilt through being pierced by mosquitoes. The oil from the higher lying districts is therefore of greater value, since that insect is not harboured there. The harvest extends from November to April. This spring, however, no olives are to be seen, last year having been in this respect one of those perfectly unsuccessful years which unfortunately almost alternate in equal numbers with the good harvests. From old olive trees there sometimes separates a substance (gum resin) which formerly, though probably only very seldom, was kept in pharmacies as "Gummi Oleæ," but up to the present has not been exactly examined. In 1816 Pelletier prepared from it a bitter crystalline substance, named by him "olivil," the composition of which, according to the analysis of Sobrero, of Turin (1843), agreed with the formula $C_{14}H_{18}O_5$. Submitted to dry distillation olivil yields an oily liquid which would appear to present a great similarity to eugenol (caryophyllic acid). A more exact comparison of these two substances would be very interesting. In the Riviera this exudation from the olive tree is unknown. From the older literature it appears that formerly it was collected in Sardinia and South Italy, but this has not been done for a long time, so that it might now be very difficult to meet with this substance in sufficient quantity. Dioscorides mentions that the tears exuded from the Ethiopian wild olive tree were used as a medicine, and Pliny calls the olive resin occurring in Arabia, and used as a vulnerary, "*enhaemon.*" In the pharmacy of the middle ages this product was called "elemi," a name, as is known, since transferred to quite a different resinous substance. It scarcely requires to be mentioned that the olive tree of Ethiopia and Arabia was possibly not the *Olea Europœa*, so that the elemi of the earlier centuries may be as little referable to the gum resin of the olive tree as that of to-day. Still it is questionable what Pliny may have understood by Ethiopia, and to be remembered that in the district northwest of the Red Sea the *Olea europœa* grows wild. As two noteworthy facts in plant geography it may be mentioned that in the middle ages the olive culture was carried on for some time at the Lake of Geneva, but appears to have then been annihilated by the frosts, and, on the other hand, that at one time olives occasionally reached maturity in very favourable situations in London. The leathery evergreen leaves of the olive attracted attention in the old pharmacies. The Leipzig *Apothekertaxe*

* From the *N. Repertorium f. Pharmacie*, vol. xxv. 1876.

for 1699, for instance, has "folia oleæ, Olivenbaumsblatter."

As to the beauty of the olive tree the opinions of northerners are divided. One must wander and rest in the olive groves near Mentone, Monaco or Villafranca, in order to become acquainted with the charms that are peculiar to it. The venerable trunks, which have already bestowed food, fuel and valuable timber upon generations and generations, will have to be viewed in the diffused sunlight, with glimpses here and there of the sea. Just now its dull foliage stands in vivid contrast to the fresh grass which flourishes admirably in the slight shadow. Between the broad leaves of the different species of oat and other grasses rises a profusion of the *Allium neapolitanum*, nearly allied to the *Allium ursinum*, but more elegant, vigorous, and scarcely giving off the usual odour from the parts above the soil. Associated with these are the colour-gems of the gorgeous *Anemone coronaria* and *A. hortensis*, the *Tulipa Clusiana*, *Gladiolus segetum*, and *Centranthus ruber*, the well-known odour of *Cheiranthus Cheiri*, which disputes the precedence with the small profusely blossoming *Lobularia maritima*, Desv. (*Alyssum maritimum*, Lam.). German home memories are stirred by the *Anemone Hepatica*, *Bellis*, *Ajuga*, and *Helleborus fœtidus*, to which the semishade of the olive groves is suitable. More pharmaceutico-chemical considerations arise when the edges of the terraces and banks shine with *Iris*, *Ruta bracteosa*, *Verbascum sinuatum*, *Anchusa italica*, and *Euphorbia serrata*, or when *Hyoscyamus niger*, *Solanum miniatum*, *Ecballium Elaterium*, and *Mentha rotundifolia* show modestly in the back ground of manure and rubbish heaps. But mostly a speedy end is made to these floral beauties and grassy carpets, the soil round the stems being dug up and loosened in order to prepare it to take up manure or to expose it to the action of the atmosphere. But grass and vegetables may be seen under the olive trees as permanent plantations.

Many trees in this district correspond perfectly to the striking picture of the Greek olive trees drawn by J. F. Julius Schmidt, the Director of the Observatory at Athens. "Wonderful is the appearance of the very old olive trees to be seen here. With their lower stems, sometimes burst asunder, sometimes opening like an archway, twisted spirally, then again fashioned pyramidally, covered with knots, with hemispherical and quite irregular stone-coloured excrescences, the lower part often resembling a large block of stone, from the crevices in which rises a freshly foliaged thicket. Notwithstanding its wasted foundation, in which frequently tall shining green aroids and other plants lie hidden in spacious cavities of the trunk, protected from the vehement north wind, the aged tree supports a privileged existence. In its life and vigour it equals its younger neighbours and shows no signs of diminishing vitality."

The discovery of the original home of the more important cultivated plants has latterly awakened an enhanced interest, and botanists have not been deterred from the investigation of this question notwithstanding its difficulty. The olive tree appears probably to have been originally limited to the south-eastern countries of the Mediterranean basin, and at a very early period to have spread westward. Willkomm is of opinion that it occurred in the countries all round the Mediterranean Sea and in its islands. He finds one support for this opinion, among others, in the certainly not strictly proved presumption, that, for instance, in olden times entire forests of wild olive trees (*oleaster*) existed in Majorca. The same may be asserted of Sardinia and Corsica, though it appears with certainty, from Roman records, that the introduction of the olive into Corsica cost much labour. Already in the earliest period of western cultivation the countries of the Upper Indus to the Suleiman mountains possessed in the *Olea ferruginea*, Royle (*Olea cuspidata*, Wallich), a species very similar to the olive tree of the Mediterranean district. In the former, however, the thorns of the oleaster are wanting and the leaves are shining on the upper side and rust-coloured beneath. The fruit of this tree is smaller than the cultivated olive, but rich in oil. Is the rusty-leaved olive-tree the original form of the *Olea europæa* of to-day? In the modern tendencies in these questions probably the habit is not too carefully considered. The Garden of the Palazzo Orengo will yield probably at a not very distant period valuable data in this direction. The specimens of *Olea ferruginea* there are meanwhile still weak pot plants, the leaves of which present no very decided character.

In the olive forests of the Riviera, which cover mountain and valley, a visible change is becoming manifest far and wide. The light green leaf-lobes are just beginning to unfold on the grey, plump, fantastically intertangled branches of the fig trees; these, however, are only isolated, starting here and there sufficiently from masonry or rock to show through the grey green foliage of the olive groves without becoming a special feature. The fig forms so important a portion of the food of Italy that our chemical ignorance in respect to this valuable fruit is very astonishing. Whilst the olive has found an observer in the Neapolitan chemist, De Lucca (1864), who has pointed out a connection between the mannite generally so abundant in the family of the Oleaceæ and the fat oils, we are lacking any knowledge of the chemical antecedents in the fig, or even trustworthy analyses of it. Before maturity the fig abounds in a disagreeably tasting milky juice and contains much starch; what eventually becomes of this? Is the sugar from the commencement only grape sugar, or is its subsequent exudation something more than a purely mechanical appearance? Is the sugar accompanied by much or little protein matter? Such questions have to be investigated in order to obtain a glimpse into the consideration of this important food material.

Very usually the leaf-tufts of the sea onion (*Urginea maritima*) grow luxuriantly at the foot of the fig tree where it is seen by the peasants with pleasure. When in the summer the blossoms of the sea onion appear on stalks a metre in height, the insects show a special predilection for them and spare the ripening figs. This bulb is thus met with in regions much further removed from the coast, as it grows also throughout the south of Spain and Portugal, in inland districts of Greece, Cyprus and in the Balearic islands, at an elevation of 800 metres. Impossible as it is to cultivate this plant in the north, Charles the Great had the idea (in 812) of transplanting the "*squilla*" to Germany, a certain indication that the fig and the laurel were afterwards to follow. As little can we impeach the German father of botany of inaccuracy when he opportunely gave the names "earth onion" to the "scilla." As cultivated in this country the entire bulb is below the soil; it belongs to the form with white, not red, scales, and occurs on the coast much more rarely than in the higher ground. By the sea is met with here and there *Pancratium maritimum*, an amaryllidaceous plant, the bulb of which, considerably smaller than that of the *Urginea maritima*, appears to resemble it in chemical respects, and formerly was usually known as *Scilla minor*.

The distinguishing trees of this plant region bear evergreen stout leathery foliage; only a few other trees belong with the fig to the minority which cast their leaves every year. Thus there is the now miserable-looking pomegranate tree, with its slender young shoots, at first brown coloured, the thin naked ramifications of which do not produce a pleasant impression. Near it frequently stands the much more peculiar looking thorny jujube tree (*Zizyphus vulgaris*, Lamk.); the lanky branches of which, cracked here and there, at present show no leaves. Like the *Olea ferruginea*, and *Punica Granatum*, the *Zizyphus* is a native of Northern India, and yields there a very agreeable acid fruit, whilst the Italian jujube has a rather insipid sweetish taste.

Still more in the summer time do the vine and the *Arundo Donax*, indispensable to the vine cultivator, contribute to the peculiar appearance of the landscape; at present both of them are only beginning to sprout, and they always take up far less space than the olive tree.

Here and there a dense crown of foliage rising from powerful knotted stems shines out in the midst of an olive grove, or alone on the sunny shore the tree spreads out its half-bared roots often over a surprising circuit. It is the St. John's bread tree, *Ceratonia Siliqua*. Certainly it is to be found nowhere else in Upper Italy or in the Central provinces, but probably in the south of the peninsula. However the Riviera di Ponente, especially the country round Monaco, has trees to show which equal those of the *piana* of Sorrento and Amalfi. This tree is decidedly less hardy than the olive, but it comes from Central Africa, where the olive is not known. On the Ligurian coast it bears the historic name of "caruba," an Arabic designation recalling a people to whom Sicily at one time owed a season of prosperity, during which not only Islam but also trade and valuable economic plants were introduced into Spain and Southern Italy. The *Ceratonia* can only be reckoned an economic plant, however, to the extent that the pods are given to horses. It appears remarkable that artificial cultivation has not yet succeeded in improving it so as to give a savoury fruit. Even the St. John's bread from South Italy and Cyprus is always a truly leathery dainty. Would not an attempt to obtain a better product from this stately tree be remunerative?

The multiplication of so conspicuous an evergreen tree would also suit the landscape to a high degree, since in respect to its rich full green foliage, which may be compared to that of our oaks and apple trees, it stands in striking contrast to the olive tree. The long rigid petiole, not unfrequently a foot in length, is provided with three to five, but most frequently with four pairs, of sessile leaflets, which are often nearly round, but mostly ovate. The breadth of the entire leaf at its base, *i.e.*, the length of the lowest pair of leaflets, frequently reaches seven inches, so that notwithstanding the leaves are only simply pinnate, the impression of a very complex ramification is produced. As it does not, like so many other pinnate leaves, bear a terminal leaflet, the enormous head of foliage assumes a rounded outline, which would appear to be somewhat too regular, did not the separate leaves by their variation in colour and shape exclude uniformity. The divisions of the leaf are not spread out flat, but incline somewhat towards one another, and on the under side are of a lighter though duller green than on the upper. The two surfaces also differ in their behaviour in other respects. The upper surface can easily become moistened with various liquids,—dilute alcohol, for instance; not so the under side. The leaf tissue is of very firm texture, but each separate leaflet is always in motion, which even in a calm gives to the whole foliage a lively appearance.

Many other trees of the same division of the Cæsalpineæ possess, in contrast to *Ceratonia*, doubly pinnate leaves. Indeed in examining the St. John's bread tree critically exceptions to the ordinary form of leaf are not unfrequently found, especially where one of the lowest leaflets is replaced by one consisting of two to four pairs of leaflets, usually not quite opposite, and often with a terminal one. Frequently the second leaflet of the lowest pair is also transformed. The variations from the ordinary leaf form are, however, never sufficiently numerous to influence the appearance of the tree. It presents, therefore, very great peculiarity quite apart from the flowers and fruit, which also have characters repeated in no other instance. On these accounts the genus *Ceratonia* was rightly set up for the sake of this tree only, and it has not since been enriched by a second species. This explains the remarkable fact that botanists have not found leisure to endow it with several names, and it is everywhere called by the name Linnæus gave to it. At present, in April, the tree shows neither blossom nor ripe fruit; only exceptionally are found isolated belated but still quite young crooked pods, which explain far better than the ripe ones why the Greeks named the tree *Ceratonia* (horn-fruit tree).

The *Nespole di Giappone*, the evergreen Japanese medlar tree (*Eriobotrya japonica*, Lindley; syn. *Mespilus japonica*, Thunberg) makes an appearance here and there, scattered singly in the olive groves, especially in the neighbourhood of houses. Although not an absolutely tall tree, the *Eriobotrya* attracts the eye through its beautiful foliage, consisting of simple leaves, closely crowded together, the upper side of a shining dark green colour and the underside grey. The rather stout lamina is very strongly developed, attaining a length of 16 inches and a width of 5 inches; it is very slightly serrate and beautifully marked with a delicate network of veins. Not only is the yellow subacid fruit, which ripens in early summer, prized in the Riviera and the mountain villages, but it has also been plentifully cultivated for a longer time in South France (*bibassier*) and India. Our earliest acquaintance with this fruit tree, indigenous to China and Japan, we owe to the traveller, Engelbert Kämpfer, who has unmistakably described it under the name of "*bywa*," in his "Amœnitates exoticæ" (Lemgo, 1712, p. 800).

(*To be continued*).

COLOGNES FOR THE SICK-ROOM.*

BY GEORGE LEIS.

There is, undoubtedly, a want felt, if not expressed, among the people as well as our practitioners, for a preparation that shall at once serve as a pleasing perfume, an antiseptic deodorizer, and a medicated cosmetic lotion.

Such a lotion the writer has endeavoured to place before this Association, after having made numerous experiments, results of which are given below in as brief a form as possible.

Pharmaceutists are well aware of the fact that during the past years we have had innumerable compounds and chemicals offered as antiseptics, the merits of each being vaunted and extolled in its turn. After repeated trials of these new remedies, there is still a feeling predominant among those interested in the subject, that the desideratum has not yet been acquired. Some of the best disinfectants are in themselves objectionable; they either possess a disagreeable odour, or will stain and corrode. Ferrous sulphate (copperas) and manganous sulphate, though not really offensive, are comparatively inert. Iodate of calcium prevents decomposition, but if used as a local application causes too much pain. Acetic acid or vinegar is at first grateful and refreshing, but becomes sickening. Chloride of lime (erroneously so-called) as the formula shows, Ca (OCl) Cl, is an uncertain compound, whose virtue depends wholly upon the amount of free chlorine it liberates; chlorine being an irritant, corroding gas, no one would desire to have it in a room containing articles of vertu or delicate metallic ornaments. Permanganate of potassa is also a very good disinfectant; but unless sprinkled and brought into contact with the air, is not so effective as thought, and in sprinkling the solution, it will necessarily produce stains upon everything it may come in contact with; hence this is not at all desirable. Hydrate of chloral is quite offensive, and the vapour stupefying. Carbolic acid or phenol, to which so much has been ascribed, is perhaps the best antiseptic we have in use at the present day, but its odour is certainly intolerable to an invalid; its preparations are the less useful as they are less offensive.

I have now fully delineated the objections to the various disinfectants for the use of the sick-room. What we need, in my opinion, is a preparation that shall possess

* Read before the American Pharmaceutical Association.

equal, if no greater, efficacy than any now in use, without irritant properties and unpleasant odour. Such a body, we hope, is to be found in salicylic acid.

Salicylic acid seems to be related, to a certain extent, with many organic disinfectants now in use, and we may, perhaps, consider the efficacy of such disinfectants to depend on their near relationship to salicylic acid. For instance, oleum gaultheriæ procumbentis (oil of wintergreen), said by some chemists to possess remarkable absorbent and deodorizing powers, consists almost entirely of methyl salicylate. Oleum spirææ ulmariæ (oil of meadow sweet), also considered of value, is generally regarded as the aldehyde of salicylic acid. Oxybenzoic acid is isomeric with salicylic acid, $C_7H_6O_3$. Salicylic acid is intimately related to the aromatic series of acids, most of which possess antiseptic properties in a greater or less degree. Carbolic acid itself may be obtained from salicylic acid by dry distillation.

Numerous experiments made recently by the writer have fully corroborated those made by others. Salicylic acid has proved itself to have undoubted properties to prevent putrefaction and check the development of organic growths and parasites. Meat, lightly covered with salicylic acid in substance, remained sweet, while similar portions, in the same atmosphere, become offensive. Meat dipped in an aqueous solution of the acid, made the strength of 5 gr. each of salicylic acid and borax to 1℥ of water, also remained wholesome. The putrefying process was easily arrested in several compounds made for the experiment, by a free use of the salicylic acid.

No theory as to the manner in which salicylic acid exerts its influence has been advanced, but it probably acts as an antiferment, and in this manner annihilates the organic bodies produced by fermentation.

The following formulas are such as I have experimented with to my own satisfaction, and only hope they may prove as effectual and as satisfactory in the hands of others:

No. 1 ℞—Acidi Salicylici . . . . ʒ ss.
Spiritus Vini Rectificati . . . . f ℥ iv.
Olei Cinnamomi . . . . gtt. j.
„ Bergamii . . . . gtt. xv.
Balsami Peruani . . . . f ʒ ss.
Make a solution.

In order to make a solution of the above formula, dissolve the balsam of Peru in the spirits and filter, then adding balance of ingredients. The aromatics used in perfuming the above solution are as nearly chemically compatible to salicylic acid as practicable.

No. 2. ℞—Acidi Salicylici . . . . gr. xx.
Olei Gaultheriæ . . . . . . gtt. v.
Spiritus Vini Rectificati Diluti . f ℥ ij.
Mix.

In the above recipe, in the place of olei gaultheriæ the same amount of olei anisi may be added, which is also of itself a powerful deodorizer, and may be preferred by many.

The basis of these solutions is salicylic acid, and any other combinations of odours can be added if desired which would harmonize with the salicylic acid. I give one for an example:

Salicylic Acid . . . . gr. xx.
Farina Cologne . . . . f ℥ ij.
Mix.

Any one of the above recipes will be found adapted for the use in sick-chambers, to neutralize the infected atmosphere attending fevers. In typhoid fever they will neutralize the fecal evacuations, which are pre-eminently contagious. In rooms that have been closed for months, without necessary ventilation, they would destroy the microscopic fungous growths inevitably present. The lotion should be diffused in the room with the aid of a spray tube or atomizer. Its presumptive analogy to benzoic acid would suggest its application as a cosmetic, the lotion to be added to the water used for ablution. A dilution applied to erysipelas is productive of ease to patients. Its balsamic properties promote the healing of cuts and sores, besides freeing them from morbid atmospheric influences.

I hope I have shown the many advantages and powers of salicylic acid over other disinfectants to the entire satisfaction of the readers.

Although owing to the comparatively high cost of salicylic acid, it would possibly not be brought into general use, yet for minor purposes of disinfection its introduction in such a form will doubtless be met with a fair demand.

The name of such a preparation might be appropriately called *Lotio Antiseptica Fragrans* (Fragrant Antiseptic Lotion), which, in my opinion, gives the properties of the lotion in its name.

NOTES ON THE JOYOTE OF MEXICO.*

BY PROFESSOR ALFONSO HERRERA,

Member of the Mexican Society of Natural History.

In the damp, hot regions the fertile mountains of the great Mexican Cordillera grows a tree remarkable for its thick foliage, the elegance and beauty of its golden coloured flowers, and the uncommon form of its fruit. The Aztecs called it *Joyotli*, hawks-bell, on account of the use they made of the nuts as bells, but others say that it takes its name from the property of the seeds to cure the bite of the Crotalus, rattlesnake; and the wise physician, Felipe II., says: "The ancient Mexicans made use of the milky juice that the tree produces in abundance, for curing deafness and cutaneous diseases. They applied the leaves topically in toothache, and as an emollient and resolvent to tumours, and lastly, they used the fruit to heal ulcers."

At present the fruit is called huesos ò codos de fraile, bones or friar's elbow, perhaps for its resemblance to the human elbow. Among the people these seeds have a great reputation in hemorrhoids, and are applied topically after being triturated and mixed with suet.

The joyote is the *Thevetia yccali*,† DC., Cerbera thebetioides H. B., nat. ord. Apocynaceæ, tribe Carisseæ, an elegant tree whose numerous branches are covered with a greenish silver-grey epidermis, with grey wrinkles, longitudinal furrows and protuberances somewhat spirally arranged; its leaves are sessile, linear, acuminate, dark-green above and pubescent and of a lighter colour beneath, with some prominent transverse veins; the margin is entire and revolute; size, fourteen centimetres long and seven millimetres wide. Inflorescence cymose, calyx five-parted, lobes lanceolate, acuminate and beardless, corolla salver-shaped, pubescent in the lower part of the tube and throat, the tube widened above to bell-shape, the throat with five ovate appendages covered with white hairs; beneath are the stamens alternating with the lobes of the corolla; anthers sessile and lanceolate, opening with two lateral fissures. Ovaries two, united at the basis and free above, flat on the face and convex on the back, unilocular and biovulate, united on top by a fleshy ring with five incisions alternating with the lobes of the calyx. The stigma is black, head-shaped, with ten ribs at the base and a bilobulate conical top. The ovules are amphitropous, sub-globular, of parietal placentation, equidistant between the base and top of the ovary. Drupe ovoid-globular, green, with a large crest about the middle extending to near the base, but more prominent above, and with a slight furrow, and terminating in two small nipples on each side. Epicarp smooth and green; mesocarp greenish-white, very laticiferous; endocarp woody, of a dirty yellow colour, and the same form as the fruit, pro-

* From the *American Journal of Pharmacy*, April, 1877.

† Hernandez has corrupted the word *Foyotli* of the Aztecs into *iccotli*, and De Candolle used the latter as the specific name of this plant.

vided with a complete woody partition in the direction of its small diameter, and with two false ones in the other direction; corresponding with the latter towards the apex is a furrow, and near the base another one, corresponding to the true partition. Seeds four, commonly two abortive, inserted near the middle of the false partitions, on the margin with a small wing; spermoderm thin and papery, endopleura distinct and reticulate. Albumen none, radicle eccentric, horizontal, conic and short; cotyledons orbicular, unequal and oily, the internal surface transversely wrinkled; near the centre in the direction of the radicle a prominent crest; flowers in July.

Mr. Berlandier found, near Tampico, a variety of this species, to which he gives the name of *glabra*, because it has smooth leaves. We have also *Thevetia ovata*, DC., which is readily distinguished by its ovate-elliptic leaves, white-tomentose on the under surface. Somewhat westward the *Thevetia cuneifolia* is found; its flowers are called *Meriendita*. The variety *anclieuxi* is found about Tonatepec. All these species and varieties are commonly known only by the vulgar name given above, but in the State of Talisco they are called *Narcisos amerillos*.

The excessive acrimony of the seeds of the joyote attracted my attention, and induced me to investigate them. The small quantity at my disposal and other circumstances have prevented a fuller investigation, but incomplete as it may be, it may well serve as a basis for further observations.

The seeds of the joyote were conveniently divided, and by pressing in a common press, yielded 40 per cent. of oil resembling almond oil; its density at 20° C. is 0·9100; at 10° it becomes turbid, and at 0° C. it acquires the consistency of common lard. Concentrated sulphuric acid imparts a yellow, changing to rose colour, and afterwards into deep orange-red; it is a non-drying oil, and appears to be composed of olein and palmitin. The residual powder was percolated with ether, and the liquid evaporated left a residue of about the same quantity as the oil previously obtained. Distilled water was afterwards used to extract albuminous and extractive matters, and finally the exhausted substance was treated with 85 per cent. alcohol. The filtered liquid was evaporated spontaneously, and yielded a white substance, crystallizing in four-sided prisms. These crystals were inodorous, but excessively acrid, insoluble in water, and very little soluble in ether, bisulphide of carbon, fixed and volatile oils; but easily soluble in alcohol; not volatile, and not combining with acids or bases. When treated with dilute sulphuric acid, they decompose into glucose and a resinoid substance; the principle is, therefore, a glucoside. Its solution is not affected by nitrate of silver, the chlorides of platinum, gold or iron, iodide and iodate of potassium, tannin, potassa, ammonia, the alkaline carbonates, or by ferro- and ferrid cyanide of potassium. I propose to call it *thevetosin*, although *thevetin* would probably be a more appropriate name for this principle.

Some experiments made on various animals by Mr. Luis Hidalgo Carpio with the active principle of the Thevetosa Iccotli (Codo de Fraile) seeds seemed to prove that, (1) the thevetosin is very venomous; (2) that it has a violent emetic action depending upon the nervous system, like tartar; (3) that it acts on the respiration, making it difficult by paralysis, more and more complete on the external muscles of respiration.

These experiments, made on different kinds of animals, indicated that the emetic action of the different products of the joyote seeds is constant in all animals that can vomit; that the muscular system of respiration becomes paralytic, and that this paralysis can extend in some cases to the other muscles. The author thinks that thevetosin, acting so powerfully upon the animal economy, may probably become of importance, and be employed more advantageously than curare.

MEETING TO PROMOTE EARLY CLOSING.

A numerously attended meeting of chemists and druggists, convened for the purpose of considering the subject of early closing, was held in the theatre at the house of the Pharmaceutical Society, 17 Bloomsbury Square, on Wednesday evening last. The chair was taken at half-past eight by Mr. George Webb Sandford.

The CHAIRMAN, in opening the proceedings, said that there were many persons who could have filled the chair on the occasion better than he could do it, and perhaps there were many who were more enthusiastic, but he knew that there were none who were more earnestly desirous to promote the cause of early closing than he was himself. He had had a very long experience of the question of early closing, and he had, for himself, overcome the difficulties attending it, and he would ask other persons engaged in the same business also to endeavour to overcome them. When he first made his appearance in Piccadilly, the business was carried on from half-past six in the morning till eleven at night, but he was happy to say that twenty years ago he began to close at nine o'clock, and for the last four years his shutters had been closed at seven o'clock, and the shop had been finally closed at eight. He mentioned that as something which he had been able to do quite irrespective of his neighbours, and he had no occasion to repent in the smallest degree of the step he had taken. Of course he had always somebody in attendance after the shop was closed. He felt that chemists stood in a peculiar relationship to the public, for they were appealed to in certain emergencies, and it would be almost inhuman of them to refuse to supply medicines at any time at which they might be wanted. He was aware that there were differences in different neighbourhoods, and that while a business in the city might be closed at seven o'clock, a business in another neighbourhood might necessarily be kept open till nine o'clock. He, therefore, hoped that those who spoke that evening would not attempt to fix on the meeting a hard and fast line as to the hour of closing. What they wanted to do was to enlist every chemist and druggist to give his moral support to the early closing movement. He held in his hand a note which he had received, since he came into the room, from Mr. Felix Stevens, of Judd Street. Mr. Stevens expressed sympathy with the meeting, and wished it success. He had been instrumental in obtaining early closing at Clifton, and it was found to work well. United action, said the writer, was what they wanted. He had another letter which had been sent to him by Mr. Hills, who was one the most earnest supporters of the movement. Mr. Hills began by saying that he thought that the best way of carrying out the early closing movement was for chemists to cultivate a better knowledge of each other; and while he thought it advisable that they should be as obliging as possible to their customers, at the same time, if they adopted an earlier closing of their window shutters, they would be educating the public to supply their wants in medicine at the same time as they did their general shopping. The writer added that some kind of provision must be made for emergency. Mr. Shaw, of Liverpool, had written to him (the chairman), to state that some two years ago, a movement was made in Liverpool, and a small bill headed, "Notice to the Public," was issued to the customers. As far as educating the public was concerned, he (the chairman) had found, in his own experience, that they were very easily educated. When he was a young man the shops in London kept open till eleven or twelve o'clock. They must all admit that the wear and tear of chemists and druggists was very far beyond that of other tradesmen. They had to attend to a responsible business all day long, and to keep at it until eleven o'clock was, he might say, a very great danger to the public. There was a very great strain in the dispensing of medicines, and it behoved shopkeepers to provide as much relaxation as they could for their assistants. In taking the position of chairman that evening, he did so as an individual, and he was not there to represent the Council of the Pharmaceutical Society; but in saying that he by no means wished to imply, for a moment, that the Council were not favourable to the movement. They gave it their moral individual support, although they felt that if they took it up in their collective capacity as a council, and told a man when he must shut up his shop, they would introduce discord.

Mr. HARRIS (Highgate) moved the first resolution:—

"That the earlier closing of shops and offices of other trades having become almost universal, and many chemists and druggists having adopted earlier closing with advantage, this meeting deems it desirable to extend further so beneficial a change, and suggests to their brethren, chemists and druggists generally, an adoption of shorter hours of business."

Mr. LOWE (Portland Place) seconded the motion. He entirely concurred with the remarks which the chairman had made with regard to the necessity of unity. He did not see much difficulty in getting earlier closing if druggists were united, although he was afraid that it would be difficult to obtain unity in some neighbourhoods.

Mr. GREENISH (Dorset Square) said that for a period of five and thirty years he had been identified, more or less, with early closing. About five and thirty years ago he formed one of a deputation to the Council of the Pharmaceutical Society to ask them to give their moral support to the question. The answer was, and the deputation expected and wished for no other, that they would do all in their power as regarded exercising their moral influence, but they could do nothing as a council. He could bear out the statement of the chairman that at that time business began early in the morning and often extended till after twelve o'clock at night. He and other assistants had had to take out medicines after that hour, and that had happened in one of the historic houses of London. Upon going into business for himself he carried out the views which he had always held by closing his shop at an earlier hour on week days, and during almost the whole period he had closed it altogether on Sundays. He had not put a brass plate on his door to state that medicines could be obtained at any hour, but he had given his customers distinctly to understand that his establishment was never left without himself or one of his assistants being within reach. He had adopted the plan of putting up his shutters at eight o'clock, and closing finally at half-past eight, and that practice had never been attended with any inconvenience. He was only too happy to have the opportunity of following certain pursuits which were not immediately connected with his business and which were, perhaps, a little more congenial to his feelings than the vulgar habit of earning a living. The practice of putting up the shutters before the shop was finally closed tended to educate the public on the subject. Many, he had no doubt, would leave that meeting brimful of good intentions with respect to early closing, but if they went out the next night and saw a red light or a window shutter down their resolution would give way. What he would recommend each of them to do would be to go home and put his own shutters up, and, others doing the same, early closing would be an accomplished fact.

The resolution was carried unanimously.

Mr. W. C. JONES (Bayswater Road) moved—

"That this meeting is of opinion that the window shutters might be closed at 8 o'clock, and the doors at 8·30 without inconvenience to the public, and that even on Saturdays, with due regard to the requirements of the neighbourhood, an abridgment of the hours of labour might be effected."

He thought that the time had come when chemists and druggists could close shops earlier than formerly without inconvenience to the public. The matter only wanted unanimity on their part in order to be carried out.

The motion was seconded by Mr. WHITE (Regent's Park).

Mr. OWEN (Islington) did not at all believe in putting the shutters up half an hour before the door was closed. If they were going to put their shutters up at eight o'clock he should be very glad indeed if they would close their doors at the same time. To put up the shutters without shutting the doors was a mockery and a delusion, and it was an inducement to prolong the hours to an indefinite time. He had always shut customers and everybody in at nine o'clock and let them out at the side door. He should be glad to adopt an earlier hour. He believed that there was no good in the late hours. The public would appreciate those who took care of themselves.

Mr. HAMPSON (St. John Street Road) said that he closed his place of business earlier than his neighbours closed, but he did not judge his neighbours harshly on that account. Districts differed in their character and circumstances, and perfect unanimity in the time of closing could not be expected. He thought, however, that meetings of that kind would be very beneficial in promoting something of a right kind of opinion amongst druggists themselves, and he hoped that there would be some efforts made in the various localities of London to bring the chemists together to discuss the matter amongst themselves. Let chemists begin in their own localities and find what could be done. He earnestly desired to initiate some effort in his own neighbourhood, and he believed that if his friend, Mr. Owen, would join him they would be able to do some good, and he had great pleasure in supporting the resolution.

The motion was then carried unanimously.

Mr. POSTANS (Baker Street) moved—

"That while suitable arrangements should be made to supply the necessary requirements of the public on Sunday, this meeting recommends that door shutters as well as window shutters should remain closed on that day."

He said that they must not lose sight of the fact that early closing like all real progress was of slow growth. Whatever resolution they might pass they must not be deluded into the idea that they would find all shops closed at eight o'clock on the following night. The note from Mr. Hills which had been read by the chairman was so thoroughly practical in every respect that he (Mr. Postans) might be pardoned for alluding to it. He agreed with the writer that it was especially necessary that the public should be educated in the movement. It was also necessary that chemists and druggists should be thoroughly organized. As a stepping-stone towards success they had, as the chairman had told them, the sanction of the Council of the Society, which was shown in the fact that the use of the theatre had been granted for the present meeting. The approval of the Council must add very considerable to the weight of the object of the meeting. He confessed that he did not quite see why it was that they in England were so late in their business, when they were by no means so late in other countries. In Dublin and Edinburgh all druggists' shops were closed at eight o'clock, and he believed that in many districts they were closed at seven.

The motion was seconded by Mr. COOPER (Gloucester Road).

Mr. BETTY (Camden Town), thought there might be some difficulty in carrying out at once the last resolutiou passed, that they should close their shops at a specific hour, though he believed that they could all act up to the spirit of the resolution. But there was no doubt as to the motion now before them, which was that they should keep their shops closed the first day of the week, and that Sunday should be observed by chemists and druggists in the same way as it was observed by the great majority of the trades of the country. He was rather averse to half measures. If a chemist did business on Sunday let him proclaim the fact at once by taking all his shutters down instead of adopting the present practice of taking down one or two shutters, which made the shop look as if some one was dead there. The practice of keeping up a portion of the shutters on Sunday was most absurd. Let them either proclaim honestly, as the publicans did, that they were prepared to do business on the Sunday, or let them join in the general practice of observing the first day of the week.

Mr. ANDREWS (Leinster Terrace) was glad to find that the Sunday question was not to be left out. The resolution was not uncalled for. One Sunday a little while ago he went through a considerable partion of London, and found a very large proportion of chemists' shops with either some of their window shutters down or the door shutters down, and he found this to be the case in some of the larger shops at the west end of London. He did not wish to bring any odium upon individuals, but he wished to throw a little odium on the principle, which was a very bad one.

Mr. STACEY said that he could support the motion very heartily, as he could every resolution that had been passed that evening. Mr. Andrews had referred to the fact that some of the west end houses had their shutters down. It was, however, almost a matter of necessity in some cases that the shutters should be down, but it was his desire to discourage Sunday trading to the utmost. Chemists, however, had a public duty to perform or, otherwise, he should have closed his shops on Sunday long ago. They were bound to have some one on the premises to attend to the necessary requirements of the public in dispensing. In some houses it was almost impossible to avoid having the door open. Where iron shutters were in use they were obliged to have the shutters up in order to obtain light, although they kept the door upon the spring. To the passer-by it looked as if the shop was courting business although that was not the case. As the owner of a tolerably large business in three different houses in London it was his most decided wish to close those houses entirely on Sunday, and if he could have seen his way he should have done so long ago. But he did not think that chemists were justified in taking such a step. However, he cordially supported the idea that Sunday trading should be discouraged to the utmost extent. With regard to the general subject, he had very great sympathy with the early closing movement. When he went into business first he worked from seven in the morning till eleven at night, but for several years he had locked up at nine o'clock. He agreed with Mr. Greenish that it was very desirable to put the shutters up half an hour before the door was closed. It helped the business very much if the porters or the boys could do a certain amount of work in the evening instead of leaving it until the next morning, and that work could be done if the shutters were put up while it could not be done if the shop was kept fully open. His aim was to let every assistant out as early as possible although it was not desirable to expose to the public the fact that the shop was bare. The practice of having the shutters up before the door was closed also tended to educate the public, and he believed that it was one of the most important means of helping to educate them. It might be very easy indeed for those who were not in the west end of London to educate the public, but it was not easy in the west end where the public were composed of a different character and element of beings from those anywhere else. At the west end they had to deal with the aristocracy and with gentlemen and with "gentlemen's gentlemen." The manservant would receive a prescription to be made up, perhaps at five o'clock but he did not choose to bring it until he had served up his coffee and could light his cigar and fetch the medicine. This was a great difficulty at the west end, and it lay more with the servants than with the masters. It might be taken as a rule, however, that a chemist who closed at eight o'clock would do an equally good business with his neighbour who kept open till ten or eleven.

Mr. OWEN said he thought that Mr. Stacey must have forgotten while making his remarks on Sunday closing, that the chairman was in business at the west end. If the chairman had closed on Sunday, Sunday closing among druggists at the west end could be carried out. As to their opening their shops on Sunday, Mr. Betty had pointed out that they ought to do it entirely, or not at all. He (Mr. Owen) had shut up thoroughly on Sundays for nearly twenty-five years, and he had never had a single complaint of his shop being closed on Sunday. The few shillings he used to earn on Sunday were entirely made up during the week. He believed most absolutely in shutting up on Sunday, and giving every possible chance to their young men to go to a place of worship. If they failed to go, the responsibility was their own.

Mr. ANDREWS said that when he spoke, he was alluding in no way to the practice adopted by Messrs. Corbyn.

Mr. HORTON objected to the idea that those who kept their shops open on Sundays did so for the sake of the few shillings which they might obtain. But he remembered that, when he was an apprentice, an early closing movement was started, and it was agreed by the chemists in the town in which he lived, that they would close at eight o'clock. For a short time the arrangement worked very well, but at length the apprentices were sent round to see whether the shutters of all the shops were up, and when a man found that his neighbour failed to close, he refused to close his own shop. He believed that they must not be guided by their neighbours, but they must determine that they would endeavour to close at a proper hour themselves. He had latterly been putting up his shutters on a Sunday, for the sake of educating the public. When he went away from the present meeting, he would endeavour to make arrangements to avoid taking down the shutters at all on Sunday.

Mr. GEORGE HARRISON said that he was not a chemist and druggist, but he took a very great interest in early closing, and he had done so for more than a quarter of a century. As to educating the public, the chemists and druggists appeared to have been doing that for the last twenty-five years and they had achieved very little. Were they going on for another twenty-five years? The time of closing rested with chemists themselves. It was true that their business was entirely different from many other businesses, but he believed that if the assistants had stirred themselves in that matter they would have got earlier closing very soon. He would say, respectfully, to chemists and druggists that he was ashamed of them as a trade for not closing earlier. They ought to close at seven o'clock, although, no doubt, it was right that medicines should be supplied at all hours of the night in case of need.

Mr. POUND (Leather Lane) said that when he first went into business the time for closing in his street was eleven. He had brought it down to ten and subsequently to nine o'clock. If he could get another man in the street to close at eight he would close himself at that hour. [A voice, "Close without him."] In his neighbourhood a great deal of money was taken between eight and nine.

Mr. WILSON wished to make a few remarks from an assistant's point of view. It behoved proprietors as much as possible to endeavour to shorten the hours of business. He had lived in the west end for some time; and the hours there were from half-past seven till ten o'clock, the shutters being put up at nine o'clock. He was now in the city where the hours of business were from nine in the morning till eight at night. Three-fourths of the assistants left at six o'clock. Of course the city could not be made a rule for the west end. It was found that more work was done between nine and six than used to be done formerly between nine and eight. With regard to closing entirely on Sundays he did not think the difficulty was so great as Mr. Stacey seemed to imply.

Mr. HORTON said that it was a fact that a great number of assistants were very fond of closing early, but when they got into business for themselves many of them showed a great tendency to keep open late.

Mr. TAYLOR (Baker Street) said that there was no one more desirous than himself to close early. He put his shutters up at eight o'clock, and he had gone to the expense of about £24 to have his shutters altered so that he could wind them up himself, but as a rule he did not shut the door till ten o'clock. For a time he had the door closed earlier, but he was so much annoyed by persons knocking at the private door that he was at last glad to get back to the old system, but still he should try the new system once more. When the shutters were up his assistant left him all the work to do.

Mr. TURNER (Great Russell Street) said that four years ago he began the practice of putting up his shutters at eight o'clock, and closing the door at half past nine. He thought he could now safely close finally at nine o'clock. He had always kept his shop closed on Sundays.

Mr. TAYLOR added that he received many prescriptions by post at eight o'clock in the evening and they had to be made up the same night. It was impossible to legislate strictly for such a business as that of druggist.

Mr. SMITH said that his experience was similar to that of Mr. Taylor. He believed that as long as the door was open the public would come.

The resolution was carried unanimously.

Mr. LONG proposed—

"That with a view to carrying out the previous resolutions, Messrs. Hills, Sandford, Carteighe, Stacey, Greenish, Hampson, Owen, Horncastle, Andrews, W. G. Jones, Long, Butler, W. O. Jones, Stockman, Matthews, Drury, Postans, Taylor and Betty, be appointed a committee, with power to add to their number, to take from time to time such steps as they may deem expedient."

He said it was now about twenty-six years ago since Mr. Kennedy, the secretary of the Early Closing Association came to the place where he was then an apprentice. On that occasion he was innoculated with early closing principles which he had ever since believed in and acted upon. Some fourteen years since a large public meeting was held at the Kensington Vestry Hall, when the numbers were so large, that if he remembered rightly, all could not obtain admission. At that meeting it was resolved that every respectable person would purchase before, and every respectable tradesman would close at eight. The meeting was productive of much good, which had not entirely died out; not wishing to be considered otherwise than respectable, he (Mr. Long), closed the next evening at eight, and had done so ever since. The association had visited Notting Hill again, and feeling interested in the movement, he attended their meeting, and like other trades the chemists had formed a committee and held several meetings, among others, that which was reported in the Journal in February, at which it was resolved to hold a general meeting, which had resulted in the meeting that evening. He hoped that now there would be a good strong committee formed to prevent previous efforts being lost, and it remained for each individual to aid the movement, and then when they were asked "Well, what have you done?" they would be able to point to a united, friendly, and influential body who had found the advantages of early closing. There had been a preliminary meeting to decide on the resolutions that evening, and like the protocol they had been very much modified and reduced to the most modest resolutions possible. It was originally proposed to close shutters at seven, and door shutters at eight, but it had been deemed advisable to propose in the first instance eight for shutters and eight thirty for door shutters; but he need hardly say that any one wishing to close earlier or already so doing, acting as pioneers in their neighbourhood, should do so. It must be apparent that as long as they kept the shop open it was an invitation to the public to come, and many persons made a practice of coming at the last moment; but he believed the general public to be most anxious to comply with all reasonable regulations. He sincerely trusted that ere long they would be able to close at an earlier hour still, and he was not introducing a chimerical idea, for in many large provincial towns they closed at seven, and had done so for a long time and had a half holiday in the week.

Mr. BUTLER seconded the resolution. He mentioned that he was one of the persons that had prepared the resolutions for the meeting. When they were under discussion it was suggested that seven o'clock should be the hour mentioned in the resolution as the time for closing the shutters, but he had protested against the proposition, because he felt that it would not be carried. He submitted that eight o'clock was the best time to put up the shutters and half-past eight to close finally.

Mr. KENNEDY (Secretary of the Early Closing Association) said that he felt pleasure in being present that night by invitation to represent the Early Closing Association. The Notting Hill and Bayswater committee of the Early Closing Association had been the instrument through which the present meeting had been convened, and he thought that there was very great praise due to the whole of the gentlemen forming that committee, for the zeal which they had manifested, and the success which had attended their operations. He believed that the effect of this meeting would be very beneficial indeed over the whole of the metropolis. Chemists and druggists were almost the latest in closing, of any tradesmen in London, and he had often thought that when the hours were prolonged, the business was absolutely degraded in the estimation of the public. The artisan worked only fifty-four hours and a half in the week, while the chemist, at a moderate calculation, worked eighty hours, to say nothing of Sunday. His conviction was that chemists might close at an earlier hour without any loss. With regard to servants, if those persons knew that the shops would be closed if they come late, they would be obliged to go in proper time. He believed, as one of the speakers had said, that a very great deal of practical good would come of local meetings. The board of the Early Closing Association would be happy to give any assistance in their power in aid of any steps that might be taken to bring about a curtailment of the present protracted hours of business.

The motion was carried unanimously.

Mr. HORNCASTLE moved

"That the best thanks of this meeting be and are hereby given to the Council of the Pharmaceutical Society for kindly granting the use of their theatre for the present meeting."

He cordially agreed with most of the remarks that had been made that evening, and he was pleased to observe that so strong an appeal had been made to introduce individual effort in the matter. It was by such effort that so much progress had been made hitherto in the matter of early closing. They were deeply indebted to those gentlemen who had led on in the matter and who by their example had smoothed the way for smaller members of the trade to follow.

The motion was seconded by Mr. MATTHEWS and carried unanimously.

On the motion of Mr. STACEY, seconded by Mr. GREENISH and supported by Mr. LONG, a vote of thanks was accorded by acclamation to the chairman, Mr. George Webb Sandford, for his kindness in presiding over the meeting and for his able conduct of the business.

The CHAIRMAN in acknowledging the vote said that at the beginning of the meeting he felt very diffident about taking the chair, but whatever feeling of that kind he might have had had entirely vanished through what he might call the success of the meeting. It had been a very great pleasure to find them all so well disposed towards promoting an object which he had very much at heart. In this movement there must be mutual forbearance and individual action. If their neighbours did not do right let them set their neighbours a good example.

The Pharmaceutical Journal.

SATURDAY, APRIL 21, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

EARLIER CLOSING.

THE very successful and unanimous meeting held last Wednesday at the Society's House will undoubtedly give fresh impetus to the movement in behalf of the earlier closing of chemists and druggists' shops. Considerable concurrence of opinion at a meeting upon this question might of course have been safely predicted, but the harmony that prevailed, and the cordial approval accorded to all the resolutions brought forward, was due manifestly to the tact with which the promoters of the meeting had drawn up their propositions, anything like what might have appeared to some to be an extreme course being carefully avoided. Eight o'clock for putting up the window shutters, and half-past eight for closing the door, were the times to which the meeting gave its adherence, and to secure which a systematic effort is now to be made. In many establishments, this plan already obtains, and thus its feasibility is demonstrated. But it will be a great gain to have it more uniformly adopted throughout the metropolis, and then those who have so far acted as pioneers may feel justified in making a still further advance.

One great encouragement to persevere in the agitation until a satisfactory conclusion is arrived at is to be found in what has been already accomplished. Long as are the hours to which we are now habituated, it is rather startling to be reminded that a quarter of a century ago the business in some first-rate pharmaceutical establishments began at seven in the morning and lasted until eleven or twelve at night. We do not doubt that the shortening of these hours appeared to many employers of that time impracticable, but the result has been attained, and such days have gone never to return. Nor can we doubt that the time will come when the pharmacist will have as much faith as the linendraper in himself and his brother tradesmen, and will decline to have the standard of his day's labour fixed by the whims of servants or the vagaries of a few Ishmaelitish competitors. But the rate at which that good time shall approach will depend very much upon the manner in which individuals carry out deliberately the resolutions arrived at during the excitement of a public meeting. As was well remarked by one speaker, there is a danger of persons who leave such a meeting as that of Wednesday last, full of good intentions as to putting up the shutters henceforth at an earlier hour, having that enthusiasm sadly checked by the apparition of the coloured shadows of their neighbour's carboys on the pavement.

Scarcely second in importance was the subject of the third resolution, that relating to Sunday closing. The united testimony of Messrs. OWEN, GREENISH, HAMPSON, BETTY, and others, showed its practicability; as to its desirability there can scarcely be any controversy. As was unanimously conceded, arrangements should always be made to allow of the supply necessary medicines; but, in our opinion—unless Sunday trading be really desired—everything suggestive to the public that dealing in drugs or medicines on that day is courted or favoured should be carefully put out of the way. But we are afraid that Mr. BETTY's sarcastic challenge, either to shut up entirely, or to take down the shutters entirely and trade openly on Sundays, like the publican, was not wholly undeserved in some quarters.

In order to secure the advance already made, and to favour fresh progress, an influential Standing Committee was appointed by the meeting to watch the progress of the movement. We would suggest that a small handbill, similar to that used in Liverpool, should be drawn up under the sanction of this Committee, and that this should be taken as the platform at the local meetings which we hope will now be organized.

PHARMACY IN VICTORIA.

AT last the efforts, spread over several years, of the pharmacists of Victoria have been successful, and an Act to regulate the practice of pharmacy in that colony has passed the Legislative Assembly and Council. This law, as will appear in our *résumé* applies to the practice of the business of a chemist and druggist generally, and it was supplemented later in the same session by one dealing specially with the sale of poisons.

The new Act, which was to come into operation on the first day of the present year, is divided into four parts. Part One relates to the establishment of a "Pharmacy Board of Victoria," to consist of a President and six other members. The first Board is to be appointed by the Governor in Council, and is to consist entirely of persons who would be entitled to registration under the terms of the Act; this appointment is to be for three years, after which time the Board will be elected by the registered pharmaceutical chemists of Victoria from their own body according to regulations to be made by the Board and sanctioned by the Governor in Council. Power is given to the Governor to remove the President or any other member of the Board. The persons nominated to form the first Board are Mr. J. BOSISTO, Member of the Legislative Assembly, whose name is well known in connection with the *Eucalyptus* industry; Mr. C. R. BLACKETT, Honorary Secretary of the Pharmaceutical Society of Victoria; Mr. W. JOHNSON, Government Analyst, and Messrs. H. BRIND, G. E. GREEN, J. HOLDWORTH and G. LEWIS. The Board is to have the power to appoint a Registrar and other officers necessary for the purposes of the Act.

Parts Two and Three provide for the keeping of a correct "Pharmaceutical Register of Victoria," and persons enrolled on this Register are to be described in all regulations, etc., as "Registered Pharmaceutical Chemists." This Register is to contain the names of persons not less than twenty-one years of age who have (1) at any time before the commencement of the Act kept open shop for not less than two months as chemists and druggists or homœopathic chemists engaged in the dispensing of prescriptions of legally qualified medical practitioners; (2) those who have previous to that time been employed as dispensing assistants for not less than three months in such a shop, or for not less not less than three years as dispensing chemists in hospitals, benevolent asylums or other public institutions; (3) those who hold certificates of competency as chemists and druggists from the Pharmaceutical Society of Great Britain or any College or Board of Pharmacy recognized by the Board; and (4) those who have served not less than four years' apprenticeship with a registered pharmaceutical chemist, attended one course of lectures and passed examinations in materia medica and medical botany, and practical chemistry at the University of Melbourne or other recognized college and passed examinations under the superintendence of the Board in practical pharmacy and any other subjects prescribed by the Board and approved by the Government. This latter examination, however, is not to include the theory and practice of medicine, surgery or midwifery. A rejected candidate may present himself for re-examination after six months.

The Fees payable under the Act are, for examination before the Board, as above specified, Three guineas, after which the successful candidate is to be registered for a further payment of One guinea. The fee for registration of persons who are not compelled to be examined is Two guineas.

Amongst the miscellaneous topics dealt with in Part Four, it is provided that upon the death of a registered pharmaceutical chemist actually in business at the time of his death it will be lawful for any executor, administrator or trustee of his estate to continue the business under the superintendence of a registered pharmaceutical chemist for a period of twelve months, and no longer, unless by permission of the Board of Pharmacy. The penalty for any unregistered person carrying on the business of a chemist and druggist or assuming any variation of the title is to be ten pounds for each offence and he may also be committed to prison for six months.

The Poisons Act restricts the sale of the poisons mentioned in a schedule to legally qualified medical practitioners, registered pharmaceutical chemists, and dealers in poisons holding a certificate from the Pharmacy Board. These certificates are to be issued by the Board under certain guarantees, and upon the payment of one guinea, to persons living in places at least four miles distant from any city, town, or borough, and in which no registered pharmaceutical chemist has an open shop.

The Schedule of Poisons is divided into two parts and varies but little from the English schedule. Chloral hydrate is included in the first part, and "cyanide of potassium and all metallic cyanides," is remitted to the second. The second part also includes the line, "Arsenical preparations except green and other coloured paints and pigments." Besides the restrictions as to registration, labelling, etc., found in the English Act, no sale of a poison in the first part of the schedule is to be made in Victoria to a person under eighteen years of age, and strychnia, as well as arsenic, is to be coloured before sale, except where such colouring would render it unfit for the purpose required.

The Act does not extend to the sale of poisons contained in medicines compounded according to the prescriptions of medical men, or to homœopathic medicines, except the crude mother tinctures or when of a greater strength than the third decimal potency; neither is it to interfere with the sale of patent medicines, photographic materials, veterinary medicines, fly and similar poisons, except poisoned seed for vermin. Wholesale transactions are also exempt, provided the dealer has a written order for the supply of the poison, and that the sales be recorded and the packages be labelled "poison."

AN ACTIVE CANTHARIDAL VESICANT.

A "COUNTRY CHEMIST" recommends in the *Pharmacist* an "acetic cantharidal vesicant," prepared by exhausting the flies with acetic ether, as was suggested in the paper read by Mr. JAMES DEANE at an evening meeting of the Pharmaceutical Society last session. But the testimony he brings as to the efficacy of the preparation has a little more novelty. A physician who had kindly undertaken to give it a "proofing" applied for a second supply, which he received in a bottle. Being on his way to pay a professional visit several miles distant, he deposited the bottle in his coat-tail pocket. When he reached home he was in a position to testify to the efficiency of the preparation and had satisfied himself that "half an ounce would produce a good sized and very lively blister."

It will not be out of place to refer here to a statement, recently made, that in Algeria the military surgeons meet with cases of cantharidian cystitis among the soldiers, produced by eating the flesh of frogs, which in the months of May and June feed almost exclusively upon species of cantharides.

CINCHONA CULTIVATION IN JAVA.

The report given of the bark harvested during the latter part of last year in Java is scarcely so favourable as those previously published. The total quantity of bark obtained during 1876 was about 2000 pounds and to obtain that quantity upwards of 56,000 trees were stripped. Greater part of this bark was obtained from the *Cinchona succirubra* and *C. Calisaya* (*javanica*), and it contained an amount of quinine ranging from 0·58 to 1·27 per cent. together with from 0·18 to 4·78 per cent. of cinchonidine, small amounts of quinidine and some cinchonine. The Schukraft bark was poor in alkaloids. The Ledger bark, amounting to 1862 pounds, contained from 3·38 to 7·22 per cent. of quinine. The Crown bark contained between 3 and 4 per cent. of quinine.

During the last three months of the year 4432 plants of *C. Ledgeriana* and 2279 plants of *C. officinalis* were planted out, and in the nursery there are 205,030 seedlings of *Ledgeriana*.

INTERNATIONAL CONGRESS OF BOTANISTS AND HORTICULTURALISTS.

The Botanical Society of France and the Central Society of Horticulture have resolved to hold a Congress on the occasion of the International Exhibition in Paris between the 16th and 22nd of August, 1878, and a circular has been sent out inviting the cooperation or botanists and horticulturalists. The Organization Committee includes the names of Dr. Baillon, Dr. Chatin, M. Planchon, and several other botanists of eminence; the President is M. Lavallee, and the Secretary is M. Mer.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held at 17, Bloomsbury Square, W.C., on Thursday evening next, April 26th, 1877, at eight o'clock, when a paper will be read by Mr. H. G. Greenish on "Oxalate of Cerium," and Mr. R. H. Parker will show some experiments on the presence of Cinchonidine in Quinine.

LEGACY TO THE BENEVOLENT FUND.

A legacy of £10 to the Benevolent Fund has been received from the Executor under the Will of Mr. Joseph Bower Williams, Associate in Business of the Pharmaceutical Society, of Kinver, near Stourbridge, formerly of Kingswinford, Staffordshire.

Mr. James Dewar, Jacksonian Professor of Natural Experimental Philosophy in the University of Cambridge, Honorary Member of the Pharmaceutical Society of Great Britain, has been elected Fullerian Professor of Chemistry at the Royal Institution, in the place of Dr. Gladstone, resigned.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

The seventh meeting of this session was held in the Society's Rooms, 119a, George Street, Edinburgh, on Wednesday evening, 13th April. The chair was occupied by Mr. William Gilmour, President of the Branch—

The subject of the evening was:—

Experimental Illustrations of Recent Modes of Water Analysis.

BY J. FALCONER KING, F.C.S

Analyst for the City of Edinburgh.

One of the most important applications of chemistry to technical purposes is in the examination of substances intended for common consumption. For many years the processes which we possessed and employed in this department were of a very crude and unsatisfactory description. Of late, however, these old processes have either been entirely discarded and replaced by others, or have been very much improved. As examples of this improvement, I may mention my friend Dr. Muter's process of butter analysis. Ten or twelve years ago an analysis of butter was confined to determining the amount of salt, water, curd, etc., and no attention worth speaking of was directed to what is by far the most important adulterant viz., foreign fat, and the reason of this most serious neglect was simply our inability to detect or estimate with any degree of certainty, any of this ingredient which might be present. Then, again, take the important article of food, bread. We all know that this substance at one time, at all events, was occasionally adulterated with alum, etc., but as no short reliable process was known for the detection and estimation of this salt when occurring in bread, the law was rarely brought to bear upon defaulters who endangered the public health by adulterating in this way the staff of life. Now, however, things are changing; we have now an admirable and easily workable process for the detection and estimation of alum in bread, so that this form of adulteration is, I believe, rapidly disappearing.

It used to be said of some of the old processes for the detection of alum in bread, that they were so good and delicate, that they not only never failed to detect alum when it was present, but even often succeeded in doing so when there was no alum present at all. I might enumerate some more of these processes, such as those employed in the examination of wine, whisky, etc., but my time is short enough for the work proper which is before me. I merely mentioned these one or two improvements to introduce that which is a short experimental illustration of the great improvements which have taken place in late years in our modes of water analysis. It would be almost amusing, if it were not such a serious matter, to think of and criticize these old processes, such as that for the detection of alum in bread, but when what used to be and in some quarters was until quite recently, the process of water analysis, the process by which such an important article as water was declared to be suitable or the reverse for domestic purposes is described, one is apt to be disgusted rather than amused. Formerly, either from some wrong ideas or from inability to detect or estimate certain substances, that which is frequently the most potent cause of bad water was seldom or never determined. The results of an analysis of water, as reported by chemists a few years ago and as reported by some even yet, show with great minuteness the amounts of the different salts which are present, a matter, the determination of which is a tedious and, unless in very exceptional cases, a useless operation. Besides the entries showing the amounts of the different salts present, there was introduced at the end of the analysis a figure which was supposed to represent the amount of organic matter which the water contained. It would be difficult indeed to say what this figure really did indicate, but not so difficult to say what it did not. Whatever it was, it was certainly not organic matter. It was arrived at by noting the loss, after certain deductions and allowances had been made, which a water residue suffered when it was exposed to a red heat. There could hardly be a greater mistake, as I dare say all who hear me now will admit, than to imagine that the loss of weight here really represented the amount of organic matter present in the water; or even supposing that it did correctly show the amount of this ingredient, there could hardly be a greater fallacy than to regard it as a correct mode of judging of the suitability or unsuitability of a water for domestic use. I should here mention, however, that tonight I am to be understood as speaking simply of the analysis of waters intended for domestic use, and not of such as are intended for manufacturing operations, such as brewing, tanning, paper-making or the like.

In table B I show the mode in general use in former years, and which is still used in some cases, in reporting the results of an analysis of water. From that table it will be seen that by far the greatest amount of time and labour has been bestowed upon ascertaining the exact amount of calcium carbonate, etc., which the water contained, and also upon eliciting other similar information, all of which is of little or no value, while the ingredient which should have had most attention is pushed in at the end as if it was of little or no consequence.

When I say that a knowledge of the exact amount of the different lime and magnesia salts in a water intended for domestic use is not of much use, I do not wish it to be understood that my opinion is that the character of a water as a beverage is not influenced by the presence or absence of these ingredients. We all know for example that it is not a proper thing to imbibe in the water we use large quantities of carbonate or sulphate of lime or other earthy salts; but what difference does it make, whether the water we drink contains two or four grains per gallon of carbonate of lime or sulphate of lime, and yet the only information we get from such an analysis as this is in regard to these points. As showing in any way the quality of the water, the item at the end, the so-called "Organic Matter" is simply absurd. It is so in the first place, as it does not show in any way the amount of organic matter present; and it is so in the second place because even though it was a correct measurement of the real amount of organic matter present, it tells nothing whatever of the nature of that.

It would then simply show the quantity and not the quality of that. Reporting in this way is something the same as if a chemist who had analysed the contents of a stomach, reported that he found so much foreign matter present without mentioning whether the foreign matter was pea soup or prussic acid.

We are all aware that certain kinds of organic matter are perfectly harmless, while others we know certainly are very deteterious.

For example one water we will say is mixed to a small extent with gum arabic or wheat starch, and another is contaminated by some decomposing animal matter. By this mode of analysis both of these substances would be described as organic matter and if the former water contained twice as much as the latter of this organic matter, it would be condemned as being the worst; whereas we all know that the reverse would be true. A grain or two per gallon of such things as sugar or starch would not do much if any harm, while even an exceedingly small quantity of decomposing animal matter we are well aware is by no means an unimportant element of impurity in a water intended for use as a beverage.

The peculiarity of the mode of water analysis which I have adopted is that while a proper amount of attention is given to the saline constituents, such as carbonate of lime, chloride of sodium, etc., the most important part is determining the quantity of deleterious matter present, I do not pretend to estimate the total amount of organic matter, indeed I question very much whether that could be done, but even though it could it would not, as I have already indicated, be of much use in enabling us to arrive at a safe conclusion as to the suitability of a water for domestic use. What we want is the amount of really deleterious matter present, and the estimation of that in such forms as nitrogenous organic matter, nitric acid, iron, lead, copper, arsenic, etc., occupies the principal share of my attention in making an analysis of water.

My analysis when finished is reported in the form exhibited in table B. There it will be seen I set forth, 1st. The amount of total solid residue, which is divided into volatile and fixed. The fixed residue is next tested, and if from the results thus obtained it is deemed necessary, the principal salts are determined and the result written out, either *in extenso* or in the short form given in the table.

I will now proceed to demonstrate experimentally, as far as time will allow, the modes I pursue for the determination and detection of the different ingredients named in the table.

1. Total residue—by evaporating one pint carefully in a platinum basin in a place free from dust; carefully weighed, ignited and again weighed; noting carefully any peculiar change which may may take place on ignition.

2. Residue dissolved in dilute acid; any insoluble filtered off and examined; most likely silica: ammonia and ammonium chloride added to filtrate; any precipitate filtered off and examined; lime and magnesia then estimated and if those when calculated into salts fall much below the saline residue a fresh portion may be evaporated and further examined.

3. Saline and albumenoid ammonia as follows. Process described.

4. Nitric acid. Qualitative and quantitative. Process described.

5. Chlorine. Process described.

6. Iron. Process described.

7. Lead, copper, arsenic, etc. Process described.

8. Hardness. Process described.

9. Colour. Process described.

Mr. H. C. Baildon proposed, and Mr. John Nesbit, Portobello, seconded a vote of thanks to Mr. King for his interesting exposition, which was warmly responded to by a large and appreciative audience.

The Hon. Secretary announced the following donations: To the museum: Specimen of Radix Aconiti Heterophylli, from Dr. Moinet; Algarobilla Beans, from Mr. William Wallace, of Glasgow.

To the Library: 'The Year Book of Pharmacy for 1876,' from the editor.

The Chairman intimated that the last meeting of the session would be held on Monday, 23rd April, when Dr. A. P. Aitken, chemist to the Royal Agricultural Society, and Dr. William Craig, Lecturer on Materia Medica, Edinburgh School of Medicine, had promised to give papers.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The usual monthly meeting of this Association was held in Anderson's College, on the 11th inst. Mr. Kinninmont, vice-president, presiding. The business of the evening was the reading of a paper on "Paracelsus," by Mr. Samuel McCall Frazer. The paper gave a brief but interesting sketch of the life and career of Paracelsus as a physician, and the great opposition he had to contend against in endeavouring to establish the use of such chemicals as mercury and sulphur in the treatment of disease. Mr. Frazer also touched upon the philosopy of Paracelsus, and concluded by referring to the more important discoveries he made in the domain of medicine and pharmacy. At the close Mr. Frazer was awarded a warm vote of thanks for his most interesting paper.

The arrangements for the botany class, to be commenced on the 17th inst., by Professor Keddie, in the Free Church College, were then announced and the assistants connected with the Association urged to take advantage of it. Attention was also called to the announcement made in the report of the last meeting of the Council of the Pharmaceutical Society that Mr. D. Frazer had decided not to stand for re-election, and after some of the members had expressed their regret that Mr. Frazer had come to such a decision and their high appreciation of his work as a member of the London Council, the following motion was unanimously agreed to:—"That this meeting sincerely regrets the President's decision to retire from the London Council at this time, and instructs the secretary to convey to Mr. Frazer its warmest thanks for the great service he has rendered the trade generally, and especially the druggists of the West of Scotland, by the earnest and disinterested manner in which he has discharged his duties as a councillor at the London Board, since his first election in 1871; and trusts that he may, at some future time, be induced to stand for re-election."

Two new members were proposed and the proceedings were brought to a close.

REGISTERED CHEMISTS' ASSOCIATION OF LIVERPOOL.

The second annual meeting of the Registered Chemists' Association of Liverpool was held at the Royal Institution, Colquitt Street, on Thursday, April 5, at three o'clock, p.m., when the report of the committee and the treasurer's financial statement, duly audited by two members, were read and adopted. Mr. Abraham was unanimously re-elected president, and Messrs. Woodcock, Shaw, Fletcher, Blackbourn, Mackinlay, Stewart, N. Joseph, Wm. Evans, and Wm. Wright, were elected members of committee, in place of those who retired by seniority, and to fill two vacancies which had occurred. At a meeting of the committee on the 17th inst., Mr. Redford was unanimously re-elected vice-president, Mr. Shaw, treasurer, and Mr. Benjamin Dickins, hon. sec., in place of Mr. Wharrie who retired from the office. It was resolved that a second and re-arranged edition of the 'Retail and Dispensing Price Book' should be at once got up.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, W.C., on Thursday evening, April 5, 1877, when a paper was read by Mr. G. W. Bullen on "Starches." The author explained at the commencement that he had not treated the subject with reference to any particular branch, but in as general a manner as possible as he thought that would prove of most benefit and use to them as students. The following is a short abstract:—

"The substance known as starch or fecula is a highly organized body, occurring almost universally in the vegetable kingdom. It is incapable of assuming the crystalline condition, but has a cellular structure and is not producible by artificial means but only under the influence of the so-called vital force. Starch is found in greater or less abundance in all parts of plants, more especially in those organs that are of matured growth and excluded from the light. Starch is not, however, confined to the vegetable kingdom, as a substance almost identical with it has been found in certain animal tissues, as the brain, spleen, kidneys, etc., but this variety differs in being more or less associated with azotised matters. Starch belongs to the class of bodies termed carbo-hydrates, its formula being $C_6H_{10}O_5$. There are several other substances having precisely the same formula as starch, viz., dextrin, inulin and cellulose, which resemble one another in many respects; *e.g.*, they all possess the same percentage composition, each one is also capable of being converted into sugar, and upon treatment with nitric acid, oxalic acid is one of the products in the case of each. The character of these isomerisms is not as yet understood, so that they are provided with identical formulæ.

"Starch is almost always deposited in the form of granules, which vary very much in size and shape according to the source from whence they are obtained and the inequality of pressure and growth at different parts of the surface. The smallest granules are obtained from maize, rice and cereals generally, the largest from columba root, tous-les-mois, potato and maranta. With reference to the mode of development of the starch granule, several theories are maintained. Some observers, and, among others, the late Dr. Pereira, believed that the granule was composed of concentric scales of deposit of varying thickness, and that the striated lines were due to the edges of the scales being visible. Others consider the granule to be composed of an external membrane containing within it granular matter and describe the concentric lines as corrugations of the investing wall. According to Nägeli and Sach the granules are developed by internal deposition or intussusception. This theory is mainly founded upon the distribution of water through the granule, the exterior being supposed to be denser and less watery than the interior and the striated lines to be formed by sharply defined watery layers. The most popular theory is that which maintains the development by external deposition, and, from what has been written up to the present, this one seems to have the preference. Starch exhibits varied and numerous phenomena when placed under the influence of certain chemical and physical agents, such as polarized light, heat, nitric and other acids, both concentrated and diluted, iodine, etc.

"The method of obtaining starch varies according to the source. One of the simplest is that adopted for obtaining it from the potato. The tubers are first washed and cut into slices or rasped by machinery; the pulp thus obtained is placed upon a sieve and repeatedly washed by a stream of water; the starch passing through is allowed to settle, washed and dried. Potato starch is principally used in the manufacture of dextrin and glucose syrup. In obtaining starch from wheat a more complex method is requisite, because in wheat the starch is accompanied by an azotised material termed gluten. The grain is first coarsely powdered, wetted with water and allowed to ferment. It is then transferred to a large vat, mixed with a large quantity of water and the fermentation allowed to proceed for three or four weeks. During this operation the gluten of the grain undergoes putrefaction and by its action converts the sugar of the seed and part of the starch into lactic and acetic acids, which dissolve that portion of the gluten which has escaped putrefaction. The starch thus obtained is repeatedly washed, then drained, cut into square pieces, which are placed upon half burned bricks so that they absorb the moisture. It is then packed in paper, labelled, and placed in a stove, where it splits up into characteristic columnar masses, the cause of which phenomenon is not conclusively known. In the preceding process much of the starch is wasted, the whole of the gluten is lost, and offensive gases are also evolved from the putrefying nitrogenous matter. These losses and inconveniences were met by Mr. O. Jones, in 1840, when he took out a patent which he applied to the manufacture of starch from rice. The value of this process consisted in dissolving out the gluten by means of a weak alkaline ley, consisting of about 200 grs. hydrate potassium or sodium to one gallon of water. The gluten may be recovered by neutralizing the alkaline liquor with sulphuric acid.

"The majority of the valuable dietetic starches, as Maranta starch, from *Maranta arundinacea*, Portland arrowroot, from the tubers of *Arum maculatum*, East Indian arrowroot, from the rhizomes of *Curcuma angustifolia*, Brazilian arrowroot or tapioca meal and tapioca, from the juice of *Manihot utillissima*, Tahiti arrowroot, from the roots of *Tacca oceanica*, sago, from the interior of the stems of several species of sago palm, tous-les-mois, from several species of *Canna*, are all obtained from their respective sources, either directly, according to one of the two methods adopted for obtaining it from the potato or from wheat, or a modification of those methods."

A vote of thanks was then accorded the author for his interesting paper; also, votes of thanks to Professor Attfield and Mr. Holmes for microscopic slides and diagrams.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The Molecule and the Atom.*

BY PROFESSOR G. F. BARKER.

(*Continued from p.* 846.)

Our second question concerning the atom refers to its motion: Have the atoms within any molecule a motion independent of that of the molecule itself? Since, while all molecules in the gaseous state are of the same size, they contain widely different numbers of atoms, and thus without interfering apparently with each other, it follows that the spaces separating the atoms within the molecule must be far greater than the diameter of the individual atoms. The *à priori* argument, therefore, renders highly probable the existence of atomic motion within the molecule. And the actual facts observed justify this conclusion. Clausius has shown on the dynamical theory of heat that the total energy of all the motions in a gas is proportional to the absolute temperature.† But the total energy of a gas is made up of that due to the progressive motion of the molecules as a whole, and of that arising from the vibratory and other motions of the constituent atoms. And as these are parts of a connected system, it is evident that there must be a definite ratio between the total energy of any gas, and the energy of the progressive motion of its molecules, which is the measure of the temperature. This ratio has been actually measured in the case of air and of several other permanent gases. The most satisfactory evidence, however, of the existence and of the nature of atomic motion is afforded by the phenomena of spectrum analysis.‡ Since within certain limits the atoms within any molecule do not part company, it is clear that their motion must be of the nature of a vibration or a rotation while that of a molecule is progressive. It is obvious then that molecular motion must be excessively complicated, and its expression entirely beyond the powers of analysis. But, on the other hand, atomic motion is simple, being either directly harmonic, or capable, by Fourier's theorem, of resolution into a definite number of harmonic motions. Consider now what takes place in a gas at ordinary temperatures. The molecules, moving with great velocity, are continually impinging upon each other. The shock of the impact not only alters the direction of the moving molecule, but it sets into motion its atomic system; and this vibration, which is harmonic, preserves its character during the whole of the free path it traverses, or until the next encounter. While, therefore, the amplitude of the vibration is determined by the force of the collision, the period is fixed by the constitution of the molecule. If, now, the temperature of the gas be raised, the velocity of its molecules will be increased, and with the increased force of collision the amplitude of the atomic vibration will become greater. And if this vibration, when its amplitude becomes sufficient, be communicated to the surrounding ether, it will produce therein waves of a definite length and refrangibility. These, when analysed by a prism, will give a spectrum consisting of bright lines corresponding to these refrangibilities. The spectrum lines of the elements, then, represent simply disturbances of the ether by regularly vibrating molecules. Hence, the spectrum becomes a test for the vibration of the atoms within the molecules; and, therefore, since the period of vibration is fixed for every atom, a test for the atoms themselves wherever situated, provided only their light can reach the eye. The period of the hydrogen atomic motion in the laboratory coincides exactly with that which takes place on the sun, on Sirius, or even in the remotest nebula of space.

The greater the tenuity of the gas, the longer, obviously, is its free path, and the greater the time during which the harmonic vibration is uncomplicated by collisions. Hence the purity of the spectra of rare gases such as hydrogen, and of all gases when rarefied artificially. If, on the other hand, the density of a gas be increased, the free path is shortened, the collisions become more frequent, the regularity of the vibration is disturbed, and the spectrum lines widen to bands. Finally, the molecule has little or no free path, its motion becomes complicated, waves of all lengths are produced, and, as Frankland and Lockyer have shown,* the spectrum becomes continuous. The same result is attained by an increase of temperature. The increased velocity of the molecule increases the shock of collision, and consequently the amplitude of the vibration. At the same time waves of shorter period are developed, so that the final result is a continuous spectrum as before. In the case of liquids and solids, as we have seen, the molecules have scarcely any free paths. Whence it follows that liquids and solids, when incandescent, can give only continuous spectra. This is a well-known fact.

A third argument for the existence of atomic motion is based on the phenomenon of dissociation and on the mechanical theory of electrolysis. The opinion has been expressed by Clausius† that under certain circumstances the atomic vibration developed by molecular collision may be so intense as to overcome the attraction by which these atoms are held together, so that they go wandering about seeking new partners. If the conditions are such that during a given interval of time as many of these atoms unite as separate, and this in the same way, then evidently there will be no change in the composition of the gas. But if the temperature is so high that there are more separations than unions, the unions being less complex, then there is dissociation. The same assumption Clausius makes use of to explain electrolytic decomposition.‡ If, while this rapid decomposition and recomposition of molecules is taking place, some directive force be introduced, tending to urge certain of the atoms in one direction, and others in the opposite, there will obviously be a tendency for similar atoms to unite, since they find themselves associated. Hence, electrolysis produces simpler molecules from complex ones. Wiedemann has adopted this hypothesis, and has extended it, by compar-

ing the phenomena of electrolysis to those of diffusion.* He believes that the electric conductivity of an electrolyte depends upon the coefficient of diffusion of its constituent elements through each other.

The power of atoms to enter into combination with each other is usually ascribed to a force of attraction resident in them. The combining power of an atom is distinguished: first, by the quality of its action; and second, by the quantity of this action. The first of these was prominently recognized in Berzelius's electro-chemical system,† and the elements were classified as relatively positive and negative, according as they were evolved in electrolysis at the negative or the positive pole. The entirely distinct character of these two parts which the elements may play, and the wide differences of properties which are apparently due solely to this difference of quality in the combining power, go far to give it a prime importance. But why, for example, the union of hydroxyl to chlorine should yield an acid, and to potassium a base, we cannot as yet form any idea. The quantity of the combining power possessed by an element, as at present used in chemistry, is somewhat ambiguous, it being employed in two different senses. In the first place, it signifies the quantity of a standard element, with which the atom can combine, and under this definition is commonly called equivalence. Its second signification refers to the strength of the attraction with which an atom holds another of whatever kind; this conception is fixed in the word chemism. There is at present no known relation between the two quantities now defined. An atom may have a large equivalence, and at the same time its chemism may be very feeble. Indeed, from certain facts it would appear that in a certain sense the chemism of a body is inversely as its equivalence.

The equivalence of an atom is measured always by the number of hydrogen atoms with which it can combine or which it can replace. But as the whole value of the idea depends upon the invariability of the standard, and as there is no good reason why the hydrogen atom alone of all the sixty-four at present known should have an invariable equivalence, it cannot be long before the conception of equivalence will be merged in some higher generalization. There is no question that the theory now under discussion has been and still is of the greatest service in chemical science, the whole superstructure of organic chemistry resting on the tetrad character of carbon first established by Kekulé.‡ Notwithstanding all this, it is impossible to form any conception of its real essence. Why, for example, should the equivalence of an atom vary by two, so that when once even it always remains even? Again, what shall determine the upper limit of equivalence? The highest equivalence of any atom which has thus far been directly ascertained is six in tungsten, when it forms the hexachloride; though indirect evidence renders seven and even eight probable. Clarke, in a paper read before this section last year,§ came to the conclusion, from geometrical considerations, that the highest equivalence possible to any atom is twelve.

We have already defined chemism as an attraction between atoms, in view of which they unite with one another. Relatively, approximate measures have been made of the value of the chemism for different atoms; but no determination of its absolute strength has yet been given. One of the most successful early attempts to measure the chemism of atoms is that of Berthollet. In his 'Statique Chimique'‖ he formulates the two laws known by his name, which have been of much service,

‖ 'Essai de Statique Chimique.' 2 vols. Paris, 1803.

especially as modified by Dumas.* He rejected the idea of an "elective affinity," and showed that when a base in solution was acted on by several acids, it was divided among them, the activity of each acid being proportional to its chemical mass; or, as we should say to-day, to the product of the reciprocal of its equivalent by the number of equivalents.† In the light of present science, we see that he mistook physical for chemical phenomena, and that his laws are founded upon molecular rather than upon atomic attraction. Let me observe here that the tables of affinity so called, found in text-books, though now fortunately more rare than formerly, are useless for the same reason.

For nearly all the light which has been thrown in recent years upon chemism, we are indebted to electrical and thermal investigations. The magnificent development given to the science of energy during the past one or two decades, while it has not enabled us to approach nearer to the essence of attraction, has yet enabled us to measure it accurately in terms of work. The strength of gravity is expressed in units of work or foot-pounds, the force being greater according as more work must be done against it in moving a body of given weight through a given distance. But as Joule has shown that one heat-unit is mechanically equal to 772 foot-pounds,‡ it is evident that the force may be measured in terms of the heat absorbed in overcoming it, or in terms of any other force so employed.

Considering in the first place electrical investigations in this direction, we find that the force of chemism has been shown by Thomson to be capable of expression in a perfectly definite measure, that measure being electromotive force.§ The numerical value, he says, of the electromotive force which expresses the resultant chemism involved in a given reaction is equal to the mechanical value of the whole heat evolved during this reaction, when one electro-chemical equivalent of each substance entered into the combination. The electro-chemical equivalent here referred to is the same as that derived by Faraday from electrolysis, and according to which he classified the elements.‖ It may be defined as that quantity of matter which has the same combining or replacing power as one part of hydrogen by weight. If, for example, an electric current of precisely the same strength acts upon hydrochloric acid, water, and ammonia, for every molecule of hydrochloric acid decomposed, one half of a molecule of water and one third of a molecule of ammonia will suffer decomposition. It will be noticed that the quantity of hydrogen set free is the same in each case, and hence that that of the other constituent, being the quantity which combines with one part of hydrogen, is its electro-chemical equivalent. By this rule, therefore, the quantities represented by H, Cl, $O_{\frac{1}{2}}$ $N_{\frac{1}{3}}$ $(SO_4)_{\frac{1}{2}}$ are electro-chemical equivalents of these bodies. Precisely as, in accordance with the theory of energy, force is evolved in chemical union, so in electrolytic separation it is absorbed. Hence there is developed in the circuit a counter electromotive force which is proportional exactly to that fraction of the energy which is transformed into chemism.

In case there is no resistance in the external circuit, and consequently no work done there by the current, all the heat evolved appears in the battery cells themselves; while if chemical decomposition takes place in the external circuit, there is less heat in the battery, the kinetic energy of heat being converted into the potential energy consumed in overcoming chemism.

But the most light which has been thrown on chemism has been that derived from thermo-chemical investiga-

tions, particularly those of Berthelot* and Thomsen.† In these investigations the object has been to make a careful study of the thermal changes which take place during chemical reactions. The results which have been obtained are formulated in three most important laws by Berthelot, which are as follows: ‡

1st. The amount of heat set free in any chemical reaction whatever is a measure of the total work, both chemical and physical, accomplished in the reaction.

2nd. If a system of bodies, either simple or compound, taken under definite conditions, undergoes physical or chemical changes capable of bringing it to a new state without producing any mechanical effect exterior to the system, the amount of heat which is set free or absorbed as the effect of these changes depends only on the initial and final state of the system; and remains the same, whatsoever be the nature or the order of the intermediate stages.

3rd. Every chemical change which is effected without the aid of foreign energy, tends to the production of that body or system of bodies which evolves the most heat.

The value of these laws to the elucidation of all questions of chemical dynamics can hardly be over estimated. We have now, however, to concern ourselves only with the third, in illustrating the subject under discussion. In the first place, it should be observed that this law is a necessary consequence of the theory of energy. The amount of energy which a body has is a measure of the force with which it can combine. If such a body in combining does not part with all its heat, it will have the power of entering anew into combination, *i.e.*, it will be unstable. Hence, the larger amount of heat which the body loses in combining, the more stable the compound which is formed. The analogy with mechanical equilibrium is complete.

Parliamentary and Law Proceedings.

Attempt to Poison by a Servant.

On Tuesday, at the Manchester Police Court, Martha Baker, 59 years of age, was charged with attempting to murder her mistress, the wife of Mr. French, an accountant carrying on business in Manchester. Mrs. French being unwell on Wednesday morning, the prisoner was sent to the surgery of Mr. Rix for a bottle of medicine. Mr. Rix gave the prisoner the medicine, and when she returned home the prisoner said Mr. Rix had told her to make Mrs. French take the medicine, and that she must not mind if it made her sick. Mrs. French took two doses, and the result was that she was rendered very ill, and on the bottle being sent back to Mr. Rix he found red precipitate in such a quantity as to cause death if Mrs. French had taken much of it. The precipitate had been put into the bottle after it left his hands. He denied that he told the prisoner that the medicine would make Mrs. French sick, or that she was to make her take it. After giving Mrs. French the medicine, the prisoner told Mr. French that she was afraid to stay in the house alone as his wife might die at any moment. On being apprehended the prisoner said she did not administer the poison, and then asked, "Have you found out where I bought it?" She was remanded. —*Times.*

Review.

TABLES OF MATERIA MEDICA. A Companion to the Materia Medica Museum. By T. LAUDER BRUNTON, M.D., F.R.S., etc. London: Smith, Elder and Co. 1877.

The avowed object of the author has been to make these tables useful as a companion to the materia medica museum, so that by using this little work the student may be able not only to recall what he has learned from lectures and text-books, but to marshal the knowledge he has obtained. The principle which the author has built upon throughout is the law of association. The articles are grouped together in such a way that the student takes first in order the substance from which the other compounds are derived; thus among the acids sulphuric is taken first because it is used in the preparation of all the other acids. In this way the student learns first the tests for the most frequent impurities; for instance, after having glanced through the reactions of sulphuric acid, the use of the chloride of barium test for all the other acids becomes apparent and the fact is thus classified in his memory. In the introduction the student is directed how to use the tables, and we must confess that if he conscientiously follows out the author's directions he will find the tables exceedingly useful and will feel that he has been led to classify his information and improve his memory. The great danger in works of this kind is, lest students should substitute them for text books, and so obtain a superficial knowledge only.

The tables are divided into inorganic and organic, and an index is furnished at the end. Without the latter it would be somewhat difficult to find an article in the inorganic portion, for the tables begin with oxygen and pass on through carbon, sulphur and iodine, etc., to the acids, so that the arrangement as a whole in this portion is difficult to be understood. In the organic portion the drugs are arranged under their respective natural orders and are in consequence found with comparative ease without the use of the index. An alphabetical arrangement of the drugs in each family would, however, have been an improvement.

Great difference in type is observable throughout the list of names of the substances and appears to have been intended to give prominence to some articles and not to others, but this prominence does not appear to have anything definite about it, and we have searched in vain for any clue to its meaning. Under each substance its source, preparation, properties, reactions, impurities, source of impurity, tests, action, uses and doses are given in as few words as possible, and we congratulate the author upon the success with which he has been able to convey a vast amount of information in so succinct and clear a manner.

It is scarcely possible in this age of books to find one which is entirely perfect and this one is no exception. Although the author has consulted most of our recent standard works on materia medica, including 'Pharmacographia,' he has failed to apprehend in some cases the real meaning of the writers; thus *Empleurum serrulatum* is stated to have leaves which differ from those of *Barosma serratifolia* in not having an oil gland. Pareira brava is ascribed to *Cissampelos Pareira.*

In the organic portion the name of the substance is followed by its source, botanical and geographical; the name of the part used, mode of preparation; its distinctive characters; names of substances resembling it, how they may be distinguished; the composition of the substance, its action, use and dose.

The list of substances which may be mistaken for each other will probably prove very useful to medical students, though we venture to believe that no pharmaceutical student would confound colocynth fruit with Indian bael, or veratrum viride and valerian with arnica or senega, nor sarsaparilla with arnica. The book is of a very convenient size although a little too large for a breast pocket, and the type is very clear; and if the work be conscientiously used, as directed by the author, we feel sure it will not only be acceptable, but very useful to students of medicine preparing for examination. We cannot, however, recommend it to students of pharmacy who wish to pass the examinations of the Pharmaceutical Society.

Medicine Measures.

Sir,—Before proceding further in the discussion about the mode of measuring medicines, it might be as well to consult and ascertain the opinion of those first interested, namely, the prescribers.

I would like to know why the dispenser should take upon himself the responsibility of reforming the present system. Surely it is known to the physician and to most people, that table, dessert, and teaspoons vary in size, and knowing it, I believe as a rule the smaller size is adopted.

It is not unusual for a physician to prescribe a measured tablespoonful and so on, and sometimes he will distinctly order that a measure glass be provided, showing that he prefers to impress accuracy on the patient himself; besides it is not wise to exercise too great eagerness or anxiety that your customer should take an accurate dose of medicine; the motive is not always disinterested, and in many cases, where arsenic, strychnine and other potent ingredients form part of a prescription, it is quite opposed to the wish of the physician that any uneasiness or curiosity should be raised in the mind of his patient by the officious act of pointing out that the medicine must be accurately taken.

Referring to exceptional cases, where the patient is too poor or unwilling to invest in an ordinary measure glass, and the bottle cannot be accurately graduated, it is a very simple and inexpensive fact, as Mr. Long suggests, to present your customer with a phial the exact size of the dose required.

With due deference to the opinions of those gentleman who have interested themselves in this matter, I look upon the proposed alterations and suggestions as an unnecessary interference between the physician and the patient, and adding one more link to the chain of responsibilities which already encircles the business of a chemist and druggist.

THOMAS W. HORSLEY.

Notting Hill, April 17, 1877.

Sir,—After reading Mr. Proctor's paper and the discussion which ensued on the subject, "Medicine Measures," in your impression of last week, I feel impelled once more to offer a suggestion, made me by last year, which at the time met with a little ridicule at the hands of one of your correspondents, but which, notwithstanding, I continue to think would be a means of surmounting the present difficulty if adopted.

I would propose that the spoon shall continue to be recognized as hitherto, with the modification detailed below until, at least, the public become better acquainted with the more correct graduated measures. In the next place, makers should be required to produce spoons of the exact capacities of f℥ss, fʒij, fʒj, etc., stamped with some distinctive mark, which may easily be determined upon; for instance, the words:—"Official," "Medicinal," or "Imperial," might be prefixed, the inscription reading somewhat thus:—

Official Tablespoon
(Capacity—Half a fluid ounce).

This would enable the physician to designate, in familiar terms, the exact quantities he wished to be administered; and the dispenser would feel safe in translating the signs f℥ss, fʒj, etc., into such words as "Official Tablespoonful," "Official Teaspoonful," knowing that such stamped spoons would have the capacities so indicated.

If prescriber and dispenser concurred in insisting upon the use of the stamped articles, and those only, I do not think the public would be long in adopting the system also. Meanwhile, however, such "Medicine Measures" as those Mr. Proctor has been at so much pains to bring to perfection might be dispensed or sold wherever practicable; but in those neighbourhoods where the medical man does all his own dispensing I am afraid a long time would elapse ere such desirable accessories to the sick-room could be found in general use.

April 10, 1877.

Ignorance, and the Cost of Teaching.

Sir,—On reading the report of the appeal on the Runcorn milk of sulphur case one is struck with the very different amount of consideration shown by the Bench to the two contending parties. To the analyst who frankly confessed his entire ignorance of medicine, pharmacy, and the sale of drugs, every indulgence was shown, whilst to the druggists credit was barely given for knowing anything, even their trade; indeed, but for the evidence of Mr. Pemberton the defence would have failed. All honour to him for nobly daring to come forward in defence of an oppressed trade, and for his vindication of the utility of a medicine hitherto despised by most of the medical profession. No one can doubt after reading his evidence that the preference shown by the public for the old fashioned article has been founded on practical experience of its superiority. Yet this medical evidence, to which alone the partial victory is due, should not have been necessary, the point in dispute being a matter of fact not of therapeutics. It should have been limited to the single question, "Is the article complained of, the substance usually known by the name employed in purchasing it?" and if there had been much anxiety to do justice no difficulty would have been found in establishing that such was the fact. The question of the presence or absence of certain ingredients is quite irrelevant, and as to the injurious nature of either one or other, there is not a single medicine which is not injurious, according to the opinion of some author.

But what concerns the trade most of all in this case is the attitude of the magistrates toward the analyst, and this really ought to have our most serious attention. It reminds us of an old story, told in all times and in all languages, of the clown who picked up a snail thinking it was some fruit and who, finding his mistake on biting it, endeavoured to conceal his ignorance and disappointment by exclaiming with an air of judicial severity, "Take that, for being so like a plum." What the snail thought of the transaction we are not told; probably some dim idea crossed his gelid brain that he was the victim of injustice, and that the superior creature might have gained information at less cost of suffering to him, but reflecting that the strongest are always in the right, he slunk off silently to get his wounds healed. Now the world has up to this time considered that the gist of the story lay in the laugh excited by the clown's clumsy attempt at deception, but the Knutsford magistrates throw quite a new reading into the old text, as they are evidently of opinion that ignorance of a subject is a complete justification for inflicting suffering upon an innocent being. The scene in court after luncheon is worthy of remembrance. After conclusive proof had been given that the analyst by a little inquiry might have assured himself that over two centuries ago several substances were known by the name of milk of sulphur, and of these one secured popular favour and has been continuously used till now, and that one was the very article about which the action was brought, you might expect from the aristocratic guardians of public morality something like a homily upon the sin of taking up hastily an evil report against our neighbour. Nothing of the kind: the court evidently sympathized with the poor analyst in his defeat by a parcel of tradesmen who knew only their business. A fellow feeling for the official, who knew nearly as little about the matter as themselves, led them to feel deeply for him. *Le pauvre homme*, they don't expect him to have the knowledge of Mr. Pemberton! Certainly not; nor of any of the druggists either. It might have embarrassed him and prevented the action.

Whilst ignorance, invested with authority, has such privileges who would wish or labour for knowledge?

As for the reasons given for refusing costs, the absence of milk of sulphur from the Pharmacopœia, I have entirely failed to fathom its application to the case. The only thing known to me at all resembling it is:—

"At Kilve there was no weathercock
And that's the reason why."

Alas for us poor druggists! How much has it cost the trade to dispel the ignorance of some five or six public analysts! After all it is but a few who have made us suffer, for wherever the position is occupied by one of common sense and knowledge of the business of life, we have nothing to fear. Spirit of nitre, citrate of magnesia, milk of sulphur, and other substances, have in turn been the cause of heavy expenses, which knowledge, on the part of prosecutors, might have spared us.

But is it justice that we should be made to pay through the ignorance of others?

Shall we quietly sink into the position of a subject-race, having no right but the privilege of paying our "droits de seigneurie?"

There is a necessity for some general action on the part of all the trade, and the sooner this is begun the better the hope of success.

ALEX. KINNINMONT.

EMULSIONS.

Sir,—After reading the paper on "Emulsions," by Mr. E. Gregory, in the *Pharmaceutical Journal* of 14th inst., I proceeded to experiment for myself, adopting his last process, No. 9. When using castor oil and balsam copaiba, the results were most satisfactory, but when oil of turpentine was used, no result could be obtained that could be by any means termed an emulsion. After repeating the process two or three times I resolved to add more water, and I find that the best emulsion is formed with one part of acacia, two parts turpentine, and two of water; although a very excellent one can be produced by three-quarter parts of acacia, two parts turpentine, and two and a quarter parts water. Mixing first the acacia and turpentine, and adding at once the water, was the process I adopted, the result being an excellent emulsion in a few seconds. If any one is able to produce an emulsion on the plan No. 9, in Mr. Gregory's paper, I should be pleased to hear how it is to be done, for I confess it is beyond my powers.

4, *Cornwall Terrace, Rye Lane, Peckham.*

EARLY CLOSING.

Sir,—In view of the meeting about to take place in London, for discussing the means of promoting the earlier closing of pharmacies in the metropolis, a few words of practical experience may not be out of place, as the initiation of these innovations is always more or less surrounded with difficulties, and but too often results in disappointment and failure.

Some ten years since, with the desire of bringing about a similar change in Belgravia, I invited all my neighbouring chemists to my house to discuss the subject in a friendly manner, the result being an unanimous agreement to close our shop doors and turn out the outside lamps punctually at 9 o'clock, on Saturdays at 10·30, and on Sundays to keep our door as well as window-shutters closed, to abstain from lighting outside lamps, and further, to sell no articles but such as were required for medical purposes.

Having secured the signatures of all our neighbours for a considerable radius, our next step was to print and to circulate a large number of small hand-bills among our customers and over the counter in daily business, giving notice of our united action, and asking their assistance and consideration in enabling us to carry out the arrangement.*

The result of the effort was, I may safely say, a very great success, a few, but very few, partially broke through the engagement, and adopted various devices whereby to evade it, but the mass most faithfully adhered to it, and up to my leaving London, through ill-health, in 1874, within a few minutes of Big Ben striking nine, every one of our shops would be found closed, and on Sundays, with the few exceptions mentioned, not one of us, by open door or coloured lamp, invited the public to enter, while at the same time a ring at the bell or a turn of the handle was always sufficient to obtain admission and the needed supply, whether on Sundays or other days. The closed door and the partially lighted shop had a moral and persuasive influence upon the public mind, and to a large extent reduced our Sunday and late work to a minimum.

The great secret of success is the cultivation of friendly feeling and sympathy, rather than a petty jealous supervision, and an honourable firm adherence to the engagement, notwithstanding the delinquencies of a few.

EDWIN B. VIZER.

Belgrave House, Cliftonville, Brighton.

* Vide *Pharm. Journ.*, s.s. vol. 8, p. 257.

Sir,—In reply to the letter of a West-end Assistant, respecting the lethargy of the Bayswater and Notting Hill chemists, I wish to draw his attention to the fact that so far back as the year 1856, in the month of February, the late Mr. J. Garle, Mr. G. Y. Sharpe and myself, canvassed the whole district from Shepherd's Bush to Great Western Railway, and obtained the consent of all save one to curtail the hours of business by closing finally at 9 o'clock, a step then far advanced compared with the very long hours, viz., till 11 and in some cases half-past, but finding the one dissentient in Westbourne Grove destroyed the harmony otherwise existing throughout the district, the then existing chemists of Notting Hill and Shepherd's Bush resolved to close their shops at 9 o'clock from the first week in April of that year. And although many competitors afterwards opened businesses they, the older and longer established, honourably kept to their agreement, notwithstanding their rivals kept and do keep open (some still to most unreasonable hours), although others have somewhat fallen into the example set them, and the successor of the late Mr. Garle has for several years past closed entirely at 8, thereby being the pioneer of what may be done throughout the district. My object in addressing you is to enlighten your correspondent that although possibly all has not been accomplished that is desirable, yet a long stride in the right direction was made in the year 1856 by the then existing chemists of the neighbourhood, and to remove the slur of apathy or lethargy from several now in business and who will gladly welcome, I feel certain, a further reduction of the hours of business if the whole brotherhood will unanimously join in such a much to be desired arrangement. It rests with themselves quite as much as with the public, the bulk of whom will soon be educated to the change, and then, as very graphically expressed a few years ago, the "white slaves" will be released from their thraldom. "White slaves" was a theme which led to several letters in Journal some years back.

ONE OF THE FIRST EARLIER CLOSERS.

"*Syrupus*, P.B."—(1) *Bartramia pomiformis*; (2) *Tortula subulata*; (3) *Bryum bimum*; (4) Send a larger specimen; (5) *Atrichum undulatum*; (6) *Pogonatum nanum*; (7) *Ceratodon purpureus*.

H. Bartlett.—We are unable to answer the question without knowing the nature of the formula. The Act of Parliament is explicit with respect to details.

"*Inquirens*."—It is beyond our comprehension.

"*Local Sec.*"—The muddiness probably arises from the presence of albuminous matter, due to imperfect clarification, and might be removed by filtration through cotton.

B. B.—(1) No, the presence of nitrites is not in itself an indication of the fitness or unfitness of water for drinking purposes. (2) Wanklyn's 'Water Analysis,' published by Trübner.

F. B. Langdon.—(1) Water Lane, Blackfriars. (2) We believe the lists are published in the weekly medical journals.

C. B.—We cannot answer the question, as much might depend upon the circumstances of each case.

T. Horton.—It is impossible to name the plant without the flowers.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Manning, Mr. Hallaway, Mr. Gostling, Omega, Fair Play, Juvenis, J.B., A.J.R.

"THE MONTH."

The bright green tint of spring is now prevalent everywhere, and many a wood is gay with the delicately tinted flowers of the wood anemone and the golden cups of the marsh marigold, while the pale yellow tufts of primroses are scattered like nosegays in many a sunny copse and hedgerow. Even in the smoky city, the flowers feel the genial warmth and moisture of the atmosphere, and the flower stalls are gay with deutzias, genistas, polyanthuses, cinerarias, wallflowers, and many another well known household favourite. In the Botanical Gardens so large a number of plants, having more or less medicinal interest are now coming into blossom, that it is difficult to decide which best deserve the fullest notice.

In the Apothecaries' Gardens, at Chelsea, the delicate lilac blossoms of the labdanum plant (*Cistus Creticus*, L.) may be seen in the hothouse. The flower is much like a rose in shape and general appearance, but the petals have a crumpled look like those of the red poppy, and are just as fugacious. The opposite entire leaves and the hypogynous stamens at once distinguish the plants of this order from those of the rose family, while the five persistent sepals and the opposite leaves distinguish them equally well from the poppy family. The leaves, although not furnished in this climate with much of the resin for which the plant is famed, yet still possess a certain amount of fragrance. The odour is particularly pleasant and very persistent, and it seems strange that while such a disagreeable drug as opopanax has been turned to account by the perfumers, labdanum should have fallen into undeserved neglect.

Several American medicinal plants are now in blossom in the same garden; most prominent among these are the pale purple flowers of the *Geranium maculatum*, L., the root of which is official in the United States Pharmacopœia under the name of Cranesbill, but which, equally with *Heuchera americana*, L., is sometimes known as alum root. Like most of the Geraniaceæ, it possesses powerfully astringent properties. It is occasionally to be found cultivated in gardens in this country, and bears some resemblance to our native species, *G. sylvaticum*, L., and *G. pratense*, L., from which it differs in its angular stem furnished with reflexed hairs and in the upper leaves being opposite.

Another less conspicuous plant is the yellow-root (*Xanthorrhiza apiifolia*, Willd.), official in the secondary list of the United States Pharmacopœia, which has small purple flowers, looking very like those of the *Aucuba japonica*; this is now also to be seen in blossom. *Asarum Canadense*, L., known in the United States as wild ginger, may now be seen in blossom in company with its European relative *A. europœum*. The flowers are small, solitary, dingy purple bells, bearing some resemblance in colour and shape to those of belladonna, and generally scarcely raised above the ground, so that it is only by carefully looking among the leaves that they are seen at all. These little plants belong to the order Aristolochiaceæ, which is remarkable for the singularity of its flowers. In the Canadian plant referred to, the leaves are somewhat kidney-shaped, and when young are folded in half (affording an instance of conduplicate vernation), shortly stalked and all radical. The flowers are remarkable for having the parts usually in multiples of three, the superior calyx being three-parted, and the stigma divided into six parts; the twelve stamens are very curious, all of them having the connective prolonged beyond the anther into an awl-shaped process, so that the anther appears as if it were sessile on the middle of the filament. Six of the stamens are longer than the others, and their anthers rest between the stigmas, the other six are shorter than the style, and are opposite to the stigmas; all of the anthers are extrorse, so that self-fertilization is scarcely possible. The English species is very similar in appearance, but the leaves remain throughout the winter, those of the Canadian plant withering away. The Canadian species is also a much more variable plant, the flowers being sometimes four-cleft, and having sixteen stamens and eight stigmas; the leaves also very variable in outline. The leaves of the English plant form an ingredient in cephalic snuff, and the root possesses emetic properties in doses of ½ to 1 drachm. Wild ginger is used to promote perspiration and expectoration.

Another lowly plant, *Gaultheria procumbens*, L., belonging to the heath family, and official in the United States Pharmacopœia under the name of wintergreen, is now bright with its red coral-like fruits, which are very conspicuous among the dark shining green leaves of the plant. The oil yielded by these berries and by the whole plant is the well known oil of wintergreen of commerce and is remarkable for being the heaviest known essential oil, its sp. gr. being 1·175.

The pretty little scurvy grass, *Cochlearia officinalis*, L., is the only representative of medicinal cruciferous plants as yet in blossom. Its small bluish white or white flowers may be found equally on the mountain and on the sea shore, and are a common feature in rocky districts. Formerly the plant had a high repute for the cure of scurvy; Gerard speaks of it in his Herball as an undoubted remedy for that disease, and states that it cures fetid breath, etc. A small form of the plant, *C. Danica*, L., with the stem-leaves stalked, often occurs some distance inland in maritime districts, decking the hedge-banks with its small white flowers.

In the economic house at Kew Gardens, the Barbadoes aloes, *Aloe vulgaris*, Lam., may now be seen in blossom. The leaves are much broader than those of the Socotrine aloe, and the flowers are of a pale yellow colour, the outer segments of the flowers having a green stripe down the middle; the flower spike is forked. The grass which yields citronelle oil, *Andropogon Nardus*, L., is just coming into flower. *Chloranthus inconspicuus*, Sw., and *Jasminum Sambac*, L., the flowers of which are used in China for flavouring tea, may also be seen in blossom here. *Pelargonium capitatum*, L., one of the species which yield oil of geranium, is noticeable on account of the rough appearance of its leaves, due to its hairs being furnished with bulbous bases. The leaves resemble in shape those of the common pelargoniums, but the flowers are small and are very similar in appearance to those of the "oak geranium." The castor oil plant, the cotton plant, and the coca are also still in blossom in the same conservatory, while the ipecacuanha will be in flower in about a week.

In the open ground the Berberidaceæ are well represented, particularly in the herbaceous ground, where the *Podophyllum peltatum*, L., is just sending up its leaves, looking like so many small, green, folded umbrellas, each leaf being bent backward on the leafstalk, and its lobes folded in a convolute or twisted manner; in another week it will be freely in flower. The *Jeffersonia diphylla*, Pers., or twin-leaf of the Americans, has a white flower, not unlike that of *Podophyllum*, but only about half the size; it is especially remarkable for the leaves being binate and somewhat reniform. The flowers arise directly from the ground, and not from the fork of a double leaf as in the *Podophyllum*. The capsule is very curious, looking somewhat like a poppy fruit, only the stigma is raised on a short stalk, and the ovary when ripe opens half-way round horizontally, the upper portion forming thus a hinged lid which when open exposes the seeds attached to one parietal placenta. The anthers, as in most other plants of this order, open by valves. The root is used by eclectic practitioners in the United States in syphilis, and as an expectorant instead of senega. Another flower belonging to this order, *Epimedium alpinum*, L., although not used in medicine, is well worth examining on account of its curious structure, the inner row of petals being formed into horn-shaped nectaries.

Among the umbelliferous plants, the caraway is just coming into flower, and is easily recognized by the stipules at the base of the leaf-sheath, stipules being very rare in this order. It is not a little singular that this plant, which is a northern species, produces in Morocco a variety of robust growth, which forms fruits nearly twice as long as the ordinary kind. The Alexanders (*Smyrnium Olusatrum*, L.), the root of which was formerly and in some districts is still used by herbalists, is now conspicuous with its shining green leaves and yellow flowers, which on account of their fæcal odour attract hundreds of blowflies. In the Chelsea Garden every umbel was dark with blowflies, while at Regent's Park the common yellow dung-fly was to be seen on every tuft of flowers. The leafstalks of this plant were formerly used as a pot-herb. Among the labiate plants the rosemary is now a very noticeable object, its pale greyish-blue flowers contrasting strongly with its dark green leaves. The latter, which are linear in shape, somewhat like those of lavender, but shorter and narrower, are strongly revolute and covered at the back with a white down, consisting of stellate hairs. The flowers terminate short axillary branches, and appear to unfold in a very irregular manner, each little tuft opening centripetally, and having the appearance of a corymb; this is probably due to the fact that it is made up of axillary cymes in which only one flower of each is developed. The calyx appears at first sight to have only three teeth, but upon slight pressure the upper tooth is seen to be divided into two, so that there are four in all. The style protrudes considerably beyond the ringent corolla, and becomes after a time bent downwards. The stamens are only two in number, and the anthers are very slightly attached to the tips of the filaments. Only one lobe of the anther appears to be developed, the other being represented by a short spur or subulate point on the other side of the filament, which, it has been suggested, may represent, in connection with the portion of the filament above it, an elongated connective similar to that occurring in *Salvia*, to which genus it also approaches in the form of the calyx.

The cherry-laurel (*Prunus Lauro-cerasus*, L.) may now be seen in bloom, not only at Kew, but in gardens and shrubberies generally, especially where sheltered by other trees. The shining green lanceolate leaves taper rather abruptly at the base, and are furnished with small teeth (serratures) at the margin, which being recurved partially conceals them. On the under surface of the leaf below the lowest pair of veins, and close to the midrib, may be seen from two to four shallow depressions; these are glands, which exude a saccharine matter in spring and soon assume a brownish colour. It is rather remarkable that the leaves, which, when punctured, give off an odour of prussic acid, may be dried and powdered without doing so, until moistened with water. It might almost be inferred from this, that the amygdalin, and the emulsin or other similar substance, must be contained in separate cells. The white, rather small flowers are arranged in erect axillary racemes, and in structure are similar to those of the plum and blackthorn. The cherry-laurel must not be confounded with the true or noble laurel (*Laurus nobilis*, L.), so called because the leaves were used by the ancients for making victors' crowns. This shrub is now also in flower, and is worth examination on account of its curious anthers. The leaves are of a darker green than those of the cherry-laurel, and taper more gradually towards the base; the margins of the leaves also are wavy but not serrulate. The flowers are small, yellowish-white, and are arranged in small, almost sessile, twin umbels in the axils of the leaves, each umbel being furnished with a small involucre of scaly bracts. The calyx is 4-parted. In the male flowers there are twelve stamens, each furnished near the base with two yellow sagittate glands. The anthers dehisce by valves. In the female flowers there are four sterile stamens, alternating with the lobes of the calyx, each furnished near their apex with a pair of glands. The fruit, commonly known under the name of bay berries, yields upon pressure a semi-solid fat, known as oil of bay, in lieu of which oleum viride is often wrongly supplied in retail shops. The bayberry powder used by herbalists is not, as might be supposed, the powdered berries of this plant, but is prepared from the root-bark of an American plant, *Myrica cerifera*, L., a catkin-bearing plant, nearly allied to our own bog myrtle (*Myrica Gale*, L.).

In the economic house at the Botanical Gardens, Regent's Park, the Barbadoes aloe (*Aloe vulgaris*, L.) is now coming into blossom, and the mango (*Mangifera Indica*, L.) is covered with pyramidal panicled cymes of small yellowish white flowers. The leaves are large and lanceolate in outline. The bark of this tree has been used for restraining mucous discharges, and the leaves for chest affections and disorders of the liver.

In the open ground *Carum Carui*, *Asarum Europæum*, and *Daphne Laureola* may be seen in blossom, as well as the little lungwort (*Pulmonaria officinalis*) with its spotted leaves and pink or blue flowers. This plant was formerly held in considerable reputation for pulmonary diseases, a reputation which it first obtained from a belief in the old doctrine of signatures, and retained for a considerable time by reason of its demulcent properties. The lungwort now sold by herbalists is not this plant, but a lichen, *Pulmonaria officinalis*, sometimes also called oaklungs.

On chalky pastures and banks, the little pasque flower, *Anemone Pulsatilla*, L., with its dull purple bell-shaped flower, may now be looked for. The root of this plant is used by homœopaths to form a tincture, which, under the name of "Pulsatilla," is used to restrain mucous discharges. The flower-stalk (scape) is furnished with a whorl of bracts which, like the leaves, are finely divided. When in bud, this involucre is immediately beneath the flower, and the flower-stalk is then only two or three inches high. By the time that the hairy purplish calyx has fallen, the flower-stalk has so elongated that the fruit has become removed 3 or 4 inches from the involucre, and the styles of the carpels have become developed into long feathery tails which render the head of fruit a conspicuous object. The plant is rather local, but where one plants occurs, there are generally hundred of others.

In the Edinburgh Botanical Gardens, Professor Balfour kindly informs us that the Asarabacca, *Helleborus viridis* and other species, and *Arctostaphylas Uva-ursi*, are all in blossom in the open ground. The latter plant we have not observed in flower, in either of the London Botanical Gardens. Another plant of the heath family, the trailing arbutus, or ground laurel (*Epigæa repens*, L.), has been in splendid blossom during the past month, and has formed one of the most noteworthy features on the rockwork. Its little white bells tinged with red, are as fragrant as they are pretty, and should render the plant a general favourite. The stem and leaves have been used in America for the same complaints as uva ursi, and are said to have succeeded where the latter has failed. Another plant, *Polygala oppositifolia*, L., which is also in flower in the London Botanical Gardens, although not used in medicine, is worthy of notice by those who are studying botany, on account of its flowers having a falsely papilionaceous appearance. This is due, partly to the two lateral sepals being large and petaloid, and partly to the lower large petal forming a kind of keel.

Through the kindness of Dr. Moore, Director of of the Botanical Gardens at Dublin, we are enabled to say that the following medicinal plants may now be seen in blossom there: *Erythroxylon Coca*, *Drimys Winteri* (growing in the open air); *Nicotiana Virginica*, *Arctostaphylos Uva-ursi*, *Cochlearia officinalis* and *Daphne Laureola*. *Polygala chamæbuxus*, a small procumbent plant with leaves shaped like those of the box tree, is now also in flower. It possesses properties similar to those of senega.

The chiretta in commerce at the present time is of very inferior quality. Specimens of the spurious kind described by Professor Bentley have come under our notice during the past week. This kind is easily distinguished by its less bitter taste, by the absence of pith, and by the woody portion of the stem being thicker than in the genuine kind. Some specimens of chiretta possessing the solid well-marked pith of the genuine kind, but having hardly a trace of bitterness, have been lately met with. Possibly this may be owing to damage during sea voyage. We advise our readers to taste their chiretta before preparing or dispensing an infusion made from it.

It is quite time that some steps were taken by Government to appoint an inspector of the drugs which come into the London and other markets. Only last week the public sale of eight bags of partly mouldy ergot was recorded in the *Public Ledger*. It would be instructive to ascertain how many human lives are likely to be endangered by the administration of ergot which has thus lost its activity and how many dispensing establishments are likely to have their reputation tarnished by the unwitting sale of bad ergot.

It was scarcely to be expected that the concession granted to an English firm of exporting mummy bones from Egypt should have brought anything into the drug market; nevertheless, during the past month, a quantity of mummy asphalte has been offered for sale and purchased by private contract, for use, it is believed, as a brown pigment. To what base uses may we come at last!

In the April number of the Chemical Society's Journal, there is a note by W. R. Hodgkinson and H. C. Sorby on *pigmentum nigrum*, the black colouring matter contained in hair and feathers. When these are treated with warm dilute sulphuric acid, red or brown solutions are obtained, which exhibit decisive absorption spectra, but the authors do not state clearly whether they regard this coloring matter thus dissolved or the insoluble black amorphous matter as the *pigmentum nigrum*. They give some analyses which are as follows:

Several species of—	C.	H.	N.
Corvus (mean of 10 analyses) . . .	55·4	4·25	8·5
Ciconia alba (mean of 2).	55·5	4·8	8·5
Corvus pica (mean of 2).	49·5	4·8	7·6

After this, the authors remark that the composition of egg albumin, which contains sulphur and 7 per cent. of hydrogen, is very similar. We do not quite perceive the similarity, nor do we well see that the above analyses support the formula the authors deduce from them, viz., $C_9H_8NO_4$, or $C_{18}H_{16}N_2O_8$. Of course, anything may be true, and there are few things without some show of reason; madness has at times method in it, but this appears to be more than some authors have.

R. Nietzki* has described a new glucoside existing in the flowers of *Cichorium Intybus*. It is said to crystallize in long white needles, soluble in hot water, alcohol, and ammonia, but insoluble in ether. It melts at 250-255°, and on boiling with dilute acids, splits up thus—

$$C_{32}H_{34}O_{19}+2H_2O=C_{20}H_{14}O_9+2C_6H_{12}O_6.$$

All these glucosides are extremely interesting compounds, but with each new addition to the list, it is to be regretted that we generally hear more of the glucose to be obtained from them severally than of any accompanying products; presumably, they are not so easy of detection, nor do they admit of such ready investigation as sugar.

M. Berthelot† has ascertained that ozone formed by the action of the electric discharge upon oxygen will not oxidize nitrogen in the presence of pure baryta water into nitrite or nitrate, but if the ozone be furnished by the slow oxidation of moist phosphorus it does so in a small degree; thus, in one experiment M. Berthelot obtained less than one-twentieth of a milligram of nitrate (of barium?). This is a very small amount, but that nitrate is formed at all would be an interesting fact if the author had in the first place established the proposition that phosphorus by its slow oxidation yields ozone. Some chemists are sceptical about this matter, and regard the product as peroxide of hydrogen; but this is of course of secondary importance.

Apropos of this subject, it is interesting to note a paper by M. Corne,‡ an abstract of which is fur-

* *Arch. Pharm.* (5), 4, 327-337.
† *Compt. Rend.*, lxxxiv., 61—64.
‡ *Journ. de Pharm.* (4), xxii., 425.

nished in the April number of the *Journal of the Chemical Society*. The author describes his paper as setting forth a "New Reaction for Iodates and Iodides," which consists in adding to such solutions a few drops of water in which phosphorus has been kept for some time; iodine is then immediately liberated. The reaction, however, does not take place in the presence of an excess of alkali, and this is not to be wondered at. As neither phosphorus nor phosphoric acid can give this reaction, the author illogically concludes that it must be the result of the presence of phosphorous acid; perhaps it may be, but more probably it is due to peroxide of hydrogen. Therefore, until this matter is settled, it is best to refrain from entering into the uses of this new reagent and the application of this new reaction as set forth in the author's paper.

Were it not for the consumption of space, many other instances of similar scientific advances which have come to light during the month might be adduced, but they can be found in the *Journal of the Chemical Society*, from which we now pass on to "fresh woods and pastures new."

Numberless as are the articles that have been written about our milk supplies, and the necessity of a pure milk supply, the medical press still continues to float new articles and to impress humanity with the stated necessity. Thus, in the *Medical Times and Gazette* of the 21st inst., there is an editorial article on pure milk, setting forth the dangers of impure milk in communicating typhoid fever, and we are assured that the Aylesbury Dairy Company do their best to give their customers the best and safest article they can command. Doubtless this is so, and it is equally true of many other companies and individuals, but what is the good of the best, if the best is not worth having? And where is the test? Surely no chemist can say, "This milk is impure, and will give you typhoid fever if you drink it, and this other sample is pure and will not do so"! It is quite true that a chemist might tell if a certain sample of milk contained a large quantity of sewage, but no chemist can certify, and no medical man can certify, to the absence or presence of disease germs in ordinary samples of milk; therefore, the meaning of the second article, in the above quoted journal, on "The Aylesbury Dairy Company," is somewhat hidden, notwithstanding the analyses by Mr. Wanklyn which are therein quoted. "A rose by any other name would smell as sweet," although it may have poison to its core; and in the same way the contaminating influence, if any there be, in milk is not to be exposed by chemical analysis.

The public analysts have had further cases of peas containing copper; and there has been another case of tea adulterated with iron, which could be detected by the magnet! It is almost sad to think how persistently the public will continue to demand poisonous articles in spite of the learning and skill exhibited by the analytical "back bone and sinew" of this country.

Beyond these cases, there have been several prosecutions for the sale of sweets coloured with plumbic chromate. In one instance it was found that the sweets contained one fifth of a grain to the ounce, while in the second the analysis revealed the presence of twice this quantity of plumbic chromate. Both the dealers who had sold the sweets were fined on the showing that chromate of lead is a cumulative poison. But, in a third case, concerning the sale of a sugar-cured American ham, which had been coated with a composition containing the same substance, the summons was dismissed, on the ground that the composition was only a coating, and was not an admixture.

All this is extremely interesting, although it is to be feared that there are some who will fail to recognize this distinction without a difference.

It is convenient to notice here some researches recently communicated to the Académie des Sciences of Paris, by M. Richet, respecting gastric juice. He finds that the mean acidity of this liquid, when pure or mixed with food, amounts to 1·7 grms. per 1000; that this is almost invariable, and not dependent upon the quantity of fluid in the stomach. The consumption of wine or other forms of alcoholic drinks, as well as sugar, decreases the acidity, which reaches its maximum during digestion. M. Richet seems also to have ascertained that the sensation of hunger is not dependent upon the acidity or the emptiness of the stomach, a conclusion which derives support from other considerations. The gastric juice is secreted by the rennet glands and from these the juice flows out during digestion; in fact, digestion cannot take place without it. The sensation of hunger is to a great extent a nervous phenomenon, and one which is alleviated by causes which exercise an action upon the stomachic nerves. Among such actions is that of alcohol, a fact which was fairly established by Sir Benjamin Brodie, and which explains the observation of M. Richet to the effect that alcohol decreases the acidity of the stomach. Tobacco-smoking exercises a like influence, although probably through a different channel.

Simultaneously with advances in science, occur attempts, in other more practical directions, based generally indeed upon a scientific groundwork, to perfect either the apparatus used by the investigator or the instrument used by the surgeon in his treatment of disease. Among these there may be fairly noticed a perfected form of "Throat Spray," introduced by Messrs. Corbyn, Stacey and Co. This particular form is constructed upon the principles observed in all such pieces of apparatus, but is particularly good in kind. It is intended for the application of remedies in the shape of fine spray to the throat, mouth, and eye, in such a manner as to avoid causing any pain by the impinging of the liquid particles against sensitive parts. With the instrument there is also supplied a ton gue depressor and an eye piece, both of which are int ended to localize the spray to the affected regions.

J. Hertz† has extracted from a Mexican species of shell-lac, termed "Soma de Sonora," which exuded from the *Mimosa coccifera*, a body which he has designated "sarcosinic acid." This name has been given to it by reason of its apparent relationship to sarcosine, which substance has the same empiric formula ($C_3H_7NO_2$), but is not of an acid character. Hertz has examined the silver salt ($C_3H_6AgNO_2$), also the salts of barium, sodium, and calcium.

Scarcely have chemists recovered from the excitement caused by the discovery of gallium, before further studies in similar directions bring to light yet another new metal, which has been christened

* *Bull. Soc. Chim.* [2], xxvi., 450.
† *Arch. Pharm.* [3], viii, 244—251.

"Lavœsium," in honour of Lavoisier. This alleged discovery is the work of M. Prat, who states that lavœsium exists in many minerals, but more especially in iron pyrites. It is described as a silvery white metal, of a malleable and fusible nature, and forms salts which are colourless and highly crystalline. One of the most characteristic reactions furnished by its salts is that with ammonia, which gives a precipitate very soluble in excess; the potash precipitate is insoluble in excess. The spectroscopic characters of the new metal are perfectly characteristic, and consist of two sets of lines in the indigo; two sets of simpler lines in the bright green; and some blue, violet, and secondary lines, making in all a total of twenty-three lines.

Notwithstanding the interest appertaining to this statement, there are many possible sources of error to be eliminated before it can be entitled to absolute acceptance. Chemists will await with anxiety further information from M. Prat, and it will afford M. Mendeleef* and Mr. Newlands, another opportunity of testing the correctness of their particular views regarding the nature of the chemical elements and the mathematical principles underlying the atomic weights of bodies. The name of Mr. Newlands deserves mention in connection with this subject, because he claims to have foretold the existence of gallium even before Mendeleef, by virtue of a theory similar to that more recently made public by him. The Chemical Society of London did not see their way to publish Mr. Newlands' theory at the time he brought it before their notice.

Dr. W. von Knieriem† has for some time past been engaged upon a study conducted with the view of determining the origin of uric acid and urea. He finds that in the fowl the digestion of protein compounds gives rise to asparaginic acid, leucin, and glycocoll, just as these substances are formed by the digestion of proteids by mammals, and Dr. Knieriem concludes that these bodies constitute the antecedent stages of uric acid formation. The same antecedent stages, with the exception of salts of ammonia, he considers, relate to the production of urea in mammals. These ammonia salts are for the most part eliminated from the bodies of birds. It would be interesting to apply a similar process of investigation to serpents, whose dung is so largely composed of uric acid.

But what is far more important to bear in mind in connection with this subject, is the recent work by Schützenberger on the albuminous principles, by which it was tolerably well established that the urea group enters into the molecular constitution of albumin, and as proteids are modified forms of albuminous principles, it leaves little doubt that the urea excreted by mammals is derived from albuminous substances.

Dr. Richard Goddefroy has published‡ some analyses of the ashes of *Xanthium spinosum*, which was some time since recommended as a specific for hydrophobia, but which has since been proved to be useless for the purpose. He finds (1) that the ash of the leaves and spines of the plant contain most carbonate of potassium, while the ash of the stems is comparatively free from this substance; (2) that phosphate of lime exists most abundantly in the ash of the seeds, while the least amount occurs in the ash of the leaves and spines; (3) the ash of the stalks contains most silica; (4) that ferric oxide occurs in the greater amount (14 per cent.) in the ash of the stalks and the least in that of the leaves and spines.

Ten years having elapsed since the publication of the last edition of the French Codex, there has naturally been a large accumulation of new medicaments for which there exist no authorized methods of preparation. The subject has been under the consideration of a commission appointed by the Société de Pharmacie de Paris, which has drawn up a report that has now been adopted by the Society. In this report, directions are given for preparing the various constituents used in the compounding of the new medicinal agents.

Dr. Cech * has recently called attention to viridic acid, which is a green colouring matter obtained from the coffee bean by atmospheric oxidation in the presence of moisture. According to a previous investigation of this substance, by Rochleder, it is non-nitrogenous in character. Dr. Cech recommends it as suitable for use in imparting a green colour to articles of food, and from its innocuous nature it is certainly to be recommended in preference to copper salts, which are highly poisonous. *En passant* it may be observed that on more than one occasion viridic acid has been mistaken for copper in coffee.

THE GENUS COPAIFERA.*

BY PROFESSOR H. BAILLON.

In the preparation of the botanical portion of an article to appear under the word "Copaiva" in the *Dictionnaire Encyclopédique des Sciences Médicale*, the author has had to undertake some researches upon the principal sources of that drug and these have given rise to the following article. For the general characters of the genus the reader is referred to the author's *Histoire des Plantes* (pp. 140, 162, 192, figs. 123-128).

It is not very long since it was believed that all the copaiva of commerce was produced by the *Copaifera officinalis*, a species of which the geographical distribution has been much too extended in classic works, and which grows spontaneously only in Trinidad, Venezuela, Columbia, and in the south-western part of North America, starting from San Salvador. It is cultivated in several tropical countries in both hemispheres, notably at Martinique, and it sometimes attains a rather fine development in our hot-houses, where it occasionally flowers. It is a tree of medium height, sometimes tall, with hard wood of good quality; it is therefore sought for industrial purposes, as are also *C. pubiflora* and *C. bracteata*, which are said to yield the "purple wood" of commerce. The *C. officinalis* is glabrous, and has alternate branches. Its leaves have three or four pairs of oval-lanceolate leaflets, 6 to 10 centimetres long, 3 to 5 centimetres wide, supported on a petiole about ½ centimetre long, jointed at the base. These leaflets are nearly opposite or alternate, furnished with slender pinnate veinlets, which ramify and anastomose, forming a delicate network. They are rounded or slightly attenuated at the base, almost regular, and more often unsymmetrical, the side of the leaflet nearest the rachis being always the narrowest. The summit is acute or shortly acuminate, the tapering usually obtuse at the extremity. The limb is covered with fine translucent points, which are reservoirs of essential oil. The flowers are arranged in compound axillary racemes, equal to or a little shorter than the leaves. Their secondary divisions are alternate and distichous, bearing alternate flowers, solitary in the axil of a caducous bract, sessile, or supported on a short

* *Journal de Pharmacie et de Chimie* (4), vol. xxv. p. 251.

pedicel. The calyx is globular in the bud, glabrous externally, covered internally with slightly crowded silky hairs, with four (rarely three) rather thick pointed concave, imbricate segments. The staminal filaments are inserted around a small receptacular cup, covered with glandular tissue; in the cultivated plant there are sometimes eleven or thirteen, and the alternate sepals are the shortest. The substipitate ovary is orbicular, compressed, glabrous or having fine silky hairs upon the edges. The slender arched style, nearly twice as long as the ovary, has a very slightly swollen stigmatiferous summit, and is entire or divided into two not very distinct papillar lips. The fruit, borne on a pedicel nearly ½ centimetre long, is elliptical, with convex valves externally, about 3 centimetres long, and 2 wide, which are finally subligneous, pale brown within, and terminate in a short apiculus. The seed, 1½ centimetre long and 1 wide, is ovoid, with smooth shining integuments, black, and has an exalbuminous embryo, the cotyledons of which are elliptical, planoconvex, and hide the very short radicle which does not appear on the surface. The fresh seeds give off a strong odour of tonka bean. This species is the *Copaiva* of Jacquin. Its juice is the *Tacamahaca* of Venezuela, the *Aceite de Canime* of New Granada, the *Capivi*, *Cupayba*, and *Copaiba* of the natives. In the old English pharmocopœias it is called *Balsamum Capivi.* Under the name of *Copaifera officinalis* it is believed that Linnæus confounded several species. Desfontaines also has reserved the name *C. Jacquini* for the plant of the Antilles, Columbia and Venezuela, the one to which Kunth and Humboldt have preserved the name *C. officinalis* (*Nov. Gen. et Sp. Pl. Æquin*, vii. t. 659).

Copaifera pubiflora, Benth. (in Hook *Lond. Journ. Bot.* ii. 101) is a species found first in British Guiana, notably by Schomburgck, and distinguished, as its name indicates, by the pubescence of all the parts of its flowers, especially the calyx. It is used for the extraction of the oleo-resin of copaiba, and appears to the author to be very near to *C. officinalis* in all its characters, especially in its flowers. But Bentham, in his more recent works, considers it to be only a form or variety, with pubescent flowers and more acute leaves, of *C. Martii*, Hayne.

Bentham has given (*Mart. Fl. Bras.* 243) the name *Copaifera rigida* to a Brazilian species from the provinces of Piauhy and Goyaz, which is used for the extraction of the oleo-resin, and has thick coriaceous leaves. It is a small tree, of which all the parts, except the rust-coloured tomentose inflorescence, are glabrous in the adult plant. The leaves have three, more rarely two, pairs of leaflets, supported on a very short articulated petiole, elliptical, oval, oboval, or elliptical-oblong, obtuse at the two extremities, sometimes emarginate at the summit, or shortly attenuated at the base. They are 2 to 4 inches long, and 2 inches broad, and are rigid, coriaceous, entire, with the margin recurved, glabrous and glossy above, duller underneath, finely penniveined with parallel veinlets and not dotted. The flowers are numerous, small, united in handsome compound racemes as long or nearly as long as the leaves, loosely ramified, and covered with a fine brown down. The flowers are distichous, nearly sessile, articulated upon the divisions of the inflorescence. The segments of the calyx, which are unequal, thick, two lines or more long, are nearly glabrous outside, and silky and covered with stiff hairs within. The ovary is covered with down, at least on the edges. The style and stamens are exserted.

The *Copaifera Martii* is a species from northern Brazil: it has been found at Cujuba, in the province of Mato Grosso, at Pará, near the Amazon, and at Maraca de Santarem. It grows also in British Guiana, where it is worked for the extraction of copaiba (Hayne, *Arzn.* x. t. 16; Nees, *Pl. Offic.*, *suppl.*, t. 44; Benth. *in Mart. Fl. Bras.*, *Legum-Cœsalp.*, 244). It is a moderately tall tree, the young organs of which are often finely pubescent, but very soon become quite glabrous. The leaves, although thinner, recall rather those of *C. rigida.* They have two to four pairs of leaflets, which are nearly opposite, have a very short petiolule, and are oval, elliptic or oval-oblong, obtuse at the summit, more rarely emarginate or shortly and obtusely acuminate, rounded at the symmetrical or scarcely symmetrical base, 2 to 4 inches long, 2 to 3 inches broad, almost coriaceous, without dots, glabrous and slightly shining above, paler and duller underneath, with numerous slightly prominent parallel veinlets, recalling much those of *C. rigida.* The inflorescence, in compound ramified racemes, is at first covered with a ferruginous silky tomentum. The ramifications bear distichous imbricated bracts, which finally become glabrous, and are rather thick, concave, acute, and ciliate at the edges, and fall off early, even before the flowering, together with the bracteoles, which are analogous to them. The flowers are sessile. The segments of the calyx touch or slightly overlap each other at the thick edges; they are glabrous externally, and covered within by a silky down. The stamens and style are exserted. The ovary is supported on a short stalk, and is hispid at the margins; its slightly flattened faces are generally glabrous. The fruit is nearly an inch long, and slightly compressed. The ovoid, nearly globular, seed is said to be devoid of an arillus. There is a variety of this species (*pubiflora*), having the calyx covered within and without with silky down, and the leaflet more clearly acuminate than in the type, and often more unsymmetrical. This species has, as before remarked, many characters that approach *C. officinalis*, and if the specimens of *C. pubiflora* examined by the author were authentic, he sees nothing to oppose their being considered a variety of *C. officinalis*, which would in this way become closely associated with *C. Martii.*

Copaifera Langsdorffii, Desf. (*Mem. Mus.*, vii. 377) is the species best known of those that yield the copaiva of Brazil (DC., *Prod.* ii. 969; Hayne, *Arzneig.* x. t. 19; Berg. et Schm., *Darst. Offic. Gew.* i. t. 6; Benth. in *Mart. Fl. Bras.*, *Legum-Cœsalp.*, 242, t. 63, 1). It is the *C. nitida* of Hayne (*op. cit.*, t.27), and the *C. Sellowii* (t. 22). Bentham believes that it is also the *C. Jussieui* of Hayne; but that plant had not been examined by him, neither is it to be found in Jussieu's herbarium. It is usually a rather small tree, or a shrub, and much branched. It is said, however, sometimes to be a large tree, sixty feet high. The branches and petioles are covered with loose hairs or finally glabrous. The inflorescence is covered with a rusty coloured down. The leaves consist of three to five pair of leaflets, which are shortly petiolate, opposite or alternate, oval or oblong, obtuse at the summit, more rarely slightly acute or shortly and obtusely acuminate; at the base they are rounded, nearly equal, or more or less unsymmetrical. They are sometimes at least an inch long, or even attain 1½ or 2 inches, and are about an inch broad; very different dimensions are met with in a single specimen. They are slightly coriaceous, sprinkled with translucent dots, glabrous, rather smooth, sometimes shining, and have numerous parallel and finely anastomosing veins. The flowers are sessile or nearly so, and are united into compound branched racemes, but the branches are usually rather few. The segments of the calyx are unequal, white, or, it is said, spotted with rose colour, more than two lines long, glabrous or scarcely pubescent without; and bearing silky rust coloured hairs within. The style is curved and twisted at the summit, the stigma being capitate. The stamens have long exserted filaments, and oval anthers, surmounted by a small apiculus. The fruit is shortly elliptical or suborbicular, compressed, 1 to 1½ inch long, surmounted by a curved apiculus; base of the style rugose, and dotted externally; the seed has rather a large arillus.

Numerous varieties of this species have been distinguished, under such names as *grandiflora*, *laxa*, and *glabra*. The last two are made species by some authors: the one is the *C. laxa*, of Hayne (*Arzn.*, x. t. 18), and the other the *C. glabra* of Vogel (in 'Linnæa,' x. 410). The first has branches and petioles which are villous and the leaflets usually pubescent underneath. The second has smaller leaflets, and the calyx glabrous or slightly hairy within. The leaves of *C. grandiflora* attain a length of 2 or 3 inches, and are very obtuse at the two extremities. It has been collected near Bahia, in the province of Goyaz, and perhaps near Rio de Janeiro. *C. laxa* grows at Minas Geraes and Goyaz. The typical plant is said to be common at St. Paul, Goyaz and Minas Geraes. It is found also in the Serra d'Araripe, province of Ceara, in the dry woods of the province of Bahia, and at Cujaba, in the province of Mato Grosso.

Copaifera Guianensis, Desf. ('Mem. Mus.,' vii. 376, t. 9), has long been considered as furnishing all the copaiba which comes to Europe by Cayenne. It grows in all the Guianas, and also in the north of Brazil, where Spruce met with it between Manaos and Barcellos. The species is rather near to *C. officinalis*; but it has shorter and more obtusely acuminate leaflets (DC. Prod., ii. 508; Hayne, Arzn. x. t. 13). It is a tree, 30 or 40 feet high, glabrous in all its part, except the inflorescence. The leaves have three or four pairs of leaflets, which are petiolulate, oval-elliptical or oblong, rather long and narrowly acuminate, slightly unsymmetrical or symmetrical at the base, rounded or subcordate (3 to 5 inches long), slightly coriaceous, smooth and shining above, covered on both sides with numerous slender veinlets, and with translucent dots. The common petiole is about 6 inches long. The flowers are united into compound branched racemes, which are axillary shorter than the leaves, and covered with a very fine whitish tomentum. The flowers are small, inserted upon the divaricate ramifications of the inflorescence, nearly distichous and sessile. The bracts are orbicular, ciliate, scarcely half a line long, and caducous. The lateral bracteoles are smaller than the bracts, but resemble them. The divisions of the calyx are 2 lines long, covered with silky hairs within, and externally with a very fine down. The stamens are slightly exserted. The more or less hispid ovary is biovulate, and the fruit stipitate, glabrous, about 1 inch long, and ¾ inch broad. Bentham considers that the *C. bijuga* of Hayne (Arzn., x. t. 16) should be referred to this species.

Copaifera oblongifolia, Mart. (Hayne, Arzn., x. t. 23), is a Brazilian species, met with in the provinces of Goyaz and Minas Geraes, especially in the plain near Chapado do Parana and towards the banks of the Rio Claro. It is a medium sized or rather tall shrub, much branched, with the branches and petioles nearly glabrous, or covered with loose hairs. The inflorescence is covered with a ferruginous down. There are six or eight pairs of leaflets, which are nearly sessile, opposite, oblong, obtuse, unsymmetrical at the base (½ inch long), coriaceous, covered with translucent dots and numerous veinlets, reticulated, shining above and pale beneath. Most of the inflorescence is shorter than the leaves. Bentham remarks (Mart. 'Fl. Bras.' 242), that the flowers and fruit are the same as in *C. Langsdorffii*, Desf., from which *C. oblongifolia* scarcely differs, except by the more numerous and often smaller leaflets. The author (M. Baillon) considers it at least doubtful whether this species yields copaiba, if it be remembered that it is most frequently represented by individuals with slender trunks which could hardly be worked profitably.

Copaifera multijuga, Hayne (Arzn., x. 17), is but doubtfully referred to this genus by Bentham. Baillon believes that he saw the plant some years since in the Imperial Herbarium at Vienna; and that it seemed to approach by its foliage more nearly to the genus *Dialium* than *Copaifera*. The tree is found in Para and the neighbouring regions, and the branches and petioles are covered with a rusty down. The leaves (which are rather similar to those of *Crudya amazonica*) have five to six pairs of leaflets, mostly alternate, with long petiolules, oblong or oblong-lanceolate, acuminate, unsymmetrical, rounded at the base, 1½ to 2 inches long, slightly coriaceous, scarcely shinning, glabrous, covered with pellucid dots, the nerves, with the exception of the principal one, scarcely visible. Is it certain that this plant yields copaiva? In any case it does not appear to be referable to the genus *Copaifera*.

Probably the oleo-resin of copaiva was not originally extracted from the *Copaiferæ* of Central America, but from Brazilian species, and from *C. Langsdorffii*. It is, therefore, very possible that this was the principal one to which Linnæus attributed the name *C. officinalis*. In fact, one of the earliest documents known in Europe on this question, as noticed by Hanbury, was a treatise by a Portuguese priest, who lived in Brazil from 1570 to 1600. His manuscript was translated into English, and published in 1625, by Purchas ('Pilgrims and Pilgrimages,' iv. 1308). Among many other natural products of the country, the author notices the *Cupayba* as a large tree, from the trunk of which when deeply incised there ran in abundance a clear oil, much esteemed as a medicine. [M. Baillon then quotes Hanbury's description of the collection of copaiva ('Pharmacographia,' 201).]

The name of copaiva is wrongly given to an oleaginous liquid, extracted by incising the trunk of the *Dipterocarpus* and other trees of the same family, in the Indian Archipelago. Its properties are nearly the same, but from a botanical point of view there is no relation between the plants of the two groups. In India, also, the juice of a plant very near to the *Copaiferæ* in its organization, the *Hardwickia pinnata*, Roxb., is used like the true copaiva.

There are some *Copaiferæ* in Africa, where they are called "Gorskia," but the author is not aware whether they are used medicinally. Their fruit is flattened, and their leaves have two multinerved leaflets (Boble, in Peters., Mozamb., Bot., i. 15, f. 3). In the seed of *C. mopane*, Kirk, of tropical Africa, the cotyledons are much developed, corrugated, and dotted with reservoirs of resinous juice. *Guibourtia copallina*, which is thought to yield, partially at least, the substances known in England as "African red gum," and "yellow gum," has been referred by Bentham to the genus *Copaiferæ*. In the "Histoire des Plantes," the author has named it *C. copallina*. At the Gaboon, there is a doubtful *Copaifera*, which he has named *C.* (?) *Mannii*.

The author is unable to say anything *de visu* of *Copaifera Beyrichii*, Hayne; *C. Sellowii*, Hayne; or *C. Blancheti*, Benth., as they do not exist in the Paris Herbarium. They also are said to be used in the extraction of the oleo-resin.

SILICOTUNGSTIC ACID AS A REAGENT FOR ALKALOIDS.*

Dr. Richard Godeffroy has ascertained the fact that silicotungstic acid is probably the most delicate reagent for alkaloids, nearly all of which, even in highly dilute, neutral, or faintly acid solutions, yield a precipitate with an aqueous solution of this acid. The sensitiveness of the reaction was tested by experimenting with the hydrochlorates of quinia, cinchonia, and atropia, with the following results:—

An aqueous solution of quinia hydrochlorate gave, with a few drops of an aqueous solution of silicotungstic acid, a distinct precipitate, even in dilutions containing only 0·004 per cent. of the alkaloidal salt. Opalescence could be still observed in presence of only 0·002 per cent., corresponding to $\frac{1}{50000}$ of quinia hydrochlorate.

A solution of cinchonia hydrochlorate was rendered cloudy in presence of only 0·0005 per cent., or $\frac{1}{200000}$ of the alkaloidal salt.

A solution of morphia hydrochlorate was made opalescent in presence of 0·0065 per cent., or $\frac{1}{15385}$ of the salt.

None of the known alkaloidal precipitants, such as platinic chloride, potassium iodohydrargyrate, iodized potassium iodide, etc., show any reaction in such high dilutions.

The precipitates produced by silicotungstic acid are

* *Arch. d. Pharm.*, Nov., reprinted from *New Remedies*.

soluble with more or less difficulty in concentrated hydrochloric acid; they are decomposed by solution of caustic potassa, which causes the separation of the alkaloids and the formation of an easily soluble potassium silicotungstate. On shaking the precipitates with caustic ammonia, they are at first dissolved to a clear solution, which, however, soon becomes cloudy from separation of silica. Ignition of the precipitates leaves behind an insoluble mixture of silica and tungstic anhydride (anhydrous tungstic acid).

Silicotungstic acid is best prepared by boiling sodium tungstate with freshly precipitated gelatinous silica. To the resulting solution is added solution of mercurous nitrate, which causes a precipitate of yellow mercurous silicotungstate, which is well washed with water upon a filter, and decomposed by an equivalent quantity of hydrochloric acid. Silicotungstic acid goes into solution, and mercurous chloride (calomel) remains behind. The clear filtrate is evaporated, to drive off the excess of hydrochloric acid, and furnishes, on spontaneous evaporation, large, shining, colourless octahedra of silicotungstic acid, which effloresce in the air, melt at 36° C., and are easily soluble in water or alcohol. We are therefore enabled to precipitate the alkaloids even in alcoholic solution, by using a similar solution of the acid. Marignac has found that this acid does not produce insoluble or difficultly soluble precipitates with any metallic salt, and Godeffroy adds that only cæsium and rubidium salts—but both even in very dilute solutions—are precipitated by it, and that it produces in a neutral solution of ammonium chloride a white precipitate, which is very difficultly soluble in large quantities of water.

PREPARATION OF LITHIUM CARBONATE AND SOME NEW COMPOUNDS OF LITHIUM FROM LEPIDOLITE.*

BY E. FILSINGER.

The lepidolite, reduced to fine powder, was treated with strong sulphuric acid containing some nitric acid, in a large brick trough, at a gentle heat. It was heated with constant stirring till it gained consistency enough to be made into balls, which could be easily introduced into a reverberatory furnace. The slight excess of sulphuric acid was driven off at a gentle heat, the temperature was then raised, and the pieces while still hot were treated with water in vessels lined with lead. The residue consisted of almost pure silica, for which a market is easily found. As lithium does not replace potassium in alum, a sufficient quantity of potash is added to transform all the sulphate of aluminium present into alum. On evaporation the alum separates in powder. It is removed, dried in a centrifugal machine, and on recrystallization is obtained in fine crystals. The excess of alumina is then precipitated from the mother-liquor by milk of lime, and the excess of sulphuric acid by barium chloride. The barium sulphate obtained is a marketable article. The liquid is then evaporated, and the mixed chlorides of lithium, potassium, sodium, calcium, and sometimes barium, exhausted with absolute alcohol. The lithium and calcium chlorides are dissolved. The calcium is separated as oxalate, and the lithium chloride evaporates and crystallized. It is precipitated with ammonium carbonate and ammonia, and brought into the market in the form of carbonate. The advantages of this process are complete consumption of the crude material; cheap reagents; common plant; precipitates which are easily washed, and a number of marketable chemicals, *e.g.*, silica, alumina, potash alum, and lithium carbonate.

Borates of Lithium.—Of these the author has prepared three. The first was prepared by boiling equivalents of boracic acid and lithium carbonate till carbonic anhydride was no longer evolved. On treatment with alcohol it was obtained as a granular precipitate. Its formula is $Li_2B_4O_7 + 5H_2O$. Even with excess of lithium carbonate no less acid salt was obtained. It lost two equivalents of water at 200°. The second salt was prepared by saturating one equivalent of boracic acid with lithium carbonate, and adding another equivalent of acid. It was precipitated with alcohol. Its formula is $LiB_3O_5 + 3H_2O$. Under the microscope it has a crystalline appearance. The third salt was prepared by boiling lithium acetate with boracic acid till all acetic acid was expelled, and evaporating over sulphuric acid. Crystalline crusts deposited, of the formula $Li_2B_8O + 10H_2O$. The author was not successful in preparing a more acid salt than the last described; such salts might, however, be probably formed by use of lithium hydrate. The flame reaction of $Li_2B_4O_7$ shows only that of the base; and second gives a flame with a green border; while the third exhibits the colours both of base and acid. Sulphuric acid separates boracic acid from dilute solutions of the second and third, but not from the first.

* *Arch. Pharm.* [3], viii., 198—219. From the *Journal of the Chemical Society*, April, 1877.

CYCLAMIN, OR ARTHANATIN.*

Professor De Luca, of Naples, has ascertained that cyclamin may be used as a substitute for curare, and recommends it as a remedy against tetanus. *Cyclamen Europæum*, L., "sowbread" or "hogs' bread," nat. fam. Primulaceæ, is a native of southern, eastern, and central Europe, and contains a poisonous glucoside in the fresh tubers. Drying, boiling or roasting the latter entirely destroys the substance. These tubers are used in Sicily, after proper treatment, as food for hogs, and are even eaten, roasted, by the common people in some parts of Russia. When eaten in the fresh state, the roots produce vomiting and diarrhœa, often with inflammation of the intestinal canal and sometimes with fatal effects. They were used already by the ancients, and Dioscorides as well as Pliny recommends them as remedies against jaundice, constipation, cutaneous eruptions, enlargement of spleen, freckles and lymphatic swellings; besides, in form of decoction, against the bite of poisonous serpents and as an external application to wounds. While the juice of the fresh tubers, when absorbed by the blood from wounds, is apt to have fatal effects, the application of a decoction, in which the poisonous substance must have been destroyed, to wounds is unobjectionable. *Radix cyclaminis* or *R. Arthanitæ* was yet officinal about one hundred years ago in Germany.

Saladin, Buchner, Herberger, De Luca, and Martius have prepared cyclamin and studied its effects. The two last-named investigators prepared it from air-dry, Saladin from fresh tubers. These are gathered in autumn, pounded to a pulp, extracted with a small quantity of water, the extract is evaporated at a temperature not exceeding 60° C., the syrupy residue exhausted with absolute alcohol, the alcoholic solution treated with animal charcoal and then allowed to evaporate spontaneously in a warm place.

According to Saladin, cyclamin forms small white crystals; according to Martius and De Luca, however, a white amorphous mass, possessing no odour, but a very acrid taste. It belongs to the chemically indifferent or neutral principles and has the composition: $C_{20}H_{34}O_{10}$. It is easily soluble in alcohol and water, insoluble in ether, chloroform and carbon disulphide. The aqueous solution, according to De Luca, foams like soap-suds, and when heated to between 60° and 70° C. separates the cyclamin in a coagulated form. Concentrated sulphuric acid dissolves it with a yellow colour gradually passing into violet. By boiling with dilute mineral acids it is separated into glucose and cyclamiretin, which latter is insoluble in ether and water, but soluble in alcohol. Emulsin produces the same decomposition at 30–35° C.

Pelikan's experiments with this substance upon frogs show that it belongs to the irritant poisons. Schroff administered it in quantities of 0·2 gm. (3 grs.), and the toxic effects disappeared after the lapse of about one hour.

The Pharmaceutical Journal.

SATURDAY, APRIL 28, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PRICE OF QUININE.

THE bark sale held last Tuesday was remarkable for the large quantity of East Indian bark put up, and still more for the high prices which it commanded. Even the red bark, which is the produce of *Cinchona succirubra,* and is generally characterized by containing a very large proportion of cinchonidine, together with a comparatively small amount of quinine, was sold at prices as high as those which were paid some months ago for bark suitable for the manufacture of quinine. Some of the crown bark from the plantations in the Madras Presidency realized from twelve to fifteen shillings a pound, in consequence of the large amount of quinine that it contains, and the great demand that there is now for bark.

The prices given for these parcels of bark were not in all instances proportionate to the amount of quinine contained in them. This may be partly due to the circumstance that particular lots were bought for making pharmaceutical preparations, more on account of the appearance of the bark than from any better reason, since it often happens that bark of good external character fetches a price altogether out of proportion to the amount of alkaloid it contains. The contrary is also true sometimes, and at the last sale some bark containing a high percentage of quinine was not bid for to the extent of its relative value, but was bought in at a merely nominal price. It is at the same time deserving of notice, that several parcels of bark containing chiefly cinchonidine realized a very high price.

The fact that such unusual prices have been paid for bark seems to indicate that there is little prospect of a reduction in the price of quinine, which is now upwards of three times the price it was some six or eight months ago, and consequently the present seems a favourable opportunity for some effort to be made to introduce into legitimate use cinchonidine and the other alkaloids associated with quinine.

The results that have been obtained by the medical commissioners entrusted with the inquiry into the relative febrifuge value of these alkaloids have sufficiently shown that they are not much inferior to quinine in their efficacy, but as yet little has been done in this country towards the practical application of the experience gained by the trials made in India. None of these alkaloids are official in any of the existing Pharmacopœias, although the much less satisfactory preparation called quinoidine or amorphous quinine is contained in the German Pharmacopœia; and though salts of cinchonidine are abundantly manufactured in a state of purity and of a crystalline character equal to the best qualities of quinine salts there is not any recognized use to which these preparations are applied in this country.

It would therefore seem that by the introduction of cinchonidine into use very considerable service might be rendered, and the influence of the high price of quinine in restricting its use might be to a very great extent made up for, with great advantage to certain classes of the community. Moreover the adoption of this course would probably contribute somewhat to prevent the substitution of cinchonidine for quinine and its admixture with that alkaloid in the manner that we have recently pointed out to be frequent.

THE ROYAL SOCIETY.

THE following fifteen gentlemen have been selected by the Council of the Royal Society to be recommended for the election as Fellows, at the annual meeting on the 7th of June: Professor JAMES DEWAR, M.A.; Sir JOSEPH FAYRER, M.D., K.C.S.I.; Rev. NORMAN MACLEOD FERRERS, M.A.; THOMAS RICHARD FRASER, M.D.; BRIAN HAUGHTON HODGSON, F.L.S.; JOHN W. JUDD, F.G.S.; WILLIAM CARMICHAEL M'INTOSH, M.D.; ROBERT M'LACHLAN, F.L.S.; Professor JOHN WILLIAM MALLET, Ph.D.; HENRY B. MEDLICOTT, M.A.; HENRY NOTTIDGE MOSELEY, M.A.; Professor OSBORNE REYNOLDS, M.A.; WILLIAM ROBERTS, M.D.; Professor JAMES THOMSON, LL.D.; Professor WILLIAM TURNER, M.B. There were fifty-three candidates.

THE NEW YORK DRUG TRADE.

IN an annual review of the drug trade of New York for the year 1876, presented by Mr. D. C. ROBBINS to the Chamber of Commerce in that city, it is stated that imports of drugs and chemicals for the year ending June 30, had declined in value, as compared with those of the previous year, nearly six millions of dollars. This falling off is considered to be indicative that the manufacturing interests are suffering under the economy that has been forced upon the people by the stringency of the times. It is estimated to be distributed as follow: chemicals, 3,000,000 dollars; drugs, including seed, 2,000,000 dollars; spices, 500,000 dollars; and crude drugs, mainly used in the arts, 500,000 dollars.

A few chemicals, however, showed an excess over previous yearly importations; as for instance, crude argols, used in the home manufacture of cream of tartar and tartaric acid, the importation of which has almost ceased on account of the extreme protective duties. The importation of soda ash has also considerably increased, whilst that of carbonate and bicarbonate of soda has decreased for similar reasons.

The importation of crude medicinal drugs has been the least affected, their consumption having been very steady. The consumption of opium increases yearly, and in a greater ratio apparently than the increase of population of the country, the quantity being 228,742 lbs. in 1876, against 188,238 lbs. in 1875. A large quantity of this drug is imported in a prepared form for smoking, and is received at San Francisco for the use of the Chinese population. There was also a considerable increase in the quantity of cinchona bark imported.

MASSACHUSETTS LIQUORS.

From the Second Annual Report of Professor James F. Babcock, Inspector and Assayer of Liquors to the Commonwealth of Massachusetts, we gather that according to his experience, the malt liquors met with in this district, are absolutely free from coculus indicus, picric acid, strychnia, or any other bitter except that of hops and malt. Some of the wines examined contained added spirit, but no fuchsine or artificial colouring matter was detected in the ports or clarets, though the quality of most of the samples was poor. "Raw" whiskies were rather plentiful, but the chief admixtures met with in the different kinds of spirit were caramel and water, the latter of which, unlike an authority nearer home, Professor Babcock looks upon as an adulterant.

PITURY, AN AUSTRALIAN RIVAL TO COCA.

Baron von Mueller, of Melbourne, has at length determined the botanical source of the "Pitury," a stimulant long known to be in use by the aborigines of Central Australia and said to be of marvellous power. After some years of efforts to obtain a specimen of the plant he has now received some leaves, and has with certainty determined them to belong to *Duboisia Hopwoodii*, F. Muell., a bush referred to the order *Solanaceæ*, or *Scrophulariaceæ*, which grows sparingly in the desert scrubs, from the Darling river and Barcoo to West Australia. In a recent communication to the *Australian Medical Journal*, Baron von Mueller states that the natives chew the leaves to invigorate them during their long foot journeys through the deserts, just as coca leaves are used in South America. Those living near the Barcoo travel many days' journey to obtain the precious foliage, which is broken into small fragments and carried about by them in little bags. It is also employed to excite courage in warfare.

THE NORTH BRITISH BRANCH.

Amongst the official notices will be found the particulars of four courses of lectures for the Summer Session, for which tickets on special terms may be had on application to the Honorary Secretary of the North British Branch. The lectures are on Botany, by Professor Balfour; Materia Medica, by Dr. W. Craig and Dr. F. W. Moinet; and Practical and Analytical Chemistry, by Dr. S. Macadam.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

April 18th, 1877.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Fourteen Candidates were examined. *Five* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Carter, William Robinson ......Rusholme.
Cowie, John ....Glasgow.
Dodd, Thomas Hunter ....Sunderland.
Donaldson, David.................Edinburgh.
Dott, David Brown ....Edinburgh.
Ellis, George.......................Banff.
Hall, Robert ....Hartlepool.
Jepson, Joseph Morley ....Grimsby.
Robertson, Alexander ....Broughty Ferry.

April 19th, 1877.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was also present.

MINOR EXAMINATION.

Eight Candidates were examined. *Three* failed. The following *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

McNicol, John ....Glasgow.
Richardson, George ....Quatre Bras.
Rogers, James Isaac...............North Shields.
Tweedie, Alexander ....Edinburgh.
Whyte, James Samson...............Montrose.

MODIFIED EXAMINATION.

Two Candidates were examined. *One* failed. The following passed and was declared to be qualified to be registered as a Chemist and Druggist:—

Rae, William.........................Aberdeen.

EXAMINATIONS IN LONDON.

April 18th, 1877.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Six Candidates were examined. *One* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Baldwin, Arthur Henry ....Clifton.
Cook, Robert, jun. ....Great Grimsby.
Peacock, William Henry.........Durham.
Sandwith, William Henry ......Scarborough.
Strongitharm, William George .Birmingham.

MINOR EXAMINATION.

Twenty-two Candidates were examined. *Eight* failed. The following *fourteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bristed, John..........................Margate.
Burden, John Britten ....London.

Fell, John James ....Lancaster.
Gooch, William Hobbs............Norwich.
Hardwick, Stewart ....Sleaford.
Hart, James ....Sunbury.
Longman, John Ham ....Exeter.
Palmer, Charles Edward ....Ely.
Pickup, John Arthur ....Bacup.
Shepherd, John William ... .Settle.
Smith, William Ross ....Chester.
Story, George Arthur .... Bourne.
Tuck, Walter Barber ....Eastbourne.
Worfolk, George William ......Leeds.

April 19th, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was also present.

MAJOR EXAMINATION.

Five Candidates were examined. *Four* failed. The following passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Duffus, Alexander ....London.

MINOR EXAMINATION.

Sixteen candidates were examined. *Six* failed. The following *ten* passed and were declared qualified to be registered as Chemists and Druggists:—

Barnes, James William ....Spalding.
Beacock, Joseph Henry ....Barton-on-Humber.
Griffin, Joseph Thomas ....Oldbury.
Hoult, Joseph Emanuel ....West Bromwich.
Jones, Thomas ....Tenby.
Marris, Wm. James Graburn ...London.
Moses, Joseph ....Bishop Auckland.
Paull, John ....London.
Pheasant, William ....Clapham.
Wright, John Charles ....Wolverhampton.

MODIFIED EXAMINATION.

Eight candidates were examined. *Four* failed. The following *four* passed, and were declared qualified to be registered as Chemists and Druggists:—

Garrett, Thomas Philip ....London.
Howard, Samuel Bird ....Hadleigh.
Hussey, Robert ....London.
Wrighton, Alfred ....Birmingham.

April 25th, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, Taylor and Umney.

MINOR EXAMINATION.

Twenty-eight Candidates were examined. *Twelve* failed. The following *sixteen* passed and were declared qualified to be registered as Chemists and Druggists:—

Broadbent, John ....Manchester.
Furness, Thomas ....Chesterfield.
Gant, Joseph ....Spilsby.
Greenhill, Samuel Osborne ......Colchester.
Griffiths, John Moore ....Birkenhead.
Harris, Walter Thomas ....London.
Lund, William John ....Lancaster.
Mortlock, William John ....Peckham.
Parker, John Wortley ....Barnstaple.
Portway, John Bernard ....Bury St. Edmunds.
Pottinger, Thomas ....Dartford.
Roberts, William ....Swansea.
Simpkins, George Starr ....Minchinhampton.
Temple, Frederick Staveley ..Hull.
Williams, William ....Carmarthen.
Wilson, William Alexander ...Birmingham.

April 26th, 1877.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-nine Candidates were examined. *Twelve* failed. The following *seventeen* passed and were declared qualified to be registered as Chemists and Druggists:—

Bennison, Richard ....Stokesley.
Capes, Howard Hawksley ......Epworth.
Clark, Frank........ ....Liverpool.
Edwards, James ....Halesworth.
Giles, William Egbert ....Penydarran.
Greenough, Hugh Fairhurst ...Manchester.
Hadwen, Walter Robert ....Woolwich.
Hendy, Albert ....Bristol.
Hetherington, Thomas............Penrith.
Hinks, John ....London.
Jones, Thomas Pryce ....Wrexham.
Lewin, Arthur Clayton ....Plymouth.
Pyefinch, John ....Shrewsbury.
Redford, George Alfred ....Liverpool.
Robinson, William Prior.........Waterloo.
Wills, Vincent Andover ....Blaenavon.
Yates, Ebenezer ....Manchester.

PRELIMINARY EXAMINATION.

The undermentioned Certificates were received in lieu of the Society's examination:—

Certificates of the College of Preceptors.

Hubbard, Daniel L...............Eastbourne.
Levett, Herbert ....Maidstone.

Certificate of the Royal College of Surgeons of England.

Odhams, George Frederick ......Faversham.

Certificate of the University of Cambridge.

Prentice, Hector Vaughan ......London.

Certificate of the University of Oxford.

Blunt, Thomas P...................Shrewsbury.
Latham, Walter Joseph ....Spalding.
Lewitt, Frederick William ......Leicester.
Pars, Charles Frederick R.......Lincoln.

The Report of the College of Preceptors on the examination held on April 9th, was received.

Three hundred and twenty-three candidates had presented themselves for examination, of whom *one hundred and forty-five* had failed. The following *one hundred and seventy-eight* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically).

Alexander, John ....Glasgow.
Allison, John ....Coldstream.
Andrew, Edward Oliver ....Welshpool.
Armstrong, F ....Workington.
Atkins, Ernest ....Woolwich.
Axford, Sidney Bertram ....London.
Ball, James ....Mevagissey.
Baxter, William ....Bromley.
Bence, Frederick Herbert ......London.
Benson, Matthew..................Wigan.
Bolton, John ....Maidenhead.
Bowen, Ivor ....Brecon.
Bowes, John William ....Pocklington.
Bowman, Edmund ....Leith.
Bradbeer, John.....................Windsor.
Broad, Benjamin William ......Monmouth.
Brogden, Charles Henry ....Hyde.
Brough, Frank Thomson ....Northampton.

Browne, Thomas Ellis ....Exeter.
Bulmer, John ....Pocklington.
Butchart, William Henry ......Leeds.
Byrd, Edward John..............Leeds.
Cadge, John ....Kingham.
Cappell, Robert......................Crieff.
Careless, John .. ..Birmingham.
Cartwright, Arthur ....Alford.
Charge, Arthur William ......Chichester.
Charlesworth, Moorehouse ......Saltaire.
Chipchace, Charles Herschel ...London.
Claridge, Charles ....London.
Clarkson, Richard Bell ....Newark.
Clayton, John Henry ....Thirsk.
Clayton, William Hatch.........Newcastle-on-Tyne.
Close, Thomas ....Middlesborough.
Collins, Charles Edmund.........Saltley.
Crawford, Thomas ....Leith.
Crofts, John Ernest...............Leicester.
Crossley, Frederick ....Guernsey.
Crow, William Edward ....Louth.
Davies, Sylvanus Howell.........Carmarthen.
Davies, William ....Newcastle Emlyn.
Davis, George Albert ....Cheltenham.
Dawson, James.......................Bridge of Allan.
Dee, Arthur Henry ....Tewkesbury.
Drummond, George ....Edinburgh.
Dunstan, John Frederic ....Truro.
Eaton, Charles Arthur............Hull.
Edgar, Frederick George.........Southsea.
Evans, David.........................Lampeter.
Evans, William......... ....Pontypridd.
Everingham, Fredk. Adolphus...Market Weighton.
Frise, Jesse Symons ....Chesterfield.
Gaskin, John Henry...............Wolverhampton.
Gaylard, James Ratcliff ....Uxbridge.
Gibson, John.........................Barnard Castle.
Goldby, Frank ....Abingdon.
Gough, Arthur ....Keynsham.
Graham, Henry.......................London.
Greenway, John Wells............Ottery St. Mary.
Haines, William Edward.........Hereford.
Hall, Charles..........................Leighton Buzzard.
Hanson, Christopher ....Buckhurst Hill.
Harrison, Oliver Herbert.........Totteridge Park.
Harvey, James.......................Edinburgh.
Haward, Edgar ....Darlington.
Heath, Walter Edwin............Coleshill.
Heaton, John ....Burnley.
Hinnell, James ....Bury St. Edmunds.
Hobbs, John Kingdon ....London.
Hodges, Thomas Walter.........Fueford.
Horton, James Edward ....Wolverhampton.
How, Thomas McKay............Kirriemuir.
Howell, William ....London.
Hubbard, A. E. L. F. W. A....Downham Market.
Hughes, Evan Cromwell.........Birmingham.
Hughes, William...................Llandyssil.
Humphreys, Charles Evan......Llanfair.

The Questions for Examination were as follows:—

First or Preliminary Examination.

April 9th, 1877.

(*Time allowed: three hours for the three subjects.*)

I. LATIN.

1. Translate into English:—Ita ancipiti proelio diu atque acriter pugnatum est. Diutius quum sustinere nostrorum impetus non possent, alteri se, ut coeperant, in montem receperunt, alteri ad impedimenta et carros suos se contulerunt; nam hoc toto proelio, quum ab hora septima ad vesperum pugnatum sit, aversum hostem videre nemo potuit. Ad multam noctem etiam ad impedimenta pugnatum est, propterea quod pro vallo carros objecerant et e loco superiore in nostros venientes tela conjiciebant, et nonnulli inter carros rotasque mataras ac tragulas subjiciebant, nostrosque vulnerabant.

2. Parse the words *nostrorum, impetus, receperunt*, and *venientes*.

3. Give all three degrees of comparison of the adjectives *superior* and *brevis*, and of the adverbs *acriter* and *diu*.

4. Decline together *hoc proelium* ('this battle'), *acer impetus* ('a fierce attack'), and *atra nox* ('black night').

5. State the chief uses (*a*) of the accusative case; (*b*) of the ablative case.

II. ARITHMETIC.

[The working of these questions, as well as the answers, must be written out in full.]

6 Subtract Five hundred and four thousand and seventy-six from Fifteen millions eighty-four thousand and nine.

7. How many yards of cloth worth 3*s*. 7½*d*. a yard must be given in exchange for 144 yards of cloth worth 18*s*. 1½*d*. a yard?

8. Find, by Practice, the value of 84 cwt. 3 qrs. 14 lbs. at £12 11*s*. 8*d*. per cwt.

9. From $\frac{2}{5}$ of $8\frac{2}{3}$ subtract $\frac{2}{7}$ of $2\frac{1}{5}$.

10. Reduce $\frac{7}{16}$ and $9\frac{4}{5}$ to decimals; and multiply the one decimal by the other.

11. A wheel makes 400 revolutions in rolling over $2\frac{1}{2}$ miles. Find its circumference in metres, centimetres, etc.

III. ENGLISH.

12. State clearly the functions of adjectives, adverbs, and prepositions.

13. Explain the difference between transitive verbs and intransitive verbs, and between verbs in the active voice and verbs in the passive voice. Arrange the following verbs in two classes, according as they are transitive or intransitive:—[*I*] *ran*; [*he*] *heard*; [*the letter*] *was sent*; [*they*] *are gone*; [*we*] *shall arrive*; [*he*] *had lost*.

14. Parse each word in the following sentence:—"Full many a flower is born to blush unseen."

15. Write a short account of Sir Walter Raleigh, or of King Henry II., or of the Duke of Wellington (*only one*); or a short essay on one of the following subjects:—(*a*) Self Control; (*b*) Vivisection; (*c*) Railways.

MEETING OF THE NORTH BRITISH BRANCH.

The Scientific Meetings of this Session closed with the eighth of the series, which took place on the evening of Monday, 23rd April, in the Society's Rooms, 119A, George Street, Edinburgh. Mr. Wm. Gilmour, President of the Branch, presided. The programme of the evening consisted of a description of the Medicinal Plants of Scotland, illustrated by diagrams and specimens, by Dr. Wm. Craig, Lecturer on Materia Medica, Edinburgh School of Medicine. This lecture will appear in a future number of the Journal.

Dr. Andrews P. Aitken, Chemist to the Highland and Agricutural Society, then delivered a short address on the subject of Fermentation. It was a process, he said, that had been known from the earliest times, but until recently it had been very little understood. Passing in review the various theories of fermentation, he dwelt especially on the two which a few years ago were so hotly debated between Liebig and Pasteur. Liebig maintained that fermentation was due to an instable chemical compound called a ferment, which, in the act of splitting up or undergoing a chemical change, was able to communicate that molecular change to some other bodies capable of receiving it. These were called fermentescible bodies, and that the free action of the oxygen of the air was necessary to the process. Pasteur, on the other hand, declared fermentation to be the result of living germs, which multiplied in a saccharine liquid at the expense of the oxygen dissolved in it, but when that was used up they took oxygen from the saccharine liquid, and in so doing caused it to be decomposed into alcohol, carbonic acid, etc. When fungi, such as blue mould, grew on the surface of a liquid containing sugar, albumenoid matter, etc., it used the atmospheric air, and no sugar was decomposed; but if the fungi were then plunged beneath the liquid, it still continued, though with difficulty, to live, and in doing so decomposed the sugar into alcohol and carbonic acid. Fermentation was therefore due to the prolonged vital activity of a fungus, which was cut off from a supply of free oxygen. This was an exhausting process, and the vitality of the ferment required to be restored by occasional admission of air, which enabled it to multiply rapidly, and thereafter produce a more vigorous fermentation.

The lecturer then described a few of the more common ferments, and explained the condition of their vitality, and the methods employed to study their character and history.

In the course of his address he referred specially to the fermentation of beer, and as it contains some points of considerable interest to brewers, we quote it in full.

When barley has been steeped in water for some time, and then spread, damp, on a floor at ordinary temperature, it germinates. From three to seven little rootlets appear, and the embryo within the seed begins to grow. During this time the starchy matter in the seed is being converted into sugar. The barley is then dried in kilns, and is called malt.

The malt, when crushed and dissolved in water, yields the sweet wort or malt liquor of the brewers.

It has long been known that if this wort is exposed for some time to the air it begins to ferment, *i.e.*, it puts on an appearance of boiling; bubbles of carbonic acid gas continually rise in it, and the sugar of the wort is converted into alchohol. This process of fermentation immediately stops if the liquid is boiled. If wort is boiled in a tube or flask, and if the vessel is hermetically sealed, or even plugged with cotton wool, while boiling, the wort may be allowed to cool, and will never ferment, but remain quite unaltered for any length of time. In the latter case there is free access of air to the wort through the cotton wool, so that it cannot be the air alone which causes the wort to ferment.

A little examination of a fermenting liquid will show a sediment, or scum, which, when examined through the microscope, will be found to consist of cellular bodies, having a definite shape and in an active state of growth. The most familiar substance of that kind is the yeast plant (*Torula cerevisiæ*), composed of small, roundish, nucleated cells, which when put into fresh wort immediately bud and grow with great rapidity, the wort in the mean time entering into brisk fermentation.

A minute germ of *Torula* is sufficient to begin the process, and as these germs are floating abundantly in the air, they cannot fail to alight on wort when exposed to the open air. This is the cause of spontaneous fermentation.

When the yeast plant alone is added to wort, either spontaneously or otherwise, the products of the decompositions of sugar are alcohol and carbonic acid, along with notable quantities of succinic acid and glycerine.

In all commercial beer there are found, however, lactic acid and a little acetic acid. These are impurities, and Pasteur, in his beautiful research on the maladies of beer, has traced their origin.

They are caused by the action of other germs than that of the yeast plant. The lactic and acetic ferments, which floating in the air have sown themselves in the sweet liquid along with the yeast plant, and have set up fermentations different from that of the yeast plant. Sour beer, turned beer, ropy beer, putrid beer, etc., have all been found to be associated with the growth of special germs. Each malady has its germs, and if care be taken to exclude the germ, the malady does not appear.

Cold weather kills or benumbs, and prevents the multiplication of these minute germs, hence in cold weather beers are much less subject to disease, and the colder months of the year are best suited for brewing purposes. In this country it is possible to brew in warm weather, from one great cause among others, that our brewers make use of the high fermentation, *i.e.* fermentation by means of a species of yeast that tends to float on the top of the wort.

The bubbles of carbonic acid on rising to the surface are entangled in the yeast, and form a thick layer of froth, termed "the head," which, covering over the fermenting wort, protects it to a considerable extent from contamination by germs of disease falling on it from the air. The practice which prevails in most breweries of beating back "the head" into the wort, so as to oxygenate it, and hasten the fermentation, by bringing the yeast into better contact with the wort, contaminates the wort with the germs of disease that had been intercepted by "the head." The mischief thus brought about would be greatly lessened if brewers would skim off the upper surface of the head before beating it back. On the Continent, where the lower fermentation is employed, it is impossible to brew good beer in summer.

The lecturer remarked that for practical brewers one of the most valuable results of Pasteur's research was the method he proposes for obtaining a pure yeast. He found that by the growth of yeast alternately in pure wort and pure solution of sugar, the germs of disease were killed off, and the germs of yeast, which were hardier and immensely more numerous, survived.

This simple experiment was one that could easily be carried out by brewers on a large scale, and with careful attention to the purity of yeast (and the microscope presented a means of testing its purity), it seemed probable that good sound beer might be brewed as easily in warm as in cold weather.

There were no doubt many other precautions which required to be taken, but it was quite certain that the researches of Pasteur had thrown a flood of light upon the *rationale* of the process of fermentation, and brewers would do well to make themselves acquainted with his works, that they might be able to escape much of the loss incident to their trade.

The lectures were warmly received by the meeting, which was the largest of the session, and at the conclusion, the audience heartily responded to a vote of thanks to the Lecturers. The vote was proposed by Mr. J. R. Young, and seconded by Mr. Ainslie.

Mr. Mackay intimated the donation of a number of botanical specimens for the Herbarium, from Mr. Wm. Gilmour, and took occasion in moving a vote of thanks to Mr. Gilmour for the donation, to refer to the very able manner in which he had so long presided at the meetings of the Branch, and the many original and instructive communications he had been at the trouble to prepare for them. This vote required no seconding, and the manner in which it was responded to must have been very gratifying to Mr. Gilmour.

Provincial Transactions.

SOCIETY OF CHEMISTS AND DRUGGISTS, ABERDEEN.

The annual meeting of this Society was held in the rooms, St. Nicholas Lane, on March 20th, Mr. Coutts, President, in the chair. The Treasurer presented his annual report, from which it appeared that £10 6*s.* 0½*d.* stood to the credit of this Society. The meeting then proceeded to the election of office-bearers, when Mr. Cruickshank was proposed President, Mr. Ritchie, Vice-President, Mr. Mackay, Treasurer, and Mr. Strachan, Secretary. On the proposal of Mr. Mackay, the Price List Committee was reappointed to revise and report.

Mr. Strachan brought under the notice of the meeting the desirability of the chemists of the neighbourhood being represented on the Council of the Pharmaceutical Society or on that of the North British Branch in Edinburgh. It was finally resolved that Mr. Reid, be requested to allow himself to be nominated for election, but he declined the honour.

The membership of the Society for the present year numbers thirty-two.

An adjourned meeting was held on April, 19th, Mr. Cruickshank, President, in the chair.

A memorial from the assistants and apprentices was read, respectfully requesting that the hourss of business be reduced from eight p.m. to seven p.m. After a considerable amount of discussion, in which most of the members present took part, it was agreed that at present, while they were always willing to accede to the requests of their memorialists as far as lay in their power, they could not unanimously recommend the desired reduction The feeling of the meeting was that they would arrange to allow those of their assistants or apprentices who desired to attend existing classes or lectures.

The Secretary laid on the table a letter from Mr. Fairlie requesting a deputation to attend the special meeting of the Trade Association to be held in Edinburgh on the 25th inst. After some discussion the subject was allowed to drop, no deputation being appointed.

The Secretary proposed that the best thanks of the Society were due to the Pharmaceutical Society for their kindness in sending them a copy of the Register as well as a copy of the Journal as published, which was seconded by Mr. Mackay and unanimously agreed to.

Mr. Paterson moved that assistants and apprentices be admitted as associates of this Society on payment by assistants of 5*s*. and apprentices of 2*s*. 6*d*. yearly, and that monthly meetings of this Society be held. This proposition created a considerable amount of discussion. Ultimately it was seconded by Mr. Ritchie and unanimously agreed to. A few years ago classes were started; but, owing to the small amount of interest displayed on the part of the apprentices, they were abandoned. It now appears that this motion or something akin has been sought after by the younger members, so as to atone for their predecessors' neglect. It is hoped that at some not very distant date the object of the above motion will be attained, viz., that classes will be again started with a sort of co-interest, when larger attendances will be expected. The present high price of quinine seemed to be the all-absorbing subject; it was finally agreed that the price for the present should be 1*d*. per grain and 4*s*. per drachm.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, April 19, Dr. Gladstone, President, in the chair. After the announcement of visitors, confirmation of the minutes of the previous meeting, etc., the following certificates were read for the first time:—Messrs. W. H. Ellis, W. Lapraik, J. L. Notters, T. Scarf, H. G. Stacey. The following papers were read:

1. *On the Estimation of Manganese in Spiegeleisen, and of Manganese and Iron in Manganiferous Iron Ores.* By E. Riley.

Estimation of Manganese in Spiegeleisen.—There are two methods now in use: (*a*) *the direct method.* The pulverized spiegeleisen (about one gramme) is dissolved in dilute nitric acid sp. g. 1·2, a little chlorate of potash and hydrochloric acid added to destroy the soluble organic matter from the combined carbon; the solution diluted to about a litre is neutralized with carbonate of soda or ammonia, acetate of soda or ammonia added, the solution boiled, the basic peracetate of iron allowed to settle and filtered off. This precipitate is redissolved in hydrochloric acid, and the process repeated to ensure complete separation of the manganese. The filtrates are evaporated to one litre and a half, allowed to cool, two to four c.c. bromine added, the solution well shaken, ·880 ammonia added in excess, the solution heated gradually for an hour, boiled for a few minutes, the precipitate allowed to settle, filtered (the filtrate should be evaporated and tested for manganese), dried, and ignited in a muffle or over a gas blowpipe for half an hour: (*b*) *the indirect method.* The finely powdered spiegeleisen (about one gramme) is dissolved in dilute sulphuric or in hydrochloric acid, the liquid diluted with recently boiled, cooled distilled water, and the iron estimated volumetrically; to the percentage of iron thus obtained five per cent. is added for carbon and impurities; the difference is assumed to be manganese. The results obtained by this method are usually too low, from the formation of soluble organic matter during the process of solution. This error can be obviated by using nitric acid for a solvent, evaporating to dryness and heating. The oxides of iron and manganese are then dissolved in hydrochloric acid, the solution largely diluted and reduced with sodium sulphite. Results obtained thus agree very closely with the direct method. The author gives fourteen analyses, showing that the addition of five per cent., for impurities, to the percentage of iron is a fair one. Thus, for all practical purposes, the indirect method is sufficiently accurate and can be accomplished in one hour, the direct requiring five or six hours. The author strongly recommends the use of acetate and carbonate of ammonia instead of the corresponding soda salts in the direct method, and proves by check experiments with pure sulphate of manganese, etc., the statements of Fresenius and others, that the presence of ammoniacal salts prevents the complete precipitation of manganese by bromine and ammonia, to be erroneous. On the other hand, if soda salts be used the ignited precipitate will contain soda. The author considers that sulphur cannot exist in spiegeleisen. He determines the carbon by dissolving the iron in neutral chloride of copper, and after complete solution of the iron and precipitated copper, the carbon is filtered on asbestos and burnt with oxide of copper in a current of oxygen. The carbon determinations by the colour test are unsatisfactory for high percentages of carbon. According to the author, the percentage of carbon varies with the percentage of manganese. The methods of Mr. Parry (*Chemical News*, vol. 29, p. 86), and of Mr. Galbraith (*Chemical News*, vol. 33, p. 49,) were considered, and stated to be undesirable methods.

Estimation of Manganese in Manganiferous Iron Ores.—These ores contain baryta, many contain oxide of zinc and some potash or soda in appreciable quantities. The use of ammoniacal salts, as mentioned in the previous part of the paper prevents any large error from the presence of the oxide of zinc, but it is difficult to get rid of the baryta; even in the presence of sulphuric acid it remains in combination with the manganese, and is precipitated with it unless special precautions be taken. Lime, if present, may also be precipitated with the manganese. After insisting on the importance of taking fair samples, and of determining all the constituents directly, the author gave the following process as the one which yielded the best results:—One gramme of the ore dried at 100° C. is dissolved in hydrochloric acid, the silicious matter separated by filtration, and the larger portion of the free acid driven off. The liquid is made up to about one-third of a litre, and allowed to stand four hours after adding a few drops of sulphuric acid to separate any baryta. The solution is now diluted to about one litre, neutralized with ammonia and after the addition of acetate of ammonia boiled, allowed to settle and filtered; the unwashed precipitate is redissolved in hydrochloric acid, and again precipitated with ammonia and acetate of ammonia. The basic peracetate of iron, after settling, is filtered off and washed three or four times with boiling distilled water containing a few drops of acetate of ammonia. The filtrate is evaporated to one litre and a half, when cold, two to four c.c. of bromine added, and the process completed as described above. After ignition the precipitate should be dissolved in a small quantity of hydrochloric acid, the residue, if any, filtered off, a drop of sulphuric acid added, and the precipitate (if any occurs) separated. It is most important to test the ignited Mn_3O_4 for impurities, baryta, zinc, lime, etc. Chlorine can be substituted for bromine, but without advantage.

The sulphide of ammonium process the author considers to be most objectionable.

Estimation of Iron.—The author recommends a standard solution of bichromate of potash, the results being usually a little high. As a reducing agent, sulphite of soda prepared in the laboratory is used, the purchased samples being always impure; bisulphite of soda should not be used. The percentages of iron in sixty samples of steel rails are given, determined by weighing as Fe_2O_3, and by standard solution of bichromate of potash; the mean difference between the two methods is ·073 per cent.

Dr. Gladstone said that the Society must feel greatly indebted to Mr. Riley for giving them the benefit of his experience in so elaborate a manner, especially as the determination of manganese had now become a matter of such great importance.

Mr. Field asked if Mr. Riley had tried hydrated oxide of lead in suspension for effecting the separation of barium, manganese and iron. Cobalt and nickel were entirely separated from iron by its use.

Mr. Riley said that the acetate of ammonia process was so beautiful that he should prefer it; and besides, there would be the additional trouble of getting rid of the lead. In answer to Mr. Heathfield, the barium, in the case of a sample of ore containing 14·87 per cent. Ba. was combined with the manganese.

2. *On a Method of Detecting small Quantities of Bismuth.* By M. M. Pattison Muir, F.R.S.E.—The author finds that the following test liquid (see "Researches on Bismuth," *Pogg. Ann.*, lxxxviii., p. 45, by R. Schneider) is a very delicate qualitative test for bismuth; twelve grm. crystallized tartaric acid and four grm. stannous chloride are dissolved in caustic potash so as to produce a clear liquid having a distinctly alkaline reaction. This liquid must remain clear at 60—70° C. To the liquid to be tested is added a considerable quantity of tartaric acid; it is warmed and made alkaline with caustic potash; a few c.c. of the stannous chloride solution (which the author proposes to call Schneider's reagent) are now added and the mixture warmed to 60—70° for a few minutes. If bismuth is present a brownish black colour is produced, from the formation of hypobismuthous oxide (Bi_2O_2). One part of bismuth in 210,000 parts of liquid may be thus detected. The absence of mercury must be secured before applying the test. Copper and manganese interfere slightly. Lead, arsenic, antimony, iron, cobalt, nickel, and chromium not at all. The author hoped to have perfected a volumetric method from the above reaction but has not succeeded.

Mr. Field mentioned that the precipitation of iodide of lead was an exceedingly delicate test for the presence of bismuth. If no bismuth was present, the iodide of lead was precipitated of the usual yellow colour: if one thousandth part of bismuth was present, the precipitated iodide was of a distinctly darker colour.

3. *On Certain Bismuth Compounds. Part V.* By M. M. Pattison Muir, F.R.S.E.—By precipitating a nearly neutral solution of bismuth nitrate with potassium ferricyanide, washing by decantation, and drying *in vacuo* over sulphuric acid, pure bismuth ferricyanide is prepared as a tawny yellow amorphous powder, with a shade of green; its formula is Bi_35FeCy_6. It is unaltered in moist or dry air; suspended in boiling water hydrocyanic acid is evolved; it is partially decomposed by drying at 100° C. By the action of chlorine, bromine and nitric acid, bismuth ferrocyanide is converted into bismuth ferricyanide. The ferricyanide is decomposed by the action of chlorine, when suspended in water or in the presence of cold or hot solutions of caustic soda. A method for analysing bismuth ferrocyanide and bismuth ferricyanide is given. Bismuth ferricyanide is converted by sodium amalgam into the ferrocyanide. When heated in closed crucibles both salts yield a black-brown mass, containing iron, bismuth, carbon and small quantities of cyanogen.

4. *Notes on Madder Colouring Matters.* By E. Schunck, Ph.D., F.R.S., and H. Roemer, Ph.D. *Continuation.* Munjistin, purpurin, and purpuroxanthic acid.

Munjistin.—The authors found this substance to resemble purpuroxanthic acid, softening at 125°, fusing at 130°; when further heated it evolved carbonic anhydride, and was converted into purpuroxanthin. After criticizing the conclusions of M. Rosenstiehl (*Compt. Rend.*, lxxxiii., 827), who states that his purpurin is identical with purpuroxanthic acid, and that the latter is formed from pseudopurpurin, the authors claim, having been the first to discover among this series of bodies one containing a carboxyl group, to be left for the present in undisturbed possession of the field they have opened up, *i.e.*, the preparation and examination of such members of the series as are formed from alizarin and its isomerides, as well as from the isomerides of purpurin by the substitution of n H by n CO OH.

Purpurin.—The specimen examined had a melting-point which remained constant after it had been converted into the acetyl compound and again liberated; its formula was $C_{14}H_8O_5$; it was easily soluble in boiling spirits of wine, yielding a yellow solution, from which it crystallizes on cooling in thin flattened prisms of a deep orange colour; the crystals lose water at 100° C., and contain one molecule of water. Purpurin melts at 253° but begins to sublime at 150° in red plumose or acicular crystals. It is slightly soluble in boling water and dissolves in ether, readily in carbon disulphide, benzol and glacial acetic acid. It dissolves in concentrated sulphuric acid, in caustic potash, soda lye, sodium carbonate solution, and ammonia. These solutions give absorption spectra. In alcoholic potash and soda purpurin is almost insoluble. It forms with baryta and lime water purple lakes. A solution of purpurin in caustic alkali loses its colour on exposure to the air, the purpurin disappearing entirely; this is due to oxidation. Purpurin dissolves in boiling alum liquor, forming a pink fluorescent solution containing purpurin in a loose combination with alumina. This solution is precipitated by the addition of a little sodium carbonate or ammonia, though the liquid may still retain an acid reaction. An alcoholic solution of purpurin gives with lead acetate a crimson precipitate, soluble in excess of alcoholic lead acetate. The precipitate obtained with alizarin is insoluble in excess; with copper acetate purpurin in alcohol gives a dark reddish yellow precipitate; a solution of alizarin becomes purple, but gives no precipitate.

Triacetylpurpurin softens at 193° and melts at 198° to 200° C. It is decomposed by dilute caustic potash yielding purpurin. Analysis gave the formula, $C_{14}H_5(C_2H_3O)_3O_5$.

Brompurpurin is obtained by digesting purpurin with carbon disulphide containing bromine at 150—200° C. It crystallizes from glacial acetic acid in dark red needles, melting at 270°. Its properties resemble those of purpurin. Its formula is $C_{14}H_7BrO_5$. By heating pure purpurin for six to seven hours in sealed tubes to 300° C a small quantity of quinizarin is formed and a quantity of byproducts. No alizarin is formed. Quinizarin crystallizes in bright red needles, melting at 193—194° C. Its ethereal solution is strongly fluorescent; it is soluble in alum liquor, giving a red solution with two absorption bands.

The Society then adjourned to May 3, when the following papers will be read:—

1. "On Some Points in Gas Analysis," by J. W. Thomas.
2. "On Nitroso-β-naphthol," by Dr. Stenhouse and Mr. Groves.
3. "On the Action of Pyrogallate of Potash on Nitric Oxide," by W. J. Russell and W. Lapraik.
4. "Asbestos Cardboard and its Uses in the Laboratory," by W. N. Hartley.

Parliamentary and Law Proceedings.

EXPLOSION OF NITRO-HYDROCHLORIC ACID.

At Bow Street, on Saturday, April 21, Messrs. Rouch and Co., who were represented by their manager, Mr. G. H. Turner, were summoned for having sent out a dangerous explosive liquid, and causing damage to a tablecloth and other property in chambers occupied by Captain Hawley Smart, at St. Martin's Chambers, Trafalgar Square.

Mr. Montagu Williams, in support of the summons, said that the matter had been taken up on public grounds by Captain Smart, a gentleman in the military service, but also well known as an author and novelist. If he had been pursuing his literary occupations at the time of the explosion he might have been deprived of his eyesight or otherwise injured for life. It appeared that on the morning of the 9th April a boy delivered at the chambers a small packet, resembling a medicine bottle. There was no address written on the bottle, and the boy was unable to say for whom it was intended. The landlady, Mrs. Billingham, thinking that it must be for Captain Smart, desired the servant to place it on that gentleman's table, and it was left there till the return of the captain between 10 and 11 at night.

Captain Smart deposed that he saw the packet lying on his table. He looked at it for a moment, and then sat down in front of the fire with his back towards the table. Suddenly he was startled by a loud explosion, like the bursting of a soda-water bottle, and he saw that the packet on the table had disappeared. The room was filled with smoke and a suffocating vapour, causing him to open the door and windows, and as both the tablecloth and table appeared to be burning, he procured a wet cloth and took other means to prevent the spreading of fire. He found that the bottle had been splintered to atoms, and the neck of it, with a cork still in it, was found upon the floor. Stains caused by the contents of the bottle were to be seen on the carpet, the furniture, and a portion of his own wearing apparel, and he burnt one of his fingers through taking up a fragment of the bottle. The label of Messrs. Rouch was still adhering to the bottle. He sent to them for an explanation of the matter, but they treated the inquiry with such nonchalence, not to say rudeness, that he resolved to place the matter in the hands of his solicitors.

Mr. G. H. Ogston, analytical chemist, of Mincing Lane, described the mixture as a most dangerous one, stronger than nitric acid, and more destructive than vitriol. It was known as *aqua regia*, and was a combination of nitric and hydrochloric acids, and he was surprised that any chemist could have sent out such a preparation without a proper description of it, and a caution as to its dangerous character written outside.

The defence was that the mixture had been made up from the prescription of a medical man, and, when sent out by the boy, was accompanied by proper instructions, the prescription, and the address of the gentleman for whom it was prepared, viz, Major Furlong, who resided in another set of chambers under the same roof as Captain Smart. It happened that the boy neglected to deliver the prescription, etc., and address. With respect to the statement that the clerk of Messrs. Frere, complainant's solicitors, was treated with insolence by Mr. Rouch—who said that it was an attempt to extort money, and that he was as "smart" as the complainant—it was alleged that the complainant and his solicitors had behaved in a very "bumptious manner," and that Mr. Rouch consequently lost his temper. It was urged that the occurrence was merely accidental, and that there being no wilful intention the complaint could not be sustained; but Mr. Flowers remarked that such an explosion would probably have happened in Major Furlong's chambers with similar or worse results. The defendant said if the instructions had been delivered with the bottle it would have been seen that the bottle was to be kept in an upright position, and the defendant's boy was called to prove that he lost the paper at the time, but, finding it afterwards, delivered it the next morning.

Mr. Flowers said there had been great carelessness, and fined the defendants 40*s.* and £2 12*s.* 6*d.*, the amount of damage done by the explosion.—*Times.*

Obituary.

Notice has been received of the death of the following:—

On the 29th of March, 1877, Mr. William Thomas Aylesbury, Pharmaceutical Chemist, Edwardes Terrace, Kensington. Aged 31 years.

On the 9th of April, 1877, Mr. Alfred Kent Laslett, Chemist and Druggist, Hadleigh. Aged 38 years. Mr. Laslett had been a Member of the Pharmaceutical Society since 1869.

On the 10th of April, 1877, Mr. Thomas Brand Steckles, Chemist and Druggist, Newcastle-on-Tyne. Aged 39 years.

On the 10th of April, 1877, Mr. John Clarkson Sutcliffe, Chemist and Druggist, Barnsley. Aged 33 years. Mr. Sutcliffe was an Associate of the Pharmaceutical Society.

On the 13th of April, 1877, Mr. Thomas Buckley Booth, Pharmaceutical Chemist, Eccles. Aged 59 years. Mr. Booth had been a Member of the Pharmaceutical Society since 1853.

On the 17th of April, 1877, Mr. John Jerrard Flower, Chemist and Druggist, Fulham Road. Aged 55 years.

On the 20th of April, 1877, at his residence, 25, Palace Gardens Terrace, Mr. John Sanger, senior partner in the firm of Sanger and Sons. Mr. Sanger had not been actively engaged in the business for several years past.

PREPARATION OF MEDICINAL PEARLS.—The mass for forming the capsules consists of gelatin, gum arabic, sugar and honey. This is rolled out into sheets of suitable thickness. One of these sheets is placed on top of an iron plate having a thickness of 0·6 centimetre, into which holes of a diameter of 1 centimetre have been bored. The gelatinous mass, while still pliant, sinks into these holes by its own gravity, forming a hollow hemisphere in each concavity. The ether or other medical preparation is then introduced, and the orifices are closed by another sheet of the gelatinous compound.

A second iron plate, furnished with holes corresponding exactly to those of the first, is now applied and securely fastened by suitable screws. The whole apparatus is now reversed in such a manner that the superior plate assumes the inferior position. Concavities will thus be formed in the second sheet of gelatin in the same manner as they previously were in the first. In order finally to separate the pearls, the entire arrangement is subjected to strong compression between iron plates in a powerful press. A. W. M.—[*Translated from "Hager's Hand-book of Pharmaceutical Practice,"* 1876.]—*American Jour. Pharmacy.*

Santonin and Strychnine.

Sir,—In the Journal of February 17th was reported a case of poisoning by santonin mixed with strychnia. At the time of reading it, I remembered having seen a similar case reported some years ago, but could not bring to mind any of the circumstances; I was, however, so persuaded that my memory was not at fault, that I have been diligently searching through my books and have at last succeeded in finding the looked-for information. In the *Journal de Chimie Médicale* for January, 1860, at page 23, is an article entitled "Accidental Poisoning by Santonin mixed with Strychnia." As I do not remember having seen this French journal at the Square, and as the subject is an important one, I think that I may venture to intrude upon your space, giving you a complete translation of said article, which now follows.

"It will be remembered that there was recently a fatal case of poisoning which occurred in Brussels, by means of santonin administered as a vermifuge and which was afterwards found to contain four-fifths of strychnia. The *Espana Médica* recounts a series of similar accidents which happened in the Brazils, by the use of santonin bought from the same chemist. Fortunately only one of these poisonings was followed by death. A servant for whom 0·30 gram of santonin had been prescribed, mixed with 0·40 gram of calomel, to be taken in two doses, at two hours' interval, but the second dose was only to be administered in case the first had not had an aperient effect. A quarter of an hour after having taken the first dose, the patient was seized with tetanic convulsions, which passed away. At the time indicated, the second dose was administered, but she did not take it quite all, saying that it was too bitter. The convulsions reappeared and the poor girl died in a quarter of an hour's time. The *post-mortem* failed to discover any appreciable cause to account for the death and the report being spread of several other accidents due to the same substance, the Society of Pharmacy became alarmed and commissioned two of its members, Messrs. Janvret and Vieira to analyse the suspected medicament.

"Having obtained eight grams of santonin from the same shop, C——— Street, No. 113, they first of all remarked that it contained two kinds of crystals, some being in rhombic prisms, flattened, and with a slightly bitter taste, such as are usually those of santonin, the others in masses of square prisms and very bitter, as are those of strychnine. By means of a magnifying glass they were able to separate 0·30 gram of these last crystals. By submitting them to the action of sulphuric acid, which gave no colour, of nitric acid, which turned them yellow, of sulphuric and nitric acids and bi-oxide of lead, which produced a blue colour changing to violet and lastly to yellow, and by testing in various manners an alcoholic solution, the certitude was obtained that this was really strychnine. A complementary experiment was, however, indispensable; 0·05 gram of the strychnine extracted from this santonin were administered in a bolus to a dog of ordinary size. In five minutes' time it was seized with convulsions and died in ten minutes. A second dog took, in the same manner, 0·20 gram of the santonin submitted to the commission. The same symptoms appeared and killed it in fifteen minutes. As a counter proof, 0·20 gram of pure ordinary santonin were administered to a small dog, producing no effect whatever.

"From these facts, scrupulously observed, the commission decided that the santonin in question contained strychnine, and that that substance existed in it to the extent of 20 per cent. (*Espana Médica et Gazette Médicale de Lyons.*) A country doctor, living in Belgium, having bought some santonin from a druggist, administered this vermifuge to a young child, who shortly died poisoned. The so called santonin was examined and found to contain one-sixth part of strychnine. The doctor was condemned to pay a small fine for having, without previous examination, made use of a substance proceeding from a druggist's."

"The cases becoming numerous, we ask, how is it that sometimes santonin contains strychnia?"

With this question of the editor the article concluded, and so far as I can make out the subject rested here. This was seventeen years ago, and such a length of time having elapsed it is useless trying to trace the supply of Mr. Sherrat's santonin to the same source from which the other poisoned samples were obtained.

There is here a mystery which it would be important to discover; these cannot be mere ordinary accidental mixings of strychnine, for why should santonin be more liable to this accidental mixing? These two products are obtained by very different processes; it cannot therefore be especially convenient to prepare them at the same time, they being thereby more likely to become mixed through carelessness. The last operation of recrystallization is alike in both cases, but as I have no knowledge of how these operations are practically carried out by manufacturing chemists, I do not know how far this would render an error possible. Does a plant exist containing strychnia, and yet at all similar in appearance to the *Artemisia Santonica* or any other plant from which santonin is usually extracted? If so, is the Pharmacopœia process for the preparation of santonin capable of producing strychnia at the same time? Do manufacturing chemists usually follow Pharmacopœia process for the preparation of santonin; if not, is their process more likely to extract any strychnia present? I put these questions for competent persons to answer, for although I may have my own opinion upon the subject it can be of no value in a matter of so much moment.

There is one more possible source of error existing in the slight similaritude of names; would not a careless and absent-minded warehouseman be liable to mistake strychnine for santonin, or in the event of a verbal order being given at some distance off and spoken quickly, would it not be possible to misunderstand one for the other? Then comes the question of the labelling; a man must be very absent minded indeed, to put up one thing and label it another, although if two warehousemen are working together, one will very likely put up and the other finish off, in which case it is possible for the finisher off to verbally order his companion to put up santonin; he puts up strychnine through misunderstanding the word, and it is finished off in the usual way and labelled santonin. This theory supposes that the retail chemist has a certain quantity of pure santonin remaining in his stock bottle which mixes with the strychnia received in mistake. Strychnine and santonin being two words very much alike in most languages favours this supposition; and I will also give you following translation of an extract from Darvault's 'Officine,' last edition, where under the head of strychnine will be found at page 888:—"The initial of its name, some physical resemblance, have been the cause of terrible mistakes between this energetic poison and a simple vermifuge, *Santonin.* Attention!"

Having had no experience in the wholesale trade, I merely wish to suggest this and ask whether it could happen. Wilful adulteration is not to be thought of, for besides the danger of the admixture, strychnia is more costly than santonin.

In the three cases mentioned in the French paper, the proportion of strychnia varies from four fifths to one sixth, and the quantity present in the Manchester santonin must have been considerable, Dr. Walker having suffered the symptoms of poisoning through merely tasting it. The difference of percentage of strychnia present only proves that these were not all one and the same sample of poisoned santonin.

In addition to these four cases, we now have the alarming contents of Mr. Willson's letter in your issue of Feb. 24th, which shows that the poisoned santonin is probably more general than we suppose, and if there have not been more fatal cases, it is only due to the small doses usually employed. Mr. Willson takes it for granted that in the German case the poisonous symptoms were due to the santonin, but as it is not mentioned whether the santonin was examined for strychnia, and considering the facts now on record, I think that we may conclude that in Germany there also exists santonin mixed with strychnia, for in all likelihood the physician in charge of the case used the very same sample of santonin for his experiments on the lower animals.

Bearing in mind that convulsions often accompany worms in young children, it would not be surprising to find that in many cases of slight convulsions caused by the strychnia in santonin, the medical man has attributed the symptoms to the worms; one might almost go further and ask whether death caused by strychnia could not be mistaken for convulsions.

I have spoken on the subject to a Spanish chemist, who informs me that he has often remarked that santonin is more bitter at times, but he had not noticed the existence of two different crystals. Of course the difference of bitterness may be due to a larger or smaller quantity of photosantonic acid present, just the same as it may be to strychnia.

Chance has thrown these facts in my path, and it has been my duty to lay them before you, so that steps may be taken to discover the cause of this fatal admixture and to prevent its recurrence.

April 19, 1877.

THE BURNING OF CARBON BISULPHIDE FOR DISINFECTING PURPOSES.

Sir,—My attention has been drawn to a letter sent some months ago, by Mr. T. W. Keates, to the *Lancet*, on the subject of disinfection,—"A Mode of Generating Sulphurous Acid." He recommends strongly the burning of bisulphide of carbon, using for the purpose an ordinary spirit lamp, with precautions, which he details.

For some eight or nine years I have been employing this method, but instead of using a glass lamp, have preferred the ordinary sponge lamps, which are to be bought at any ironmonger's for 6*d*. each. They possess two advantages—they are not breakable, and do not spill when overturned; on the other hand they are not easy to extinguish, and the flame is unprotected.

Would it not be worth someone's while to devise and produce a special lamp for the combustion of the bisulphide? It should be made, I think, of lead, and have a cup dipping into a joint moistened with glycerine. The addition of a perforated dome of earthenware would be an improvement.

The glycerine joint might not strike one as necessary, but I fancy it would be difficult, seeing the extremely low ignition temperature of the bisulphide, to apply a screw cap to the lamp when hot.

THOS. B. GROVES.

MEDICINE MEASURES.

Sir,—I take the opportunity of this discussion on "Medicine Measures" of suggesting (I don't know whether it has been done before or not) what I think will be the best method of writing the directions for mixtures, viz., to use the words "Medical" or "Medicine" as a prefix to the words "tablespoonful," "dessertspoonful," and "teaspoonful." It has the advantage over such words as "accurate," "measured," etc., as it brings before the patient, in a plain and unmistakable manner, the information that there is a particular sized spoonful to be taken—a "medical spoonful"—and it then becomes his duty to provide himself with one, and whether he obtains a glass graduated to tablespoonfuls, etc., a china spoon, or a Proctor's medicine measure, and whether he buys it, or gets it given, it does not matter, the chief thing being done, informing him he has to take a medical tablespoonful, dessertspoonful, or teaspoonful, as the case may be. Also, prescribers would not in any way have to alter, either their calculations, which they would have to do should the sizes of the spoons be increased, or their form of directions, as ʒj, ʒij, ℥ss, would mean as before a tea, dessert, and tablespoonful, only they would be medical spoonfuls. It would in all probability not be long before every household was educated to the knowledge that there was a difference between a "medical" and an ordinary spoon, and had one, in the shape, either of a spoon, graduated glass, or an accurate measure of some kind, set apart for taking medicine.

With hospitals, perhaps, it is a more difficult matter, but it might be got over by having a plain and easily understood notice hanging in the rooms in which the patients are waiting for their medicine, informing them that a "proper medicine spoon or measure" may be had when receiving the medicine, for the sum of, say, one penny.

In conclusion, I may remark our duties and responsibilities are already onerous enough, without our unnecessarily increasing them, and that when we have prepared the medicine, and labelled it in accordance with the "intention" of the prescriber "we have done our duty."

JOHN HALLAWAY.

52, *Castle St., Carlisle.*
April 18, 1877.

COUNTER PRESCRIBING.

Sir,—As the legitimacy of counter prescribing is now being called in question, it may be interesting to your readers to know the interpretation which was given by the judge in the case, *Apothecaries' Company* v. *Greenough*, of the word "dispense" in the 28th section of the Apothecaries' Act, 1815. (See 'The Law Journal Reports,' 1842.') The word "dispense," in that section, must mean either by selling in their shops, or by administering for a specific disease, provided that they only charge for medicines, and not in any other capacity. Formerly it was considered that no one could prescribe but a physician (*College of Surgeons* v. *Rose*, 6 Mod. 44), which was overruled by the House of Lords (1 Bro. P. C., 78, 1st Edition.) If your readers will take the trouble to refer to this case, they will see that the defendant, Greenough, who was declared to have practised as an apothecary, had "attended sick persons, administered medicines to them and made charges." It now remains to be seen what interpretation will be given on this said 28th section by the Court of Queen's Bench, and we await this decision with considerable anxiety, not that we want to practise as apothecaries, but it is of serious moment to chemists and druggists, and also to the public, to know, whether the prescribing of a few lozenges for a sore throat, or a draught for a headache, is an infringement of the Apothecaries Act.

Cannot the Council of the Pharmaceutical Society take up the question with a view to its amicable settlement? If not, and should a decision be arrived at adverse to chemists, apothecaries' shops must take the place of many of our pharmacies. But surely, then, legislation must be obtained to require all future apothecaries to possess a qualification for dispensing which shall be equal to the "Minor" of the Pharmaceutical Society.

F. P. GOSTLING.

Diss, Norfolk,
April 17, 1877.

SUNDAY CLOSING.

Sir,—I for one strongly uphold the keeping of the Sabbath as it should be kept, and I think chemists, as a rule, might set a better example in that respect than they do at the present time. I often go out for a walk on a Sunday, and in the evening especially, greatly to my abhorrence, do I see seven tenths of my brethren with the door-shutter down, the gas flaring, and pomades, perfumes, etc., displayed for sale on the counter, just as though it were an ordinary week day. I maintain that such a proceeding is anything but creditable to the honourable profession to which we belong; it brings our calling down to a level with lollipop and cigar shops.

This is my plan with regard to the management of Sunday. The shop-door is not open at all the whole day, and the needful amount of medicine is supplied at the private door. The following notice is affixed to a brass plate on the door-shutter (not forgetting there are some places without a private entrance, then the shop-door has to be resorted to): "Attendance on Sundays, before 10 A.M. and after 7·30 P.M. Please to ring the bell. Orders placed in the letter box at other times shall receive early attention."

I find this scheme works remarkably well, and I would strongly advise my "brother chips" to have a similar notice affixed in a conspicuous place on the door. When I first took to business, about a year ago, I instantly closed on Sunday, and I have lost nothing by so doing, consequently I shall always adhere strictly to that principle. Before my time here, the shop-door was always on the swing in the evening, and a light shining brightly within, but I very soon altered matters.

I do not pledge myself to stay at home all day long, and if people come at other times, and I am not in, they must call again, which in nine cases out of ten they do. I really do think that employers are cruel to expect an assistant to stay in the whole day; I have been served so myself in different places, and oftentimes not five shillings were taken all through those dreary hours, which seemed more like days, and I was glad when Monday made its appearance. Therefore, I can deeply sympathize with any assistant who has to go through that trying ordeal. The fact is we make ourselves too cheap by half, but I sincerely hope that, as time wears on, there will be an improvement in this respect, and that we shall see every chemist closed on the Sabbath day.

With regard to the early closing movement, I shall be most happy to fall in with any reasonable proposition. I think closing windows at 8, and door at 8·30 a very good one, and will gladly work it in my district, should my neighbours do likewise.

A BEGINNER.

Highbury Park,
April 23, 1877.

Sir,—In reply to "Student's" remarks, in the *Pharmaceutical Journal* of 21st inst., on the process No. 9, in Mr. E. Gregory's paper on "Emulsions," I wish to say, that after reading of his difficulty in obtaining a good result by following "plan No. 9" given by Mr. Gregory, I first prepared an emulsion according to ingredients and process given by "Student," with a most satisfactory result.

Next, I followed Mr. Gregory's "No. 9," and having "Student's" remarks in my mind, was rather astonished on, almost at once, obtaining a result by every means entitled to be "termed an emulsion."

In both cases, I first added, gradually, the turpentine to the acacia, mixing them well together, then added at once, in the one case two, in the other, one and a half parts of water, both "came" quickly and beautifully, and if any difference at all, that by the process of "Student" came easiest.

Having marked both, I set them aside, on the 21st, and to-day, the 23rd, both emulsions are "as like as two peas," each having a "cream" on the surface, the under portion remaining like milk.

I repeated process No. 9 to day, with the very same result. Perhaps "Student" may try again, after reading how "plan No. 9" behaved in the hands of

ANOTHER STUDENT.

Glasgow,
23rd April, 1877.

EMULSIONS.

Sir,—Replying to the letter of "Student" in your last issue of the Journal, I beg to inform him that it is quite possible to produce a perfect emulsion according to the form No. 9 in Mr. Gregory's paper (vide *Pharm. Journ.* April 14th).

The *modus operandi* which has yielded in my hands the greatest satisfaction is as follows:—One part acacia was put into a mortar and well triturated with two parts oil of turpentine: one and a half parts of water were then added at once and well rubbed, when a beautiful emulsion was obtained in one minute. This has remained perfectly unchanged for eight hours, and is miscible with any quantity of water.

Continuing the experiment, the same proportions were used, first rubbing the water with the acacia, then adding the oil *guttatim* This also yielded a good emulsion but occupied half an hour to complete the trituration. I therefore consider the process No. 9, above referred to, to be by far the preferable one, and hope "Student" will preserve in his attempt to produce it.

GLYCERINE OF PEPSINE.

Sir,—Some years back I made a solution of pepsine in glycerine, which has come into extensive use, owing chiefly to the recommendation of Dr. W. B. Richardson, F.R.S. This compound is known as "Acid Glycerine of Pepsine;" and I am induced to call the attention of your readers to this title, lest otherwise they might confound my preparation with those of other makers having somewhat similiar names. I may state that I have found my acid glycerine of pepsine to possess very much greater digestive power than any liquid form of pepsine with which I am acquainted. This can easily be tested by any one who will make the following experiment:—Take fifty grains of hard boiled white of egg, sliced thin, place it in a wide mouthed bottle with half a fluid drachm of acid glycerine of pepsine, and six drachms of dilute hydrochloric acid (two fluid drachms of hydrochloric acid B.P. in one pint of water). The mixture to be stirred occasionally with a glass rod, and allowed to stand at the ordinary temperature, when the albumen will gradually but slowly dissolve. To make a series of comparative experiments, let the operator take two, four, or more times the quantity of any other fluid preparation of pepsine, and observe the results. Those who are not accustomed to test pepsine will find the employment of hard boiled white of egg preferable to fibrine.

SPECTRUM ANALYSIS.*

BY PROFESSOR REDWOOD.

Among natural phenomena there are none more calculated to excite our admiration and wonder than those presented by the rising or the setting sun, by a rainbow, and by the sky on a clear starlight night. An intelligent observer of these phenomena cannot fail, at some period of his life, to have indulged in speculation as to what the objects presented to his observation are, and how they have been brought to his perception. He has been told that for all his ideas of things that are beyond his sense of touch he is indebted to an agent, itself invisible, which is the medium of communication between his organs of vision and objects which may be separated from him by distances either small or immensely great, extending even into the abyss of fathomless space. He has learnt that the chief source of this wonderful agent, which we call light, as far as we are concerned is that glorious orb which shines upon us by day and leaves us in comparative darkness by night. He may have been told that the sun is distant from us about 92,000,000 of miles, a distance which, Sir John Herschel says, a cannon ball would occupy seventeen years in travelling, yet that such is the velocity with which light travels, that it performs the same journey in eight minutes, its rate of travelling being about 190,000 miles in a second of time. He knows, for it is a matter of common knowledge which is sown broadcast in these days of extended education, that philosophers have constructed theories to explain the phenomena referred to, and to account for the way in which they are brought within our perception;—that by some philosophers light has been supposed to consist of particles of a particular kind of matter, infinitely small, emitted from luminous bodies, darting through space in straight lines, striking against, rebounding from, or penetrating and sometimes passing through those bodies which lie in its way,—this being the theory of Sir Isaac Newton, which has been known as the corpuscular theory or theory of emission; while other more modern philosophers, with what is now considered to be stronger evidences in their favour, assume that light is not a sort of matter but a condition of matter, that it is caused by a tremulous or vibratory condition which bodies assume when they become luminous, and that this vibratory condition is communicated to and propagated through an ethereal medium which fills all space, has a high degree of elasticity, and is so greatly attenuated that we have no evidence of its being affected by gravitation,—this being known as the wave theory of light.

Now, there exists a very close relationship between light and heat and chemical action which necessarily brings the study of all these subjects into the department of chemistry.

Chemical action developes heat, and heat developes light. So also both heat and light induce chemical action.

We have a good illustration of the development of light from heat in observing what occurs when we send a current of electricity through this wire. The wire first becomes hot, and then it becomes luminous, the light increasing with the increase of temperature.

And we have a good illustration of the development of heat by chemical action in this little jet of flame produced by the chemical combination of hydrogen and oxygen gases. But here at present we have no evidence that the heat produces light, for although the heat of this flame is as great as the heat of that wire, the light emitted from them is very different. The one is brilliantly luminous, while the other is practically invisible. This difference is due to the fact that light can only emanate from the solid particles of matter, and the denser the matter,—that is, the greater the number of particles in a given space,—the greater will be the amount of light produced by the heating of such matter. There are very few solid particles in this gas flame and therefore it gives very little light, but if I introduce solid particles by putting a platinum wire into it, the heat which is already in the flame when communicated to the wire renders it as luminous as the other wire.

Having thus associated heat with chemical action and light with heat, we may say, in accordance with accepted theories of modern science, that not only is heat a mode of motion but that light and chemical action are so also.

Now, as we shall be chiefly engaged this evening in examining and studying some of the phenomena of light, it will be well to commence by considering what the mode of motion is by which we may account, and by which physicists are accustomed to account, for light in some of its various conditions.

In doing this, it is essential for our purpose to assume that no such thing exists in the universe as a perfect vacuum. We may also assume that no such thing exists as absolute solidity or continuity of parts in any form of matter except those particles or atoms of which bodies are composed. Masses are made up of atoms, but there are spaces between the atoms which, in common with all other space, are filled with the ethereal medium which we call the luminiferous ether. This ether is so infinitely attenuated that, as I have already said, we have no evidence of its being affected by gravitation, yet it possesses a very great degree of elasticity.

It is necessary to assume that the ether that fills the spaces between the atoms of bodies acquires increased density there, but that it does not acquire proportionately increased elasticity. In consequence of this change of density in the ethereal medium which fills the spaces between the atoms of transparent bodies, light travels through such bodies with velocities which are diminished in proportion as the densities of the bodies are increased.

This result accords with what is known to occur in the case of sound, the velocity of which increases with the elasticity, but diminishes with the density of the medium through which it is propagated. Now, if the luminiferous ether in transparent bodies had its density and elasticity increased so as to maintain their proportions unaltered, the one would exactly neutralize the other, and there should in that case be no alteration of velocity; but by assuming that its density is increased to a much greater extent than its elasticity, the observed effects of the transmission of light through different transparent bodies is easily accounted for.

It is to the alteration in the velocity of light when it passes from one medium into another of different density that we ascribe the refraction or bending of the rays; and it is by means of refraction that we shall be enabled presently to effect the analysis of light.

* Lecture delivered before the Pharmaceutical Society of Great Britain, on Wednesday, May 2, 1877.

Light, then, is a state of motion of the luminiferous ether, originating in a condition of motion of bodies which, when they are in that condition, are said to be luminous.

The grosser forms of matter, which are distinguished from the luminiferous ether by their being affected by gravitation, are capable, under the influence of heat, or electricity, or chemical action, of exciting the luminiferous ether, and throwing it into a tremulous or vibratory condition.

This vibratory condition of the ether is itself imperceptible to us, except when a continuous line of such vibrations reaches the retina of the eye from either a luminous or an illuminated body, the latter being a body which instead of originating light by exciting the luminiferous ether, merely changes the direction in which a line of vibrations or ray of light is travelling; and when any of these rays impinge upon the retina of the eye they render the object from which they proceed visible, that is to say, they excite motion in the optic nerve which communicates with the brain, and produces a sensation or image.

Now, we have to deal with the luminiferous ether, and to consider what kind of motion the ether undergoes in the propagation of light. In doing this we must first assume that the ether itself is composed of parts or particles, infinitely minute, which are held in their normal state by a force which gives to it great elasticity, but admits of the particles moving to and fro through infinitely short distances, with almost inconceivable rapidity.

If we compare the transmission of light with that of sound, taking for granted the conclusions arrived at by physicists, we shall find that there is a marked difference between them. In both cases the effect is due to vibrations. In the case of sound, it is due to vibrations that are propagated through a material medium, usually through air. In the case of light it is due to vibrations through a medium which is independent of the recognized forms of material matter.

The vibrations to which sound is due consist in the movement to and fro of particles or little volumes of air in the direction in which the sound travels. The vibrations are *longitudinal*, in a line coinciding with the direction of the sound.

On the other hand, the vibrations to which light is due consist in the movement to and fro of particles of the luminiferous ether in a direction *transverse* or at right angles to that in which the light is travelling.

If we assume the existence of a line of particles of the ethereal medium in a quiescent state, and conceive a luminous body, such as a candle, to be the source from which light is to be propagated through such particles by throwing them into a state of vibration, we may readily suppose that the particles would begin to move, not all at once, but progresively one after another, commencing with the particles nearest to the luminous body. The first particle would begin to move before the second, and the second before the third; and as they would all move to the same extent, to and fro, across the line of light, the position of the particles when in motion would necessarily represent a series of waves.

But the idea thus formed is that of motion or vibration of the particles in one plane only, and it is necessary to assume a more complex mode of motion than this in a ray of common light. It is assumed that the plane of vibration is constantly shifting, that there are a few vibrations in one plane then a few in another plane, and so on as the ray travels along, this shifting of the plane of vibration occurring very irregularly, but occurring in all conceivable planes around and through the line originally formed by the particles in their normal state of rest.

A round ruler, or this model, may be taken to represent or afford a rude idea of a ray of common light.

But it is now necessary for us to endeavour to dissect this ray of light, and we are enabled to effect this dissection or analysation of the ray by taking advantage of the effect produced upon it on causing it to pass through transparent bodies of different densities.

At the moment of its passing from one medium into another of different density, if it enters the new medium in a direction oblique to the surface at which it enters, it is bent or *refracted*, and when it is refracted at two surfaces which are not parallel to each other, as, for instance, in passing through a prism of glass or other transparent substance, the different parts of which the white light is composed are to some extent separated from each other, and we thus find that the separate parts possess colour.

This, which is prismatic analysis of light, is the first step we take in the direction of analysation. We are here pulling the elements of light asunder, so that we may examine and study the separate parts of which it is composed. The result of this *dispersion*, as it is called, of a ray of light is the production of the *spectrum*, in which we have the colours of the rainbow painted on the screen with a brilliancy far surpassing anything we can produce by the use of artificial colours or pigments.

Now, the question is, what do these colours signify, and what is the difference between one colour and another?

The answer to this question is, that these are effects resulting from the greater or less rapidity with which the vibrations occur, and the conclusion arrived at is, that a ray of common white light is composed of several sets of vibrations travelling together with equal velocity, but each set consisting of vibrations differing in frequency or rapidity from the others. The vibrations of least frequency are those at the red, and those of greatest frequency are those at the violet end of the spectrum.

Each of these sets of vibrations forms a separate series of waves, and these waves differ in length just as the vibrations from which they result differ in frequency; the least frequent vibrations produce the longest waves, while the most frequent vibrations produce the shortest waves.

Prismatic analysis was first studied by Sir Isaac Newton, who, admitting a beam of sunlight through a round hole into a darkened chamber, obtained by means of a prism an oblong image of coloured light on a screen, and the image thus produced presents seven distinct colours, which are known as Newton's prismatic colours. But the spectrum produced in that way is not now recognized as a pure spectrum, because the colours overlap each other, and thus produce intermediate colours.

Dr. Wollaston, at a later period, obtained a much nearer approach to a pure spectrum, by admitting the light through a narrow slit. In this case the spectrum is a long band or ribbon of light, the colours of which may, by narrowing the slit, be reduced to four, namely, red, green, blue and violet.

Several suggestions have been made with the view of simplifying the mode of representing the composition of white light. It is now generally assumed to consist of three elementary colours, and these have very generally been supposed to be red, yellow, and blue. Sir David Brewster adopted this view, and the observation of the results of mixing artificial colours or pigments appears to justify the opinion that Newton's prismatic colours may be all produced with red, yellow and blue. But the study of coloured lights produced by the prismatic analysis of white light leads to a different conclusion.

Wollaston reduced his spectrum to four colours, namely, red, green, blue and violet, and he found these to bear the quantitative relation to each other of 16 parts of red, 23 of green, 36 of blue, and 25 of violet, in 100 parts.

Dr. Thomas Young, one of the highest authorities on the subject, recognizes three simple sensations as those produced by a ray of white light, these sensations when separated being those of *red*, *green*, and *violet*, and it has been shown that not only can white light be produced by the union of those three colours, but that orange and yellow can be produced by the union of green and red, and that blue and indigo can be produced by the union of green and violet.

We therefore take red, green, and violet, as the three elementary colours from which all others may be produced.

I must refer you to the diagram which represents what are assumed to be the number of waves that are formed within the space of an inch, and the number of vibrations that occur in a second of time, in each of the elementary colours.

Waves of Light.

	Waves in 1 inch.	Vibrations in 1 second of time.
Red..............	34,000	482 millions of millions.
Green...........	45,000	550 „ „
Violet...........	60,000	707 „ „

Now, we have produced our spectrum by Dr. Wollaston's method of passing the light through a narrow slit, but we have not the advantage here that he possessed of employing the light of the sun. We are using the best representative of sunlight that we can command, namely, the light of incandescent charcoal brought to an intense heat by a current of electricity. The luminous body from which this light emanates consists of solid carbon which forms the terminals of the conducting wires of a Groves' battery of 40 cells. These carbon terminals when brought together touch each other only at a few points and thus offer obstruction to the free passage of the electric current; heat is therefore developed; the carbons become hot, and if they be now gradually separated to a small distance from each other, the current is maintained, an arc of light fills the space betweeen the two points, through which small particles of incandescent carbon are constantly flying from one terminal to the other, while the points themselves being intensely heated are the source from whence our light emanates. The magnified image of this is thrown on to the screen, so that you there see the whole mechanism of the production of the light.

I will now shut off the light which has been passing from the lantern in a direct line to the screen, and, sending it in another direction through two prisms, filled with bisulphide of carbon, will cause it to travel round a corner and so reach the screen by a different route. In passing through the prisms the light is turned from its original course, and it is largely dispersed in consequence of one part of it being refracted more than another, the bisulphide of carbon contributing to the dispersion.

We thus produce our spectrum, which you will observe is a continuous band of light, of different colours, but without any interruption of light from one end to the other.

This is the result always obtained when the luminous body from which the light is derived is either solid or liquid. But it is not the result obtained with the light of the sun.

It was Dr. Wollaston who first, in 1802, discovered, on closely examining the nearly pure spectrum of sunlight, which he obtained by adopting his method of prismatic analysis, that there were several dark lines running across the spectrum and interrupting its continuity. These lines are not seen in Newton's spectrum, the effect being there obscured by the overlapping of the colours.

Afterwards, Fraunhofer of Munich, in 1814, by increasing the length of the spectrum and using a telescope, was enabled to trace about 600 of these dark lines, which are now called Fraunhofer's lines.

I must refer you to the drawings, for a representation of these dark lines. There is no difficulty in detecting the more prominent of them in the solar spectrum, but it long remained an enigma as to what was their cause.

We have reason to believe that this enigma has now been solved; but before attempting to explain the manner in which the phenomena of Fraunhofer's dark lines are accounted for, I purpose bringing under your notice the spectra produced by some other lights besides that I have hitherto employed.

I have already alluded to the fact that the light emitted from luminous bodies, when in the solid or liquid state, yields spectra which are continuous throughout the illuminated band, the light consisting of rays of all degrees of refrangibility within the range of the two extremes.

To this must now be added the statement that if the luminous body be in the condition of a gas or vapour, the light emitted by it may consist of rays of several limited degrees of refrangibility, which will produce a spectrum consisting of one or more bright bands of coloured light with intervals more or less completely dark.

Any substance that can be converted into a luminous vapour may in this way produce a spectrum peculiar to itself, and we thus have a means of identifying substances and of detecting their presence when existing in a state of admixture with other substances, which in many cases is of great value to the chemist.

It will be perceived that we are here entering upon the practical part of the subject of spectrum analysis.

With a little modification of our lamp we shall be able to make the intense heat produced by the electric current a means of converting some of the metals into vapours of sufficient luminosity to yield spectra that may be projected on to the screen.

In doing this we shall work with the carbons a little wider apart than we have hitherto had them, so that the arc of flame between the points, rather than the points themselves, should be the source of light.

We use a large carbon now for the lower terminal, and the end of this is hollowed out so that it may support the bit of metal which is to be heated by the electric current until it melts and is converted into vapour, which will give colour to the flame and also a characteristic spectrum.

My son who has taken charge of the lamp, which requires rapid and skilful manipulation in the experiments we are going to perform, will make the necessary adjustments for producing the required effects, while I endeavour to explain the results.

The first metal I propose using is thallium, which the President has had a good deal to do with, especially in the production of its compounds. This metal owes its discovery to spectrum analysis, and it yields a very distinct and beautiful spectrum. On heating some of it in the electric lamp, it is converted into a beautiful green vapour, which fills the space between the carbon terminals. By allowing the light to pass directly from the lamp to the screen you are enabled to see the carbon points which are now less heated and less luminous than they were in previous experiments, the electric current being more freely transmitted by the metallic vapour than it was by the incandescent carbon alone. The green vapour of the thallium, so beautifully painted on the screen, forms an arc of light, some rays of which, by stopping their direct passage to the screen, and allowing them to pass through the slit and the prisms, are gathered up into a single band of green light, which forms the spectrum of this metal.

We now remove the carbon cup in which the thallium has been heated, and introducing a fresh carbon cup, subject a bit of silver to the same treatment. It melts and boils, emitting a vapour which, as you will perceive, is not distinguishable in colour from that of the thallium vapour. But if we now stop the direct passage to the screen, and send the light through the prisms, we obtain a spectrum which differs from that of thallium, inasmuch as it consists of two green bands instead of one, and these do not occupy exactly the same position as the thallium band did in the space that would be occupied by a continuous spectrum of white light.

Removing the silver with its carbon support, we will now introduce copper, which, treated in the same way as the other metals, yields again a green vapour, the spectrum of which, however, is distinctly different from either of those previously obtained. We have now three or four bands of red, several of green, and also of blue.

Changing now again the carbon support on which we have had the copper, we will next introduce a bit of zinc. The colour of the bright vapour of this metal as it is thrown directly on to the screen, you will observe, is a beautiful violet. Remark the splendour of the luminous arc of violet light, which we can increase to some length by separating the carbons, as the metal freely volatilizes and carries the current of electricity from one pole to the other forming a bridge of coloured light. But we must now close that passage from the lantern, and send the rays by another route to be analysed by the prisms, and to have the component parts of the light gathered together and displayed on the screen as the spectrum of zinc. You will see that it consists of a red band, and three very beautiful blue bands, wholly distinct and different from anything we have had before.

Following copper and zinc we will now introduce a bit of brass, and here we shall see that the spectrum of this metal at once reveals the elements of which it is composed. We have the characteristic bands both of the copper and the zinc, showing the power of this method of analysis for indicating the component parts of compound bodies.

I have now only one more metal to bring under your notice, namely sodium. This metal gives a very characteristic yellow band, which is easily produced, but I fear we shall not be able now to produce it in a state of purity on account of the atmosphere of our lantern having so much volatilized matter from the metals we have been already operating upon. I am anxious, however, to show the bright yellow sodium band, and will ask you to disregard some of the other bands, which will appear with it, and which are caused in the way I have stated.

It is this yellow sodium band that we are going to endeavour to convert into a dark band, and failing the accomplishment of that result I should have failed to demonstrate one of the principal objects I have had in view, namely, that of showing that the bright bands which characterize the several metals, and which you have seen, may be converted into dark bands.

It has been found, by very careful and accurate admeasurement of the positions occupied by the bright bands in the spectra of many of the metals as compared with the solar spectrum, that the bright bands in the one correspond with the dark bands in the other. It has also been shown that when light of a high degree of luminosity passes through a luminous atmosphere of lower illuminating power, the one light may absorb out of the other that portion of light which corresponds in refrangibility with its own. This result has been proved experimentally and explained theoretically, but time will not admit of my entering minutely into this part of the subject on the present occasion.

I must, however, endeavour to show you that if we introduce the vapour of sodium into the flame of a Bunsen's lamp, in front of the slit from which the light of the carbon points is issuing, and then allow the light to pass through the prisms, the spectrum so produced will have a dark band in the place of the usual bright sodium band.

This reversal of the bright bands of the spectra of the metals, and the establishment of the coincidence of such bands with dark bands in the solar spectrum, was the great discovery of Kirchhoff, which not only affords an explanation of the cause of the dark lines in the solar spectrum, by assuming that the sun consists of a solid or liquid nucleus in a highly heated state with a luminous atmosphere surrounding it, but it indicates that we have the means of detecting, and that Fraunhofer's dark lines prove, the presence in the sun's atmosphere of certain metals, including those, with perhaps one or two exceptions, which we have been using this evening.

By spectrum analysis, therefore, we are enabled to reveal the composition of substances within our reach and to detect the presence in them of elements which may be there in such minute quantities that they cannot be discovered by other means, and we are also enabled in the same way to investigate the composition of bodies so far distant from us as the sun and even some of the fixed stars, the distance of which is vastly greater than that of the sun, for it has been calculated by astronomers that a ray of light cannot reach the earth from the nearest of the fixed stars in less than five years.

Nor does the power and application of spectrum analysis terminate here, for, as I will now show you, when a ray of white light is made to pass through substances in solution such as chlorophyll, the colouring matter of cantharides, lobelia, etc., part of the light is often absorbed so as to yield spectra with dark bands which are sometimes characteristic. A large number of results of this description have been obtained which are interesting and may prove to be of value in analytical researches.

But I must reserve much of what I have latterly alluded to for future communication, and if I may judge of the interest you take in the subject by the evidences you have afforded this evening, it will be a pleasure to me to extend the number of these evening meetings, at which I may be enabled again to use the electric lamp with other instruments we possess for the illustration of these and other phenomena of light.

CALIFORNIA MANNA.*

The *Druggists' Circular* has received from a California correspondent some cuttings of cedar and pine, covered with saccharine matter which old Californians call "honey dew," and which is only found in quantities in extremely dry seasons, when the trees are said to be literally covered with it. The specimens were submitted to Prof. George Thurber, who furnished the following notes:

"The specimens consist of terminal twigs of two conifers: a pine of the section with ternate leaves (three in a cluster or sheath), but which cannot be accurately identified without the cone; and the California white cedar, *Libocedrus decurrens*. Specimens of both are freely incrusted in a stalactitic manner with a nearly pure white substance. A friend who stood by as I opened the box at once declared them to be fragments of a Christmas tree; you made a similar comparison in your note accompanying them, which shows that the resemblance of the incrustation to candle drippings at once suggests itself. The taste recalls that of manna, and if a fragment is carefully separated, that is not in direct contact with the stem or leaf, it is free from any terebinthinate flavour. It is one of the numerous saccharine exudations classed under the head of *manna*, to indicate a common method of production, rather than identity of chemical characters.

"While the manna of commerce is furnished by a species of ash (*Fraxinus Ornus*), similar exudations, more or less valued in the countries where they occur, are produced by trees of widely different families. The *Leguminosæ* and *Rosaceæ* contain manna-bearing plants; a tamarisk, a cistus, a willow, and one or more oaks, afford similar products; even the genus Eucalyptus, of which so much is now expected, has a manna-yielding species; with all these very dissimilar plants producing sugary exudations, it is not so surprising that we should find them in a family where they would be least expected, judging from its ordinary 'naval store' products—the *Coniferæ* or Pine Family.

"Manna from the conifers is, however, no recent thing. The Briançon manna, employed in France early in the last century, is from a conifer, the European larch (*Larix Europæa*), and received its name from being collected in the mountains about Briançon, where it is still gathered by the peasants for their own use, though no longer in commerce. It is found in midsummer adhering to the leaves of the larch, and is collected early in the day, as it disappears with the heat of the sun. The old writers mention the Manna of Lebanon, which some authors say was afforded by the Cedar of Lebanon (*Cedrus Libani*), but others assert that it was only a synonym for gum mastic.

"One of the finest pines of that country of magnificent trees, our Pacific coast, is known to cultivators as Lambert's Pine (*Pinus Lambertiana*); this reaches the height of 200, and even 300 feet, and is useful as well as grand, its wood serving there for all the purposes that the white pine does with us. Ordinarily, this tree exudes only turpentine, and but little of that; but when the tree is injured by being partially burned, it yields a saccharine substance, formerly used by the settlers for sweetening their food, on which account the tree is known all along the coast as the 'Sugar Pine.' According to Professor J. S. Newberry, 'Pacific R. R. Reports,' vol. vi., 'Botany,' p. 44, the laxative properties of this pine-sugar are known to the frontiersmen, who make use of it as a medicine. He says: 'Its resemblance in taste, appearance, and properties to *manna* strikes one instantly, and but for a slight terebinthine flavour it might be substituted for that drug without the knowledge of the druggist or physician, its physical and medical properties are so very like.'

"The pine, however, among the specimens in question, is not the sugar pine (*P. Lambertiana*), as that species belongs to the section having five leaves in a sheath, and shows that there are at least two species of our far Western pines which produce a manna. The observation as to its production by *Libocedrus* is, so far as I am aware, quite new, and adds one more to the manna-yielding genera.

"As to the cause of this exudation, so long as the phenomenon in the manna ash, where there has been abundant opportunity for study and observation, remains unexplained, it is hardly worth while to conjecture in the present case, in which we have only the results.

"Manna is exuded from this ash spontaneously, the tree being wounded merely to increase the product. It only occurs in warm and dry countries, and is greatly affected by the character of the season. We have in the specimens, and also in the sugar produced by the sugar pine, not only an exudation, but one very unlike that usually yielded by the tree. The ordinary exudation from these trees, in common with others of the pine family, is turpentine, an oleo-resin. In these cases the character of the exudation is entirely changed, and we have a form of sugar, belonging to an entirely different class of principles. In the sugar pine this appears to be effected by destroying the vitality of the tree by partial burning; in the specimens before us it is ascribed to extreme drought.

"As some of the products resembling manna are due to the punctures of insects, I examined a portion of this by dissolving the sugar from a stem; a few fragments of what appear to be remains of *aphides* were found in the solution, but none attached to the twig. I have not been able to make any examination of the optical or other properties of the sugar."

TAXINE, A POISONOUS ALKALOID PRESENT IN THE LEAVES AND SEEDS OF TAXUS BACCATA, L.*

BY W. MAVINÉ.

Although cases of poisoning by yew berries have been confirmed in former times and also recently, the poisonous effects of the fruits and seeds of the yew tree are disputed from many sides, while the strongly toxic action of the other portions of the tree are known generally.

Lucas isolated from the leaves of this tree three grains of a body which he calls taxine, and gave a few reactions regarding it. For its preparation Stass's method for detecting alkaloids was followed out, without giving satis-

* *Chem. Centr.*, 1876, 166—167. From the *Journal of the Chemical Society*, April, 1877.

factory results. The following process was more successful:—The leaves or seeds are powdered, and repeatedly exhausted with ether; the extracts are mixed, and the ether is distilled off. The residue which when obtained from the leaves forms a green resinous mass, having a peculiar aromatic smell and sharp taste, while that from the seeds is a large quantity of a fatty oil, was repeatedly shaken up with water, acidulated, and slightly warm. The water separated from the residue was filtered, and in the clear and colourless filtrate the taxine was precipitated by ammonia or fixed alkali, in snow-white bulky flakes. When washed and dried over sulphuric acid, it forms a white crystalline powder, which is scarcely soluble in distilled water, readily soluble in acidulated water, alcohol, ether, chloroform, benzine, and carbon disulphide, insoluble in petroleum and ether. It has no smell, but a very bitter taste. Pure concentrated sulphuric acid reddens it; nitric, hydrochloric, and phosphoric acids dissolve it without change of colour. With most of the reagents characteristic of alkaloids—tannic acid, phosphomolybdic acid, potassio-mercuric iodide, potassio-cadmic iodide, potassio-bismuthic iodide, iodo-potassic iodide, potassio-argentic cyanide, potassic bichromate, picric acid—it yields, in an acid solution, amorphous precipitates. Platinic chloride, auric chloride, mercuric chloride, potassio-platinous cyanide are not precipitated. It does not form crystallized salts with the ordinary acids. It is nitrogenous (evolves ammonia when heated with freshly ignited soda-lime), melts at 80°, and burns without residue when heated more strongly. Taxine is present in the leaves in larger quantities than in the seeds of the yew tree.

THE FERMENTS CONTAINED IN PLANTS.*

BY C. KOSMANN.

There appears to exist in the buds of trees and young leaves of many plants a natural ferment which is capable (1) of transforming cane-sugar into glucose, (2) of converting starch into dextrin and glucose, and (3) of resolving a glucoside, such as digitalin, into glucose and digitaliretin. The method adopted to show the presence of the ferment was as follows:—The buds or young leaves were chopped and macerated in cold water; after twelve hours the liquor was strained off, filtered, and a portion warmed with Fehling's solution to see if any precontained glucose was present. 1·5 to 4·0 grams of sugar were then added and the solution allowed to remain for some hours at a temperature of 18° to 30°. Generally at the end of twenty-four hours the whole of the sugar was inverted, and a syrup of glucose could be obtained by evaporation, which had a powerfully reducing action upon the copper solution. Instead of sugar, starch-paste was sometimes used, which, when acted upon, was converted as above mentioned. No gas was evolved in these experiments, on the contrary oxygen was absorbed: a microscopic examination of the deposits which occurred also revealed the presence of much organic life.

The ferment was proved to exist in the following plants:—Buds of *Ulmus campestris*, *Populus nigra*, *Quercus pedunculata*, and *Corylus avellana*; in the flowers of *Cornus sanguinea* and *Prunus spinosa*; in the young leaves of *Chelidonium majus* and *Digitalis purpurea*.

An infusion of digitalis leaves reduced a considerable quantity of digitalin on exposure to sunlight, resolving it into glucose and digitaliretin. The latter substance was collected as a precipitate, dissolved in alcohol, and submitted to suitable tests whereby it was recognized.

Extraction and Purification of the Ferment contained in Digitalis.—To a concentrated infusion of the young and fresh leaves, its own volume of strong alcohol was added. After twelve hours the greyish-white precipitate which had fallen was collected, washed and dried. It was then redissolved in water, the solution filtered from a little insoluble matter, and again precipitated by the addition of alcohol. The white precipitate was washed with alcohol, and then dried on glass. The dry substance was greyish-white, granular, soluble in water, and was not rendered blue by iodine. Under the microscope it presented the appearance of granules adhering to one another. It possessed eminently the power of decomposing cane-sugar, starch-paste, and soluble digitalin, acting thus quite as energetically as a strong infusion of the leaves of the fresh plant.

THE ALKALOIDS OF CELANDINE (CHELIDONIUM MAJUS).*

BY E. MASING.

Celandine contains two alkaloids, chelidonine and chelerythrine (sanguinarine), which form with Mayer's iodide of mercury and potassium, insoluble salts having, in the case of chelidonine, the formula $C_{19}H_{18}N_3O_3I.HgI_2$. These alkaloids were estimated at given intervals in the growth of the plant by extracting with alcohol of 75 per cent. containing a little acid, and titrating with Mayer's solution. The chelerythrine, $C_{19}H_{17}NO_4$, is calculated as chelidonine. A long table of results is given, including determinations of the amount of alkaloids every few days from May to September. The general results are: a diminution in the total amount of alkaloids before flowering, and a marked increase after a few days. The young plant gathered in autumn shows a regular increase of alkaloids. This may be explained by assuming the alkaloids to be the immediate precursors of the albumin, and that they are gradually transformed into albuminous substances. The weather is also an important factor in the amount of alkaloids. In rainy weather the consumption is greater than the production, and the percentage is decreased; while in fine sunny weather consumption and production are nearly in equilibrium, the production having a slight advantage. These changes are more noticeable in the root than in the leaf. A good soil influences the formation of alkaloids, for plants grown in a garden were found to contain double the amount of alkaloids found in wild plants. The largest amount of alkaloid is 1·09 per cent., and the smallest 0·27 per cent. The average appears to be about 0·6 per cent.

THE MILKY JUICE OF THE FRUIT CAPSULES OF PAPAVER RHŒAS.†

BY O. HESSE.

A statement by Selmi, according to which the unripe fruit capsules of the wild poppy contain an alkaloid similar to morphia, induced the author again to examine the milky juice that flows from such capsules upon being scratched. This juice, collected in the morning under a clouded sky, gave 35 per cent. of dried residue at 100°; some obtained after half an hour's violent storm gave only 34 per cent.

The milky juice is at first mostly white; sometimes, however, it is of a beautiful citron yellow colour, and then quickly changes in the air to a dark brown. Ferric chloride produces with it an intense red colour, probably indicating the presence of meconic acid.

4·4 grams of dry residue examined by trustworthy methods gave no trace of morphia or an alkaloid similar to it; whereas 0·090 gram gave equal to 2·1 per cent. of rhœadine and traces of another partially crystallizable alkaloid, to which the author promises to return on a future occasion.

As rhœadine is the principal alkaloïdal constituent of these fruit capsules, the author considers it would have been present in the "new substance" that Selmi prepared from this *Papaver*. Rhœadine is not coloured by ferric chloride, but agrees somewhat with morphia in being almost insoluble in ether.

The Pharmaceutical Journal.

SATURDAY, MAY 5, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, *17, Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary, 17, Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL REPORTS.

ONCE more an opportunity is afforded the Members and Associates of the Pharmaceutical Society of estimating the work performed for them by their Executive, and of considering the position in which the Society stands as compared with that of former years. For not only will they find on another page the Report adopted by the North British Branch at its Annual Meeting last week, but, in accordance with a resolution passed by the London Council on Wednesday, almost simultaneously, they will receive an early copy of the Report to be presented at the Annual General Meeting of the Society on the 16th inst.

In referring first to the North British Report it is satisfactory to note that it shows a marked advance, at once the justification and the reward of the increased expenditure in connection with the Society's establishment in Edinburgh. Whether reference be made to the number of students using the new rooms, the issue of books from the Library, or the result of the educational arrangements, it will be found that there has been considerable progress made. The only expression of regret relates to an increase in the percentage of failures at the different examinations in Edinburgh, but we agree in thinking that the new regulations as to the examination fees will probably affect these figures favourably also. Certainly, Messrs. GILMOUR and KINNINMONT, after three years' valued services as President and Vice-President, are to be congratulated upon being able to hand the affairs over to their successors in so prosperous a condition. Fortunately for the Branch, too, it still retains its indefatigable Honorary Secretary, Mr. MACKAY.

Turning to the Report of the Council to be presented to the Annual General Meeting of the Society, we may, without presuming to anticipate its discussion at the proper time and place, venture to remark that there are many points in it which are subjects for congratulation. So far as the Financial Statement is to be taken as indicating the present and prospective strength of the Society, the advance of education as tested by examination, and the growth of the class of which the Society is the acknowledged representative, we think the indications are to be considered satisfactory. A larger number of persons have paid a larger total amount in subscriptions than in any previous year in the history of the Society. As compared with the previous year, also, there has been a considerably larger number of candidates for each of the examinations, but with a much reduced percentage of failures. It would be difficult to say in which case this relative increase has the most important significance, but it will be reassuring to those gentlemen who have feared that the stringency of the examinations would prevent a sufficient number of youths entering the trade to find that the increase of Preliminary candidates on the previous year has been at least 25 per cent., whilst the rejections have fallen from 50 to 42·4 per cent.

Another matter for congratulation is that no measure specially affecting the interests of chemists and druggists has been proposed in Parliament since the last meeting of the Society. With the fact that many prosecutions for infringements of the Pharmacy Act have been successfully carried through, our readers will have already become acquainted through the reports in our columns, but it is not so well known, or at any rate it is often lost sight of, that in a still greater number of cases the Registrar succeeds in compelling offenders to discontinue their illegal practices without going into a law court.

There have been some special causes of expenditure during the year that are referred to in the report, and which require no explanation here. But naturally we are gratified to find that the expenditure in respect to this Journal has been now reduced to an amount that represents little beyond the cost of postage.

THE ADULTERATION OF FOOD AND DRUGS IN CANADA.

THE reports recently presented to the Canadian Inland Revenue Department by the analysts appointed under an Act passed in 1875, shows that a considerable amount of sophistication occurs in some articles of food and drugs in the Dominion. Milk, of course, has been found adulterated. Hardly any of the mustard, pepper, ginger, cloves, or cinnamon examined has been pure. Six samples of mustard each contained two-thirds of wheat flour and turmeric. Five out of six samples of ginger contained 10 to 15 per cent. of wheat and rice flour. All the ground cloves contained clove bark, and from all the so-called "cinnamon" cinnamon was entirely absent, its place being taken by cassia, mustard and pea meal. Dr. J. BAKER EDWARDS, the analyst for Montreal, reports of five samples of quinine wine submitted to him, that only one was in accordance with the official formula, the others being in fact potable stimulants, containing as much alcohol as is present in most ports and sherries, and but little quinine. One sample deserves special remark. According to Dr. EDWARDS it consisted of inferior red wine, coloured with logwood, citric acid, sugar, tincture of gentian and orange, and traces of strychnia and brucia from a small quantity of tincture of nux vomica. Its alcoholic strength was 68 U.P., and it contained one grain of sulphate of quinine in three fluid ounces.

BOTANICAL LECTURES AND DEMONSTRATIONS AT THE GARDENS OF THE ROYAL BOTANIC SOCIETY.

It will be seen by reference to the advertisement of the School of Pharmacy of the Pharmaceutical Society of Great Britain, that Professor Bentley will commence his course of lectures and demonstrations on Systematic and Practical Botany, at the Gardens of the Royal Botanic Society, in the Regent's Park, on Saturday morning, May 12th, at eight o'clock. These lectures will be continued on the succeeding Friday and Saturday mornings, till the end of July. On p. 901 will also be found the announcement respecting the Botanical Prize for 1878.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held at 17, Bloomsbury Square, W.C., on Thursday Evening next, May 10th, at eight o'clock, when the following papers will be read;—"The Luminosity of Flame," with experimental illustrations, by Mr. Harold Senier, and "The Qualitative Analysis of the more commonly occurring Scale Preparations, Alkaloids, etc.," by Dr. A. Senier, F.C.S.

THE CINCHONA ALKALOIDS.

Our statement last week that none of the cinchona alkaloids except quinine are official in any of the existing Pharmacopœias requires a slight modification. Mr. Fritz, of Vienna, has kindly reminded us that sulphate of quinidine is included in the Austrian Pharmacopœia of 1869 and the Hungarian Pharmacopœia of 1871.

Mr. E. W. Giles of Melbourne, South Australia, has been recently elected a Fellow of the Royal Geographical Society, a distinction which he has well earned by a series of gallant and laborious explorations in the great island continent. In his latest expedition (which our readers may remember to have seen chronicled some months ago in the *Illustrated London News*), he succeeded in attaining the goal of the Australian explorer's ambition, by crossing an unknown region from the central telegraph line to Perth on the Western Coast and returning by a new and more northerly route in the latitude of the Murchison River, the time occupied by the double journey extending over thirteen months.

The country traversed was desolate to the last degree, with few water places at long intervals, and the exploration has not therefore been rich in practical results, but this circumstance added infinitely to the perils and privations of the journey.

We may claim Mr. Giles as at least collaterally associated with pharmacy, being the cousin of Mr. Giles of Clifton. He has been a diligent collector of the flora of the regions traversed by him, and has catalogued a large number of plants at the end of his published journals.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 2, 1877.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Cracknell, Frazer, Greenish, Hampson, Hanbury, Hills, Mackay, Owen, Rimmington, Robbins, Sandford, Shaw, and Stacey.

The minutes of the previous meeting were read and confirmed.

The following being duly registered as Pharmaceutical Chemists were respectively granted a Diploma stamped with the Seal of the Society:—

Baldwin, Arthur Henry.
Cook, Robert, jun.
Duffus, Alexander.
Peacock, William Henry.
Sandwith, William Henry.
Strongitharm, William George.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Babb, James	Upper Sydenham.
Baldwin, Arthur Henry	Clapham.
Cook, Robert, jun.	Great Grimsby.
Ferguson, William Harry	London.
Kidd, William Champley	Upper Norwood.
Peacock, William Henry	West Hartlepool.
Sandwith, William Henry	Scarborough.
Squire, Alfred Herbert	London.
Strongitharm, William George	Walsall.
Thomas, Harry Alma	London.
Wilkinson-Newsholme, G. T.	Hellifield.

Chemists and Druggists.

Knowles, Thomas, jun.	London.
Netten, Henry John Thomas	East Stonehouse.
Pownall, Thomas Robinson	Bolton.
Wheeler, John Buchan	London.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account and having tendered the subscription for the current year were elected "Associates in Business" of the Society:—

Minor.

Ashwell, Lawrence Thomas	London.
Atwell, Benjamin Arthur	Castle Cary.
Broomfield, Robert William	Liverpool.
Cowgill, Brian Horatio	Burnley.
Donald, David	Perth.
Dyson, Alfred	Bacup.
Fawthrop, Thomas	Portslade-by-Sea.
Fuller, Thomas	Manchester.
Gregson, James Kenyon	Blackburn.
Harriman, Edwin	Liverpool.
Heyland, Charles Philip	Redcar.
Hunter, Frederick William	Newbottle.
Hunter, John Carswell	Glasgow.
Key, George Brown	Kirkcaldy.
Langbeck, Hugo Waldemar	London.
Marris, Wm. James Graburn	London.
Morris, Thos. Henry Vaughan	Hereford.
Myott, Frederick	Halifax.
Oliver, Frederick Bailey	Folkingham.
Pechey, Thomas Pollard	Leicester.
Perry, Horatio Nelson	Gravesend.
Pitts, Thomas Cruso	Norwich.
Read, John Henry	London.

Roberts, William ....Pontlottyn.
Stephens, George Thomas ......Hereford.
Stoddart, Joseph ....Sunderland.
Storie, Robert ....Dalkeith.
Sweetman, Robert ....Ludlow.
Verity, William ....Liverpool.
Weedon, Joseph ....Bexhill.
Wellington, James ....Oakham.
West, Arthur Henry ....South Norwood.
Wilks, Maurice....................Burnley.
Worfolk, George William ......Leeds.
Wylie, David Neil ....Edinburgh.

Modified.

Boutall, George Squire ....Kingsland.
Brooks, Owen ....Llandudno.
Clarke, Richard Thomas ....Gravesend.
Goucher, Levi Tom ....Sheffield.
Harrison, William Dale ....Sheffield.
Harvey, Henry....................Newark-on-Trent.
Knight, John Edward............Hampton.
Norman, Henry ....Canterbury.
Phillips, Benjamin ....Poona, India.
Powers, Thomas ....Birmingham.
Richardson, Thomas James......Carlisle.
Sutton, William Denny ....Thame.
Thompson, Alfonso de Lamartine...Haydon Bridge.
Thorburn, Henry William ......Bishop Auckland.
Watson, William ....London.

ASSOCIATES.

The following having passed their respective examinations and tendered (or paid as Apprentices or Students) their subscriptions for the current year were elected Associates of the Society:—

Minor.

Arblaster, Charles ....Birmingham.
Barnes, James William ....Spalding.
Beacock, Joseph Henry ....Barton-on-Humber.
Bennison, Richard ....Stokesley.
Bristed, John ....Margate.
Burden, John Britten ....London.
Carter, William Robinson ......Rusholme.
Clark, Frank ....Liverpool.
Cowie, John ....Glasgow.
Dodd, Thomas Hunter............Sunderland.
Dott, David Brown ....Edinburgh.
Edwards, James ....Halesworth.
Fell, John James ....Lancaster.
Forrest, John Kerr ....Edinburgh.
Gant, Joseph....................Spilsby.
Gooch, William Hobbs ....Norwich.
Greenhill, Samuel Osborne......Colchester.
Greenough, Hugh Fairhurst ...Manchester.
Greenwood, Dennis ....Cambridge.
Griffin, Joseph Thomas ....Oldbury.
Griffiths, John Moore ....Birkenhead.
Hadwen, Walter Robert ....Woolwich.
Hardwick, Stewart ....Sleaford.
Harris, Walter Thomas ....London.
Hart, James ....Sunbury.
Hoult, Joseph Emanuel ....West Bromwich.
Jones, Thomas ....Tenby.
Kent, James Stephen ....London.
Longman, John Ham ....Exeter.
Lund, William John ....Lancaster.
McNicol, John ....Glasgow.
Marshall, Charles William ......Devonport.
Moses, Joseph ....Bishop Auckland.
Palmer, Charles Edward.........Ely.
Parker, John Wortley ....Barnstaple.
Parkinson, Frederic William ...Peterborough.
Pheasant, William ....Clapham.
Pickup, John Arthur ....Bacup.
Portway, John Bernard ....Bury St. Edmunds.

Pottinger, Thomas ....Dartford.
Redford, George Alfred ....Liverpool.
Richardson, George ....Quatre Bras.
Robertson, Alexander ....Broughty Ferry.
Robertson, William ....Peebles.
Robinson, William Prior.........Waterloo.
Rogers, James Isaac ....North Shields.
Shepherd, John William.........Settle.
Temple, Frederick Staveley ...Hull.
Thompson, Harry....................Norwich.
Tuck, Walter Barber ....Eastbourne.
Turner, George Thomas ... .London.
Wells, Albert Charles ....Leamington.
Whyte, James Samson ... .Montrose.
Williams, William ....Carmarthen.
Wright, John Charles ....Wolverhampton.
Yates, Ebenezer ....Manchester.

Modified.

Ham, William ....Oxford.
Howard, Samuel Bird ....Hadleigh.
Taylor, Isaac....................Doncaster.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination and tendered their subscription for the current year were elected Apprentices or Students of the Society:—

Allison, John....................Coldstream.
Ball, James ....Mevagissey.
Benson, Matthew ....Wigan.
Bower, Henry ....Norwich.
Crossley, Frederick ....Guernsey.
Curry, Nicholas ....Spennymoor.
Dawson, James....................Bridge of Allan.
Dee, Arthur Henry ....Tewkesbury.
Edgar, Frederick George.........Southsea.
Goldby, Frank ....Abingdon.
Greenway, John Wells............Ottery St. Mary.
Hall, Thomas Wright ....Bristol.
Hildyard, William ....Woodbridge.
Hobbs, John Kingdon ....London.
Howell, William ....London.
Humphreys, Charles E. ....Llanfair.
Jacks, David Russell ....London.
Jackson, George ....Hartlepool.
Kirk, John Henry ....Belgrave.
Lakeman, Jasper J. ....London.
Miller, John William .... Preston.
Norburn, Albert Edward ......London.
Parish, Henry ....Birmingham.
Plant, James Robert ....Leicester.
Pottage, Edwin....................Beverley.
Rhodes, Alfred Barrett ....Manchester.
Rook, Barnard ....Sittingbourne.
Smith, Alexander C. T. ....Horselydown.
Todd, Joseph....................Carlisle.
Warrick, Frederick Walmsley .London.
Wheeler, Wilfred Nevill.........London.
Whitlock, Draycott Kelly ......Southampton.
Williams, Robert Edwin.........Cheltenham.
Woollings, Frank ....London.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The following names were restored to the Register of Chemists and Druggists:—

Edwin Constable, 223 Green Lanes, Small Heath, Birmingham.

Thomas Nash Williams, 13 High Street, Aberdare.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was read and adopted and sundry accounts ordered to be paid.

Library, Museum, and Laboratory.

The Librarian's report stated that the average attendance for the preceding month had been, day, 19; evening, 11. Circulation of books in town, 143; in the country (to 17 places), 138. Also that 'Bloxam's Laboratory Teaching,' and 'Thorpe and Muir's Qualitative Chemical Analysis,' which had been missing from the library, had been returned. The number of books now in the library is about 4830, 60 having been added since the beginning of the present year, and nearly 300 in 1876.

The purchase of the following books was recommended by the Committee:—

Fownes' 'Chemistry,' by Watts, 12th ed.; 'British Manufacturing Industries,' edited by Bevan; 'Industrial Classes and Industrial Statistics,' by Bevan; Arnott's 'Physics,' by Bain and Taylor; Artus' 'Hand-Atlas sämmtlicher medicinisch-pharmaceutischer Gewächse,' 5e auflage; Three new copies of the British Pharmacopœia to make up the original number.

The Curator had reported the average attendance in the museum for the past month, which had been, day, 16; evening, 4. Also that most of the articles asked for by the Bristol Pharmaceutical Association could be supplied from the Society's museum without detriment. The Committee had instructed him to send as many of the articles asked for as possible.

Professor Attfield had reported 77 entries in the laboratory since the commencement of the session; 48 students being now at work.

Professor Bentley had reported that there were 40 students in his class at present.

Professor Redwood had reported that his class numbered 32.

The Committee had also drawn up the Annual Report, which was now submitted.

The report and recommendations were received and adopted, and a few verbal alterations having been introduced into the Annual Report it was ordered to be issued with the voting papers.

Benevolent Fund.

The report of this Committee included recommendation of the following grants:—

£20 to the widow of a late member, aged sixty-seven, in very delicate health, who is left destitute.

£10 to an associate in very bad health, who received a like grant last year.

£10 to the widow of a registered chemist and druggist. aged fifty-nine. Applicant's late husband had received two grants.

£10 to the orphan daughter of a late member, who has previously received nine grants on various occasions.

The report and recommendations were received and adopted.

Benevolent Fund Dinner.

The Sub-Committee appointed to make arrangements for the dinner reported the progress that had been made.

Mr. Hills suggested that a good effect would be produced on the subscriptions if a special appeal were made for the purpose of making provision for the education of orphans, more than hitherto it had been possible for them to do.

The President said that it could be fairly pointed out that if more money were forthcoming, a great deal more good might be done, and a very important point might be made of the education of orphan children. There was an unlimited field for benevolence in that direction.

Mr. Mackay was very glad to hear these remarks, and wished so know whether the idea was to endeavour to found an orphan asylum, affording both board and education, or to provide only for the education of the orphans.

Mr. Hills thought the effort should be limited to the provision of education.

Mr. Mackay inquired if that was not now done to some extent.

The President said the Council had hitherto generally limited the grant in each case to about £20, which was often not enough to secure the election of a child into an asylum, although that was generally the best way of providing for an orphan.

Mr. Mackay asked if it was proposed to get children into existing asylums.

The President thought that would be a better mode of procedure than spending money on bricks and mortar for their own glorification and the benefit of architects.

Mr. Shaw drew attention to the fact that the annual charge for annuitants was £720, of which only £480 was received from the investments, leaving £240 to be taken from the subscriptions. He thought it would be well to make an effort to raise the amount of the investments to £20,000.

The President observed that a great many people were not in favour of more money being funded, but would rather see it spent, relying on the generosity of the future to provide for its own necessities.

Mr. Robbins thought it would be very impolitic to appeal for increased support in order to invest the money.

Mr. Owen said there need be no lack of arguments for an appeal, since the amount of assistance was often limited for want of funds. He believed the largest amount ever voted to one case was £30; but if £100 or £120 could be given to secure the election of an orphan into an asylum, a substantial benefit would be conferred.

Mr. Sandford drew attention to the rule which had enabled the Council on one occasion to expend a hundred guineas in purchasing the admission of a child into an orphan asylum.

Mr. Robbins thought such a privilege should be confined to the orphan children of members of the Society, which would be an inducement to many persons to become members, who now say they can see no advantage in doing so.

The President pointed out that subscriptions were received from persons not members of the Society, and as it was wished to encourage that still more he did not think such a regulation as that suggested by Mr. Robbins would be wise. With regard to the approaching dinner he thought a special appeal should be made for annual subscriptions as much as for donations.

The report was received and adopted.

Royal Botanic Society.

A letter was read from the Secretary to the Royal Botanic Society, stating that the usual facilities would be afforded to students attending Professor Bentley's classes.

Chemists' Assistants' Association.

Mr. Betty presented a Memorial from some Members, Associates and Students of the Society, who were desirous of forming a Chemists' Assistants' Association, asking that the use of the Society's Lecture Theatre might be granted for the purpose of holding a meeting on June 6th. The objects of the proposed association were described to be the promotion of friendly feeling among assistants; the support of those principals who are desirous of shortening the hours of labour; the discussion of all matters affecting the welfare of assistants; and the reading and discussion of papers possessing scientific or trade interest.

Mr. Hampson moved that the prayer of petition be granted.

Mr. Greenish seconded the motion.

The President stated that the holding of such a meeting on a Wednesday evening seriously inconvenienced the professor in giving his lecture on the following morning.

Mr. Hampson then suggested that the use of the room be granted provided a convenient evening could be arranged.

Mr. Greenish said he understood that there would have been no necessity for this new association but for the fact that membership in the School of Pharmacy Students' Association was limited to those who had studied in Bloomsbury Square.

Mr. Sandford, Mr. Hills and other members took exception to a sentence in the petition which stated one of the objects of the proposed society to be the "support of those principals who adopted the early closing system," as tending to show a spirit of coercive trades unionism.

Mr. MACKAY thought the request ought to be refused, but there might be an intimation that if the objectionable phrases were withdrawn the room might be lent if a convenient time could be arranged.

Mr. STACEY remarked that at the recent meeting in favour of early closing, a resolution of thanks to the Council was passed for the use of the room, and for the moral support thereby given. If the Council granted this request, it would be giving its moral support to this new association.

Mr. HAMPSON said the use of the room had recently been granted for a meeting of employers, and he hoped the Council would grant a similar favour to the assistants, without scrutinizing too closely the wording of their memorial.

Mr. OWEN said the Council did not commit itself to anything except the loan of the room.

On being put to the vote the motion was lost.

HOUSE.

The report of this Committee referred to several matters of detail connected with the house arrangements, gas, water supply, etc. The octagon laboratory had been inspected by the Committee, and was considered to be now very excellently arranged for examination purposes.

Mr. GREENISH bore testimony to the great improvement in the octagon laboratory, and hoped that the dispensing department in the examination room would be improved, so as to make it more in accord with the arrangements generally found in a dispensing establishment.

The PRESIDENT said the matter had not escaped attention, and some improvements had been adopted, but he did not see how the desired result could be obtained, except by making structural alterations in the room. The examiners were always present, and if a young man did not readily lay his hand on what he wanted, he had only to ask for it, when it would be given him at once.

Mr. CRACKNELL and Mr. BOTTLE having stated the results of their experience in the examinations,

The report and recommendations were adopted.

LAW AND PARLIAMENTARY.

The report of this Committee contained particulars of several cases of alleged infringement of the Pharmacy Acts, into which inquiries had been made by the Solicitor or by the Secretary.

THE SALE OF CHLORAL HYDRATE.

The Committee also reported that a letter had been received from the coroner at Carlisle, calling attention to an inquest in a case of death from an overdose of chloral hydrate, where the jury had recommended that chloral hydrate should be added to the list of poisons in schedule A of the Pharmacy Act, 1868. He also called attention to the fact that a qualified chemist might keep any number of shops managed by unqualified assistants.

The PRESIDENT said the Council had previously received recommendations that chloral should be placed in one or other of the poison schedules. This substance was now in very general use, and was frequently employed simply as an intoxicant, especially by habitual drunkards. He thought, therefore, it was high time that some step should be taken by the Council to place this article on the list of poisons, without waiting for further pressure from outside.

Mr. SHAW thought chloral hydrate should be put into part 1 of the schedule, if anything were done. There had been several communications on the same subject, and he thought it was time something should be done.

The VICE-PRESIDENT said he had also received a communication from the coroner, showing the importance he attached to the subject.

Mr. HAMPSON suggested that the matter be referred to the Law and Parliamentary Committee, and that the coroner be informed that it was under consideration.

This was agreed to unanimously, and the report and recommendations of the Committee were received and adopted.

PROVINCIAL EDUCATION.

A letter from the Bristol Association was read, thanking the Council for the grant made last month.

The Oldham Association had also written to thank the Council for the grant made to it.

THE PRELIMINARY EXAMINATION.

A letter was read from a member of the Society in the Isle of Man, pointing out the hardship inflicted on young men in that island, in having to go to Liverpool to pass their Preliminary examination.

The PRESIDENT said it would be obviously desirable to make Douglas, Isle of Man, a local centre, and so get over the difficulty.

A resolution to this effect was carried unanimously, and Mr. William A. Brearey was appointed Superintendent.

REPORT OF EXAMINATIONS.

April, 1877.

ENGLAND AND WALES.

NUMBER OF ATTENDANCES OF MEMBERS OF COUNCIL AT COUNCIL MEETINGS FOR THE YEAR 1876-77.

Atherton, John Henry	9
Atkins, Samuel Ralph	9
Betty, Samuel Chapman	11
Bottle, Alexander	10
Brown, William Scott	1
Cracknell, Charles	11
Frazer, Daniel	8
Greenish, Thomas	11
Hampson, Robert	10
Hanbury, Cornelius	11
Hills, Thomas Hyde	11
Mackay, John	6
Owen, John	11
Rimmington, Felix Marsh	7
Robbins, John	10
Sandford, George Webb	10
Savage, William Dawson	11
Schacht, George Frederick	8
Shaw, John	11
Stacey, Samuel Lloyd	7
Williams, John	11

Number of Council Meetings during the year, 11.

BOTANICAL PRIZE FOR 1878.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom, between the first day of May, 1877, and the first day of June, 1878; and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Merit, will be given at the discretion of the Council. In the event of none of the collections possessing sufficient merit to justify the Council in awarding medals or certificates, none will be given.

Competitors must be Associates or Apprentices or Students of the Society, and under twenty-one years of age.

The collections must consist of phanerogamous plants and ferns, arranged according to the natural system of De Candolle, or any other natural method in common use, and be accompanied by lists, arranged according to the same method, with the species numbered.

The collector must follow some work on British botany (such as that of Babington or Hooker), and state the work he adopts. The name of each plant, its habitat, and the date of collection, must be stated on the paper on which it is preserved.

Each collection must be accompanied by a note, containing a declaration signed by the collector, and certified by his employer, or a pharmaceutical chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself, between the first day of May, 1877, and the first day of June, 1878, and were named and arranged without any other assistance than that derived from books.

In estimating the merits of the collections, not only will the number of specimens be taken into account, but also their rarity or otherwise, and the manner in which they are preserved, and should a specimen be wrongly named, this will be erased from the list.

The collections must be forwarded to the Secretary of the Society, 17, Bloomsbury Square, on or before the first day of July, 1878, indorsed "Herbarium for Competition for the Botanical Prize." After the Prize Distribution in October, they will be retained one month, under the care of the Curator of the Museums, for the inspection of persons connected with the Society, and then returned to the collector, if required.

NORTH BRITISH BRANCH—EDINBURGH.

Annual Meeting.

The annual meeting of the North British Branch of the Society was held in the Society's Rooms, 119A, George Street, on Wednesday, April 25, at 12 o'clock. Mr. William Gilmour, President of the Branch, in the chair.

The Chairman opened the meeting by asking the Secretary to read the following annual report:—

Annual Report.

The Council have now to submit to the Annual Meeting a short account of the proceedings of the North British Branch during the past year of 1876.

The novelty of the new accommodation in connection with the operations of the Society in Edinburgh having now subsided, the Council have the pleasure to report that the arrangements made two years ago continue to work very fairly. Additional room could, however, be utilized, and the Council hope that ere long this may be obtained. Meanwhile the three rooms are used for the purposes indicated in former reports, and are open during the day as well as in the evening.

The following is the result of the attendance of young men during the year, from January 1 to December 30: 687 entered their names as having been present between 10 a.m. and 4 p.m., while 337 have used the rooms by being present from 8 to 10 p.m., making the total attendance during 1876 equal to 1024. The number who have used the rooms since this privilege was given amounts to 4203, which the Council consider in all respects very gratifying.

In connection with this matter the Council think it proper to state that acting upon a suggestion made to them, and with the concurrence of the London Council, the use of the rooms was granted to Dr. Craig and Mr. Sadler for the purpose of carrying on a short course of lectures in the evenings during the winter months, and which they undertook to do as an experiment to test the number likely to take advantage of such courses if they became fixed and regular. The former lectured on Materia Medica and the latter on Botany. Eighteen pupils connected with pharmacy took advantage of those classes, with which both lecturers appeared satisfied; but the Council much regret that in consequence of the want of lecture accommodation, no such means can be afforded for the future, as the use of the principal room for these meetings prevented many students from availing themselves of the evenings during which to carry on their studies in connection with the cabinet of specimens and museum. It may be remarked that this fact may be taken as an indication that the evening attendance would have been considerably greater but for the occupancy of the chief room during the evening by the respective lecturers.

The Honorary Secretary issued for Professor Balfour's full summer course on Botany, 7 tickets; for Dr. S. Macadam's full winter course on Chemistry, 14 tickets, 2 for his practical course—and 2 for Dr. Moinet's full summer course on Materia Medica. These complete the number of pharmaceutical students attending the various classes, making in all 43 who during last year had obtained special tickets in connection with the Society. This number contrasts very favourably with that named in the report of last year being 15 more, or 43 as compared with 27.

The Council have much pleasure in recording that the privilege of using the books in the library has been taken advantage of to a much larger extent than has ever been done before. During 1877 no fewer than 236 volumes were given out, while throughout the preceding year only 95 were in circulation; giving an aggregate of considerably more than double the number in use during a corresponding period. The Council are well pleased with this result.

The Board of Examiners have met in Edinburgh eight times during the year, and at these examinations 3 Major, 77 Minor, and 15 Modified candidates presented themselves Of these 1 Major, 41 Minor, and 5 Modified candidates were successful, the rejections being about 60 per cent. While the numbers have been fairly upheld, the Council regret to observe that the percentage of failure has been on the increase, instead of, as they had hoped, in the opposite direction. The number of Preliminary candidates who presented themselves for examination at the different centres in Scotland during the year was 115.

Under the new regulations now in force, the Council trust that for the future this state of matters will be much changed for the better. Some young men, it is believed, knowing that only one guinea was deducted from their fee in case of failure, felt that they might safely come up on the chance of passing, and therefore made their appearance before the Board, not with a fair prospect of success, but more to see the form of examination, and, if possible, pick up some information likely to be of service on their next appearance. Arrangements having now been made by which the whole fee is left in the hands of the Society, it is hoped, will exercise a salutary effect for the future, and the results prove more satisfactory to the candidates as well as to the Board of Examiners.

The scientific meetings during the Winter Session just closed have been eight in number. It must be noticed that not only have these meetings been more frequent than usual, but very valuable communications have been made. The original papers by our President and others have added much to the interest of the meetings, while the attendance with one or two exceptions has been very gratifying. A glance at our weekly Journal will at once show how valuable and important the communications have been. The Council takes this opportunity of tendering the best thanks of the Society to those gentlemen who have aided in keeping up the interest of these scientific meetings, and look forward with much confidence to the future in obtaining a repetition of what has given so much satisfaction throughout the session just closed.

The library and museum have been rendered more attractive than ever. Both have been overhauled and systematically arranged by Mr. Stenhouse, the Assistant Secretary, and contributions rare and useful are respectfully solicited from those who desire that those departments should be kept worthy of a branch of the parent Society. The want of an herbarium has been often expressed by students who have no opportunities for studying dried specimens of plants when preparing for the botanical part of their examination, and the Council have much pleasure in stating that Mr. Stenhouse has been instructed to begin the formation of one this summer.

It is right the Council think to notice two presentation portraits which have been made to the Society, and which are now hung in the museum. The one is that of the late William Tait and the other David Rennie Brown. Both the deceased gentlemen were so well known to all connected with the Society that the Council cannot help feeling that a look now and then at the portraits may assist many of our young friends to emulate as far as they can the successful labours as well as the high position in connection with pharmacy attained by both these gentlemen.

The same course has been again followed this year as to the nomination and election of the Council in Edinburgh, the result of which will as usual now be made known.

Pharmaceutical legislation up to the present time remains unaltered, but the Council have every confidence that when any movement takes place in connection with an addition to, or alteration of, the Pharmacy Act of 1868, full justice will be done alike to the public and the Society by the Law and Parliamentary Committee in London, aided as that Committee is by the full body of the Council there. It cannot be denied that the practical working of some of the clauses of the Act might be with some benefit amended; but it must at the same time not be forgotten how difficult revised legislation is to carry out. When, however, circumstances demand some change, and action be again taken to urge upon the government of the country the claims of pharmacists for a revision of certain provisions at present in practical operation, the Council here are glad to know that the same readiness and ability which have been available on previous occasions, and which have in the past been so successful still exist, and it is with confidence believed that the London Council will, when required, do their utmost to obtain in the interests of the Society such alterations as will prove satisfactory to all concerned

---

Mr. James Mackenzie made a few remarks with reference to the new regulations of the Board of Examiners, but he did so under an erroneous impression, and he recalled his expressions after the matter had been explained to him.

The adoption of the report was moved by Mr. H. C. Baildon, seconded by Mr. A. Napier, and carried.

The Chairman then laid before the meeting the result of the voting for the new Council. He stated that 196 forms for nominations had been issued, and of these 72 had been given effect to. One was rejected as informal. The Committee appointed to scrutinize and tabulate the votes had completed their work in such a way that the result might be attested by any of the audience. From the table it was found that the following gentlemen had been duly elected as Council for 1877-78 (the names are published alphabetically):—

Mr. William Ainslie ....Edinburgh.
„ H. C. Baildon .... „
„ George Blanshard........... „
„ James Buchanan .... „
„ Thomas Davison ....Glasgow.
„ William Duncanson........Stirling.
„ Daniel Frazer ....Glasgow.
„ Alexander Govan.............St. Andrews.
„ William Gilmour ....Edinburgh.
„ David Kemp..................Portobello.
„ Alexander Kinninmont ...Glasgow.
„ Alexander Napier ....Edinburgh.
„ A. Seath ....Dunfermline.
„ J. B. Stephenson ....Edinburgh.
„ James R. Young .... „

Messrs. Gilmour and Kinninmont having expressed a desire to retire from the President's and Vice-President's position, which they had held for three years, Mr. Gilmour proposed that Mr. J. B. Stephenson be elected President and Mr. Alexander Napier Vice-President. Mr. Kinninmont seconded the motion and it was carried. Both of these gentlemen accepted office and returned thanks for the honour conferred on them.

Mr. Baildon moved and Mr. Ainslie seconded the reappointment of Mr. Mackay as Honorary Secretary. The motion was carried and Mr. Mackay accepted and briefly replied.

Mr. Mackay moved a special vote of thanks to Mr. Gilmour for the very efficient manner in which he has so long discharged the duties of the chair. Mr. Stephenson seconded, and the motion was most cordially responded to.

This concluded the business of the meeting.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fourteenth and concluding general meeting of the twenty-eighth session was held at the Royal Institution, Colquitt Street, on Thursday evening, April 26. The President, Mr. Alfred H. Mason, F.C.S., in the chair. Donations of 'The Year-Book of Pharmacy, 1876,' the *Pharmaceutical Journal*, the *Canadian Pharmaceutical Journal*, and 'Proceedings of the Historic Society of Lancashire and Cheshire,' to the Library, were announced.

Before the general business the President read the following:—

Obituary Notice of the late Martin Murphy, F.C.S.

It was the mournful duty of Mr. Davies and myself as your representatives to follow to the last resting-place the remains of the late Mr. Martin Murphy, Fellow of the Chemical Society of London, and Principal of the Liverpool College of Chemistry, and I feel it is my duty this evening to say a few words to the memory of one whom we so much respected, and whose loss we, and the profession generally, have to deplore. Those who have known him from boyhood bear testimony that he was endowed with a great love of learning, and a determined will to pursue to successful issue, if possible, whatever he engaged in. At school he appears to have made mathematics his speciality, and was soon known as an advanced student. At an early age he had thoroughly mastered Euclid, and few dared challenge him in this field of knowledge, even after he ceased to give it the attention of his youth. He was originally intended for the priesthood by his parents, but circumstances occurred at the time when he should have gone to college to study theology, which prevented this being carried out. In 1845 his eldest brother induced him to leave Ireland and join him as a shop assistant in Liverpool, preparatory to entering into commercial business. Martin went, however, to Warrington and accepted a temporary engagement at Muspratt's works (then the only chemical works in this part of the country), there he met Dr. Sheridan Muspratt. The doctor had just come home from Germany flushed with high chemical honours, and was about starting a college of chemistry in Liverpool. Finding in Martin Murphy more than ordinary intelligence and a great desire for learning, Dr. Muspratt induced him to pursuade his parents to allow him to be bound for seven years, in return for which he was to receive a thorough knowledge of the science and art of chemistry. This was granted, and he soon became one of the doctor's favourite pupils, and it was prophesied that he would prove a chemist of no mean repute; we, gentlemen, can well testify how this prophecy has been fulfilled, and how in adopting this as his vocation, his parents hit upon the profession best suited to his tastes and character of mind. He had a deep love for the study, and whether he could make it answer his necessities in life as well as any other occupation or no, would not induce him to withdraw for one moment his attention from the study. From 1853 to the demise of Professor Muspratt, the responsibilities of the College of Chemistry devolved entirely upon Martin Murphy. Not only did he teach, but he performed all the analyses, and such was Muspratt's confidence in his accuracy and ability, that he ceased to examine any of his results, but adopted them as his own. In 1854-5, Muspratt's 'Dictionary of Arts and Science' was published, and I am told that three-fourths of the work was actually written by Martin Murphy, or revised and corrected by him. He told me that for two years he worked sixteen hours out of the twenty-four, and such was his interest in the work that he rarely felt exhausted; in fact, the large and varied field of scientific inquiry which the writing of that book brought before him so absorbed his mind, that he seemed almost to live in the region of chemistry for the time. Nothing else was thought of; hence in a great measure resulted the very general knowledge which he possessed in all branches of industry.

From 1864 to 1866, he was Honorary Secretary of this Association, and there are those present who can testify to the ability with which he fulfilled the duties connected with the office. In 1868, he was elected a Fellow of the Chemical Society.

After the demise of Dr. Muspratt, Murphy was strongly urged to leave the college and superintend one of the largest chemical works in the kingdom, at a very high salary. For a time the lucre seemed to influence him, but only for a time. He soon dismissed the thought, and resolved to keep to chemistry as a *profession*, even though it should prove less remunerative. The College of Chemistry he wished to make a place where students might obtain a thorough chemical knowledge in reality, and not only in name. One great characteristic he had was a thoroughness in his studies, and a fixed determination to adhere only to facts, and not to accept a statement on the *ipse dixit* of any person. He strongly advocated the necessity that in chemistry there should be no guessing, or taking things for granted; expediency had no toleration with him. He never felt so much annoyed as when a money-grubber attempted to prostrate the science to his own interest. Never did he attach his name to a certificate upon the correctness of which he was not prepared to stake his name and reputation. He had a great objection to being thought a sensationalist; wild theories he left (as he used to say) to those who had a glib tongue to propound them, and laughed at their own discomfiture rather than grieved. He always thought it was possible to reconcile the most profound scientific investigation with Holy Writ, and he did not admire those who, with only a little knowledge, professed to fathom what was, and always will be, beyond their conception.

Had he lived he purposed writing a work on chemistry, which he said would prove a handbook, not only to manufacturers, but also to consumers and others interested in the arts.

He had just completed the erection of extensive chemical works, at Old Swan, for the manufacture of oxide of cobalt, for potters' use, by a method he had devised, and he was sanguine as to very profitable results.

It has pleased Providence to take him away from us. May our loss be his gain! I had been so constantly brought in communication with him, in connection with the affairs of this Association, and learnt to appreciate his words of encouragement, that I was led to place a high estimate upon his opinion. I feel that we have lost one of the brightest ornaments of our Association, and I could not let this opportunity pass without bearing testimony to his abilities, the display of which we were so glad to avail ourselves of, and which he so willingly gave.

He died, at his residence, Old Swan, on the 23rd inst., after a painful illness, at the age of forty-eight years, and was buried yesterday, several of the leading chemists in the town and neighbourhood being present to pay a last tribute of respect to his memory. He leaves a widow and two daughters, and your Council has requested me to convey a vote of condolence with them in their bereavement.

On the motion of Mr. A. H. Samuel it was unanimously decided to embody the sympathy of the meeting in the vote of the Council.

Valedictory Address.

The President then delivered his valedictory address. He commenced by enumerating the papers read before the Association during the session, and gave details as to the attendance. Allusion was also made to the Conversazione, which was described as the most successful in the annals of the Association. The President then continued as follows:—

"Gentlemen,—You have heard a faithful report of our work this session, and I think we can only arrive at a candid conclusion that it has been most creditable and satisfactory. Each section of our members (if I may use the phrase) has been represented in the work done, the originality of the papers and practical discussion which followed. Our average attendance, though apparently small, from all I can gather bears very favourable comparison with any kindred society or association. I may add that your Committee have arranged that during the recess the museum shall be thoroughly renovated and, I think, we shall have some very handsome contributions to announce at our annual meeting. The library also will be renovated, periodicals bound, and those books requiring rebinding attended to; a thoroughly revised catalogue will be issued, and I can promise my successor that all things will be got into as smooth order as possible for him when he takes office.

"It will not be expected this evening that I trespass upon your patience with any matters not immediately associated with our proceedings, but there are one or two subjects of interest to which, with your permission, I should like to call attention.

"During the last few months considerable agitation has been raised in the chemical journals respecting the status of the Chemical Society of London, and a few of the Fellows thought it expedient to black-ball some candidates for fellowships who did not come up to their requirements. This action was strongly deprecated at the Annual Meeting of Fellows, held a few weeks ago. My own impression is that it has had a beneficial effect out of London. The ultimate result of the discussion is that the Chemical Society has now decided to elect as Associates (at a reduced fee) gentlemen who are interested in the science. It has considerably raised the fees and standard of qualification of Fellows, and also made more stringent the obligation which Fellows have to sign, and this is the full extent of its powers. But some of the leading scientific chemists have decided to form a new body, to be styled "The Institute of Professional

Chemists of Great Britain and Ireland." The objects of the organization are to be the general advancement of chemistry in its application to the arts, manufactures, agriculture, and public health. Secondly, to ensure that persons adopting the profession of consulting chemists, or acting as analytical chemists *for reward*, are qualified by study and training for the proper and competent discharge of the duties they undertake.

"The vexatious proceedings which have been taken under what, for the sake of brevity, I will call the 'Adulteration Act,' by incompetent analysts, will, I am sure, make such an announcement as the foregoing welcome, but it has occurred to me that most of our members who are not Fellows or do not think of applying for fellowships, may derive great benefit themselves, and help the Society, by becoming Associates, and I should rejoice to see all our members in the ranks, for not only would the funds which the Society gain thereby enable them to publish a far more satisfactory Journal, but the fund for original research (which has lately been so liberally endowed) would also be enriched. England is making very rapid strides in her chemical status, and the time will soon arrive when the opprobrium will be removed that the world must go to Germany and France for the best scientific chemists. One thing we shall be quite sure of, that what an Englishman does will be real, if he is tempted to get into any other man's shoes; he will find his toes trodden upon so sharply that he will be glad to extricate himself and know better for the future.

"Dr. Dupré has made a communication to a publication called 'The Analyst,' in which he says that 'during the last five years he carefully examined 165 samples of drugs and medicines purchased at the better class of chemist, shops in all parts of the metropolis, all with very few exceptions having been bought under the Latin name by which they are distinguished in the Pharmacopœia; out of the 165 samples examined no less than 71 were found to be adulterated, some to a very considerable extent. Thus, of six samples of liquor arsenicalis, not one came up to the standard of strength, one showing a dilution of 60 per cent.; of six samples of scammony, all were adulterated; and of seventeen samples of ferri et quiniæ citras tested, eleven were found deficient.' Dr. Dupré sums up his experience as follows: 'Drugs consisting of sugar, well defined chemical compounds, such as bromide and iodide of potassium, sulphate of quinine, etc., are nearly always found pure; on the other hand all such as should contain a certain proportion of active ingredients or should be the more or less altered natural products, are frequently adulterated. Out of 49 samples of the first class two only were found adulterated, whereas out of 116 samples of the second class 69 were found adulterated.'

"The editor of the *Lancet* comments upon this report as follows:—'The conviction is forced upon us that there is more adulteration in drugs than in articles of food.'

"If Dr. Dupré had reported convictions instead of the wholesale statement he has made, we might be more easily disposed to credit it, but we may fairly assume from the average results of prosecutions for the sale of impure drugs, that when the majority of cases are thoroughly investigated the analyst is at fault. When a druggist has painted upon his shop or printed on his labels 'pure drugs and chemicals' or 'genuine drugs and chemicals,' he admits that sophisticated articles are sold by some others, and he leads the public to infer the same thing, and there is not a doubt that in unfair competition dealers are tempted by the greed of gain to vend sophisticated goods; hence the value of the Adulteration Act. Any dealer zealous for his reputation does not now supply an article which does not exactly coincide with its label; but it is a matter for serious consideration whether the pharmacist may feel safe in trusting to what should be his very back bone and standard, the British Pharmacopœia. Some preparations may be made strictly in accordance with the Pharmacopœia and found deficient on analysis, and there are instances when sufficiency of description and methods for detecting sophistication are wanting. It is to be regretted that when necessary to print another Pharmacopœia these deficencies were not supplied.

"Take a recent prosecution as an example. If a druggist is to be prosecuted for selling balsam capivi as adulterated, when it answers the Pharmacopœia requirements, and at the instance of an analyst who admits in evidence that he has never studied pharmacy, when is he safe? If the value of capivi depends upon certain proportions of resin and oil (as natural capivi imported from different countries varies in these proportions) the Pharmacopœia should state what the proportions are to be, and provision could be made accordingly as in the case of scammony.

"The fraud practised by the natives of countries from whence crude drugs are imported is sometimes marvellous. Take opium for instance; it is not uncommon to find rather formidable traces of lead (without chemical analysis), in the form of bullets. Shot and leather are often found in musk pods. Some admixtures are attended with danger to life, as in the instance to which Professor Bentley called attention a short time ago, of valerian root being adulterated with white hellebore. Of course the educated pharmacist can easily detect this. And here we have evidence of the necessity for the dealer to show proof of such knowledge by being qualified at Bloomsbury Square.

"We have a public analyst in Liverpool, and we may congratulate ourselves that he is a gentleman of high scientific attainments and blessed with common sense, not disposed to institute such vexatious proceedings as milk of sulphur prosecutions. It is fair to assume that he does not neglect his duties, and that some of our members may have sold articles for his investigation; the absence of prosecution is evidence, therefore, that the chemists and druggists of this town are a most respectable body of men, fully alive to the responsibilities of their calling. I am not disposed entirely to agree with the recent decision in the milk of sulphur prosecution, the overwhelming evidence in defence brought to bear at the trial, might easily have been over-balanced by conflicting evidence from retailers, wholesale dealers, medical men, and scientific evidence even hailing from Bloomsbury Square. Either both preparations should be in the Pharmacopœia or one should be discarded. *Acid tartrate of potash* and *cream of tartar* are synonymous, why not *precipitated sulphur* and *milk of sulphur* be held also synonymous? At the same time it surely was never intended that the Adulteration Act should apply to such strained ideas, nor that the druggist should be made the bugbear in the majority of prosecutions for sale of the article.

"Since the failure of the Arctic expedition several newspaper correspondents and the editors of the medical journals have discussed the therapeutic value of lime juice. I am inclined to believe that any evidence from seafaring men disparaging the virtues of lime juice is entirely due to unsound quality, impurity, and sophistication. It is rather an important matter to us in a large seaport town that this should be investigated. A captain trading to the West Indies told me that the lime juice supplied to ships in Liverpool was obnoxious to the sailors and they refused to drink it, but when he got his lime juice where it was produced the result was contrariwise. Lime juice supplied to ships is provided under bond to save duty upon the alcohol employed to fortify it, and apparently under government control there is no doubt that large quantities of deteriorated lime juice mixed with lemon juice and fortified with very crude spirit is taken on board. If genuine racked lime juice fortified with pure spirit was always supplied, I think we should never hear complaints of its non-beneficial effects.

"The issue of the 'Year-Book of Pharmacy,' is an event of some importance, and we may congratulate our honorary member, Mr. Siebold, upon its value. The able article which prefaces the work shows that the editorial duties are in the hands of a learned man. The scientific publications which more immediately concern our interests are well worthy of our perusal. I would call attention to the reports in the *Chemical News*, of the 'Proceedings of the Berlin Chemical Society,' probably at the present time the most important chemical society in existence, and those who have noticed the articles in the *Pharmaceutical Journal*, headed, 'The Month,' will agree that they are valuable and welcome contributions.

"Before concluding, I have a little more to say about our Association. You are all aware that the only drawback we have in the successful working of our Association is the apathy which is shown towards the efforts of your council in providing classes for the education of students. Our chemistry classes have been conducted by our excellent teacher, Mr. Williams, but only seven have attended. I was present (by request) at the first lecture, and delivered a short address to the students—endeavouring to impress upon them the importance of diligent attendance and the value of the opportunities afforded to them.

"Our chief drawback is the difficulty students have to get leave of absence to attend these classes. Surely it is not too much to ask employers to grant liberty one evening each week, during the session, to enable us to obtain students. It appears to me a short-sighted policy, for there would be ample return for the self-denial exercised, in the greater ability with which students would manipulate the necessary operations in connection with their calling. Our botany classes commence on Wednesday, May 2nd.

"Although we have this drawback, it would be unfair to assume that the young men do not study. I can testify that some are early risers, and enthusiastic in their labours, and I take this opportunity to remind them of one of the most adjuncts to this Association—its library. From this they may obtain all that is necessary to stimulate them to work zealously in the profession to which we are attached. The example of another self-made man, Mr. Gossage, who has just been called away, will be my apology for reading to you the following interesting career:—

Obituary Notice of the late William Gossage, F.C.S.

"The late Mr. William Gossage, whose death was chronicled some days ago, performed services to the cause of science which merit special recognition. One of the most prominent manufacturing chemists of Lancashire, he was a self-made man; and his career was not one of uninterrupted scientific and business triumph. Disappointment as well as success, occasionally awaited him, while disaster attended ventures about which he was sanguine. The apprentice of the first quarter of the century was an extensive manufacturer at the beginning of the third quarter, and besides receiving recognition from the Chemical Society, which made him a Fellow, his name was enrolled on the commission of the peace for Lancashire. Mr. Gossage was born at Burgh-in-Marsh, Lincolnshire, in 1799, and as the youngest of thirteen children, received the merest elementary education, when he was apprenticed at twelve years of age to his uncle, a Chesterfield druggist. By rising at four o'clock in the morning he obtained time to read all the chemical works he could get hold of, while from a refugee he acquired a knowledge of French. Afterwards he started business on his own account at Leamington, where also he married. When thirty years of age he became chemist to some important works in Worcestershire, which post he held for twenty years. It was here that Mr. Gossage contrived his condensing towers of brick or stone, filled with coke or other material, to condense by contact with extensive wet surfaces, the hydrochloric acid resulting from the decomposition of salt. This was in 1836, and next year he patented a means of recovering sulphur from the residues of the black ash vats, of the utility of which he felt so certain that he subsequently contracted with Widnes alkali manufacturers to take all their waste for a certain period. These contracts nearly proved his ruin, especially as one manufacturer grimly adhered to his bond, though the others released the chemist. But Mr. Gossage's effort induced others to set about the utilization of sulphur in alkali waste with some degree of success. The deceased also did something to prevent the waste of manganese in the old process of producing chlorine in making bleaching powder. It was in 1850 Mr. Gossage established himself as an alkali manufacturer at Widnes, where he continued his labours in chemical research with profit to himself and others. The war with Russia made tallow dear, and Mr. Gossage showed how soap could be made without it. His life was active as well as long, but hard work did not harden his heart, and his death was much regretted by his employés, his fellow manufacturers, and his immediate friends. His death took place on the 9th instant, at his residence Earlsleigh, Bowdon, and he was buried in Toxteth Cemetery. The life of Mr. Gossage conveys a moral to young men of the period who feel that progress is hopeless.

"Gentlemen,—I do not say farewell this evening; if we are spared to meet in September I shall have to present our official report to you, but I cannot conclude without expressing my deep obligation to all of you for your kind assistance in enabling me to present this review of our proceedings and your ready forbearance with my shortcomings. I wish particularly to acknowledge the cheerful and invaluable assistance I have experienced from our Honorary Secretary, Mr. Williams, the minutes he has recorded and the published reports of our proceedings are quite sufficient evidence of the ability and zeal with which he has discharged the duties he has undertaken, and I desire to express my personal obligations."

A lengthy discussion followed in which several members took part, and on the motion of Mr. Shaw, seconded by Mr. Redford, an unanimous vote of thanks was accorded to the President for the address.

Mr. Woodcock (Vice-President), in eulogistic terms, nominated Mr. T. Fell Abraham as President elect for 1877-8, and the ballot being taken, the President declared Mr. T. Fell Abraham unanimously elected President for next session.

In the absence of his son Mr. Abraham thanked the meeting for the honour conferred and promised to convey the wishes of the Association to him.

The general business of the session terminated.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The annual meeting of this Association was held at the rooms, Tudor Street, on March 7th, 1877. The following elections and arrangements were made:—President, Mr. W. V. Radley; Vice-Presidents, Mr. W. Ward, F.C.S., Mr. F. Hudson; Council, Mr. G. A. Cubley, Mr. H. E. Ibbitt, Mr. G. Ellinor, Mr. W. Jervis, Mr. H. W. Maleham, Mr. J. P. Hewitt, Mr. G. Carr; Treasurer, Mr. W. V. Radley; Hon. Sec. Mr. J. Turner.

Resolved that the annual subscription be five shillings per annum, and that Mr. Warner be employed to collect the same.

Resolved that the rooms at present occupied by the Association be given up, and that the President and Secretary hire rooms for the general meetings.

Resolved that the specimens, cabinet, books, microscope and maps, be placed under the care of Mr. H. W. Maleham, 7, West Bar, to which members may have access between the hours of nine in the morning and half-past seven in the evening, subject to rules being properly carried out.

The Treasurer gave his statement of accounts for the past year, which showed that although there had been a deficiency in the amount of subscriptions paid in, still there was a small sum in hand; whereupon it was carried that the treasurer's account as read be passed, which showed a balance in hand of £6 6*s.* 9½*d.*

The best thanks of the meeting were accorded to Mr. W. Jervis, for his services as president during the past year, to which he replied, expressing regret that so little had been done during his year of office, but it was mainly owing to the apathy of the members.

A general meeting of the above Association was held in the lower room of the Cutlers' Hall, on Friday evening last, April 27th, at nine o'clock, for the purpose of considering the position and prospects of the trade in reference to the past and present prosecutions, and on other business.

The following resolutions were passed by the meeting:—

"That this meeting heartily approves of the defensive action taken by the Chemists' Trade Association, in reference to the prosecutions for the sale of milk of sulphur, and trusts that this vexatious question will now be set at rest."

2nd. "That this meeting, believing in the time-immemorial right and privilege of chemists to prescribe across the counter, in simple ailments, not indeed pretending, or by their customers understood, to be medical men in a professional sense, but merely acting as private persons, —clergymen, and others are daily doing to the great advantage of the public, particularly the very poor—hereby pledges itself to support the Trade Association in the steps it is taking in the law courts in defence of this ancient right, and calls upon every member of the trade to contribute liberally immediate pecuniary aid to the Association at the crisis of affairs."

3rd. "That this meeting, impressed with the very important results and wide spread interests pending and involved in the question of counter-prescribing, respectfully, but earnestly, appeals to the Council of the Pharmaceutical Society to aid the trade in every possible manner in fighting this great battle."

4th. "That in order to secure a fair and satisfactory representation of the chemists and druggists of Great Britain at the Council Board of the Pharmaceutical Society, it is desirable that gentlemen should be selected from various parts of the country; this meeting therefore views with satisfaction the nomination of Mr. G. A. Cubley, in whose ability and usefulness it feels the greatest confidence, and whose election it feels most anxious to support."

5th. "That the Secretary forward a copy of the third resolution to Mr. E. Bremridge, asking him to lay it before the next meeting of Council."

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

Scottish Branch.

A special meeting of the Scotch members of this Association was held in the hall of the Bible Society, St. Andrew's Square, Edinburgh, on Wednesday, 25th April last. There was a fair attendance of members from different parts of the country, and a large number of apologies had been received from gentlemen interested in the association, but who were unable to be present.

Mr. George Blanshard, of Raimes, Blanshard and Co., was called to the chair, who in course of his opening remarks, said he had great pleasure in presiding over such a meeting of his fellow pharmacists, and thanked them for the honour they had done him in asking him to do so. He was deeply attached to the Pharmaceutical Society, which he believed had done, and was still doing a great deal for the trade at large; he believed, however, that there was work for the trade association, and he hoped that the two bodies would move in perfect harmony with each other.

Mr. James M. Fairlie, convenor of committee on the Scotch scheme was then called upon to make a statement regarding the position of the Association in Scotland. He stated that the membership was somewhat over 180, and the donations and subscriptions received since July last, amounted to about £85. As yet not much effort had been made in Scotland to obtain members, the engagements connected with the British Pharmaceutical Conference meeting in autumn last having prevented an energetic canvass being made in one of the principal districts, and the scheme which had been planned was only now being put into operation. There was no doubt but that the number of members might be easily doubled, if not tripled, within the next six months, if the scheme sketched out was faithfully wrought. During the last few weeks he had been in communication with a large number of the leading pharmacists throughout the country, and with the exception of a few of the older pharmaceutical chemists, who it might be expected would be somewhat cautious, the great majority were favourable to the Association as a defence body against the unjust attacks of analysts, excise officers, or unfriendly medical men, and he thought that a personal solicitation was all that was required to obtain the hearty support both financially and otherwise, of the great bulk of the trade. This might be done without much labour if one or two in each of the ten districts in Scotland would work out the plan of the executive of the Association. Mr. Fairlie then explained the scheme, a copy of which has appeared in the *Pharmaceutical Journal.* It was expected that once a year at least a meeting of the trade would be held in the principal town in such district, when a member would be chosen for the general committee, who would act as local representative of the Association, keeping up constant communication between the members in the district and head quarters. In some of the districts the trade was ripe for local associations being formed for educational and other objects, but the question arose, Who was to move in the matter? The elder men say the juniors should take it up, and the young men say the seniors should, with the result that nobody does anything, and the whole matter is left indefinitely in abeyance. The object of the meeting that day was the appointing of a moving spirit in such matters, and if the committee was in earnest, lasting good would result to the chemists in every town, for there were many who required to be protected as well as encouraged, by their brethren who were more fortunately situated. It required united and determined effort to accomplish all the good that might be done. He hoped the trade would do its duty to itself and join the Association, and if it was necessary for them to go to the Legislature for that protection which it would appear some of the laws and law operators do not give them, it would scarcely dare to withhold from them their just rights.

On the motion of Mr. Borthwick, Selkirk, seconded by Mr. Laird, Dundee, the report was received and adopted.

The appointment of the committee was next proceeded with, and after a list of names which had been submitted by members in the various districts had been gone carefully over, it was moved by Mr. Nisbet, Portobello, and seconded by Mr. Anderson, Musselburgh, that the following be the Scotch Committee:—For the counties of Kinross, Clackmannan, and Fife, Mr. D. Storrer, Kirkcaldy; Edinburgh, Haddington, and Linlithgow, Messrs. George Blanshard, James Mackenzie, and W. H. Laird, Edinburgh; Berwick, Peebles, Roxburgh, and Selkirk, Mr. J. G. Alexander, Galashiels; Dumfries, Kirkcudbright, and Wigton, Mr. William Allan, Dumfries; Lanark and Western Counties, Messrs. Thomas Davison, J. M. Fairlie, and H. Kinninmont, of Glasgow, Mr. A. Macnaught, Greenock, and David Murdoch, Falkirk; Perth, Mr. Peter Strang; Forfar, Messrs. Charles Kerr and William Laird, Dundee; Aberdeen and Kincardine, Messrs. D. M. Mackay and Alexander Strachan; Banff, Elgin, and Nairn, Mr. William Robertson, Elgin; Inverness and

Northern Counties, including Western and Northern Islands, Mr. David MacRitchie, Inverness.

The following office bearers were then nominated on the motion of Mr. Murdoch, Falkirk, seconded by Mr. Alexander, Galashiels, viz.: President, Mr. Thomas Davison; Vice-President, Mr. James Mackenzie; Hon. Secretary, Mr. James M. Fairlie.

After some discussion, it was moved by Mr. Mackenzie, and seconded by Mr. Fairlie, that "The arrangements for district trade meetings be remitted to the committee with powers," and agreed to.

Mr. Davison proposed, seconded by Mr. Kinninmont, that "Messrs Mackenzie, Laird, and Fairlie be appointed the deputation to attend the annual meeting of the Association, to be held in London on the 15th May."

After some remarks had been made by several of those present regarding different matters affecting the interests of the trade, a hearty vote of thanks to Mr. Blanshard for presiding brought the proceedings to a close.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting of this Association was held at Britannia Chambers, Pelham Street, on Wednesday evening, April 25th, the chair being occupied by the President, Mr. J. H. Atherton, F.C.S.

Mr. H. Major, B.A., B.Sc., F.R.G.S., delivered a most interesting lecture on "Changes which the Earth has seen." The lecturer showed, by numerous illustrations, how changes are constantly going on in the crust of the earth, and have always been going on since the beginning, through the action of volcanoes, earthquakes, the constant motion of the sea, etc., and said if it had not been for volcanic eruptions bringing them nearer the surface, many of the best metals would have been out of the reach of man. He briefly referred to the changes in animal and vegetable life, rather inclining in his views to the development theory, and said the only thing in nature which did not change was the "inconstant sea," and concluded an eloquent lecture amid applause.

The President, in proposing a vote of thanks to the lecturer, said although he was about to leave the town, he wished him every success in his new home, and hoped he would sometimes pay a visit to the Nottingham Chemists' Association. Mr. J. Rayner echoed the president's hope and seconded the vote of thanks, which was unanimously carried and duly acknowledged by the lecturer.

Parliamentary and Law Proceedings.

Prosecution for Sale of Syrup of Poppies without a Poison Label.

At the Ross Petty Sessions, John Stafford, chemist and druggist, of Ross, was summoned for selling a certain poison, called "Syrup of Poppies," without being labelled as poison, at Ross, on the 7th April.

Mr. Williams appeared for the defendant.

Supt. Smith deposed: On the 9th April I found in the house of William Powell, at Upton Bishop, the bottle I now produce; it was in the same state, and labelled as it is at present; I showed it to Dr. Fernandez at the time.—Cross-examined by Mr. Williams: The bottle had been concealed where I found it; no one casually passing through the room would have been able to discover it; I don't know what it is; I won't swear it is syrup of poppies; if the label were off, I should not know what it is; the label guides me in the opinion that it is syrup of poppies.

Elizabeth Powell, wife of John Powell, labourer, of Upton Bishop, deposed: I saw Supt. Smith find the bottle produced in my house; I got it at Mr. Stafford's, chemist, in Ross; I did not see Mr. Stafford; it was a young man in the shop; I asked for a pennyworth of syrup of poppies; I had used none out of the bottle; I had not used any before; I got it to make the child sleep; I got it on the Saturday, at 2 o'clock, and Supt. Smith found it on the Monday; I had never used any with my children; I heard what Dr. Fernandez said about the condition the child was in; the label was put on when I took it to Mr. Stafford's; it was not on it before.—Cross-examined by Mr. Williams: No one was in the shop besides the young man; I will swear it; I will swear Mr. Stafford did not caution me; he was not there; I did not tell my husband when I took it home; I put it up in the cupboard; it was not because no one should see it; there were things inside the cupboard, but the bottle was not covered up.

Dr. Fernandez deposed: I have examined the contents of the bottle produced; it is a preparation of poppies, and a poison; I have no doubt that the syrup had been administered, from the appearance of the child; the woman did not deny it when I taxed her with administering the syrup to the child; I have heard her statement just given, and do not believe her, because the appearance of the child was such as denoted that a narcotic had been administered.

Mr. Williams, in the course of an eloquent address to the Bench on behalf of his client, observed that the chemists of Ross appeared to have conducted their business upon very strict principles, for during the nine years that the Act had been in force, no case had ever been brought against either of them as to the way in which they dealt with the public. He know that Mr. Stafford in particular, conducted his business with great care, and would prove that when this person went to the shop and asked for this preparation of poppies, he (Mr. Stafford) was in the shop, and he would call a witness to state what transpired, for he was assured that he (Mr. Stafford) had cautioned the woman, and that a proper label had been placed upon the bottle, such labels being constantly at hand to place upon bottles containing these and similar preparations before they were taken from the shop. If the policy of the law had not prevented his putting Mr. Stafford in the witness box, he should have been most happy to do so, and then Mr. Stafford would have stated upon oath what had really taken place. But as he could not do so, he thought that from his character and position as a respectable tradesman, the Bench would attach as much importance to his simple assurance, coming as it did through him (Mr. Williams), as they would if he were able to appear in the witness box, and when they found Mr. Stafford's assistant telling them that before the preparation was handed to the woman she was cautioned in respect of it he felt certain they would hesitate before they accepted her testimony in a case of such grave importance as this. Besides, she did not come before them with such clean hands as a person should have who appeared in support of such a prosecution as this. From the beginning of the case to the last moment when she presented herself in that Court, she had been guilty of nothing less than a series of concealments. She had concealed the purchase of the syrup in the first place from her husband. There was no doubt of that. She had put the bottle in the place where it was found by the policeman. There was not the slightest doubt about that. She had told the Bench she had not given any of it to the children; but that was contradicted by Dr. Fernandez. Would they, therefore, believe the delusive evidence of such a woman in order to criminate a respectable trademan? It was a known fact that people were in the habit of removing the label printed "poison" as they left the chemist's shop, and he had not the slightest hesitation in saying that this woman, when she went away from Mr. Stafford's, must have pulled the word "poison" off the bottle. In order to show the uniform system on which Mr. Stafford conducted his busines, Mr. Williams produced a book, showing how everything was entered that was required by law to be entered, and said there had not been a single instance from the time Mr. Stafford had been in business in which any neglect of this kind could be imputed to him; and this was a reason why he urged all he possibly could in order to controvert the evidence of a woman upon which he asked the Bench not to rely, for they certainly ought not to do so. He also asked them if they could believe that Mr. Stafford would have imperilled his reputation by such an omission, when it could be clearly shown that he had always been most careful and considerate in the transaction of his business. He thought they could fairly assume that the proper label had been put on the bottle, and, after they had heard the shopman's evidence, he hoped they would say that, although it was a case which required their consideration, they did not believe that Mr. Stafford was guilty of the offence, and would accordingly dismiss the charge. After showing the Bench the various kinds of labels used by Mr. Stafford, and directing attention to a red one with the printed word, "Poison," which he contended was the kind used on this occasion, he called,

Albert Porter, qualified assistant to Mr. Stafford, who deposed: I have been with Mr. Stafford about five months; I remember a woman coming for syrup of poppies; Mr. Stafford was in the shop; she bought a pennyworth; I heard Mr. Stafford caution her about the preparation of poppies; when these preparations are sold, I am in the habit of putting one of the labels produced marked "poison" on the bottles; I cannot swear I did so on this occasion, but, according to my habit, I think I must have done so. I have been in other chemists' shops, and have seen people take off the label as they have left the shop, especially after buying laudanum. I do not remember the day when the woman came. I believe I placed a proper label on the bottle.—By the Bench: The reason I have for believing it is that it is my custom to do so.

The Chairman said the Magistrates were unanimously of opinion that it was their duty to convict. But it was not any great reflection upon Mr. Stafford in his business, because speaking from his own experience, Mr. Stafford's business was as well conducted as any shop of the kind that he had dealt at. This was one of those accidents that would occur even when the utmost caution and care were used; and the Bench believed that the omission was accidental. But as the label was not put on the bottle, in conformity with the Act, they had no alternative but to say the charge was proved. The defendant would be fined in the nominal penalty of 6*d*., the costs being £1. 7*s*. 0*d*.

Mr. Williams remarked that there was such a coin as a farthing.

The Chairman replied that the penalty was sufficiently nominal to show that they were clearly of opinion that it was an accidental omission. He was in the habit of dealing with Mr. Stafford, and his confidence in him was not in the least shaken by this case.

Methylated Spirit as a Beverage.

At the Thames Police Court, on Tuesday, Isaac Levi, of Trighton Court, Middlesex Street, Whitechapel, appeared to answer an adjourned summons, taken out by the Inland Revenue, charging him with, on the 12th of January, unlawfully having in his possession methylated spirit, capable of being partially used as a beverage and internally as a medicine, and not being sulphuric ether or chloroform, in the manufacture and preparation of which said methylated spirit had been used, whereby he had incurred a penalty of £100.

Francis Party, an officer of excise, said that on the 12th of January he went to the defendant's house, and on searching it, found in a cupboard in the front room downstairs a bottle containing half a pint of methylated spirit, and in a recess between two rooms, a bottle containing a pint of methylated spirit. On the following day he saw the defendant, who said that he purchased half a pint of the spirit, reduced it with water, sugar, and aniseed, and drank it himself, as he could not afford to buy spirits at a public-house.

Charles Birch, chemist to the Inland Revenue, said that on the 13th of January he received a sample of methylated spirit from the last witness, and on analysing it he found it to consist of methylated spirit 41 degrees underproof, flavoured with aniseed, and seven ounces of sugar to the gallon. The aniseed and sugar would give it a medicinal effect.

Mr. De Rutzen said there was no accounting for taste. It was plain that the defendant had brought himself within the meaning of the act, and had rendered himself, liable to a penalty of £100. He had no power to mitigate the penalty less than one-fourth, and he would be fined £25.—*Standard.*

Poisonous Green Peas.

At the Liverpool Police Court, on Wednesday, April 25, Messrs. Maughan and Thompson, Elliot Street, were summoned under the Adulteration of Food and Drugs Act for selling a tin of preserved green peas which had been coloured with an ingredient injurious to health.

The sale of the peas having been proved, the certificate of the analysis by Dr. Campbell Brown was put in, in which it was stated that the peas in the tin were discoloured with a salt of copper corresponding with from two to two and a half grains of crystallized sulphate of copper. Dr. Brown was called, and said that this amount was equal to half an emetic dose. Any person who partook of the peas regularly would certainly be injured; but, like many other poisons, the copper would affect some people more than others.

Mr. James, on behalf of the defendants, said they had done everything in their power so that they should sell nothing injurious to health. He produced a warranty from Messrs. Pelling, Stanley and Co., Victoria Street, from whom they purchased the peas in question, certifying them to be perfectly pure and unadulterated by any poisonous substance. This warranty having been proved,

Mr. Raffles said the defendants had taken the very course prescribed by the Act of Parliament, and dismissed the summons. On the application of Mr. Atkinson, the letter from Messrs. Pelling, Stanley and Co. was impounded.—*Liverpool Daily Post.*

Robbery by an Assistant.

At the Liverpool Assizes, last week, George Johnson Ashmore, twenty-seven years of age, chemist's assistant, pleaded guilty to having, at Garston, on March 22, stolen twenty packets of tea, eight bottles of champagne, two bottles of whisky, two cases of perfumery, and other articles, the property of Edgar Humphries, his employer. William Henry Ashmore, farmer, brother of the other prisoner, was charged with having received the goods, knowing them to have been stolen, and was acquitted. George J. Ashmore was sentenced to four months' imprisonment.—*Liverpool Weekly News.*

OXALATE OF CERIUM.*

BY HENRY G. GREENISH.

In 1803, a substance, supposed to have been an element, was discovered simultaneously by Klaproth, and by Hisinger and Berzelius, in the mineral cerite, and named cerium. In 1839, Mosander discovered that the so-called element cerium was a compound, and contained a second element, which he named lanthanum (from the Greek λανθανω, I lie hid). In 1841 the same chemist determined the presence of a third element, didymium (from Greek διδυμοι, twins).

The earliest notice that I can find of any salt of cerium being used in medicine is in 1854, in a "Note on the Therapeutic Action of Salts of Cerium," by J. Y. Simpson, M.D.† The following is a quotation from an abstract of his note:

"He now proposed to read to the Society some very imperfect observations on the therapeutic action of some other metals, and first as to cerium, which, given in the form of nitrate, and in one grain doses, twice or thrice a day, appeared to act as a sedative tonic of considerable value, strongly resembling bismuth and the salts of silver. He had employed it, in the first instance, in cases of general chronic intestinal eruption, a peculiar and intractable form of disease, for which arsenic and nitrate of silver were generally prescribed, and where these remedies had failed, cerium had been tried with marked advantage. In irritable dyspepsia with gastrodynia and pyrosis, and in chronic vomiting, its exhibition was attended with satisfactory results, and in the vomiting which occurs during pregnancy prompt relief was afforded."

These remarks had reference to the nitrate of cerium only.

Five years later, Dr. Simpson, in one of a series of clinical lectures on the "Diseases of Women,"‡ spoke of the oxalate of cerium in these terms:

"I have not as yet said anything regarding the drug which I have found to be, of all individual remedies, the simplest and surest agent that can be administered for arresting the sympathetic vomiting of pregnancy. The drug I refer to is oxalate of cerium, which I have seen successful in curing vomiting in a larger proportion of cases than any other single remedy which I have used."

Further quotation from this lecture is not necessary for my purpose, as the remarks which follow have reference mainly to the special cases in which he found the oxalate valuable.

In 1865, Dr. Walsh, in a letter to the *Medical Times and Gazette*,§ recommended the oxalate of cerium combined with compound tincture of valerian for sea sickness, and stated that considerable relief had been derived from its use. This closes the history of oxalate of cerium till it became a Pharmacopœia preparation.

In 1867, oxalate of cerium was introduced into the British Pharmacopœia, with the following description:

"A salt, which may be obtained as a precipitate by adding a solution of oxalate of ammonia to a soluble salt of cerium."

If the soluble salt of cerium were pure this would be correct, but it would then be inconsistent with the "Characters and Tests" which are as follows:

"A white granular powder, insoluble in water, decomposed at a dull red heat into a reddish brown powder, which dissolves completely, and without effervescence, in boiling hydrochloric acid."

If the salt of cerium from which the oxalate is obtained be pure, the oxalate would be decomposed at a dull red heat into a pale yellow powder. The reddish brown colour is an indication of impurity. The salt of cerium of commerce, from which the oxalate is made, is not pure, and to the impurities contained in it this reddish brown colour on decomposition by heat is due.

Dr. Attfield* makes the following statement concerning oxalate of cerium:

"The oxalate of cerium may be obtained from cerite by boiling the powdered mineral in strong hydrochloric acid, evaporating, diluting, and filtering to separate silica, adding ammonia to precipitate the hydrates of all metals except calcium; filtering off, washing, redissolving in hydrochloric acid, and adding oxalic acid to precipitate oxalate of cerium. The preparation will still contain oxalates of lanthanum and didymium. It is therefore strongly calcined, the resulting oxides of lanthanum and didymium dissolved out by boiling in a concentrated solution of chloride of ammonium, the residual oxide of cerium dissolved in hydrochloric acid, and oxalate of ammonia added to precipitate pure oxalate of cerium."

I shall refer to this subsequently.

The following is the usual method adopted for the commercial manufacture of oxalate of cerium: †

The powdered mineral cerite is heated with a large excess of concentrated sulphuric acid for several hours and allowed to cool. The soluble sulphates formed are dissolved out by cold water. In this solution of sulphates a mass of sulphate of potassium is suspended, by which double sulphates of the cerium metals and potassium are precipitated. The precipitate is collected, decomposed by heating with carbonate of soda, and the resulting mass lixiviated with water, leaving the oxides of the metals; or the precipitated sulphates are strongly heated with charcoal, reducing them to sulphides, which may be dissolved in dilute nitric acid, and evaporated to dryness.

Another method‡ consists in the treatment of the mineral with *aqua regia*, dilution, and precipitation of the hydrates of the metals with ammonia. The precipitate is collected, washed, redissolved in hydrochloric acid, and precipitated with oxalic acid.

F. Mayer§ recommends heating the mineral with sulphuric acid, lixiviating, and passing sulphuretted hydrogen through the liquid; the sulphides are removed by filtration; hydrochloric acid is then added, and the oxalates of the cerium metals precipitated by oxalic acid. These are calcined with carbonate of magnesia, dissolved in nitric acid, and boiled in a large quantity of dilute sulphuric acid. By this means a subsulphate of cerium is precipitated. This is collected, dissolved in strong sulphuric acid, reduced by hyposulphite of soda to cerous sulphate, filtered, and oxalate of cerium precipitated with oxalic acid.

This process has the advantage of producing a pure, or nearly pure, cerium salt.

The minerals used in the manufacture are chiefly cerite from Westmanland, in Sweden; allanite and

orthite from Norway, Russia, Germany, etc. The proportion of cerium to the lanthanum and didymium contained in them is by no means uniform, varying from 50 per cent. cerium with 8 per cent. of lanthanum and didymium, to 3 per cent. of cerium, with 9 per cent. of lanthanum and didymium. If, therefore, no attempt is made to separate the cerium from its allied metals, it is evident that the oxalate of cerium will contain a very variable amount of pure cerium, and from inquiries made of manufacturers of the drug, I find that no such separation is made, and that the oxalate of cerium of commerce is the mixed oxalate of cerium, lanthanum, and didymium in the proportion in which they happen to exist in the mineral used.

I will now quote the results of the qualitative analysis of six samples of oxalate of cerium obtained from different sources, showing the impurities contained in them. They may be taken as representative specimens of the oxalate of cerium of commerce:

No.	Basylous Radicles.				Acidulous Rad.
1	Pb	Fe Ce	Ca	Mg	SO_4; tr. Cl
2	Pb	Fe	*nil*	Mg	SO_4; tr. Cl
3	Pb	Fe	*nil*	Mg	Trace SO_4
4	Pb?	Fe	Ca traces	Mg	SO_4; Cl
5	Pb	Fe	*nil*	Mg	SO_4
6	Pb	Fe Ce Al	Ca	Mg	SO_4

The chief impurities were lead, iron, calcium, magnesium, and a soluble salt of cerium, present, however, usually in small quantity. In sample 4 the precipitate obtained with sulphuretted hydrogen was probably lead, but the quantity was very small. In sample 3 lead was rather more prominent than I should have expected. A weighed quantity, 1·911 gram of this sample yielded sulphide of lead corresponding to ·021 gram oxalate, or 1·1 per cent. In the acidulous radicals I found traces of chlorides in 1, 2, and 5, sulphates in small quantity in 1, 2, 3, 4, and 5, and in considerable quantity in 6.

Referring again to the Pharmacopœia, it will be found to be stated that "Ten grains of the oxalate when incinerated lose 5·2 grains in weight;" that is, 52 per cent. I give here the amount of loss sustained by the above six samples, and by a seventh which I know to be of German manufacture:

No.	Loss per cent.	No.	Loss per cent.
1	52·3	5	52·1
2	52·9	6	32·0
3	52·5	7	44·8
4	52·3		

It will be noticed that the loss sustained by samples 6 and 7 was much less than by the other five, or, in other words, the amount of ash was much greater. The ash was in each case tested, and the impurity found to be sulphate of cerium.

A weighed quantity of sample 6 was then taken, incinerated, the ash treated with water, by which the sulphate of cerium was dissolved out, the resulting insoluble oxide collected, dried, weighed, and calculated to oxalate. It was found to be 59·8 per cent. of the quantity taken, and would represent the amount of oxalate of cerium present in the sample.

Sample 7 similarly treated gave 81·3 per cent. of oxalate.

Next the oxalic radical was estimated. This was effected by a solution of permanganate of potassium of known strength. A weighed quantity of oxalate was introduced into a flask, water and sulphuric acid added, and the mixture heated till the oxalate was dissolved. The permanganate solution was then added from a burette as long as decolorization took place. When this ceased, the whole of the oxalic radical had been decomposed, and by this means could be easily and correctly estimated.

In the accompanying table is shown the amount of oxalic radical calculated to C_2O_4 in the seven samples before treated. Pure oxalate of cerium $CeC_2O_4 3H_2O$ would yield 37·6 per cent. C_2O_4.

No.	Per cent.	No.	Per cent.
1	36·8	5	37·7
2	36·7	6	22·5
3	36·9	7	30·6
4	37·1		

Samples 6 and 7, as might be anticipated, were remarkably deficient in the oxalic radical.

I will now direct attention to the separation of the pure cerium oxide from the oxides of lanthanum and didymium, with which it is always associated. The following are the principal methods which have been recommended for this purpose:—

1.* Pass chlorine through the hydrates suspended in potash; lanthanum and didymium dissolve, cerium is left as peroxide.

2.† Boil the mixed oxides in a strong solution of chloride of ammonium; lanthanum and didymium dissolve, cerium is not acted upon.

3.‡ Boil first with dilute nitric acid, then with stronger; lanthanum and didymium dissolve, cerium is not acted upon.

4.§ Dissolve the oxides in nitric acid, evaporate till most of the nitric acid is driven off, and boil in a large quantity of very dilute sulphuric acid. The cerium is precipitated as subsulphate—

$$(SO_6HCe_2 2H_2O).$$

5.|| Dissolve the oxides in nitric acid, nearly neutralize, add acetate of soda, then hypochlorite of soda, and boil, cerium is precipitated.

The first was the process employed by Mosander in separating lanthanum and didymium, and subsequently by Damour and Ste-Claire-Deville in the analysis of a mineral. The stream of chlorine must be continued for some hours till the liquid is completely saturated. The undissolved portion is then allowed to subside, the clear liquid poured off, fresh potash added, and the process repeated. The clear liquid is boiled to precipitate some oxide of cerium held in solution, and filtered. The filtrates will contain the lanthanum and didymium; the precipitates and that portion undissolved by the chlorine will be the cerium oxide. It may be collected, well washed, redissolved and reprecipitated to free it from salt of potash; collected, dried, incinerated, and weighed as sesquioxide, Ce_2O_3. Watts says of this process, "It is long and tedious, but the result is certain and separation complete."

·871 gram oxide from sample 2 gave ·252 cerium oxide, and ·594 oxides of lanthanum and didymium, or in percentage—

Cerium	29·
Lanthanum and Didymium . . .	68·2
	97·2

leaving 2·8 per cent. not accounted for, probably due to the impurities contained in the sample, and to error in manipulation. The oxide of cerium obtained by this process is pale yellow in colour, the mixed oxides of lanthanum and didymium dark brown. Pure oxide of lanthanum is white. It is curious here to note that although the mixed oxides are easily soluble in hydrochloric acid, pure oxide of cerium is only slightly acted upon. It is difficult to reconcile this with the statement of Professor Attfield previously quoted, that "the residual oxide of cerium is dissolved in hydrochloric acid, and oxalate of ammonia added to precipitate oxalate of cerium."

Process 2. Solution of chloride of ammonium, as a solvent for oxides of lanthanum and didymium, was first brought forward by Watts.* He states that it is the easiest method, and that he has succeeded in completely separating the cerium; the boiling must be continued for some hours, the liquid occasionally renewed, and tested free from lanthanum and didymium, by oxalate of ammonia, before separation is complete.

·26 gram oxide from sample 2 was boiled in a 25 per cent. solution of chloride of ammonium for ten hours, water being added to replace that lost by evaporation, and the liquid occasionally renewed. At the end of that time the liquid still gave a precipitate with oxalate of ammonia. The undissolved oxide was collected, washed, dried, and incinerated; it weighed ·066 gram, or 21·7 per cent. of the quantity taken, and was not yet free from lanthanum and didymium. The liquids which should have contained the lanthanum and didymium were precipitated with oxalic acid, the precipitate collected, washed, dried, incinerated, and the resulting oxide boiled in dilute nitric acid. After an hour's boiling it was not entirely dissolved. This would indicate† the presence of cerium. From this circumstance I am inclined to doubt the process being reliable.

Process 3. Watts says of this process that the oxide becomes diffused through the liquid, will not separate for days, and if filtration be attempted, first passes through the filter, and then completely blocks it up.

Process 4. A weighed quantity of oxalate was incinerated, the ash dissolved in strong nitric acid, evaporated to a syrupy consistence, and introduced into boiling very dilute sulphuric acid. The precipitate was collected, washed, dried, and weighed. By this method, sample 2 yielded subsulphate of cerium, corresponding to 36 per cent. oxide of cerium. It was not, however, quite free from lanthanum and didymium. With careful manipulation and some practice, this would I think prove an easy and excellent process.

Process 5. No estimation was made by this process.

It will thus be seen that the composition of the oxalate of cerium of commerce is by no means uniform. The proportion of cerium it contains depends on the proportion of that metal to the lanthanum and didymium contained in the mineral used in its manufacture. This I have shown to be very variable. I am unable to give any satisfactory reason for the occurrence of so great a percentage of sulphate of cerium. The point in the manufacture to which we may refer it would be the imperfect decomposition of the sulphate of cerium by oxalic acid, and neglect of subsequent washing.

The presence of so large a proportion of the oxalates of lanthanum and didymium in the oxalate of cerium of commerce renders it doubtful whether the therapeutic action attributed to cerium is due to that metal alone, or whether it is shared equally by the lanthanum and didymium with which in commercial samples the cerium seems to be always combined.

THE MEDICINAL PLANTS OF SCOTLAND.*

BY WILLIAM CRAIG, M.D., F.R.S.E.,

Lecturer on Materia Medica, Edinburgh School of Medicine.

In selecting a subject on which to address you this evening, it occurred to me, that it would be neither unprofitable nor uninteresting that I should direct your attention to the medicinal plants of Scotland. This is a subject which should possess a special interest, not only to members of the North British Branch of the Pharmaceutical Society, but also to the students under their care. My object to-night is to point out to you in as brief a manner as I can, what plants Scotland contributes to the materia medica. I shall confine my remarks to those plants which are officinal in the British Pharmacopœia. There are many plants in Scotland possessed of medicinal properties which are not officinal, and there are others which are very poisonous, but whose actions are to a great extent unknown, an account of which would be very interesting, and I may on some future occasion, direct your attention to such plants. To-night, however, my time is limited, and I will, in consequence, confine my attention to plants of the British Pharmacopœia.

I shall go over in regular order the various officinal plants found in Scotland, giving in very general terms their more prominent characteristics, with the twofold object in view, of telling you what plants are officinal, and at the same time helping you to recognize them.

There are about 63 natural orders officinal in the British Pharmacopœia, and of these about one-third are represented in Scotland.

Upwards of 360 plants are officinal in the British Pharmacopœia, and of these about 24 or 25 are indigenous to Scotland, or about 1 in 15 of all the medicinal plants is found in Scotland.

In describing the plants to you I shall follow the Natural Orders as given in the last edition of Professor Balfour's 'Manual of Botany.'

Ranunculaceæ.—Only two plants in this natural order are officinal in the British Pharmacopœia. One of these, although not an indigenous plant of Scotland, is nevertheless found naturalized in several parts. I refer to the *Aconitum Napellus*. This plant is easily recognized by its short tapering root, its deeply divided leaves with five pointed segments, and its raceme of blue flowers and its peculiar hooded sepals. This plant, which is known as the common monk's-hood or wolf's-bane of our gardens, is a true native of the mountainous districts of central and southern Europe. The best authorities consider it a doubtful native of Britain. It is, however, perfectly naturalized in Scotland, and in several places around Edinburgh it grows in considerable abundance, as in Arniston Woods. In Balfour's 'Flora of Edinburgh, eight stations are recorded for this plant, all within a

* Read before the North British Branch of the Pharmaceutical Society, April 18, 1877.

radius of twenty miles of this city. I have gathered it in several of these localities. The leaves and root are officinal. It is a very important medicinal plant. It is a sedative to the heart's action, and alleviates pain when applied locally.

Papaveraceæ.—Two plants of this natural order are officinal: *Papaver somniferum*, Linn., and *Papaver Rhœas*, Linn. The first though occasionally found in a wild state in England, and even in some parts of Scotland, is not a true native of Britain. At all events it is at best a doubtful native of England and is unquestionably an introduced plant in Scotland. Being, however, extensively cultivated in our gardens, it has established itself in sandy waste places, especially near the sea, and is mentioned in Balfour's 'Flora of Edinburgh' as an introduced plant. He gives seven stations for it around Edinburgh. It grows at Donibristle, Caroline Park, etc. It is a true native of the south of Europe. It is the most important of the medicinal plants, because from it we obtain opium. It is easily distinguished from the other species by its being glabrous and glaucous. The general appearance of the plant is very different from that of the other species.

The other officinal plant of this natural order is common around Edinburgh. It is *Papaver Rhœas*, Linn., commonly called field, or red, poppy. This plant is easily distinguished from the other British species. It is distinguished from *Papaver Argemone* by its capsule, which is smooth, whereas it is covered with bristles in *P. Argemone*. It is distinguished from *Papaver dubium* by the hairs of the peduncle, spreading in *P. Rhœas*, but adpressed in *P. dubium*. The capsule of *P. Rhœas* is more rounded than in *P. dubium*. The petals are officinal. From these we make a syrup, which is chiefly used for colouring mixtures. *Papaver Rhœas* is very abundant around Edinburgh. It is more abundant than any of the other species, many fields, especially cornfields, being quite red with it.

Cruciferæ.—Three plants of this natural order are officinal in the British Pharmacopœia, all of which are found in Scotland, one of them, however, only as an introduced plant, the *Cochlearia Armoracia*, Linn., *Armoracia rusticana* of other botanists,—the common horseradish. This is an introduced plant into Scotland, and probably also into England. It is said to have established itself at Dalkeith, Duddingston, and other places near Edinburgh. It is a plant of 2 or 3 feet in height, with white flowers, and very large oblong radical leaves. The root is the officinal part, and is interesting as being sometimes confounded with the root of aconite. The two roots do not resemble each other in many points. The aconite root is short, dark coloured and tapering quickly to a point, and produces numbness when chewed. The horseradish root is long, white, cylindrical, with a hot acrid taste. The two roots are very different in appearance, but from the fact that the aconite and horseradish are frequently planted together in gardens, in winter, when the roots are dug up, the one has sometimes been mistaken for the other with sad results. The plant is given in Hooker's 'Flora,' as a Scottish plant. Babington also mentions it as an introduced plant into the flora of Scotland.

The other two officinal cruciferous plants are both natives of Scotland: *Sinapis alba*, Linn., and *Sinapis nigra*, Linn., white and black mustard. These two plants are both to be found in the neighbourhood of Edinburgh. There are three native species of *Sinapis*. *S. arvensis*, common wild mustard, is very abundant in cultivated fields, and frequently cornfields are quite yellow with it. It is easily distinguished from the two officinal species, by having its pods spreading and glabrous. The *S. alba* has yellow flowers, and the pods spreading, but the lower part covered with stiff white hairs. It is more common in England than in Scotland. It is generally found in waste places, and occurs on the shore to the east of Burntisland and other places around Edinburgh.

Sinapis nigra is more rare in Scotland. It occurs, however, on Inchkeith, at Kirkcaldy, and on the banks of the Avon in Linlithgowshire It is distinguished by its adpressed pods. In both the seeds are officinal, yielding mustard. The oil of mustard is obtained only from the seeds of the *S. nigra*.

Linaceæ.—Only one plant in this natural order is officinal: *Linum usitatissimum*, Linn., common flax. This plant is easily distinguished from others of the same genus by its erect stem, lanceolate leaves, annular root, blue flowers, and petals 7 or 8 lines long. The origin of this plant is unknown, but it has long been cultivated in Britain, and at one time was extensively cultivated in Scotland, and in consequence has established itself in various localities. It occurs on Salisbury Crags, and in other places near Edinburgh. It is to be found in various places in Fife. The seeds are officinal:

Rhamnaceæ.—Only one plant belonging to this natural order is officinal, the *Rhamnus catharticus*, common buckthorn. There are two native species of this genus. They are both shrubs, and although both are possessed of medicinal properties, only *R. catharticus* is officinal. These two species, *R. catharticus*, and *F. Frangula*, are easily distinguished from each other by the former having the leaves minutely toothed, whereas they are entire in the *R. Frangula*. *R. catharticus* has thorny branches, diœcious flowers and 4 stamens, whereas *R. Frangula* has no thorns, hermaphrodite flowers and 5 stamens. The fruit is the officinal part of *R. catharticus*. It is used for making a syrup, which as the name of the plant implies is possessed of cathartic properties. The plant is said to occur in the south of Scotland. It is not mentioned in Balfour's 'Flora of Edinburgh,' but both Hooker and Babington mention it as Scottish plant.

Leguminosæ.—Only one officinal plant of this natural order is found in Scotland, *Sarothamnus scoparius*, Wimmer, common broom. This shrub is easily known by its angular stems, its large yellow flowers, and its flat dark hairy pods. It is a very common plant in Scotland. The "tops" are the parts used, and are powerfully diuretic:

Rosaceæ.—Of the three officinal species of this natural order, only one is a native of Scotland—*Rosa canina*, L., the common dog-rose. This is a common plant throughout Scotland, the fruit of which is the part used in medicine, and is probably familiar to you all as "hips." This is the commonest of our wild roses. It is not easy for the non-botanical student to make out the various species of the genus *Rosa*, but this matters little, since not only the fruit of *R. canina* is officinal, but also the fruit of "allied species." The fruit is deprived of the seeds and afterwards made into a confection with sugar, and is useful for making pills.

Umbelliferæ.—*Carum Carui*, L., common caraway (from whose fruit is distilled the officinal oil of caraway), is found in Scotland, where it is naturalized in several localities. In Balfour's 'Flora of Edinburgh' nine stations are given for this plant. I have gathered it on the railway bank between Burntisland and Kinghorn. It is, however, in all probability an introduced plant into Scotland.

The only other officinal umbelliferous plant found in Scotland is the *Conium maculatum*, common hemlock. This plant is generally distributed over Britain, and is very abundant in many localities around Edinburgh. It is very abundant on the Castle Rock, in the Queen's Park, and at one time was found in East Princes Street Gardens, near the site of Scott's monument. It is easily recognized from other umbelliferous plants by its much divided leaves, and especially by its smooth purple-spotted stem. The seeds and leaves are both officinal; it is a poisonous plant. Poisonous properties are generally associated in the popular mind with umbelliferous plants. This, however, is the exception, not the rule, in so far as our native species are concerned. Only four of our native plants are poisonous. *Œnanthe crocata*, a plant not unfrequent in ditches around Edinburgh; this, though undoubtedly a poisonous plant, is frequently when grown in the neighbourhood of Edinburgh possessed of no poisonous properties. The *Æthusa Cynapium*, common fool's-parsley, is also very poisonous. This is a common weed in cultivated and waste places around Edinburgh. It is easily known by its long beard-like involucre. The other poisonous plant is *Cicuta virosa*, the cowbane or water hemlock. This plant is found in several localities around Edinburgh, and is very abundant at the Black Loch, near Dunfermline. It attains a height of three or four feet, and has narrow leaves.

Caprifoliaceæ.—Only one plant in this natural order is officinal, *Sambucus nigra*, L., common elder. This is a small tree, with the stem and branches full of pith. This tree is abundant throughout Scotland, and in former times was extensively planted around farm houses, from its supposed efficacy in keeping away witches. The flowers are officinal; they are of a white or cream colour, and sweet scented. From them is made the Aqua Sambuci of the B. P. They are sometimes used for flavouring jellies, and also for making "elder-flower wine." This plant is regarded by many botanists as truly indigenous to Scotland, and is recorded as such in Balfour's 'Flora of Edinburgh.'

Valerianaceæ.—*Valeriana officinalis*, L., wild valerian. This is the only officinal plant in this natural order, and is common in ditches, moist woods, and on river banks throughout Scotland. It is easily distinguished from all the other British species, by having all its leaves divided, whereas in the other British species the lower leaves are undivided. The root is the officinal part, which is short, thick, with creeping runners, and a strong characteristic odour, an odour common even to *Valerianates*. It is chiefly used as a stimulant and antispasmodic.

Compositæ.—This order contains five officinal plants, three of which are natives of Scotland. I shall briefly refer to each of these.

Anthemis nobilis, L.—The flower-heads of this plant, known as chamomile flowers, are officinal, and are used as poultices to inflamed parts. Internally, they are tonic and aromatic. The plant is mentioned by Babington and Hooker as a Scottish plant, the latter mentioning the Isles of Bute and Cumbræ as stations in Scotland. The plant grows generally in sandy places near the sea. It is not mentioned in Balfour's 'Flora of Edinburgh,' but Groves in his 'Hortus Medicus,' says "I have found it in patches growing on the banks of the water of Leith from Juniper Green to Currie."

Taraxacum-Dens Leonis, D.C.; -*Leontodon Taraxacum*, L., common dandelion. This plant is very common in Scotland, in fact it is a troublesome weed in almost all cultivated parts of the world. The plant is easily known by its runcinate leaves, its radical hollow peduncles with single heads of yellow flowers, and its achenes having a pappus of numerous single hairs. The root is the part used, and is possessed of cholagogue properties.

Lactuca virosa, L., strong-scented lettuce. This is a beautiful plant, with a stem several feet in height. It is distinguished from the other Scottish species, *L. muralis*, by having the beak of the achenes elongated, and the keel of its leaves prickly. The whole plant abounds in a milky juice, which concretes and forms lactucarium, a substance resembling opium. The whole plant is used to make the officinal extract; which is possessed of narcotic properties. This plant is found in several places in Scotland. It occurs in the Queen's Park, on the rock of Stirling Castle, and is abundant on the banks of the Almond in Perthshire. These are the only officinal plants of this natural order found in Scotland. There are, however, several species of *Artemesia* found in Scotland, the genus from whose flower-heads santonin is obtained. Several species of *Artemesia* are common around Edinburgh, and I have no doubt but santonin could be obtained from their flower-heads. Santonin is anthelmintic.

Ericaceæ.—Only one plant of this order is officinal. *Arctostaphylos Uva-Ursi*, Spreng., common bear-berry. This plant is very abundant in the Highlands of Scotland. It grows in dry heathy rocky hills. It is plentiful in the mountains of Clova, Forfarshire, on Loch-na-gar, and on the Cairngorm range of mountains. It is a low trailing shrub, with leaves not unlike those of the cow-berry, or red whortle-berry of the Highlands (*Vaccinium Vitis-Idæa*), which plant it much resembles. It is at once distinguished, however, from the cow-berry, by having the sepals at the base of the fruit, whereas the sepals are at the apex of the fruit in cow-berry. The leaves are officinal; they are distinguished from those of the cow-berry by not being dotted beneath, and from those of *Arctostaphylos alpina* by not being serrated on the edges. The leaves are possessed of astringent and diuretic properties.

Solanaceæ.—This is a very important order to us, inasmuch as it contains some valuable medicinal plants. It contains six officinal plants, three of which are found in Scotland.

Solanum Dulcamara, L., bitter-sweet or woody nightshade. This plant is known by its shrubby zigzag stem, trailing in hedges and thickets to the height of several feet, and by its upper leaves having peculiar auricles at the base. Its flowers resemble somewhat those of the common potato, a plant of the same genus. Its fruit is a red berry. This plant is not common in Scotland, but it is found in considerable abundance in several localities around Edinburgh. I have gathered it frequently. It is plentiful on the Fife coast of the Firth of Forth. The dried young branches are used as an alterative. There is another species, *S. nigrum*, also found in Scotland, and which it somewhat resembles. The two plants are easily distinguished. *S. Dulcamara* has auricled leaves, purple flowers, and red fruit, whereas the *S. nigrum* has its leaves without auricles, white flowers, and black fruit.

Atropa Belladonna, L., deadly-nightshade. This plant is known by its herbaceous stem, often several feet in height, its entire ovate rather large leaves, its large purple bell-shaped flower, and its large globular, dark shining fruit. It is found growing in many places in Scotland apparently wild. It is given as a Scottish plant by Babington, and in Balfour's 'Flora of Edinburgh' five stations are recorded for it. It grows in considerable abundance on the shore between Donibristle and Aberdour. Its leaves and root are officinal. It is chiefly used for dilating the pupil, for alleviating pain and for correcting the griping of purgative medicines.

Hyoscyamus niger, L., common henbane. This is another important medicinal plant belonging to the same natural order, found in Scotland. Like belladonna it occurs in waste places and near old ruins. It is more plentiful in Scotland than the belladonna, being especially abundant about Elie, where it grows to a large size. In Balfour's 'Flora of Edinburgh,' eight stations are given for this plant, one of them being the "debris of Salisbury Crags." I have gathered it at Craigmillar Castle and on the shore in Dalmeny Park, two stations not recorded in Balfour's 'Flora.' The plant is easily recognized by its general appearance. It is a coarse plant, 1 to 2 feet high, hairy and viscid, with a nauseous smell. The flower is bell-shaped, of a pale dingy yellow streaked with purple veins. The capsule opens by an operculum. The parts used are the leaves and young branches. Its properties are similar to those of belladonna but weaker.

Scrophulariaceæ.—Only one plant in this natural order is officinal, *Digitalis purpurea*, L., purple foxglove. This is a common plant in the upland woods and rocky glens of Scotland, and is not uncommon in the flora of Edinburgh, being found as near as Craigleith. It is a beautiful plant, in fact it is one of the prettiest of our natives. It is easily recognized by its beautiful large purple bell-shaped flowers, spotted within, and arranged on a long spike 2 or 3 feet high. The leaves are officinal. They are large, ovate-lanceolate, crenate, downy beneath and narrowed into a foot stalk. It is used for its action on the heart and as a diuretic.

Labiatæ.—We have four medical plants in this order, two of which are to be found in Scotland: *Mentha piperita*, L., peppermint, and *Mentha viridis*, L., spearmint. These two plants are distinguished by the former having its leaves shortly stalked, whereas they are sessile in the latter. Both are found in Scotland, the former as an indigenous plant in several places. It is given in Balfour's 'Flora of Edinburgh' as found at Arniston, North Queensferry (a station also recorded by Hooker) and near Crookston. The *Mentha viridis* is found in Scotland only as an introduced plant. Eight stations for it are given in Balfour's 'Flora of Edinburgh,' one of these being Granton. Both plants are used for their oil, which is stimulant and carminative.

Thymelaceæ.—Two plants in this natural order are officinal, *Daphne Mezereon*, L., common mezereon, and *Daphne Laureola*, L., spurge laurel, both of which are found in Scotland, the first only sparingly and then only as an introduced plant; the second is found much more abundantly, and is probably, though by no means certainly, an indigenous plant of Scotland. The former is found at Dalhousie and Roslin, the latter at Roslin, Dalmeny, Arniston, and several other places around Edinburgh. They are both shrubs but differ very much in apperance. *D. Mezereon* has deciduous leaves which appear after the flowers. The flowers are purple and are very beautiful, especially as they appear before the leaves and very early in spring.

D. Laureola has evergreen leaves and green flowers, which appear in the axils of the leaves.

The bark of both is used in medicine as a stimulant and diaphoretic.

Cannabinaceæ.—This order contains only two genera and three species. Two plants are officinal, of these *Humulus Lupulus*, L., common hop, is occasionally found as an introduced plant near Edinburgh. In Balfour's 'Flora of Edinburgh' eight stations are given for this plant, at two of which I have gathered it, at Canonmills Bridge and on the banks of the Esk above Musselburgh. Bentham in his 'British Flora' says it "extends over England and Ireland, and here and there into Scotland, but probably, in the North at least, only as an introduced plant, having been long in cultivation." It is a twining plant, with opposite stalked leaves, diœcious flowers, and peculiar fruit, which is a kind of membranous cone, called by botanists a *Strobilus*. The dried strobiles of the female plant are used in medicine as a feeble narcotic and tonic.

Ulmaceæ.—Only one plant in this order is officinal, *Ulmus campestris*, L., *Ulmus montana* of other botanists, the broad-leaved wych elm. This is the common wild elm of Scotland, and is undoubtedly the officinal plant of the B.P. The tree is not uncommon in Scotland. It is easily known by its peculiar fruit, which is flat, thin and leaf-like, and occurs in clusters. The dried inner bark is used as a tonic and astringent.

Cupuliferæ or Corylaceæ.—*Quercus pedunculata*, Willd., which is a variety of *Quercus Robur*, L., is the common oak of Britain and is very abundant in Scotland. It is easily known by its stalked sinuate leaves with blunt lobes and glabrous, and its acorn placed in the cup-like involucre. This plant in some parts of the highlands of Scotland covers great tracts of country. Its bark is used as a powerful astringent.

Quercus infectoria, the species from which we obtain galls, is not a native of Britain, although galls are not unfrequently produced on British oaks.

Coniferæ.—The only officinal plant of this order found in Scotland is *Juniperus communis*, L., common juniper. This plant is not uncommon in hilly heathy places in Scotland. It occurs on the Pentland Hills, at Tynehead and other places near Edinburgh. It is an evergreen shrub, several feet high, with leaves in whorls of three, linear, spreading, and ending in a prickly point. The fruit is a berry of a dark purple colour, and about the size of a large pea. The fruit is officinal; from it we obtain an oil which is a powerful diuretic.

Monocotyledones. —About fifteen monocotyledonous plants are officinal in the B. P. and of these only one has been recorded from Scotland, the autumn crocus, *Colchicum autumnale*, L., a plant belonging to the natural order *Melanthaceæ*. This plant is abundant in some parts of England and Ireland, but is a very doubtful native of Scotland. The plant has this peculiarity that its flower comes up before the leaves. The seeds and corm are officinal. They are very poisonous and are used in gout and rheumatism.

Cryptogamous plants.—Only four cryptogamous plants are officinal in the B. P., all of which, however, are natives of Scotland. They belong to three different natural orders.

Filices.—*Aspidium Filix-mas*, Swartz, *Lastrea Filix-mas* of other botanists, commonly called male fern. This is a common fern in Scotland, growing in woods and banks. It is very abundant around Edinburgh. It is recognized by its handsome fronds, three or four feet in height and growing in a circle. The fronds are bipinnate, sori are large, near the base of the segments with a conspicuous peltate indusium. The fronds are very stiff and are easily distinguished from those of *L. Oreopteris*, which in some respects they resemble, by the latter having the sori arranged along the margin of the pinnas.

The rhizome is officinal, from which an ethereal extract is made. It is the best remedy for tapeworm.

Lichenes.—*Cetraria islandica*, the *Lichen islandica* of some botanists. Iceland moss is officinal in the B. P. It is a native of the north, and as its name implies is abundant in Iceland. It is by no means, however, uncommon in the Highlands of Scotland. It occurs in the Flora of Edinburgh, being found at Swanston, Dalmahoy, West Lomond Hill and other places. It has a foliaceous appearance, a brownish white colour, paler beneath. It is used as a decotion, and is possessed of tonic and mucilaginous properties.

Fungi.—Two fungi are officinal. *Claviceps purpurea*, the ergot fungus. The sclerotium (compact mycelium or spawn) of this fungus produced within the paleæ of the common rye, *Secale cereale*, L., forms the well-known medicine called ergot. It has a spurred appearance, of a dark brown colour, and is a medicine which can always be recognized by its smell. This fungus is a native of Scotland, and is not peculiar to rye. It is found on many other grasses, as *Lolium perenne*, common rye grass, and about thirty other species. It is used for its effect on the uterus, and as an astringent to the blood-vessels.

Torula Cerevesiæ, the yeast fungus, is officinal inasmuch as beer yeast is used in medicine as a tonic and antiseptic. The fungus is common in Scotland.

I have thus endeavoured to bring before you the various medicinal plants found in Scotland. You will see that many plants of considerable importance are indigenous to this part of the island, and I trust that what I have said to-night may lead all of you, and especially the young men, to study carefully, and in so far as practicable make a collection of the "Medicinal Plants of Scotland."

PRELIMINARY ACCOUNT OF SOME NEW REACTIONS IN ORGANIC CHEMISTRY, AND THEIR ULTIMATE BEARINGS.*

BY CHARLES T. KINGZETT, F.C.S., AND HENRY WILSON HAKE, PH.D., F.C.S.

1. *Pettenkofer's Notice of his Reaction*.—It has long been known that the cholic acid ($C_{24}H_{40}O_5$) of Demarçay, the cholalic acid of Strecker, furnishes with strong sulphuric acid and cane sugar a peculiar violet colour. Pettenkofer, to whom this discovery is due, founded upon it† a test for bile and for sugar, in organic fluids. He attempted to isolate the coloured body, but his efforts were unsu-

* Read before the Chemical Society of London, on Jan. 18, 1877.

† *Ann. Chem. Pharm.*, lii., p. 90 (1844).

tended with success nor was he able to suggest any explanation of the reaction. He showed, however, that the place of sugar might be taken by that of any body which by the action of strong sulphuric acid yields grape-sugar, and ascertained, that mannite cannot thus replace sugar.

2. *Further History relating to the Reaction.*—Since the publication of Pettenkofer's notice, while some few other bodies have been observed to behave like cholic acid with sulphuric acid and sugar, no explanation has been forthcoming. Thus *taurocholic acid* ($C_{26}H_{45}NSO_7$), and glycocholic acid ($C_{26}H_{43}NO_6$) give the reaction, not improbably through splitting up by means of the sulphuric acid into cholic acid.

Hyocholic ($C_{27}H_{43}NO_5$), oleic ($C_{18}H_{34}O_2$), and lithofellic ($C_{20}H_{36}O_4$) acids are also known to yield this colour test. According to some authors amylic alcohol ($C_5H_{12}O$) gives it, while cod-liver oil is known to give it without the aid of sugar. More recently, Thudichum* has found a like reaction to be true of cerebrine, phrenosine, kerasine, stearoconite, lecithine, myeline, psychosine, and cholesterin, bodies occurring in brain substance.

3. *New Substances giving a similar Reaction.*—In following out certain lines of thought directed to the explanation of the foregoing facts, we were led by the light of the researches on terpenes and allied hydrocarbons, which have been published by one of us, to study other bodies in connection with this reaction, hitherto apparently unconnected with bile compounds.

Before proceeding to describe our new reactions and their ultimate bearings, we here give a list of substances which we have discovered to behave in common with those above mentioned.

Benzene (C_6H_6), phenol (C_6H_5OH), turpentine ($C_{10}H_{16}$), camphor ($C_{10}H_{16}O$), salicylic acid ($C_7H_6O_3$), pyrogallic acid (C_7H_6O), tannic acid ($C_{27}H_{22}O_{17}$), piperine ($C_{17}H_{19}NO_3$), morphine ($C_{17}H_{19}NO_3, H_2O$), clove and other essential oils, rape, cotton seed, colza, and mineral oils; also various fats.

Side by side with these we note the following substances, which (among of course many others) will not yield the reaction, for reasons hereafter to be expressed: benzoic and camphoric acids.

4. *Modifications of the Reaction.*—Pettenkofer himself showed that strong hydrochloric acid could be used in his test in place of the sulphuric acid, but stated that the intensity of the reaction was by no means so strong. Since then, it has been shown that acetic acid may be used in certain cases in place of the sugar. Here again, however, the colour produced is not so deep. We have found that in this direction inulin ($C_6H_{10}O_5$) can be used in place of sugar, if at the same time a trace of water be present; so also with potato starch. Inosite ($C_6H_{12}O_6, 2H_2O$) gives but a feeble reaction. We shall presently offer an explanation of all these reactions, and their modifications; in the mean time we pass on to a consideration of those substances which give the reaction without the addition of sugar.

5. *Particular Studies of Bodies yielding the Reaction without the addition of Sugar.*—In the course of Thudichum's researches, it transpired that cerebrine ($C_{17}H_{33}NO_4$), and certain allied bodies, gave by a process of decomposition (effected by means of baryta water or dilute acids) among other products sugar, but this was not observed until after it had been shown that these principles give with sulphuric acid alone the colour reaction in question. Thudichum attempted a diagnosis between this colour and that produced by bile compounds, by observing the differences presented in their absorption spectra. From the facts above given, it would appear that in these particular brain substances is present a particular group in combination with a radical related to sugar, and that through the agency of the sulphuric acid this combination is split up and rearranged, perhaps, with the elements of the sulphuric acid, in such a way as to produce a coloured compound. A similar case is presented, apparently, by the so-called hederic acid found in ivy leaves. Messrs. Davis and Hutchinson* have stated that this substance gives with sulphuric acid a purple colour, and they also observed, that when hederic acid was heated with dilute acids, there was obtained a body which reduced Fehling's solution. At the time one of us suggested that these results seemed to indicate that hederic acid is a saccharide belonging to the series discovered and investigated by Berthelot, for, if so, it would yield by a process of hydration, sugar and any acids whose residues had been previously combined therewith.

Cod-liver oil is a third instance of a body giving the colour test without the addition of sugar, and it is remarkable that this oil is said to contain acetin, a compound known to be derived from glycerin and acetic acid; remarkable because, as already stated, acetic acid can be substituted for the sugar in certain cases. It is to be observed that this reaction of cod liver-oil has been interpreted by most writers as evidencing the presence of special biliary matters in the oil, but there is no evidence on record bearing out this statement, and our observations render it doubtful.

6. *Special Investigation of certain New Reactions and Theoretical Considerations with regard to their Meaning.*—When camphor ($C_{10}H_{16}O$) is placed in strong sulphuric acid it readily dissolves, forming a yellowish red solution; when saturated the solution is of a deep red colour, and it is only upon long standing that a slight odour of sulphurous anhydride is apparent, otherwise the solution has a weakened camphor odour. This product gives with cane-sugar a most beautiful reaction; the colour is, however, as in all cases, quickly destroyed by water. From the solution of camphor in sulphuric acid, water precipitates a substance free from sulphur, and having so far as observed all the properties of the original camphor. Nevertheless, from what is to be described hereafter, it appears that in the sulphuric acid solution it exists as a sulpho-acid. When such a solution is treated with sugar, and water added to the product there results a precipitate which is slightly yellow, and after washing exhibits a tendency to cake. It is free from sulphur, but is competent to furnish, with strong sulphuric acid alone, the original violet colour in an intense degree. This result seemed at first sight to indicate that the body produced as described was a saccharide or a glucoside, and to gain information on this point many experiments were conducted, as follows:—A saturated solution of camphor in sulphuric acid was exposed to a freezing mixture, and treated with its own volume of concentrated cane sugar solution, stirring meanwhile. By adding the sugar drop by drop the temperature was kept throughout below 15° C., and thus carbonization of the sugar was prevented. There was thus formed a solid pasty pink mass, which was then treated with much water; frothing ensued, and gradual destruction of the colour. It was then filtered and the precipitate well washed. On boiling it with a very dilute solution of sulphuric acid, during three hours, the purple colour to which we have already alluded formed upon the warm sides of the dish, but ultimately no sugar could be detected in the solution by means of the copper test. From this it follows that the substance cannot be a saccharide, as ordinarily understood by that term. Nevertheless it is probable that strong sulphuric acid has the power, possibly by the abstraction of water, of entering into combination conjointly with the camphor and sugar residues. Such a constitution seems at the first blush to express the nature of the coloured body. When treated with water sulphuric acid is re-formed, and there results a combination which only requires strong sulphuric acid again to restore primary conditions.

As regards the reactions yielded by turpentine, phenol,

* 'Rep. Med. Off. Privy Council, etc.' New Series. No. III., 1874.

* *Pharm Journ.*, Third Series, No. 327, p. 275.

and benzene, a certain relation is evident between these. All these substances give, with sulphuric acid and sugar, the colour test which was supposed by Pettenkofer to be peculiar to bile. The turpentine reaction is very striking, as is also that of phenol, while that of benzene, though distinct, is not so intense. The relation we allude to, comes out from the fact that salicylic acid yields the reaction but faintly, and benzoic and camphoric acids not at all, pointing to the probability that camphor and camphoric acid stand in somewhat similar relation to turpentine, as phenol and benzoic acid to benzene; that camphor indeed may possibly prove to be the phenol of turpentine, and not a ketone as is ordinarily supposed. The hydroxylic nature of camphor is further testified by its behaviour with zinc chloride and phosphorus pentasulphide, both of which reagents by the removal of water yield cymene ($C_{10}H_{14}$). On the other hand, it is to be admitted that some of the chlorinated derivates of camphor would seem to show that this substance differs in its constitution from ordinary alcohols. There is no strong reason why it should not be regarded in both lights, for the structure of compounds is not a fixed quantity, but only a relative one to others influencing their production and their reactions.

The formulæ of these substances and others are as follows:

Benzene, C_6H_6.
Phenol, C_6H_5, OH.
Benzoic acid, C_6H_5, COOH.
Salicylic acid, C_6H_4, OH, COOH.
Turpentine, CH_3, C_3H_7, C_6H_6.
Camphor, CH_3, C_3H_7, C_6H_5, OH. (?)
Camphoric acid, CH_3. C_3H_7, C_6H_4 (OOH)$_2$. (?)

In connection with these formulæ, those of pyrogallic and tannic acids are also instructive.

Pyrogallic acid, C_6H_3, 3HO.
Tannic acid, $C_{27}H_{22}O_{17}$.
Clove oil, $C_{15}H_{24}$.

The principal idea conveyed by a study of the foregoing facts, and the generally accepted formulæ for these substances, is that all bodies which give the colour reaction under study are, on our hypothesis, which however we refrain from giving in detail, benzene derivatives. And while, for instance, piperine gives there action without sugar and morphia with it, we may assume, *pro tem.*, that the first of these substances contains both benzene and sugar radicals, while the latter contains only a benzene radical. We abstain, however, from entering into the many speculations which arise in considering the connections of particular structure, with the reaction in question. Such speculations will come in better when we know more concerning the facts we are investigating. It may be that not only is the reaction referable to a particular structure, but perhaps to a particular carbon-atomic combination. Indeed such a result would seem to be rendered necessary, by the fact that oleic acid and other members of the fatty acid series likewise yield the reaction.

As above stated, acetic acid may take the place of sugar in many of these reactions, and it is not without difficulty to attempt anything like an explanation of this matter. It certainly never gives it so strongly, but this may be accounted for by the liability of the acetic acid employed to contain water, which, be it remembered, at once destroys the colour.

It is worthy of remark, however, that the empirical formula of acetic acid multiplied by three, gives that of grape-sugar.

A further difficulty is encountered since, as shown, hydrochloric acid may play the part of sulphuric acid, for from the results above detailed there is strong evidence to show that the acid radical forms an integral part of the coloured substance. For the time it may be assumed that the colour is dependent upon the constitution rather than the empirical composition of the body, in which case a general formula representing all modifications of the reaction is tenable.

The formula of a sugar may be taken as illustrative of our meaning, in which case the coloured substance may be supposed to be derived from it by the replacement of hydrogen or hydroxyl by a benzene residue, on the one hand, and the radical sulphuryl (or corresponding acid radical) on the other hand. And such a conception is as applicable to acetic acid as it is to starch and sugar.

In short, while the whole subject is fraught with interest, it covers an exceedingly wide field. It leads, for instance, to the question of the general constitution of sugars, which, admitted though they be as polyatomic alcohols, are but imperfectly described by such a denomination. Among such alcohols phenose or hexaphenol, apparently finds a place, notwithstanding its non-fermentable character.

We propose in the future, and indeed are at present occupied upon work directed to the elucidation of some of these points, and to a further study of the saccharides and bodies shown to be related to them, by the observations indicated in this paper.

Supplement.

As the above paper when read before the Chemical Society raised some discussion, and as the Society has since requested the authors to omit in its publication all theoretical considerations relative to and arising out of the investigations with which the paper is concerned, we think it well to supplement it here with some additional observations which lend farther weight to the views therein expressed. In the first place, however, it should be stated that the authors objected to withhold the theoretical considerations in question, and hence the paper has not appeared in the Society's Journal. It is desirable once more to state that the whole communication is preliminary in nature, and that it is attempted to illustrate the views which we advance rather by the subject matter than by direct enunciation. Since writing out the paper we have found that many other substances give, with sulphuric acid alone, the violet reaction in question, and the list of those bodies giving it with sugar and acid has also been extended.

Amongst the former class for instance we have *Salicin.* This crystalline substance occurs, as is well known, in the leaves of the poplar, willow and other trees, and its decomposition by acids or ferments is thus represented—

$$C_6H_4(OH)\cdot CH_2(OC_6H_{11}O_5) + H_2O = C_6H_{12}O_6 + C_6H_4(OH)\cdot CH_2(OH)$$

That is to say it yields glucose and saligenin or salicylic alcohol. Now this latter substance is related to salicylic acid, as is seen by the formula of this last-named body, which is C_6H_4(OH)CO(OH). In other words salicylic or orthoxybenzoic acid may be viewed as derived from the alcohol by the replacement of the H_2 in the CH_2 group by one oxygen, and, viewed under this light, the fact that salicylic acid gives with sugar and sulphuric acid the violet reaction we have above described becomes one of interest and importance. It is not proposed, however, to enter here into the exact meaning, as we apprehend it to be, of this reaction; that we reserve for a future communication.

Phloridizin, a glucoside occurring in the root bark of pear, apple, plum and cherry trees, also gives with sulphuric acid a violet coloured reaction, doubtless referable to a similar state of combination as that spoken of under salicin. Phloridizin is split up by dilute acids, etc., as follows:—

$$C_{21}H_{24}O_{10} + H_2O = C_6H_{12}O_6 + C_{15}H_{14}O_5.$$

As stated in the paper, morphia and piperine, two isomeric bodies, give different reactions; the former requires the presence of sugar whilst the latter gives with sulphuric acid alone the violet colour. This phenomenon would appear to indicate the existence in piperine of a sugar-like molecule, and although this has not been proved hitherto, yet the researches of Fittig and Mielck on piperic acid are not opposed to such a notion. It is our intention to carry on an investigation in this direction so soon as opportunity may permit.

Coniferin crystals contain $C_{16}H_{22}O_8+2H_2O$, and are known to strike with strong sulphuric acid a brilliant violet reaction, and this substance, like salicin gives on decomposition with dilute acids or ferments (as shown by Tiemann and Haarmann) glucose, and a crystalline substance containing $C_{10}H_{12}O_3$, which yields on oxidation vanillin—

$$C_8H_8O_3 \text{ or } C_6H_3\left\{\begin{array}{l}OCH_3\\OH\\COH\end{array}\right., \text{ a benzene derivative viewed}$$

by the authors quoted, as a methyl-ether of protocatechuic aldehyde.

To recapitulate thus far, it has been shown that certain substances which yield by hydration glucose and some derivative of benzene, give when treated with strong sulphuric acid a violet colour. From this it may be inferred, bearing in mind the above details of the camphor experiments, that the coloured body is a conjugated compound in union with the acid or its radical, no matter whether water be withdrawn or not. Certain other benzene derivatives yield with strong sulphuric acid no colour, but in certain instances sulpho-acids (for instance phenol), and these when treated with sugar (cane or glucose) give the violet reaction also. There can be no misgiving as to the inference to be justly drawn from these observations; at least it is reasonable to believe that the acid, either by removing the elements of water or otherwise, unites the radicals of sugar and the benzene derivatives employed by means of itself and thus performs a synthetical function.

It is found, however, that only benzene derivatives of a certain type behave in this way. What is that type? This is one of the questions we propose to solve, and its solution will probably throw much light upon the relations of the fatty acid series to the so-called aromatic compounds. For it is to be remembered that palmitic acid can be obtained from oleic acid, and the latter body gives with oil of vitriol and sugar the violet reaction we are studying.

This kind of research is attended with more than ordinary difficulty and is, from the nature of the products, to a large extent of a thankless character; it is made even more so by the discouragement it has received at the hands of a "distinguished member" of the council of the Chemical Society of London.

RESEARCHES ON MELEZITOSE.*

BY A. VILLIERS.

The plant, *Alhagi Maurorum*, which exudes this manna, grows in Persia, and is used there as a purgative, under the name *Turanjbin*. After being boiled with animal charcoal, and evaporated to a syrup, it crystallized after some months in small brilliant crystals, which on recrystallization from alcohol formed large white crystals of the formula $C_{12}H_{22}O_{11}+H_2O$. It is dextrorotatory, its power being $+94°\ 48'$, or for the sodium flame, $+88°\ 51'$. On boiling with an acid, it is converted into glucose, and its rotatory power is reduced to that of glucose, viz., $+53$. It then reduces Fehling's solution. Nitric acid oxidizes it to mucic and oxalic acids. Its melting point is 140°. It is thus seen to be identical with Berthelot's melezitose. It crystallizes in monoclinic (clinorhombic) prisms.

The mannite of alhagi also contains cane-sugar, which may be isolated by treating the mother-liquor of the melezitose with alcohol, and adding ether till a slight precipitate is formed. Crystals of cane-sugar are then deposited. The mother-liquor acts like a solution of cane-sugar containing dextrorotatory foreign substances, which are not fermentable with beer-yeast.

Commenting on the preceding paper, Berthelot says† the occurence of *melezitose* in the exudations of one of the Coniferæ and in a leguminous plant, one found in France, and the other in Affghanistan, is interesting. *Trehalose* exists in Echinops, and in cut rye, also in a number of mushrooms, and moulds. As cane-sugar is found together along with its isomeric melezitose, the mode of formation of the two sugars may be imagined. Cane-sugar, melitose, and milk-sugar, are formed by the union of two polyatomic alcohols, with elimination of water, and these two alcohols are different from each other. But melezitose and trehalose yield only one alcohol when decomposed, viz., grape-sugar (glucose). The two latter sugars may therefore be compared with ordinary ether; and if the glucose obtained from each of these two sugars is the same, it must be granted that two molecules of glucose may be united in two different ways, according to the molecule of water replaced. If glucose be viewed as at once a pentatomic alcohol and a monatomic aldehyde, three distinct isomeric types may theoretically result from the union of two molecules with elimination of water, viz.:—

1st. A *mixed ether*, the water being eliminated from two alcoholic groups, one in each of the two molecules of glucose. The product would thus be a diatomic aldehyde and an octatomic alcohol. A large number of isomerides is possible, depending on the primary, secondary, or tertiary nature of the alcohol groups affected.

2nd. A *mixed aldehyde*, a monatomic aldehyde like crotonic aldehyde, formed by the union of two molecules of a lower aldehyde, with elimination of water, and at the same time a decatomic alcohol.

3rd. An *ether-aldehyde*, the alcohol group of the one molecule of glucose combining with the aldehyde group of the other, water being eliminated. This body would be a monatomic aldehyde and a monatomic alcohol.

Of these three types, only the first and last can reproduce their constituents by assimilation of water.

This explanation would be sufficient were one of the constituent molecules of glucose transformable into ordinary glucose by the prolonged action of acids. But the author has not thought it necessary to theorize on the existence of isomeric saccharoses derived from the same glucose, and capable of reproducing them like trehalose and melezitose.

SHELLAC AND SARCOSINIC ACID.*

BY J. MERTZ.

This variety of shell-lac was obtained from Mexico, where it is known as "Soma de Sonora," and called by the Indians "Arré." It exudes from the *Mimosa coccifera*, the native name for which is Tzinacaia cuitlaquahuitl. It has an astringent, bitter taste, and a yellowish or brownish colour. It is used as a remedy for diarrhœa and uterine discharges.

East Indian shellacs are treated with water, before they are delivered to the European market, to extract an acid substance and a red dye, which forms 10 per cent. of the weight of the crude gum.

The American specimen lost 6 per cent. of its weight on treatment with hot water. It was then treated with alcohol, which dissolved about half; the solution, on evaporation, left a transparent, brittle residue, which had all the appearance of good shellac. The portion which refused to dissolve in alcohol was soluble in boiling potash with a fine red colour; on addition of acid the solution became colourless, and a yellowish-white resin separated, which was partially soluble in alcohol. These reactions correspond with those of shellac.

The aqueous solution contained two substances,—a colouring matter and an acid body. The colouring matter was removed by lead acetate, and the filtrate evaporated after removal of the lead. The colouring matter was soluble in water with a fine red colour and insoluble in alcohol and in ether. It could not be obtained in a crystalline state. Its solution had a strong acid reaction and showed a strongly acid reaction. The filtrate from

* *Compt. Rend.*, lxxxiv., 35. *From the Journal of the Chemical Society*, April, 1877. † *Compt. Rend.*, lxxxiv., 38.

* *Arch. Pharm.* [3], viii., 234—251. From the *Journal of the Chemical Society*. April, 1877.

the colouring matter deposited crystals, easily soluble in water and insoluble in alcohol and in ether. They were purified by solution in boiling aqueous alcohol, from which they deposited as a powder on cooling. The formula of the acid was found to be $C_3H_7NO_2$, and it was named sarcosinic acid.

The *barium salt* is an amorphous powder, soluble in water but not in alcohol. The *silver salt*, $C_3H_6NO_2Aq$, forms yellowish-white nodules, and is reduced on exposure to light. The *sodium salt* crystallizes with 6 molecules of water, and forms colourless hexagonal tables. The *calcium salt* crystallizes with one molecule of water, and is an amorphous powder.

The acid does not evolve ammonia when boiled with caustic soda, but on heating with soda-lime it does. It melts at 195°, and chars at a higher temperature without subliming. The acid is isomeric with alanine, sarcosine, lactamide, and urethane. The two latter, however, are indifferent bodies; lactamide when heated with soda decomposes into lactic acid and ammonia; urethane into carbonic anhydride, ammonia, and ethyl alcohol. Sarcosine unites only with acids, and it is doubtful whether it is an amido-acid; it evolves methylamine on ignition with soda-lime. Alanine, when treated with nitrous anhydride, yields lactic acid. These bodies are assumed therefore to have the following constitution:—

$$\begin{array}{cccc} \begin{array}{l} CO.NH_2 \\ | \\ CO.OC_2H_5 \end{array} & CH_2\left\langle\begin{array}{l} CH_2OH \\ CO.NH_2 \end{array}\right. & \begin{array}{l} CH_2.NH(CH_3) \\ | \\ CO.OH \end{array} & CH_2\left\langle\begin{array}{l} CH_2.NH_2 \\ CO.OH \end{array}\right. . \\ \text{Urethane.} & \text{Lactamide.} & \text{Sarcosine.} & \text{Alanine.} \end{array}$$

Sarcosinic acid appears to be more nearly related to sarcosine and alanine than to lactamide or urethane; yet sarcosine is a base, while sarcosinic acid is a true acid. The acid, however, was found to form a hydrochloride and nitrate. With nitrous anhydride nitrogen was evolved and lactic acid was formed. The acid therefore has great analogy to lactic acid, from which it differs only in taste, crystalline form, and marked acid properties. The author attributes to it the same constitutional formula as to alanine, but intends to attempt to prepare it synthetically to decide wherein the difference lies. E. Reichart attributes to it the formula $CH_2.NH_2.CH_2.COOH$.

THE ALTERATION OF CANTHARIDIN IN CANTHARIDES.*

BY R. WOLFF.

The experience that cantharides kept dry remain active for a long time, whilst when damp they rapidly lose their activity, and further the property of cantharidin not to be broken up under the action of strong sulphuric acid whilst in the cantharides it loses almost directly its vesicatory action upon the skin, led the author, who is an apothecary in Buenos Ayres, to the conclusion that there must be present in cantharides some substance which, assisted by moisture, effected a change in the cantharidin. As it is known that there is an evolution of ammonia when an aqueous solution of old cantharides is heated with caustic potash the opinion appeared to be justified that ammonia might play an important part in the decomposition of the cantharidin.

To clear up this point the author extracted the cantharidin from 100 grams of *Lytta aspersa*. This species is used in Buenos Ayres, and is said to excel the ordinary *Lytta vesicatoria* in its greater activity, which, when carefully dried, the insects retain during many years. From the 100 grams he obtained 0·815 gram of pure cantharidin, and also from the green-brown oily substance from which the cantharidin had separated, upon treating it with ether and chloroform, 0·46 gram of a new body in tabular crystals, which, although it also had a vesicatory action, differed from cantharidin in its chemical properties as well as its form of crystallization.

The crystals of this new body are difficultly soluble in cold water (about 1 in 6600); they are rather more soluble in boiling water, but separate upon cooling. In alcohol they dissolve in the proportion of 1 in 680; in ether, 1 in 390; in chloroform, 1 in 60. Hydrochloric acid is without action upon them; on the other hand, they are readily dissolved by nitric and sulphuric acids, especially when hot. In the latter case, however, decomposition appears to take place, since upon the addition of water cantharidin is precipitated, ammonium nitrate or sulphate being formed at the same time.

When pulverized the new body dissolves at the ordinary temperature in solution of potash or ammonia, and upon the addition of an acid is again precipitated unaltered. If the ammoniacal solution be allowed to stand for some time in a moderately warm place, after the excess of ammonia has been given off the solution readily reddens blue litmus paper. If the ammoniacal solution be concentrated crystals of the compound with ammonia are formed, which decompose upon drying, with formation of ammonia, and are then difficultly soluble in cold water.

Upon evaporating the ammoniacal solution to dryness a white crystalline residue is obtained that appears to be insoluble in cold water, but in boiling water it dissolves without difficulty. From the solution, which reddens litmus paper, acicular crystals separate upon cooling, which are not altered upon cooling. This is a second nitrogenous compound of cantharidin. The author made no closer investigation as to the composition of these two compounds. In the remainder of the paper he simply distinguishes them as No. 1 and No. 2.

Compound No. 2, placed on the skin, acts a vesicant. It dissolves with difficulty in cold water, but readily in boiling water. In alcohol, ether, and chloroform it is very difficultly soluble, even when warmed. In acetic ether it is easily soluble and upon evaporation cantharidin is left as a residue. The crystals dissolve readily in strong sulphuric acid, and no precipitation takes place upon the addition of water. Strong nitric and hydrochloric acids behave similarly. It appears as if the acids enter into combination without causing decomposition. In ammonia this compound No. 2 dissolves rather freely, but separates in acicular crystals upon the addition of acids. If the ammoniacal solution be allowed to evaporate slowly, crystals are formed which consist of compound No. 2 and ammonia; upon drying and warming these crystals are decomposed with evolution of ammonia. It is also dissolved by potash solution, but it then separates unaltered upon the addition of acids. Upon evaporating the solution in alkali to dryness, ammonia is evolved and part of the compound No. 2 passes into compound No. 1.

No. 2 appears to undergo no change upon fusion or sublimation; No. 1 also appears to melt and sublime without loss of weight.

If solution of a zinc salt be added to solution of cantharidin in caustic potash as long as any precipitate is formed, then a sufficiency of ammonia solution to dissolve the precipitate produced, and finally an acid in excess, the compound No. 1 separates as a white granular crystalline precipitate. Salts of copper and magnesia act like the salts of zinc, as probably do others that behave similarly towards ammonia. As magnesia salts are present in considerable quantity in cantharides, the author is of opinion that these, after the death of the insect, in presence of ammonia, quickly induce an alteration of the cantharidin into compound No. 1, and that this change is more rapid and complete in proportion as the conditions are favourable, which appears to be the case in the European cantharides that so soon lose their activity. If by moisture a progressive formation of ammonia is favoured the compound No. 1 is formed, and this after a time is in turn converted into compound No. 2, which then probably enters into combination with acids contained in the cantharides. The author has no doubt that a more exact investigation of the nitrogenous compounds would afford a method of recovering the cantharidin that has undergone alteration in cantharides, the details of which would vary according to the degree of change that has taken place.

THE BENEVOLENT FUND DINNER.

WHEN recapitulating last week the other subjects mentioned in the Report of the Council we purposely abstained from making any reference to the Benevolent Fund, not because we under-estimated its importance, but in order to leave ourselves at liberty to allude to it more prominently on the eve of the festival by which we hope it will be much benefitted. So now, at the risk of being thought wearisome in telling an oft-repeated story, we shall venture once more to make an appeal on behalf of the Fund, based on the facts disclosed in the Balance Sheet, and if in doing so we err by iteration, we must plead the goodness of the cause, for "Charity suffereth long, and—is kind."

The Balance Sheet shows that in 1876 the sum of £620 was paid in annuities to twenty-four persons, at the rate of £30 each yearly. Besides this a sum of £470 was distributed in grants of from £10 to £20 each to thirty-eight persons, who were themselves registered chemists and druggists or their widows or orphans. On the other hand, the sum received in donations and annual subscriptions was nearly £1360 and the interest on invested capital amounted to £457 10*s.* making the total income a little over £1800. From this has been disbursed, as above described, a total sum of £1090, and the entire expenses charged to the Fund for administration were only £100.

It will be noted that the excess of receipts over expenditure has allowed of the investment of a further sums in consols, and this might lead a superficial observer to the conclusion that the receipts have been ample as compared with the expenditure. But such a conclusion would not be a correct one, for it must not be lost sight of that this investment does not nearly equal the responsibility incurred by the increase of four in the number of annuitants, by which step a draft for £120 annually has been drawn on the future. Whilst it may be right to rely on the generosity of the future to some extent, it is well to remember that it will too surely bring its own claimants for relief, in whom naturally the subscribers of that time will feel a greater interest than in those of to-day.

One of the most regrettable things connected with the subject is the truth of the statement made in the circular recently sent out, that of the nearly 14,000 persons registered as chemists and druggists only 2300, or about one in six, subscribe to the Fund, leaving upwards of 11,000 who are not subscribers. To speak plainly this is not as it should be; the reasons which are thought sufficient by some persons for abstaining from joining the Pharmaceutical Society have no force here. The Fund is free for the relief of all registered chemists, their widows and orphans, and the published list shows that it is so administered, and we cannot imagine that any person, because he disapproved of the aims or quarrelled with the policy of the Pharmaceutical Society, would be deterred from recommending a worthy applicant for relief, or from seeking it himself if he needed it.

Unfortunately, although the sums expended annually in carrying out the object for which the Fund was established have been as much as warranted by the income, only the fringe of the work has been touched as yet. True, we have twenty-one annuitants at £30 each, but these might be increased to fifty at £50 each without extravagance, whilst the temporary grants might be multiplied manifold. The education of orphans, which in many other callings has been already provided for, has only just been tentatively mooted. As for almshouses for the old! Well, we hope that these, too, will be provided in the good time that's coming. Meanwhile we respectfully urge all our readers to do what lies in their power towards strengthening the hands of the administrators of the Fund, by making the sum realized in connection with the Dinner next Tuesday a large one. Those who will not be present on that occasion will be able to show their sympathy with this special effort, by sending their own subscriptions and donations, and those they may obtain from their friends, to the Secretary, Mr. ELIAS BREMRIDGE, 17, Bloomsbury Square, on or before the 15th.

THE CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

BY the courtesy of the Secretary we have been favoured with an early copy of the Report to be presented to the Members and Donors of the Chemists and Druggists' Trade Association at the First Annual Meeting, to be held at the Freemasons' Tavern, on Tuesday next. The Report commences by recounting the steps that have been taken to make the objects of the Association known since its formation at Birmingham in July last. The result of these has been that the annual subscriptions from 2880 persons have amounted to £720, besides which £1028 has been promised in donations. The total income up to the 30th of April was £1661 5*s.* 6*d.*, and the expenditure £1037 16*s.* 9*d.*, leaving a balance in hand at that date of £623 8*s.* 9*d.* The law business that has been under the notice of the committee consists of the "milk of sulphur" cases at Runcorn, where the appeal was successful, the balsam of copaiba cases at Salford, and the "counter prescribing" case at Nottingham. The appeal in the last case will be heard in the Queen's Bench Division of the High Court of Justice, but the date is not yet fixed. Two leading counsel and a junior are to be engaged to undertake the argument on appeal. The interview of a Deputation with the Law and Parliamentary Committee of the Pharmaceutical Society with respect to Co-operative Stores is referred to, and it is stated that the Committee of the Association having decided to take Counsel's opinion on the subject, a Sub-Committee is engaged in instructing the Solicitor to draft a case. The formation of a Scotch branch of the Association is also recorded. No elections of the General Committee have yet taken place, it being thought desirable, in order to secure a thoroughly representative body, that the elections should be postponed until the districts have been more thoroughly canvassed. The Committee, therefore, recommend that the General Committee for the ensuing year should be appointed at the Annual Meeting. In conclusion, it is pointed out that heavy liabilities will be incurred by the Association in connection with the appeal to the High Court of Justice, and that the Association will need continued support and wider extension, as its present financial position is largely owing to special donors.

THE MEETINGS OF NEXT WEEK.

THE meetings next week in connection with the Pharmaceutical Society will commence on Tuesday, at 6.30 p.m., with the Dinner in aid of the Benevolent Fund, which will take place at the Freemasons' Tavern. On Wednesday morning, at noon, the Annual General Meeting of Members of the Society will be held at 17, Bloomsbury Square. Lastly, on Wednesday evening, the Annual Conversazione will be held at the South Kensington Museum. Full details as to tickets for the Dinner or the Conversazione will be found in the official notices, but it may be useful here to remind intending visitors to the Conversazione that the officials at the Museum decline in all cases to take charge of hats. A programme of the music will be provided as usual for each visitor.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening next, May 17, at eight o'clock, when a paper will be read by Mr. CHARLES SHAPLEY, on "Practical Dispensing."

THE EBERT PRIZE.

WE learn from *New Remedies* that the Committee entrusted with the awarding of the Ebert Prize is again compelled to report that none of the essays sent in come fully within the terms of the stipulation of the donor, that they should contain an original investigation of a medicinal substance or improved methods of merit for the preparation of chemical or pharmaceutical products. The prize has only been in existence three years, and this is the second time that it has failed to be awarded.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

ASSISTANTS' SECTION.

The final meeting of the session was held in the Managers' Library, Anderson's University, on April 25th 1877. Mr Boa, President, in the chair. There was a good attendance of members. The minutes of last meeting were read and confirmed.

The chairman then called upon Mr. John E. Fairlie to deliver a lecture on "The Sun and its Rays;" it was attentively listened to throughout, and the striking and very successful experiments were much applauded. At the conclusion Mr. Fairlie was awarded a hearty vote of thanks for his instructive lecture.

The secretary then read the committee's annual report, which was unanimously adopted.

The election of office-bearers was next proceeded with, when the president, vice-president, and secretary were re-elected; the members of committee and the assistant librarian were also re-elected.

Mr. Simpson moved "That the assistants' section appoint a committee to try to obtain a reduction of the hours of labour on Sunday."

Mr. Phillips seconded the motion and it was unanimously agreed to.

A committee was then appointed, with Mr. Simpson, convenor.

At a meeting of the committee held on the 2nd of May, it was resolved to petition the masters to reduce the time of keeping open their places of business to four hours. From 10 till 11 a.m., 1 till 2 p.m., and 5 till 7 p.m. are the hours recommended by the committee.

HULL CHEMISTS' ASSOCIATION.

A special general meeting of the chemists and druggists of Hull and the district was held at the Church Institute, Albion Street, Hull, on Wednesday evening, April 25.

The meeting was called to receive Mr. Jones, President of the Chemists and Druggists' Trade Association. Mr. C. B. Bell, President of the Hull Chemists' Association, occupied the chair, and there was a good attendance.

The President, in a few brief remarks, introduced Mr. Jones to the meeting.

Mr. Jones commenced his remarks by referring to the course taken by the Association in respect to the balsam of copaiba prosecutions and the successful appeal at Runcorn against the conviction for selling milk of sulphur, as before reported in this Journal. He then alluded to the much more serious case of Mr. Shepperley, at Nottingham. This case had caused the Association great anxiety, because they felt that if chemists were to be prohibited from prescribing over the counter it would mean ruin to many. He meant prescribing for simple cases: toothache, sore throat, or cases of that description. If prescribing for simple cases like these was to be stopped half of the chemists in the kingdom would soon have to shut up their shops. The Association did not think that was the meaning of the Act, and they had instructed counsel to look into the matter. They would have to pay heavy fees, but they did not care; they meant to argue the case in the Court of Queen's Bench. There had been a similar case at Birmingham, in which the defendant was fined £20 for prescribing. Mr. Reeves, solicitor, Birmingham, appeared for the prosecution, who had put a detective on to watch, the same as had been done at Nottingham. The Association complained that officers paid by the public should be sent round the town to get up prosecutions of this character. If any one wanted cases of this kind getting up they should employ their own officers and not men who were paid by the ratepayers. The case was reported by the Birmingham *Daily Post*, and that journal had a very sharp article on the subject, complaining of police officers being employed in work of this kind. Mr. Reeves, the solicitor, was rather stung by this article and wrote a letter to the paper with reference to it. Mr. Jones here read the letter in question, and remarked that this gentleman rather contradicted what had been said in the case of Mr. Shepperley. He might say that some astonishment had been felt at the Pharmaceutical Society not taking up this case. He understood that that Society did at first contemplate moving in the matter, but they appeared to have changed their minds. He thought the Society had been misguided by certain remarks relating to Mr. Shepperley having used a stethoscope. The Association had made strict inquiries as to the truth of this, and as to whether Mr. Shepperley when visited by patients took them out of the shop into a back room. They found that he did not use a stethoscope, for the simple reason that he had not one in his possession. The case was one of simple prescribing over the counter and therefore the Association had taken this matter up. He explained how they stood in the case of Mr. Shepperley, but if the counsel on each side, (who had all the facts before them,) would argue the case between themselves it would save a great deal of expense to both parties. They should, however, push the matter on, in the hope that they would get the appeal heard this term. Another person in Birmingham had been threatened, but the judge had allowed the case to stand over until July. Another person in a different part of the country had been also summoned, and had been convicted for visiting. The Association would do nothing in a case like that, but, when one of their members was found merely prescribing over the counter they considered it their duty to support him. One thing he would like his hearers to observe was that if ever they were threatened with prosecution for adulteration, they should always take care to have a sealed sample of the article in question. He also wished to impress upon them the necessity of only prescribing behind the counter for simple cases and on no account to go out visiting. He thought he had now stated what the Association had done and what it had in hand. They did not, however, know what course the Fates might take if this appeal went against them, but if it did, they did not intend to let the matter rest. They would ask the Local Association to help them because they meant to go to Parliament and see if they could not get an alteration of the law, in order that chemists may be able to prescribe for simple cases. He was pleased to say that at the present time the Association numbered about 2500 members, and they hoped to get a considerable increase, and in fact had done since this case had been on. He wished to impress upon those present the desirability of being united together on these matters of protection. They did not wish to attack any one, but merely to be allowed to conduct their business in a proper manner. They should put aside all petty differences and be strong and compact for the defence of their own interests and of the interests of the chemists and druggists of the whole country, and in conclusion he hoped that a large number of the chemists of Hull would join the Association which had been formed.

Mr. Baynes moved the first resolution, "That this meeting having heard the aims and objects of the Chemists and Druggists' Trade Association, as explained by the president, heartily approves of the same and pledges itself to support the Association by every means in its power." Mr. Baynes remarked that he would be the last man to encroach upon the rights of the medical profession, but for many years he, and many who were now around him, had done the same as Mr. Shepperley had done, and had done it without let or hindrance or any doubt as to its perfect legality. It so happened that in the case of Mr. Shepperley, the man prescribed for really ailed nothing at all. The Nottingham judge appeared to be very much struck with the fact that Mr. Shepperley looked down the man's throat, but that was the only way in which the chemist could tell whether anything was the matter with the man. He could not understand why the Pharmaceutical Society had not taken action in the matter. The Parliamentary committee of which, for four years, he was a member, always discussed every subject most thoroughly, and it was a very rare thing for their decision to be reversed. They knew that the Parliamentary committee did recommend this case to be defended, but the matter was shelved at the council next day. The Pharmaceutical Society had given the chemists the best possible reason for supporting this Association which he thought at one time to be unnecessary. The work which was being done by this Association was what should be done by the Pharmaceutical Society. That society had many thousands of pounds in hand as a Defence Association, and he remembered that the Pharmacutical Society was established in 1841, not only for the promotion of education but for the protection of those who carry on the trade of chemists and druggists. But for the fact of the trade being then harassed and threatened as it was now, the Pharmaceutical Society would have had no existence for a long period. He was extremely disappointed and was afraid that by the action of the society, strong moral support had been given to the Apothecaries' Company. He was afraid the cost of the case would be very heavy, but it would be nothing compared to the privileges which the trade now enjoyed and which it was sought to take away. He had done a certain amount of prescribing for many years although he did not like it, and never did. But he considered chemists were not amenable to the laws for that, and only were so when they undertook to do what they were not allowed. He would certainly join with Mr. Jones in urging upon those present never to go out visiting and that their counter prescribing be as much limited as possible. He advised them only to deal with simple cases, although what simple cases were was better understood than expressed. In conclusion, Mr. Baynes expressed his hearty approval of the resolution.

Mr. Anthony Smith in seconding the resolution dwelt upon the necessity of unity in the trade. He was sure the steps taken in Birmingham to form this Association would be the means of greatly strengthening the trade throughout the whole land and the chemists would be blind to their own interests if they did not support it. They had every reason to be grateful to Mr. Jones for coming down and giving impetus to the movement and throwing a little spirit into the trade in Hull. He had no doubt, after the explanations which they had heard, they would all join heartily in the Association which promised such beneficial results to them. If the appeal which had been spoken of terminated successfully the members of the trade would have every reason to bless the efforts of their friends in Birmingham. The resolution was then adopted unanimously.

Mr. F. Earle moved the second resolution, which was as follows: "That this meeting, recognizing the usefulness of the Trade Association, respectfully urges upon every chemist in this town and district the advisability and necessity of joining and subscribing to its funds." Mr. Earle thought this resolution must appeal to every chemist in the town with success. It was a comfort to think that for the sake of the 5*s.* subscription to this Association every chemist could rest satisfied that he would have his battles fought for him. He thought if the trade was to be attacked in the way in which it was being attacked there was enough spirit amongst the chemists to rouse them to defend themselves. The chemists were not seeking to do anything but what had been done from all time in the trade, and surely they would not submit to the indignities which it was sought to put upon them.

Mr. Councillor Chapman seconded the resolution, remarking that he believed no chemist in Hull would object to paying 5s. or even more to secure the advantages of this Association. He might say that he had visited it many times, although not recently. He had never experienced any ill feeling from the doctor, although he knew nearly every doctor in Hull. If he was the first to be attacked he should look to the Association for help, if others were attacked he should be glad to subscribe to their help.

Mr. Kirby James, from Beverley, here apologized for the absence of the Beverley chemists, but pledged those gentlemen to raise £5 or £6 yearly towards the support of the Association.

Mr. G. Myers supported the resolution, remarking that he was present at the formation of the Association, and from the enthusiastic character of the meeting he was certain the matter had been warmly taken up by the chemists in that part of the country. He thought every one in this town and neighbourhood should join this Association. He thought if the appeal case were lost many prominent chemists would be immediately summoned for prescribing over the counter, and he thought it was as well to be prepared beforehand and not be found unprepared when the enemy was at the gates. He trusted the chairman would have a goodly list of subscribers at the close of the meeting, and that some gentlemen would not only pay their subscriptions but give a donation to the funds.

Mr. Goldsmith, one of the oldest chemists in Hull, remarked that he remembered a chemist being fined £20 and costs thirty years ago for out-door visiting (he afterwards graduated as a surgeon), and he believed the law stood the same now as then and the efforts of the trade should be directed towards having it altered. He thought it was the duty of every chemist to subscribe to this Association and to make every effort to defend their right.

The resolution was then carried *nem. dis.*

Mr. G. Myers moved, "That the best thanks of this meeting be and the same are hereby given to the Executive Committee of the Chemists' Trade Association for having taken up the recent milk of sulphur case and having carried the appeal to a successful issue." Mr. Myers remarked that he did not think the chemists in this town had any fear of being unfairly treated with regard to adulteration, seeing that a prominent member of our trade was the public analyst; although the chemists did not court any favour in the matter they were not likely to be harassed by any such frivolous case as that of the milk of sulphur prosecution. He did not think the members of the trade were guilty of adulteration, but he did not mean to say that none of the drugs were adulterated. They were not, however, adulterated by those who sold them. It was very difficult to ascertain what was the standard of many drugs. These were imported in an impure state, and it was very unfair that the chemist should be prosecuted when he had no knowledge of the adulteration. The chemists courted a fair inquiry into matters of this kind, and he trusted that when any of them were attacked, as they might be, they would take the hint given them by the President of the Association with regard to sealed samples.

Mr. J. F. Smith seconded the resolution, observing that the trade was in a very unfair position with regard to prosecutions for adulteration. Nearly all the drugs for which they were most liable contained some ingredient which had been gathered with them in some manner or other in the collection. Unless there was some defined standard for drugs he did not see how it was possible to keep clear of prosecutions for adulteration of some kind or other. They might be prosecuted for nearly everything they sold, because even the dry roots contained a certain amount of dust which had clung to them in transmission to the seller.

The motion was then carried unanimously.

The Chairman said he had a very pleasing duty to perform; he begged to move, "That the best thanks of the chemists of Hull and the district be accorded to Mr. Jones for having come down from the Chemists and Druggists' Trade Association, and hopes that success will attend the efforts of the executive on behalf of the trade." He thought all present would agree with him that the services of the executive were most acceptable and that a sense of gratification was felt at the visit Mr. Jones had paid to Hull. The duties of the executive were of a very arduous character and the thanks of the chemists of the entire country were due to them.

Mr. Councillor Chapman briefly seconded the motion, which was carried unanimously.

Mr. Jones, in acknowledging the compliment, expressed his high sense of the courteous manner in which he had been treated in Hull.

A vote of thanks to Mr. C. B. Bell for presiding brought the proceedings to a close.

A large number of chemists joined the Trade Association at the close of the meeting.

On Thursday evening, April 26, Mr. S. U. Jones, President of the Chemists and Druggists' Trade Association, was entertained at a supper, given by the members of the Hull Chemists' Association, at the Cross Keys Hotel, Hull, when about twenty gentlemen sat down.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

An ordinary meeting of this Society was held on Thursday, May 3; Dr. Gladstone, President, in the chair. After the announcement of visitors, the minutes of the previous meeting were read and confirmed. A list of presents made to the library was then read by the Secretary. The following certificates were read for the first time:—J. Gardner, J. Napier, C. G. Neison, Beeby Thompson, and W. Webster, junior. Notice was given by the President that he had received a requisition, duly signed, to call an extraordinary general meeting, and it accordingly gave him great pleasure to do so. The date of the meeting was however, not stated.

The Treasurer, Dr. Russell, then announced that he had received £1000, free of legacy duty, from the son of their late Fellow, Mr. Lambert, which he had placed to the general credit of the Society.

The following papers were then read:—

(1). *On Some Points in Gas Analysis.* By J. W. THOMAS.—The author during the examination of the gases occluded in bovey lignite, found after removing the carbonic acid, an absorption of 1·3 to 3·8 per cent. by pyrogallic acid and potash. As no oxygen was present he proceeded to investigate the cause of this absorption. He found that pyrogallic acid does not liberate carbonic acid from the alkaline carbonates; moreover, oxygen is completely absorbed, though slowly, by a solution of pyrogallic acid and potassic carbonate, provided an excess of the acid is not present. Oxygen is absorbed completely and rapidly by caustic potash and pyrogallic acid in the presence of potassic carbonate, if an excess of caustic potash be present. The author next investigates the formation of carbonic oxide during the process of absorption, and finds that the error caused thereby can be reduced to less than 0·5 per cent. by using at least twice as much caustic potash as pyrogallic acid, and agitating the tube so as to hasten the absorption. Nitric oxide is absorbed by a solution of pyrogallic acid and caustic potash; the absorption is, however, not complete, owing to the formation of some nitrous oxide, the reaction being probably $N_2O_2 = ON_2 + O$. Nitric oxide is slowly absorbed by pyrogallic acid and potassic carbonate. Of course, nitric oxide and oxygen could not coexist in a gaseous mixture, but if only a small quantity, say 3 per cent., of nitric oxide be present, it is difficult to determine whether the gas is oxygen or nitric oxide, as both would be absorbed by pyrogallic acid and potash. The author, therefore, always adopts the method of adding a known volume of oxygen to the mixture to be analysed, after absorbing the carbonic acid with potash, any decrease of volume will be due to the presence of nitric oxide. In conclusion, he gives the following precautions. An excess of caustic potash should always be present, and the absorption accelerated by agitation. The alkaline solution of pyrogallate should be used in moderate excess, so as to increase the rapidity of absorption and prevent the formation of carbonic oxide. The absorption should be complete in five to ten minutes. The best liquid is a saturated solution of caustic potash and one part of pyrogallic acid to five parts of water.

(2). *Experiments on the Decomposition of Nitric Oxide by Pyrogallate of Potash.* By Dr. Russell and Mr. W. Lapraik.—The nitric oxide was prepared by the action of sulphuric acid on nitrate of potash and ferrous sulphate. Its purity was always tested by its total absorption in a solution of ferrous sulphate. Different volumes of gas were exposed to the action of pyrogallate of potash: it was found that 58 to 59 per cent. of the gas was absorbed. The authors then tried the action of pyrogallate of potash fully saturated with oxygen; in this case 76 per cent. of the nitric oxide was absorbed. The action of potash alone was now investigated; 75 to 77 per cent. of gas was slowly absorbed. The action was substantially the same in the cold, and when heated, either at the ordinary pressure or in sealed tubes. The residual gas consisted, roughly, of 90 per cent. nitrous oxide, 2 per cent. nitric oxide, 8 per cent. nitrogen. The action of water alone, in sealed tubes heated in a water-bath for a fortnight, and remaining unopened four months, set up the same decomposition, but it was not complete, and more nitrogen was formed. Pyrogallic acid alone has no action on either nitric or nitrous oxide, and alkaline pyrogallate has no action on nitrous oxide. The authors conclude by stating that the probable action of the alkaline pyrogallate is to convert the nitric oxide into half its volume of nitrous oxide, but that simultaneously another more obscure action occurs, either from the excess of potash or from certain compounds formed by the action of the oxygen on the pyrogallate. Practically, in the gases obtained by burning a water residue, a contraction of volume, on introducing alkaline pyrogallate, does not prove the presence of oxygen.

Mr. Thomas remarked that by using caustic potash, absolutely free from carbonate, he had succeeded in obtaining the theoretical quantity, 50 per cent., of nitrous oxide, but if old pyrogallate was used a larger quantity of gas was absorbed.

Dr. Russell, in reply to Mr. Neison, said the nitric oxide used was always tested to see whether it was completely absorbed by a solution of ferrous sulphate.

Dr. Armstrong was inclined to think that the reaction was not a case of simple deoxidation, but that the potassic hydrate played some part in the decomposition.

The thanks of the Society were returned to the authors of the above papers.

(3) *Contributions to the History of the Naphthalene Series. No. 1. Nitroso-β-Naphthol.* By Dr. Stenhouse and Mr. Groves.—After attempting to prepare this substance by Fuch's process (*Deut. Chem. Ges. Ber.*, viii., 625 and 1026) with results far from satisfactory, the authors devised the following process, which yielded good results. One part of pure β-naphthol was dissolved in ten parts of boiling water by means of one part by measure of caustic soda, sp. gr. 1·323; cooled and poured into 100 parts of water. This solution was mixed intimately with a liquid containing two parts by weight of 15 per cent. nitrosyl sulphate solution in 200 of water. After standing twelve to twenty hours, the precipitate of crude nitroso-β-naphthol was collected on a linen filter and washed with cold water. This was purified, in the first instance, by solution in 200 times its weight of light petroleum at 40°, filtering, and precipitating with an alcoholic solution of ammonia. This method of purification was unsatisfactory. No evidence could be obtained of the existence of a second isomeric nitrous compound. Other solvents were equally useless for purifying the crude product. The author finally obtained the body pure by precipitation as a barium compound from a solution in dilute alkali. This compound after decomposition with an excess of hydrochloric acid and washing was redissolved, reprecipitated, etc., a second and third time; finally, the nitroso-β-naphthol was obtained pure. The yield of pure substance is about half the weight of the naphthol originally taken. Full details (attention to which is necessary to secure success) of the preparation and purification are given by the authors. Analysis indicated the formula $C_{10}H_6(NO)$, OH, the hydrated substance crystallizes in minute brilliant yellow needles, which lose water at a gentle heat and become brown. The anhydrous compound obtained by crystallization from alcohol, etc., forms thin orange-brown plates or short thick prisms, melting at 109·5°. Nitroso-β-naphthol is slightly soluble in water, easily in carbon disulphide, benzene, ether, acetic acid, and hot alcohol; sparingly soluble in light petroleum. It dissolves in cold concentrated sulphuric acid without alteration, but is decomposed by heating with concentrated nitric acid; it forms green compounds with the alkalies and alkaline earths. By treating nitroso-β-naphthol carefully with dilute nitric acid, mononitro-β-naphthol is prepared as a pale yellow crystalline powder or in orange-brown anhydrous plates; it melts at 96°. Other compounds are formed by the action of nitric acid on nitroso-β-naphthol, which the authors have not yet completely investigated. By treating the barium compound of nitroso-β-naphthol suspended in dilute ammonia with hydrogen sulphide for an hour, an amido compound was formed. On dissolving this body in dilute sulphuric acid and pouring the liquid into a 10 per cent. solution of potassium dichromate, β-naphthaquinone separated in bright orange needles, melting at 96° C. Analysis gave the formula $C_{10}H_6O_2$. By treating this new substance with hydriodic acid, a hydroquinone was prepared. On boiling with nitric acid it is oxidized into phthalic acid. The authors point out that this is the first instance of two isomeric quinones (α-naphthaquinone, which is readily volatile, having already been prepared by Groves) derived from the same hydrocarbon.

(4). *Asbestos Cardboard, and its Uses in the Laboratory.* By W. N. Hartley.—This substance, specimens of which were exhibited about three-sixteenths to one-eighth inch thick, can be used for making crucible supports, sand-baths, muffles, retorts, supports, etc. It can be cut with corkborers or scissors; by moistening with water it can be moulded to any shape. After moistening it should be gradually dried and ignited, to get rid of organic matter. It stands the ordinary wear and tear of the laboratory well. It is formed principally of asbestos fibres.

Mr. Hartley, in reply to various questions, stated it could be obtained from the manufactory, 31, St. Vincent Place, Glasgow, at 4*s*. a pound.

After a vote of thanks to Mr. Hartley for bringing this substance to the notice of the Fellows, the Society adjourned to 17th May, when the following papers will be read:—

1. M. M. P. Muir and S. Suguira, "On a Slight Modification of Hofmann's Vapour-Density Apparatus." 2. J. W. Mallet, "Note on the Fluid contained in a Cavity in Fluorspar." 3. J. B. Hannay, "Examination of Substances by the Time Method." 4. W. Ramsay, "On the Dehydration of Hydrates." 5. M. M. P. Muir, "On Certain Bismuth Compounds, Part VI." 6. J. Philippson, "Theory of the Luminous and Non-Luminous Flame."

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, April 26, at 17 Bloomsbury Square, Mr. H. Senier in the chair.

The first paper read was by Mr. R. H. Parker, on the "Occurrence of Cinchonidine in Quinine". After referring to the species of the genus cinchona yielding barks of commerce and the alkaloids contained in them, the author gave the official process for the preparation of quiniæ sulphas, noting that at its termination where the hot concentrated liquid is set aside to crystallize it is stated by some that "if other alkaloids are present they remain in the mother liquor," which is far from correct. The official test for the detection of other alkaloids in quiniæ sulphas was quoted, also the test official in the German Pharmacopœia. He then proceeded to remark that Dr. Paul at the Evening Meeting, Feb. 7,* had shown that the indications of both these tests (especially of the former) were very defective, and gave his own method of examining and estimating samples of quiniæ sulphas; also giving the reasons, theoretical and practical, why the other tests failed. These, together with Dr Paul's process were enumerated. With reference to the pharmacopœial test, Dr. Paul had stated that "any one exercising his judgment would never use so much ether as is there directed." The author thought that certainly an official test should not be open to such a statement as this, but a little reflection showed it to be correct. Quinine being soluble in its own weight of ether, quinidine 1 in 30, cinchonidine 1 in 150, and cinchonine almost insoluble, it is plain that half an ounce of ether would dissolve 1 or 1½ grain of cinchonidine, this quantity occurring in 10 grains of quinine is equivalent to 10 or 15 per cent. at least, which could not possibly be detected; moreover if quinine were present (the remainder of the 10 grains taken), 2 or 2½ grains remain dissolved, equivalent to 20 or 25 per cent.

The author said that having tried Dr. Paul's process, he had found it simple, easily applied and highly satisfactory. He laid before the meeting specimens of the test compared with the official test applied to the same samples of quiniæ sulph.; also to quiniæ sulph. with 20 per cent. cinchonidine which the B.P. test passed as pure; also B.P. test to quiniæ sulph. with 30 per cent. of cinchonidine sulphate—this gave crystals after few hours.

No. 1 sample B.P. test gave no indication of impurity. Dr. Paul's test in the first two crystallizations gave a crop of crystals, the characteristic thick shortened prisms at the juncture of the two layers of liquid—also some crystals (needle shaped) at the bottom of the aqueous layer. What these latter were deserved consideration; cinchonine being insoluble in ether should appear amorphous; the iodide of potassium test gave no indication of quinidine in the original alkaloid; the only alternative left was that both sets of crystals were cinchonidine. The physical difference the author thought might depend upon the one being formed in an ethereal solution saturated with water, and the other in an aqueous solution saturated with ether.

Sample No. 2 B.P. test passed as pure; 5·0 grams with Dr. Paul's method gave 0·358 gram of crystals, equivalent to about 10 per cent. of crystallized cinchonidine sulphate. The first crop of crystals of this sample was very bulky; one tenth of the amount or less might easily have been detected.

The author had found that the delicacy of Dr. Paul's test might be increased by evaporating the filtered solutions, and again allowing to crystallize before applying the ether test. 5·0 grams were boiled with 150 c.c. of water, cooled, filtered, crystals again boiled with 150 c.c. of water, cooled, filtered, the filtered liquids mixed, evaporated by water-bath to 80 or 100 c.c., cooled and filtered (very little quinine came out here from its very slight solubility so that it could not bring cinchonidine with it), and treated as usual. In this way a much smaller quantity of ether could be used.

* *Vide Pharm. Journ.*

Another important point in favour of Dr. Paul's method was economy (especially with quinine at present price) as nearly the whole could be recovered. If pure, 5·0 grams would only lose by the above treatment 0·4 gram or about 6 or 7 grains. If impure this amount would be lost *plus* the impurity.

A discussion followed the reading of the paper, at the close of which a vote of thanks to the author was passed unanimously.

Mr. Henry Greenish then read a paper on "Oxalate of Cerium," which will be found on p. 909. A vote of thanks to Mr. Greenish also was passed.

Parliamentary and Law Proceedings.

WHAT IS THE DEFINITION OF A MINERAL WATER? THE ATTORNEY-GENERAL *v.* LAMPLOUGH.

In the Exchequer Division of the High Court of Justice, on Monday last, before Mr. Justice Cleasby and a special jury, an information was laid at the instance of the Commissioners of Inland Revenue, against the defendant, to recover a penalty of £10, for selling a bottle of "Lamplough's Pyretic Saline" without a stamp label affixed, as provided by the Commissioners pursuant to the statute.

The Attorney-General and Mr. A. V. Dicey, appeared for the Crown, Mr. Herschell, Q.C., Mr. Ince, Q.C., and Mr. E. B. Cooper for the defendant.

The Attorney-General, in opening the case, said the object of the Crown in bringing this suit was not to inflict penalties, but to settle a dispute that had existed for a long time between the Revenue Department and Mr. Lamplough, who was a tradesman residing in Holborn, and manufacturing and selling a compound or powder under the above title. Although it had been necessary to have a jury to try any dispute as to facts that might arise, the decision would probably turn upon the construction of the Acts relating to the subject, and it would be for his Lordship to decide what was the law. According to his contention it was as follows. The Act 52 Geo. III. cap. 150, amending portions of a former Act, and repealing the schedule attached to it, was passed for granting stamp duties in Great Britain so far as regards the duties granted on medicines and on licences for vending the same. Section 2 of this Act provided that if any person, whether licensed or not, sold or exposed for sale, or bought or kept "any packet, box, bottle, pot, phial, or other inclosure, containing any of the drugs, herbs, oils, waters, essences, tinctures, pills, powders, preparations or compositions mentioned and set forth in the schedule annexed to this Act, without a paper cover, wrapper, or label provided and supplied by the Commissioners of Stamps," he should for every such offence forfeit the sum of ten pounds. Section 4 provided that it should not be necessary for any person selling any of the artificial waters mentioned in the schedule to be drunk on his premises, to take out a licence, provided that such waters were duly stamped. The schedule referred to contained a large number of articles, and amongst them this item.—"Waters, *videlicet*—All artificial mineral waters, and all waters impregnated with soda or mineral alkali, or with carbonic acid gas, and all compositions in a liquid or solid state, to be used for the purpose of compounding or making any of the said waters." At the end was an addendum, which he would call a "postscript," and considered of great importance, which included also all other pills, powders, waters, etc., prepared for use externally or internally as medicines for the prevention, cure, or relief of any disorder incident to or affecting the human body, when the person preparing or selling them claims to have an occult secret or art for preparing them, or claims to have any exclusive right or title to preparing them, or when the article is prepared and sold under the authority of letters patent, or if it has at any time been recommended in any public notice or advertisement, or printed papers, handbills or labels as beneficial to the prevention, cure or relief of any ailment incident to or affecting the human body. In a subsequent Act, 3 and 4 Will. IV. cap. 97, s. 20, so much of the schedule as is contained in the words above quoted relating to artificial mineral waters was repealed. This in his (the Attorney-General's) opinion, left the law in just the condition it would have been had these words never appeared in the schedule of the previous Act. But he submitted that what he had called the postscript still applied, and as Mr. Lamplough had recommended his preparation as valuable in the relief of many diseases, and asserted in his prospectuses that on one occasion in the Court of Queen's Bench he had succeeded in establishing his sole right to make this preparation, it was submitted that it would come within the provisions of the postscript as a patent medicine, and be subject to the payment of duty. But should it be decided that this was not the case, he would also contend that the preparation was not correctly described as merely a compound for the production of an artificial mineral water, but that its value as a medicine depended upon the presence of chlorate of potash, which was not a mineral alkali but a neutral salt, and never found in a natural mineral water.

Mr. Bannister, Deputy Principal of the Laboratory, Somerset House, deposed that he had analysed a sample of "Pyretic Saline," and found it to contain 45·7 per cent. of tartaric acid, 52·4 per cent. of bicarbonate of soda, and 1·9 per cent. of chlorate of potash. Upon solution of this compound in water, tartrate of sodium was formed, carbonic acid was set free, and 1·4 per cent. of the bicarbonate of soda and the whole of the chlorate of potash remained undecomposed. Chlorate of potash was not found in any natural mineral water, although chloride of potassium was. It was supposed that the medicinal activity of chlorate of potash depended upon the readiness with which it gave up its oxygen. He thought that the other constituents would also have a remedial effect in some of the diseases referred to.

Mr. Lewin, of Somerset House, was also called and confirmed the above evidence.

For the plaintiff, the facts deposed to were not disputed. It was contended however that the preparation was strictly a composition for the production of an artificial mineral water and as such had been taken out of the schedule by the repealing clause. It was urged that many artificial mineral waters differed in composition from any natural waters, and that a decision adverse to the defendant would render potash and other waters that had been recommended as beneficial in the treatment of disease also subject to payment of duty.

Ultimately the question resolving itself entirely into one of law, the learned Judge directed the Jury to return a verdict for the Crown, for a penalty of £10, leave being reserved to the defendant to move that the verdict be entered for him, the Court to be at liberty to draw inferences from the facts.

Accidental Poisoning by Chloral Hydrate.

Mr. Carter, coroner for East Surrey, held an inquiry at Balham, on Friday the 4th inst., touching the death of Mr. Frederick Macfarlane Levison, a medical gentleman, aged 37, who died suddenly from poison, it was alleged, at Balham Hill House on the previous Saturday morning.

Dr. Holthouse, senior consulting surgeon to the Westminster Hospital, who was called, was warned that he need not answer any question which he thought might induce a criminal charge against himself. He said deceased first came to him at his private consulting rooms, 15, George Street, Hanover Square, and said he was suffering from intemperance, which he could not control at home. He wished to place himself under witness's care. He was then suffering from the chronic effects of alcohol, and an arrangement was come to by which, on the evening of the 11th April, he was taken to witness's establishment at Balham Hill House, which some time ago was opened for the cure of dipsomania. He slept in a room with an attendant named Louis Chevallez and witness prescribed for him.—The Coroner: What did you prescribe? Witness: I prescribed 50 grains of chloral for him per dose; to be given to him at eleven each night, to quiet him and put him to sleep, and if he did not get quiet and sleep under that then the attendant was to give him a second dose. There was enough for two doses made up each night in a bottle with five ounces of water; the chloral was in solution.—Coroner: Now do be particular, for this may amount to a criminal charge. Do you mean to say that you ordered this man 50 grains of chloral? Witness: Yes.—Coroner: Are we to understand that this second dose was to be given him that night by your special agency? Witness: Well, not that night, but I had given previously general orders for a second dose. I had first satisfied myself that he had no organic disease.—Coroner: Did you allow him any stimulant spirit? Witness: No; I consider it perfectly safe to cut it off all at once, and do not allow any on the establishment on principle, under any pretence whatever. There is a notice up to that effect, and any servant giving it would be dismissed.—Coroner: What in your opinion did he die of? Witness: Of chloral. But I wish to explain that what would be a large dose sometimes, to the same person would, under altered circumstances of body, be a very small one. There is no accounting for these changes in the system. An individual might with safety take 80 grains at one time, when perhaps at another time 20 grains would kill him.—Coroner: This is a very important question. This is the third death I have had lately from taking chloral. In a case I had about three weeks ago it was stated in the medical evidence that the average dose of chloral was 10 grains, and here we have 50 grains given. Witness: He told me he had been in the habit of taking 40 grains per dose himself at home.—Do you think anything would be given to him intentionally for any purpose? No, not to my knowledge.

Mrs. Ophelia Johnson said she was in the service of Dr. Holthouse, and was the matron of the dipsomania establishment. On Friday night last she made up a mixture in the bottle produced by Dr. Holthouse's orders. There would be about 100 minim drops. If anything, there would be rather less than more than the quantity ordered. The deceased was rather noisy at nights, and occasionally disturbed the house, and the medicine was given to him for producing quiet and sleep.

Louis Chevallez said, I am in the employment of Dr. Holthouse at his dipsomania establishment, Balham, and was the regular attendant on the deceased. I used to sleep in another bed in the same room with him, and it was my duty to attend him day and night. He had his supper as usual on the night of his death, and ten minutes later I gave him what I understood was a mixture of chloral, as he went to bed. When he took it he said "How very nasty or strong this is; how very irregular or clumsy (I don't know which) Dr. Holthouse is; he never seems to give it to me in the same amount of water. Give me a little milk to take the taste out of my mouth." After he had drunk it he said he felt sick. He then asked me if I would read to him the text for the day, and not to leave him till he went to sleep, but to keep on reading. About half-past twelve the deceased asked me to give him half the remaining dose, which the doctor had ordered to be given two hours after the other. Deceased then took it in his own hand, and after he had drunk half of the second dose, he said "Give me some more milk to take the taste away." He then said "I don't think I shall be able to take the other chloral—give me a little whisky in a little milk." About a quarter of an hour after he had taken the portion of the second dose, he suddenly began to breathe very hard and stertorously. I had previouly just given him a little whisky and milk. Shortly after he began to breathe so hard he had a rattling in his throat, and then he threw up a little milk, and in another moment he was quite quiet. I then felt his pulse and found him quite pulseless. I then ran out of the room and called the matron. She came, and in about ten minutes after that we called the doctor. He never complained of chloral being nauseous before. The matron told me that she had given him 100 drops of chloral, and a drop over, and that it was the strongest dose she had ever given, and that afterwards she had poured a little more in besides the 100 drops.

The Coroner: There is no doubt that the deceased has died of an over-dose of poison. The question to decide is whether there is any culpable negligence on the part of any one?

A Juror: It seems very strange that such a poison as this should be left in the hands of such people as these.

Mrs. Johnson was recalled, and subjected to a very rigid examination as to whether she had poured a little over. She admitted having said that she had poured a drop over, but what she meant was that she had drained the minim glass of the last drop, which was not usually the case, but she was certain she had not poured one drop over the 100 minims. She also gave the attendant the whisky to give the deceased.

The jury returned a verdict, "That the deceased's death was accidental through the administration of a sedative medicine in water incautiously, but not recklessly or intentionally given to cause death."—*Standard.*

On Tuesday the following note appeared in reference to this case:—

Dr. Holthouse, of the Westminster Hospital, who gave evidence in this case, writes to us (*Standard*) protesting against the manner in which the coroner conducted the inquiry, and stating that the gentleman on whose body the inquest was held had been given to intemperance since he was eighteen years of age, and that latterly he had been a regular chloral drinker. He had told Dr. Holthouse that his usual dose was 40 grains, with 20 grains of bromide of potassium. Dr. Holthouse explains that his object was to cut off both the alcohol and chloral, the former at once and the latter by degrees; that the choral, of which he never ordered any stated dose to any one, had, on all but two occasions, previously been given by himself, the largest dose having been sixty grains, taken by the patient on the night of his admission; and that on the night of the death of his patient he had not prescribed any, having expostulated strongly with him on the subject the day before, and told him it must be absolutely cut off. Dr. Holthouse had not, however, forbidden it to be given, because on no previous occasion had that been done without his direct sanction; but his attendants, relying on precedent, and with disastrous faith in the patient's own medical knowledge, administered that last dose which subsequent analysis had found to contain less than fifty grains. The invariable order given to the attendant was to allow two hours to elapse before a second dose was given. From investigations made since the inquest it would appear that the first dose could not have been taken before half-past eleven, so that the portion of the second which was used must have been taken about an hour after it, death having ensued some time before one o'clock. It is further stated by Dr. Holthouse that notwithstanding the mistaken kindness of his attendants in giving the patient a little alcohol in doses to prevent his going out and having much, the deceased did go out, and procured both drink and chloral.—*Standard.*

Sale of Chloral Hydrate.

Sir,—This subject seems to have received considerable attention at the last Council meeting, in consequence of a recommendation from a Carlisle jury that it should be added to the list of poisons in schedule A of the Pharmacy Act. I would not for a moment throw an obstacle in the way of the passing of any precautionary measures which would prevent accident or loss of life, but there is such a thing as erring on the side of caution. If this were the first time that a jury had made an unreasonable recommendation from their very partial knowledge of such matters, I could better understand the powerful influence it seemed to exercise over our esteemed President and Mr. Shaw, both of whom came quickly to the conclusion that "something ought to be done," the latter even arguing in favour of placing it in part 1 of the schedule.

A courteous reply to the coroner would certainly be in good taste, but to place chloral hydrate in the same category as morphia, strychnia, etc,, would simply be to outrage common sense and to nullify the value of the poison schedule altogether. Any serious results from the use or abuse of chloral hydrate have been very rare, and, when such cases have occurred, there has been much talk about "the growing evil," the "extensive abuse," etc, etc., with scarcely a trace of supporting evidence. We are told that it is used as an intoxicant. Well, there is no accounting for taste; but it might be safely asserted that more illness and deaths arise in any single day from the use of beer, wines and spirits than from the use of chloral hydrate since its first introduction as a medicine; yet, neither juries, coroners or judges ever suggest putting these intoxicating beverages into schedule A.

Charles Symes.

Liverpool, May 7, 1877.

The Benevolent Fund and Non-subscribers.

Sir,—The fact of having just received circulars with refence to the Benevolent Fund, and a Dinner which is shortly to take place in aid of this Fund, prompts me to write you a few lines on the subject. Having a dinner is no doubt an excellent way of raising "more supply," but then it falls to but a few who are able to take part in such a proceeding. Then, what else can be done? Why will not more subscribe annually? Is it because they can't afford, or they will not, and are heedless about the good which might be done by even a little annual help from each of those who do not yet subscribe? I scarcely think the former is their reason, but I do think it is more the want of proper thought than otherwise. Who can say he will never want help from this fund. Happy is he who really can, and happier still would he be if he put out a helping hand to those who did want. The figures are startling,—only think for one moment, out of 14,000 registered chemists only about 2300 are subscribers. Now supposing 5000 more names were added to the present list of subscribers (which number is less than half who do not yet give anything) at 5s. each, and this small amount could surely never be missed, it would mean an extra annual income of £1250. This fact ought to stimulate all non-subscribers to be charitable and send at once their "mite" to the Secretary, feeling and knowing then they would at least be helping to be a "blessing to many a poor infirm fellow chemist." With the sanction of the Council I think a deal might be done in canvassing (though some of course object to it), if some in each district of every town would undertake to go a round in his own neighbourhood; I, for one, would be willing to take my own neighbourhood, if some other brother chemist would volunteer to go with me; unity being strength, two would get on much better than one.

G. W. Pratt.

Manchester.

The Spoonful Question.

Sir,—Some dispensing chemists seem determined to make mountains of molehills,—nothing will prevent them.

(1). We all know what is intended by the respective terms "tea," "dessert," and "tablespoons."

(2). We all have graduated glasses with which those several quantities can be accurately measured, and those of us who are business-like will not omit to sell one if the customer can afford and is willing to pay for it.

(3). When the customer cannot afford to pay for one, we all have ʒj, ʒij, and ʒiv phials, which will equally well answer the purpose of a measure, one of which we can sell the customer for 1*d.* or make him a present of one if we prefer it.

Cannot the spoonful question henceforth be "quietly inurned." I feel aggrieved at its continuance. But for it I am inclined to think you would have found room for a letter that I wrote you on the subject of "cutting down prices,"—a discussion of which subject I think might have been much more useful and interesting to the trade generally than this *réchauffé* of the "spoonful," which I humbly submit has been presented to us *ad nauseam*.

Southampton. Robert Chipperfield.

Sir,—If you have a small space at disposal for discussing the above, I beg to bring forward a proposal for a new form of medicine glass.

My idea is to have a glass the size and shape of a 1 ounce conical measure, without the lip, graduated 1 T., 2 T., 1 Tab., 2 Tab., and to have plenty of room above the marks to add water when required.

A glass of this description would not be readily capsized in use, or broken in washing, and would be different in shape from ordinary wine glasses; and having few marks it would be easily understood.

It would only necessitate a dessertspoonful direction being rendered two teaspoonfuls, which is done at present when a measure glass is supplied.

Messrs. Maw and Thompson's registered spoons are very useful, but I think a glass is of more service, especially if the dose is two tablespoonfuls, or if water is to be added.

My experience of graduated bottles is that they are very inaccurate; and even supposing they were to be depended upon, many patients make mistakes in using them, taking two doses instead of one.

I think it will be generally admitted, that it is very much easier to pour liquid into a bottle up to a certain mark, than to pour it out down to a fixed point, as in the one case the bottle is upright, and shows at once, in the other we are obliged to judge first, from the quantity poured out, until we can try by the bottle standing up to hit the mark. This method of measuring the dose is very uncertain, as bottles containing a few doses returned to the chemist testify.

George Brown.

Sandown, I.W., April 24, 1877.

Sir,—I have been sorry to see so many objections raised to the introduction of the above articles by those who took part in the discussion at the "Square," following the reading of the paper on the subject; and so little said in favour of them by other pharmacists. But after the able replies of Mr. Proctor to all these objections the appearance of another unfavourable criticism in a subsequent number of your Journal induces me to write a word or two regarding the merits of these ingenious little cups designed by Messrs. Proctor.

I think they are well adapted to the purposes they were introduced for, and I believe are giving general satisfaction to those physic-takers who have seen and tried them. If not perfectly suited to all requirements, they have many good points, which ought to ensure their extensive use. Admitting they are capable of improvement, it is not too late to adopt the various suggestions tendered, and modify the terms of the label in future.

1. Their cheapness brings them within the reach of all. It is not necessary to give them away with all mixtures, but only when first dispensed; moreover, when the public get to learn the respective sizes they will not desire new ones.

2. They are more accurate than many of the usual graduated glass measures, and still more than the numerous forms of spoons vended for similar use.

3. They can be used in the capacity of drinking cup, simultaneously with its intended object, thus proving a boon to travellers, and affording a striking contrast to a practice which commonly prevails, viz., swallowing the medicine directly from the bottle—guessing the quantity.

4. By the aid of the lip spilling is avoided—a superiority over the usual household or china medicine spoons.

5. They are more easily cleaned than phials (as some propose), and not so friable; besides that viscous fluids can be more readily removed from the wide opening in the cup than through the small orifice of a narrow-necked phial.

6. There is less danger of fracture than in the case of glass measures.

7. Obviously, one of the main features has been overlooked,—the chance of mistaking graduations as in medicinal wine-glasses (not infrequent amongst the uninitiated) is entirely obviated.

8. They are very portable, occupy a small space, and fit nicely over the cork of the bottle.

Independent of all these features which recommend the vessels, they have the additional advantage, that whereas domestic spoons will rust or tarnish, these will not even become stained, and there is no fear of metallic contamination by the action of acid or alkaline mixtures. I think this important point has not been spoken of by the originator.

I see no difficulty in transferring the contents of the cup to a tumbler, etc., containing the dilnent. If the labels affixed are liable to be washed off, there is still left indelibly imprinted on the bottom the mark indicating the correct size. Again, if there is a possibility of confusing sizes, there is certainly much more of mistaking the phials which Mr. Long furnishes his customers with.

Even with accurate spoons, some patients scarcely fill them, lest the liquid overflows, while others pour in more than sufficient, the surface of the fluid being curved, owing to the attraction of the edges of the spoon.

Mythology tells us of a vulture which consumed the liver of immortal Prometheus as fast as that organ grew; and so, in a later era, there are always persons ready to condemn any new invention as an unnecessary innovation.

In conclusion, this much may be said on their behalf, they may appropriately be sold (or given away at discretion), in cases when concentrated medicines are prescribed, or a full dose ordered. I trust many, who, as yet, have remained *in silentiô*, will appreciate them more than has been done by those who have expressed their opinion.

Manu Forti.

Sunday Closing.

Sir,—I have read with general approval the remarks of "A Beginner," on the subject of "Sunday Closing," in this week's Journal.

Your correspondent affirms, "I have lost nothing by so doing, consequently I shall always adhere strictly to that principle." This, however, seems a low standard to take; in fact, it is not the correct standpoint. The command is, "Remember the Sabbath day, to keep it holy."

No worldly policy, of any kind whatsoever, can overrule that obligation. And what does "to keep it holy" mean, but to separate it from the other days, in its transactions. That medicine should be dispensed on the Sunday cannot be objected to: only, should there not be some provision for meeting really needful requirements without necessitating the opening of the shop, with the consequent exhibition of accessories, to attract and invite the purchaser?

It is clearly our duty, and should be our delight, to observe the Sabbath from religious principle, having due and preferent regard to the Divine Lawgiver, without making a proportion sum or an algebraic equation of the cash returns as the practical result of such obedience.

"Godliness is profitable unto all things, having promise of the life that now is, and of that which is to come. Faithful is the saying, and worthy of all acceptation."

Let us, then, in simple obedience of faith, comply with the condition, and assuredly the Lord will fulfil His promise.

Eusebius.

Carbon Bisulphide Lamp.

Sir,—Eighteen or nineteen years ago, in prosecuting an investigation of the effect of burning spirit solutions of several essential oils in the ordinary perfume lamp, with spongy platinum ball, I extended my experiment to solutions of chloroform, iodoform, bromoform, and bisulphide of carbon, with results which encouraged the expectation of a practical application of the method for disinfection. From a commercial point of view the cost and limited use of so elegant and convenient a method induced the making of more experiments, and resulted in realizing the burning of solutions of chloroform, iodoform, and sulphide of carbon in the ordinary methylated spirit of commerce in an ordinary spirit lamp, for which I afterwards substituted a lamp made specially for me by the York Glass Company, entirely of glass, and glass wick-holder with cup.

I have employed this mode of generating disinfecting gases on my own premises, and also for disinfecting rooms where contagious diseases had occurred, and can recommend what is comparatively a cheap plan, as well as easy of application.

The suggestion of Mr. Groves is a very good one, as insuring safety from breakage, and I have no doubt that a special lamp would find a ready sale if produced at a moderate cost. JOSEPH COUPLAND.

To the Benevolent.

Sir,—By your kindness we have been enabled from time to time to report the result of our appeal on behalf of Mrs. Fowler, and, as the subjoined statement shows, nearly £50 has been received. A little more effort will yield the £70 necessary for taking legal proceedings.

Glycerine of Pepsine.

Sir,—In the Journal of the 28th April, I notice a letter from Mr. J. L. Bullock, respecting a solution of pepsine in glycerine, in which he states that he has found it to possess very much greater digestive power than any other liquid form of pepsine, and informs us that half a fluid drachm will digest fifty grains of hard boiled white of egg. I may state that I have for some years prepared a solution of pepsine, which is known as "Elliott's Liquid Pepsine," and is in extensive use, owing to the recommendation of our local members of the profession as well as to its powerful digestive properties. Half a fluid drachm of my liquid pepsine will digest two hundred and fifty grains of hard boiled white of egg, or five times the quantity digested by Mr. Bullock's preparation. Evidently Mr. Bullock has not examined all the liquid forms of pepsine.

279, *High Street, Gateshead*. ROBERT ELLIOTT.

[*** It might have imparted some scientific value to this and the other letter referred to if the writers, instead of confining themselves to a statement of results, had described the method by which they might be obtained by other persons also. We would remind the original critic and the critic's critic that this was done by the author of the paper that gave rise to their criticisms.—ED. PH. J.].

"*Hants*."—There are so many good books on Grammar to be had that we cannot undertake to decide which is the best, neither can we say which is the best postal system. Depilatories are used for removing hair, but will not prevent its growth.

Messrs. Plomley and Watts.—The following formula for Tinct. Quiniæ Ammoniata has already appeared in this Journal ([3], iv., 993):—

℞ Quiniæ Disulphatis . . . . . gr. xxxij.
Spirit. Tenuioris . . . . ℥iijss.
Spirit. Ammoniæ . . . . . . ℥ss. M.

A. Wright.—It will be necessary to grow the seeds to determine them.

"*Alpha*."—The formula for glyconin has already been given more than once. It will be found on p. 714 of the present volume.

H. Churchill.—The formula for "Liquor de Clemens," or "Liqueur à l'arsenite de bromure de potassium," which is probably the preparation you require, is as follows (*New Remedies*):—

Arsenious Acid . . . . 1 part by weight.
Potassium Carbonate . . 1 „ „
Bromine . . . . 2 parts by weight.
Distilled Water, to make . 93 „ „

Boil the carbonate and the acid with most of the water, until they are dissolved; when cold, add the bromine and enough water to make the bulk to 93 parts. Age is supposed to improve this mixture, as the bromine gradually enters into combination. Dose, 1 to 4 drops in water once or twice daily. The solution should be kept sheltered from the light.

S. W. J.—It is impossible to make a satisfactory preparation with such proportions.

T. H. Bateman.—We cannot see how the sale of toilet soap or granular citrate of magnesia by grocers, oilmen or others can be prevented. Neither do we think that any attempt to limit the trade in patent medicines to chemists and druggists would have a chance of success.

W. O. S.—(1) *Tincture of Jaborandi* (Martindale).

Take of Powdered Jaborandi Leaves . . 10 ozs.
Rectified Spirit . . . . q. s.

Percolate until a pint of tincture is obtained. Dose, ♏x ad ʒj vel ʒij. (2) It is not starch but mucilaginous matter that separates on the addition of the spirit.

M. P. S.—We admit that the adoption of the plan you approve of would be very desirable, and have ourselves advocated it on many occasions, but at present there seems to be very little disposition to follow it by either party.

A Registered Student.—You had no alternative but to give what was asked for, so long as it was not a poisonous dose.

A. M. is recommended to make an analysis of the crystals.

M. P. S.—We believe any manufacturing chemist, or wholesale druggist would be able to supply the concentrated colours.

Fred. Rivers.—*Sanicula europœa*.

A. Mitchell.—*Cochlearia officinalis*.

C. Gorton.—Corms of some endogenous plant.

J. B.—We are strongly of opinion that the discussion of the subject to which your letter refers would not be productive of any good result.

"*An Associate*," "*Respice Finem*" and "*Honi soit qui mal y pense*."—Under the above signatures we have received letters calling in question the justice of the decision arrived at by the Council not to grant the use of the Lecture Theatre for a meeting of assistants with a view of forming a Chemists' Assistants' Association. We refrain from publishing these letters inasmuch as we think that by further direct communication with the Council any existing obstacles to the satisfactory arrangement of this matter might probably be removed.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Jackson, Mr. Brown, Mr. Mitchell, Mr. Fairlie Mr. Townsend, Mr. Garrett, S. N., A. T., F. D. B., G. B., Syrupus.

THE BENEVOLENT FUND DINNER.

A Dinner in aid of the Benevolent Fund of the Pharmaceutical Society was held on Tuesday last at the Freemasons' Tavern. About 240 gentlemen sat down. The chair was taken by Mr. John Williams, President of the Society, supported on his right and left by Dr. Risdon Bennett, President of the Royal College of Physicians, and by Dr. Buchanan, President of the Medical Society of London.

The President proposed the health of the Queen, and the health of the Prince and Princess of Wales, both of which toasts were received in the usual enthusiastic manner. The toast of the Army, Navy, and Reserve Forces, was responded to by Captain-Commandant Richardson, of Leicester (31st regiment), who referred to the great part played by chemistry in modern warfare. Captain Walker (13th Lancashire Rifles) also assured the meeting that the volunteer forces were by no means declining. He had been a member of the force since 1860, and he hoped that many others whom he saw around him would devote some part of their leisure time to the same object.

Mr. Cornelius Hanbury (Treasurer) proposed the next toast, viz: "The Medical Profession." He said the toast which he had the honour to propose could not fail to elicit a hearty response. The medical profession was a theme which suggested a flood of thoughts to his mind with associations and feelings of gratitude and veneration which he had no power to express. There was no branch of science which had not been adorned by its members and there was no class of the community who were not largely its debtors. But there were obvious reasons why this toast should command special sympathy on the present occasion; medicine and pharmacy had a common origin, and a common object, and were reciprocally dependent. The prescriber was indebted to pharmacy for the most appropriate and elegant methods of employing his remedies; whilst chemistry had supplied him with the most powerful and reliable instruments at his disposal. On the other hand pharmacy and pharmaceutical chemistry could only proceed on the lines and within the limits indicated by the observations in physiology and therapeutics of the scientific practitioner of medicine. Thus, though mutually dependent, the exalted function of the prescriber was broadly distinguished from the humble duty of the preparer and dispenser of medicines. And in their highest development the separation of the two branches became complete. But where the exigences of society or other circumstances impeded this full developement there was ever a tendency to revert to the primitive union of those now distinct functions. Something analogous was found in other professions. Thus the lawyer had his stationer; the architect his builder. Experience enabled the law-stationer to advise an ordinary customer as to the character of the stamp he might require for an agreement or other deed, and in many simple cases even to supply him with the form for a legal document. So the builder frequently acquired such a knowledge of the nature and strength of his materials and of the principles upon which they were put together as enabled him safely to erect buildings of minor importance—it might be a chicken-house, or a stable, or even a cottage,—without having recourse to an architect. Yet no one imagined that the friendly relations of these professions and their respective trades were thereby imperilled; and his own experience convinced him that there was no more reason to doubt the maintenance of the friendly relations which had happily subsisted between the members of the medical profession and those of the Pharmaceutical Society. So long as the healing art was practised the services of both would be required, and the welfare of each would be promoted by due consideration for the rights of the other. But he would not pursue this subject further. They were there that evening to promote a work of pure benevolence, and they cordially thanked those members of the medical profession who had kindly honoured them with their presence. Theirs was a profession pre-eminently distinguished by benevolence. How unostentatious and self-denying their labours often were, many of them had witnessed, and all of them had had for themselves or those dear to them to thank members of the profession for the mitigation of suffering and the relief of anxiety. Thus, both on professional and personal grounds, he asked all heartily to join in this toast, coupling with it the name of Dr. Risdon Bennett, President of the Royal College of Physicians.

Dr. Risdon Bennett, in responding, said it was quite true that the professors of medicine and of pharmacy had been from the earliest times very closely associated, but in proportion as the science advanced it was found to be essential to the progress of medicine that pharmacy should also proceed, that it should not be what it was at the beginning of the commerce between the two. But although the medical profession boasted of having made very great advances in medical education during the last fifty years, and the entrance into the profession was no longer so easy as it had been, he could not but fear, in consequence of the very peculiar relations in which pharmacy had stood to the medical profession in this country up to the present day, that tradesmen had suffered somewhat from the imperfect study of pharmacy by those who were still constrained to practise it; and he was quite sure it would be to the advantage of all parties when the severance between the two was complete. At the same time it was fair to acknowledge that that severance they did not see their way at present to complete. He trusted, however, that as the Pharmaceutical Society proceeded in its laudable efforts to educate a large class of men competent to make up prescriptions and to undertake the thorough governance of pharmacy, the medical profession would be not unwilling to give up the small portion of it which it still retained. He rejoiced to see that there had been such a manifest advance in the state of pharmaceutical science throughout this country. Even before 1815, when the Apothecaries Act was passed, there was more than one attempt to do virtually what was being now done more effectually. It might not be known to all present, that one of these associations called itself the Pharmaceutical Association of Great Britain, and that at the close of the last century it issued its missives from the Buffalo Tavern, Bloomsbury Square. He did not know how far it succeeded in its efforts, but he believed they were superseded by the Apothecaries Act of 1815. There was not a member of the medical profession who did not rejoice at the prosperity of the Society, but he rejoiced also to see that in its prosperity it was not forgetful of those in adversity, and he uttered a fervent wish that this benevolent society whose interests they were met to support might be an abundant success from year to year, and that the time would never come when those who were successful would be forgetful of those less fortunate.

The President next rose to propose the toast of the evening, "Success to the Benevolent Fund of the Pharmaceutical Society." He said it was perhaps a misfortune that it should be necessary in their body or any other for a benevolent fund to exist, but there were very few professions or callings in which it was not necessary to provide for the unfortunate or the poor. The majority in their business they knew, as a rule, were not rich men, the number of those who could so describe themselves would be very small compared with the whole of the trade, but for all that he trusted that they had not so great a proportion of poor as most other trades or even professions would show. Still it was necessary that a benevolent fund should exist, and that it should be supported by their earnest and constant endeavours. This Fund had now been established for thirty-five years, having been commenced soon after the foundation of the Society, and although in its early days it was restricted in its action to those only who were subscribers to the Fund, at which time he himself had refused to aid it in any way, he was happy to say that after a certain period a change took place, and its benefits were thrown open to the whole trade, whether they had ever subscribed to the

Society, or even to the Fund, or not. He had great pleasure in saying that since the foundation of this Fund there had been paid to annuitants no less than £3300, and in casual relief to meet immediate necessities, £2800. Upwards of £6000, therefore, had been expended, and this showed that they had been able to do much good with the money which had been subscribed. There had been altogether 30 annuitants, 15 male and 15 female, and of the more casual grants assistance had been given to 140 men and to 90 widows and orphans, but this proportion arose simply from circumstances and not from any particular arrangement. As time went on it was found that the proportion of widows and orphans asking for relief was increasing, and this was a point which the Council was watching with great interest, in fact, it was one of the most important points which had to be dealt with. The sum of money that had been expended was something like a guarantee that the Fund deserved the confidence of the subscribers, but, he need hardly say, that if the Fund were larger, or if it were subscribed to in a different form, it could do much more good, and its sphere of usefulness would be very largely increased. He, therefore, thought it his duty, especially on that occasion, to point out that it would be a very proper thing not only to increase the number of annuitants, but also to increase, if possible, the amounts granted. What was £30 a year to support a widow or a poor man, probably with a family, fallen into distress, who had once occupied a position of respectability and comfort? Again, there was one branch of usefulness in which it had been felt for some time they might extend their operations, if their funds were larger and more available—he alluded to the education of the children of the poorer members of the trade who had not the means themselves of providing a sufficient education for their children, but in whose case such a provision would be of the utmost importance to their future welfare. It had been suggested that they might make a great effort to do something in the way of bricks and mortar and provide a great school, and it had also been suggested by some that it would be still better to have an asylum for the aged, something architectural, which should show to the public what they were doing. His own feeling, however, was decidedly against the sinking of capital in such a manner, and he trusted they would still be content to do without the outward show of philanthropy, and to utilize all their money for the benefit of their recipients to the best of their means. They had two classes of income. First, the donations; such portion of which as was not expended during the year they were required by the bye-laws to invest in the funds, and it was only the interest of that money they could use in the future. All donations, therefore, must of necessity be invested, and he thought it a very proper thing that a larger amount should be so invested, because annuities should be as nearly as possible secured, and not be dependent on voluntary subscriptions. But they had tried the experiment of increasing the number of annuities beyond the amount of interest derived from their invested capital, and, he must say, that they had found most satisfactory results accrue. In fact, they had found that they could depend on subscriptions coming in to supplement what might at first sight appear a not very provident arrangement. He had no doubt that the result of that evening's gathering, and of the collection which was being made, would place them in a position of having sufficient property funded to meet the whole sum required for the annuities. But it was not only the annuities they had to meet; they could do much more good if they had a large clear annual income from subscribers, and he therefore wished to urge very strongly on his hearers that the most effective way of helping the Fund would be to increase the regular subscription list. It sounded very pleasant to hear announcements of large donations from firms and individuals, but he should like to be able to announce that every man on the Register had subscribed, or promised to subscribe, 2*s.* 6*d.* a year. They would then have abundance to meet all the claims which might come upon them. There were about 14,000 chemists and druggists on the Register, of whom it was calculated 8000 or 9000 were in business on their own account; and if he could not call on the whole 14,000 to subscribe 2*s.* 6*d.* per annum, he might fairly call on at least 5000 to subscribe on the average 5*s.* each. That would give them £1250 a year, besides the interest on their funded property, and they would thus have enough, not only to provide for all necessitous cases, but also to do a great deal of good for the children of their poorer brethren, at any rate to the extent of giving them such a good education as to be of essential service to them in after life. He might add that he had taken out the number of cases to which relief had been granted, and it appeared that 143 were connected with the Society, and 86 were not, thus showing that the Council did not, in judging of the cases before it, consider whether the applicant had been connected with the Society or not, but simply whether or not it was a proper case for relief. At present there were only about 2300 subscribers to the Fund throughout the whole trade, which he could not consider satisfactory, and he therefore appealed to all to do their best to increase the number of subscribers. But he believed the success of the Fund depended very much on the local secretaries in the various towns. He had in his mind one town where there was a local secretary who took an active interest in the Fund, and who had been able to send up a list of something like 74 subscribers; whilst he could mention another town, three times the size, in which there were only three subscribers. There were a great many local secretaries present, and he wished to impress upon them that it was not only a duty but a necessity for them that they should exert themselves in this matter, and that on their return home they would be doing the greatest benefit to their poorer brethren in the trade if they would exert themselves to place the matter fairly before their fellow tradesmen. He was quite sure that many would subscribe if they were asked, but would not take the trouble to send up subscriptions otherwise. One interesting point which had often struck those who had managed the Fund was the gratifying proofs of good they found they effected. Many cases came before them in which, after a little timely relief had been given, the recipient was restored to comparative prosperity. Not long ago a man whom they had relieved several times obtained an appointment which brought him in a fair income, and the first thing he did was to come and pay 10*s.* 6*d.* as his first subscription to the Benevolent Fund. Many such cases could be mentioned, and this showed that they were doing real good. In conclusion he would remind his hearers that he was not asking them to subscribe to the Pharmaceutical Society. It was not a question whether they liked everything done by that Society or not, but simply whether it was the best medium for distributing benevolence to the trade; whether it had done its duty hitherto in that matter, and whether it was likely to increase in doing that which it believed to be its duty. He trusted they would be able to realize from that meeting not only a considerable increase to the invested capital, but also a large increase to the regular subscriptions.

The list of donations was here read by the Assistant-Secretary.

"Success to the Pharmaceutical Society of Great Britain" was then proposed by Dr. Buchanan, President of the Medical Society. He said he was not one of those who desired to see any kind of divergence between pharmacy and medicine. He regarded medicine as having many parts,—indeed embracing almost all the sciences, physics, chemistry, botany, engineering and even law being included. Every year it was found that fresh applications of science were necessary to the success of medicine. If this were the case how could one do otherwise than look on the preparation of medicines, the business of the chemist and druggist, as an essential part of the medical art, and, having the honour to be president of the Medical Society, he had great pleasure in proposing the toast which had been entrusted to him, coupling with it the name of the President, Mr. John Williams.

The President having suitably responded,

Mr. Bottle proposed "The North British Branch." He said it was rather a long way to bring him from the lowest point of the chalk formation to speak about their friends in Scotland, but he was obliged to obey the command of the President. He was happy to say that he remembered the foundation of the Society and he must be allowed to correct the statement of the President that the Benevolent Fund was started soon afterwards, the fact being that it was founded *pari passu* with the Society in accordance with a resolution moved by Mr. Jacob Bell and seconded by Mr. Hanbury. He coupled with the toast the name of Mr. Mackay, but he could not forbear expressing his regret at parting with another of their friends from the north, Mr. Frazer.

Mr. John Mackay, in responding, said it was now many years since the birth of the little bantling in the north, which had no doubt given its parent a great deal of anxiety and some trouble; but it had safely got through all the trials of infancy, had long since cut its teeth, and required some stronger nourishment than Scotch porridge; but he was proud and happy to say that the needful nutriment was always freely afforded, and he believed the parent had no need to be ashamed of its offspring. He had no doubt that in the future the North British Branch would sustain the high reputation of the Pharmaceutical Society of Great Britain.

Mr. W. S. Brown proposed the health of the "The Visitors." He said it was very gratifying to see so many visitors belonging to the medical and other professions at this decennial dinner; and he might here say that he had never heard of such a term before, as applied to a dinner, and hoped that the festival would be either annual, biennial, triennial, or at least quinquennial. It would be invidious to mention particular names, but the presence of Dr. Nicholson, who was connected with Earlswood Asylum, led him to express the hope that at some time or other they might have an Orphan Asylum of their own, which would show the the interest taken by pharmaceutical chemists in the Fund which bore this title. He would not inflict a long speech on the meeting, because he remembered the old story of a man who, after making a long and tiresome disquisition on the question whether oysters had brains, turned to one of his hearers and asked if he thought they had. The reply was, "I should think they have, for they know when to shut up." He would endeavour to be as wise as one of those bivalves, and would only assure their visitors how heartily welcome they were, and couple with the toast the name of Dr. de Vrij, who was so well known to them from his researches on the cinchona barks.

Dr. de Vrij, in responding, said it was now thirty years since he first came to London, and he had therefore witnessed, not the birth, but the infancy and growth of the Society. As a pharmacist of forty-five years' standing he had taken great interest in the progress which they had made in that time, but he must say that they had yet a great deal to do to place pharmacy in the same status as it occupied on the Continent. One thing had particularly struck him in England, viz., the want of a pharmaceutical staff, both in hospitals and the army; and this he considered detrimental both to pharmacy and to patients. Medicine and pharmacy, he considered, should work together in the interests of humanity, each in its own domain without intruding on the other. He could say a great deal on this point, but he was an enemy to long speeches after dinner, and would therefore conclude by thanking the company in the name of his fellow visitors and himself for the kind reception they had met with.

During the evening a selection of vocal music was given by Miss Annie Sinclair, Miss Helen Heath, Mr. Lester, Mr. Mackway, Mr, Montem Smith, and Mr. Winn. Mr. Harradine officiated as toast-master.

THE PHARMACEUTICAL SOCIETY'S ANNIVERSARY.

THE past week has been an interesting one for those who care for pharmaceutical politics, for not only has it seen the customary annual gatherings in connection with the Pharmaceutical Society, but the Trade Association, taking advantage of the fact that many chemists and druggists visit the metropolis at this time, has also chosen London as the place for holding its first Annual Meeting.

On Tuesday evening the Dinner in aid of the Benevolent Fund was held at the Freemasons' Tavern, and was well attended by a large number of pharmacists and gentlemen more or less connected with the calling, whilst several leaders of the medical profession showed by their presence their sympathy with the benevolent object of the Fund. On the other hand the company generally evinced its appreciation of this and other proofs of good feeling by the way in which it received the toast of the "Medical Profession," which was proposed in a very able speech by the Treasurer of the Pharmaceutical Society. An eloquent appeal on behalf of the Fund was made by the President, and it was announced that nearly £1400 had been promised. As the list is to be kept open until Wednesday next we hope that considerable additions will be made to this sum on or before that day.

Although, perhaps, not quite so harmonious as the festive gathering of the previous evening, the Annual General Meeting on Wednesday passed off with considerable unanimity. On the motion that the Report of the Council should be adopted the absence of any allusion to certain questions which are just now seriously occupying the attention of the trade gave rise to considerable comment. However we may presume that none even of the speakers thought that these subjects—of vital interest to the members of the Council as well as to any other members of the trade—had altogether escaped attention, and that really the object of the discussion was to give utterance to the wishes of the members for the instruction of the new Council. The fact that a Bill for the amendment of the Medical Act, introduced into the House of Commons by Dr. LUSH on behalf of the Medical Defence Association, had been issued from HANSARD'S on the previous morning gave additional piquancy to the discussion, but eventually the Report was adopted unanimously. Subsequently the question of dispensing of Co-operative Stores came up again in the shape of a motion instructing the Council to proceed against one of these stores in order to try the point; but the undesirability of fettering the Council in its action was speedily exposed by Mr. SANDFORD and the motion was withdrawn.

On Friday the Adjourned Meeting was held, to receive the Report of the Scrutineers. The result of the election is that two gentlemen will take their seats at the Council for the first time next month.

Before leaving the subject of this meeting, we wish to allude to a matter in which we may be supposed to have a more immediate concern; we refer to some criticisms that were offered as to the manner in which this Journal is conducted. An instance was quoted in which we had thought it to be our duty to abstain from inserting a letter, although, as shown on p. 941, not without acknowledging its receipt, as was erroneously implied by the speaker. We would remark in reply that sometimes when we have reason to believe that a delicate and difficult subject is under the anxious consideration of the Council, we feel it would be injudicious to publish in the Society's Journal strongly expressed opinions that might possibly be embarrassing to the future action of the Society. On more than one occasion we have deemed it wisest so to act in respect to communications upon the questions of co-operative stores and counter practice, but we are bound to say that after the discussions of the present week we shall no longer feel such reticence necessary. But these cases have not been very numerous, and as to the publication of a much larger proportion of correspondence, which it s assumed we receive, we do not think that the interest which some of our readers appear to feel in the correspondence columns would be increased by an indiscriminate admission of all letters received. Another gentleman complained that the trade was not kept sufficiently informed as to novelties, and quoted guarana as an instance. Now the fact is, that it is many years since guarana ceased to be a novelty. When, in 1870, it began to attract increased attention in this country, an account of it appeared in this Journal, and that has been followed at intervals by other notices in which nearly every point of the history of this drug has been discussed. In fact, we think we may fairly claim that in respect to new articles of materia medica—not proprietary articles—we have at least been abreast of the time. Some of the notices —for instance, those on jaborandi and KOLBE's discoveries in respect to salicylic acid—having been the first, we believe, that appeared in the English language. But unfortunately the unfamiliar is often passed by as "too scientific," and with those who have a fixed idea that the Journal is ten years in advance of the trade we can only hope for posthumous recognition.

The Annual Conversazione was held on Wednesday evening, in the South Kensington Museum, which had again been placed at the disposal of the Society by the kindness of the Lords of the Committtee of Council on Education. The guests, who numbered 2446, were received by the President and Council in the Throne Room of AKBAR KHAN, in the Indian Division of the Architectural Courts. In the North Court a selection of music was performed by the Band of the Royal Horse Guards, under the direction of Mr. CHARLES GODFREY, and in the Lecture Theatre a glee party, under the direction of Mr. WINN, sang a number of glees and madrigals.

THE ANNUAL MEETING OF THE CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

THE Trade Association held its first annual meeting on Tuesday, at the Freemasons' Tavern, and this was supplemented by a public meeting in the same place. There was a very good muster at both meetings and a report of the proceedings will be found on another page.

At these meetings, as at the Annual Meeting of the Pharmaceutical Society, the principal topics were the counter practice of chemists and druggists and co-operative stores. Of course, the supposed inaction of the Council of the Pharmaceutical Society furnished food for criticism by some of the speakers, but we were glad to note, as being in accord with an opinion we have continually expressed, that there was a general deprecation of any antagonism on the part of the Association towards the Society. In fact, we doubt not that by this time, if not before, the members of the Executive of the Association have some perception that the difficulties the Council has had to contend with are not to be removed by simple declamation, and the presence of one-third of the members of the Council at the meetings was ample proof that there is no lack of sympathy with the objects of the Association.

We are the more satisfied that this tone of moderation pervaded the meeting, because it acted as a rebuke to that exaggeration which tends to injure any cause. After hearing a gentleman announce that he had long ceased to support the Society, because of its shortcomings, it is rather amusing to turn to the Calendar and find that his support was limited to one year's subscription paid eight years ago, shortly after passing his Minor examination. We venture to say that he would have occupied a more dignified position if, feeling so strongly as he says he does, he had remained in the Society and tried to make it what he thinks it ought to be, a work that can be done by the members and by them alone. Then, forsooth, this gentleman, although qualified to pass the Major, will not do so because he will not countenance the Society by the payment of the fee. Is he aware that a considerable part of the fee would be required to meet the expenses of his examination and that a man may be a pharmaceutical chemist without lending his name or his purse to the Society? As containing considerably sounder views than his own on this subject of passing the Major, we commend to this gentleman's attention the remarks of his fellow-member of the Association, Mr. SLIPPER, made at the Annual Meeting of the Pharmaceutical Society, and reported on another page.

The proceedings of the Executive of the Association from its institution received the hearty endorsement of both meetings, and the only dissentient that we noticed was a gentleman, who, wrapped in the contemplation of the MS. of a speech he had intended to deliver, did not notice that a vote of thanks to the Chairman was being passed, and that he was losing his chance of temporary fame.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening next, May 24, 1877, when a paper will be read on "The Different Methods of Flower Fertilization," by Mr. J. F. SAVORY.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 16, 1877.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atherton, Atkins, Betty, Bottle, Brown, Cracknell, Frazer, Greenish, Hampson, Hanbury, Hills, Mackay, Rimmington, Robbins, Sandford, Schacht, and Shaw.

Several individuals were restored to their former status in the Society upon payment of the current year's subscription and a fine.

After discussing other formal business the Council adjourned to the General Annual Meeting.

THE THIRTY-SIXTH ANNUAL GENERAL MEETING OF THE PHARMACEUTICAL SOCIETY.

Wednesday, May 16, 1877.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

The Thirty-sixth Annual General Meeting of the Members of the Pharmaceutical Society of Great Britain was held at 17, Bloomsbury Square, on Wednesday morning last, May 16, at twelve o'clock.

The Secretary having read the notice convening the meeting, the President delivered the following address:—

The President's Address.

At the close of my year of office as President of the Pharmaceutical Society of Great Britain I feel some diffidence on the occasion of taking the chair at the general meeting of my brother members. Conscious of shortcomings and deficiencies in the performance of my somewhat anxious duties, I can however claim that I have acted with zeal and to the best of my ability.

The Annual Report of the Council brings under your notice the more salient points of interest which have occurred during the past year as affecting the material interests of the Society and of the trade. I would now invite your attention to considerations of another order and well worthy of your earnest thought. I allude to matters connected more especially with the scientific or professional status which has always been regarded as destined to be a most important factor in the position of the pharmacist of the future.

The man who is content with simply passing through apprenticeship or studentship and then rests satisfied with barely scraping through his Minor examination, even he who, graduating as a pharmaceutical chemist, "rests and is thankful," should be aware that what he has now accomplished is properly only a first step and not the final one; and when actively engaged in business (as I trust he will be), he must remember that it is then that his real career as a pharmacist commences, that the trade is one thing, but the profession another, and that if he desires (as who would not?) to attain the highest position his station in life will permit, he must now, more than ever, use his powers of observation, reflection, and thought.

I have sometimes heard brother chemists complain of the business as dull, irksome, and disagreeable; doubtless it is so to many, and for this reason, that those points of interest, which, the intelligent eye sees on every side, in the daily practice of their business, they pass by without notice, they are content simply to work, and, working thus, literally labour.

I think I hear some of my brother members muttering, "It's all very well—how are we to do it? We've as much as we can do to attend to the mere ordinary details of business; we've no time for study or experiments, or thinking about what we can or could do; we have got to earn money, and have no time—no time!—for intellectual pursuits." This is a mistake, and one of a nature most injurious to those who make it. I am now appealing to the younger members of our body—men who have passed their examinations, who are no longer in dread of being plucked, and who are at length liberated from the tender mercies of the demon "cram." I am asking such men to pursue and not give up their studies with the mistaken notion that now knowledge is useless to them, and I am trying to impress upon them that, so far from such being the case, it is now they want all they have and much more if they had it. Now, in everyday routine of business they will find all their knowledge of money value, and that the public—the great ultimate arbitrators on their success or failure in life—will not fail to distinguish between the man who is possessed of scientific or professional knowledge and the mere tradesman.

He whose mind is directed to the science of his business, I venture to state, but seldom experiences this feeling of "labour;" he is led by circumstances to take an interest in what is going on around him, interest, not merely of the "pounds-shillings-and-pence-type," but of a far different kind; he in time becomes an "expert" in the proper sense of the term—perhaps an enthusiast! —although such a contingency would not be advisable in all cases, perhaps. After a while the tradesman becomes a "professional" man, acquires new powers with increased knowledge, and thus by a sure process not only elevates himself but the whole body to which he belongs. No man really succeeds in this life who is not thoroughly in earnest. Competent knowledge and skill must be your servants; these coupled with integrity and common sense will form the best guarantee of future success.

There are occasions when not to advance is virtually to recede, and I take it none of us would be content to be as our forefathers were, something between oilmen, grocers, perfumers, quack doctors, and pharmacists.

I speak with some experience when I say that many of the younger men who are now coming into the trade are quite aware of the force of this argument; still I wish it were more generally, even universally felt. Then we should have our meetings not only of the parent society in Bloomsbury Square or Edinburgh, but also of those various associations throughout the country, overflowing with matter and papers, the reflection of the everyday life of attentive observation bestowed by intelligence upon the business.

It is very gratifying to find from the reports appearing in our Journal that great activity of this kind does exist in many parts of the country. Still there are many ugly blanks—blanks which are to the looker-on rather unaccountable at times. Let us take the case of two large towns of equal population and apparent advantages; one is and has for years been the the centre of active pharmaceutical exertion; the other, on the contrary, has remained perfectly quiescent. It is not necessary I should mention names, unfortunately most members present will be able to supply the blanks from their own personal knowledge. Now I want to call attention to this state of things very earnestly, and to urge upon members of the trade at large, not only in the country, but in those still more desert centres of intellectual sterility—the "outskirts of London"—the desirability, nay, absolute necessity, of establishing "local associations" —where all members of the trade may unite for mutual support, sympathy, and instruction, even, I would add, for strictly trade purposes, when necessary. Such associations exist as I have stated in some places, much to the advantage of the local members, but in many what I am suggesting as desirable is only partially carried out. And here, I dare say, I shall offend some susceptibilities when

I say I am not advocating the formation of associations for the mere purpose of the education of students, however important that may be in my estimation; my earnest wish is to see associations organized for the advancement of "men in business," both in their intellectual and material interests, giving them an inducement for study and the interchange of ideas on the one hand and the legitimate ventilation of trade interests on the other.

I beg I may not be misunderstood; I am not advocating the establishment of purely scientific, or purely educational, or purely trade associations. I have rather in my mind's eye the example set by that noble band of men, who, under many difficulties and much discouragement, founded the Pharmaceutical Society itself. They looked to the scientific advancement of the chemist and druggist of the day as the basis on which to rest the future structure. Still they did not hesitate to devote their means and energies to the advancement of education and the protection of trade interests when threatened in Parliament or otherwise, although never for a single moment forgetting the honour and dignity of the Society, or allowing it to become even by inference a "trade union." All honour, I say, to men like William Allen, Jacob Bell, Morson, Deane, and to many others whose names I might add—names of men, now, alas, too often no more—but who have left their successors a legacy of noble ideas and good intentions well carried out—a legacy whose teachings we are bound to stoutly maintain, foster, and advance.

I am quite aware that to establish local associations in small towns and villages is out of the question, but there are many large towns, centres, I may call them, at present without any local society of any kind, at which the pharmacists and trade should bestir themselves, and, by earnestly setting to work, achieve the success which must follow good intentions well acted upon. In many cases—may I not say in all?—it is really one man, or at most two or three, who determine the fact whether there is a local association or not. Let those who profess to be leaders in those towns at present without associations take heed of this. I hope my words will have some effect, and I think the time of this meeting will not be wasted by my treating on this question. I am sanguine enough to hope the time will come when every large town will possess its own local society in strict association with the parent Society in Bloomsbury Square, thus both giving and receiving support, and advancing the common cause; that the smaller towns and villages will be aiders and supporters to those centres; and that the organization of the trade both for professional and business purposes will become complete.

We have lately witnessed the rise of an association, formed specially to protect the trade interests of chemists and druggists,—an association aspiring to embrace the whole fraternity in Great Britain. Some fear was felt that its action might be antagonistic to the Pharmaceutical Society. I know of no reason why it should be; its promoters emphatically disclaim any such antagonism, and although, as may be gathered from what I have said, this association only very partially meets what I believe to be a necessity of the time, I feel bound to take this opportunity of speaking favourably of what appears so useful a movement.

Thus by being true to ourselves, taking advantage of the opportunities for improvement which may or ought to be within our reach, by not being content to be merely traders, but striving to be something higher, the public will soon learn to appraise us at our true value, and thus, I believe, not only our own interests but the good of the community at large be best—secured and advanced.

The VICE-PRESIDENT moved, and Mr. GREENISH seconded, that the report which had been printed and circulated among the members should be taken as read, which was unanimously agreed to.

REPORT OF THE COUNCIL.

The month of May again brings the Council of the Pharmaceutical Society and their constituents together to review the proceedings of the past year, and take counsel on such matters as may present themselves for consideration.

The financial statement usually takes precedence of other matters in the Report of the Council, not exclusively as a question of income and expenditure, but also, and perhaps more especially, as indicating the present and prospective strength of the Society; the advance of education as tested by examination; and the growth of the class of which the Society is the acknowledged representative.

It will be seen that although the number of "Members" is slightly below the return of 1875, the total amount of subscriptions is in excess of that year's, owing to the greater accession of "Associates" and "Apprentices or Students."

The number of candidates for examination in 1876 considerably exceeded that of 1875, *i.e.*, Preliminary, 1054 against 824; Minor, 468 against 285; Major, 101 against 82. The transference of part of the practical work from the Major to the Minor examination has proved beneficial, and the fact of a reduction in the percentage of failures from 50 to 46·3, is evidence that the change has not been prejudicial to the candidates themselves.

It will be remembered that in the last Report the Council called attention to the fact that the Preliminary examination had been committed to the College of Preceptors. This arrangement has now been in operation long enough to enable the Council to judge and speak satisfactorily of its working. The percentage of failures has been even more reduced than in the Minor examination, the examiners' statistics showing only 42·4, against 50 in the previous year; thus clearly the alteration has had no deterring effect in diminishing the number of applicants. This fact is satisfactory alike to those who look anxiously for the time when only educated men will be found exercising the responsible duties of pharmacy, and to those also who have been gloomily foretelling the coming dearth of assistants.

It has frequently been said, and cannot be too often repeated, that chemists taking apprentices have in their hands a great opportunity of advancing the important interests of pharmacy in Great Britain, by insisting on a previous examination and registration of their pupils.

The amount of expenditure from year to year must necessarily vary. The increased number of applicants for examination; the better arrangement of the Museum; the publication of a catalogue; and the provision of a separate set of specimens for the use of the lecturers swell the amount of disbursements.

The North British Branch has been rendered more complete by the appointment of a paid assistant-secretary, entailing, of course, additional cost to the Society. This appointment was mentioned in 1876, but it has not hitherto formed an item in the expenditure.

On the other hand the expense of the Journal has been considerably reduced; and the Society did not expend as much for law charges as in 1875.

The new regulations announced last year for the distribution of prizes were acted on in October last, and it was gratifying to find, on the testimony of the Professors, that the recipients were well worthy of the distinctions awarded, and of the perpetuation of their names in the Calendar of the Society. An addition to these prizes will be made in several future years through the liberality of Mr. Thomas Hanbury, who has presented to the Society, as well as to the British Pharmaceutical Conference, thirty copies of 'Science Papers' by his late brother, Daniel Hanbury, and thirty copies of the 'Pharmacographia' by the same author in conjunction with Professor Flückiger.

Although it may be matter foreign to the business of the Society, the Council cannot resist the gratification of pointing out to their fellow members the gift, from the same donor, of the admirable portrait of that distinguished scholar and pharmacist, the late Daniel Hanbury.

The Library now contains about 5000 volumes, and it was found necessary to provide accommodation for additional books which had accumulated subsequently to the extensive alteration in 1873. The number of readers in the Library and the applications (both from London and the provinces) for books, furnish satisfactory evidence of the value of this part of the Society's operations. A list of books suggested by gentlemen using the Library comes monthly before the Committee, and great care is taken in the selection of those to be purchased. The legacy bequeathed by the late Daniel Hanbury continues to be applied in the purchase of standard works of exceptional value.

In the Museum considerable efforts have been made to augment the collection and to maintain it in perfect condition. Previously specimens were removed from the cases day by day for the use of the lecturers. Although such an application of them was of great value, certain disadvantages arose therefrom, and it was determined to provide as far as possible a separate collection to illustrate the lectures. Again reference must be made to the kindness of Mr. Thomas Hanbury, and the life-long work of his brother. The valuable collection of Materia Medica, and the herbarium, formed by Daniel Hanbury, both containing many historic specimens, have now become the permanent property of the Pharmaceutical Society, and a special apartment has been assigned to them.

At the Evening Meetings many interesting papers have been read and discussed. The Council cannot too urgently invite members and associates, especially the younger ones, to join in these pleasant gatherings. Besides affording opportunities for obtaining and diffusing valuable information, these periodical meetings tend to keep up that feeling of good fellowship and *esprit de corps* which is the very life blood of a society.

During the past year the School of Pharmacy has been well attended; the classes, although somewhat smaller than those of the previous session, have been marked by diligence and an evident desire on the part of the students to avail themselves of the means offered for improvement. It is gratifying also to see that many of the young men who attend the School in the day, with some others of former sessions, embrace the opportunities offered by the periodical evening meetings of the Students' Association, which are held, by permission of the Council, in the house of the Society.

No measure affecting the interests of chemists and druggists has been proposed in Parliament since the last meeting of the Society.

Many prosecutions for infringement of the Pharmacy Act have been instituted during the past year and successfully carried through. In still more cases the Registrar has compelled offenders to discontinue their illegal practices. A very daring attempt to obtain registration by fraud, which for the moment was successful, occurred at the end of last year. A candidate for the Preliminary employed another person to represent him before the Board of Examiners. The case was tried and the offenders convicted at the Central Criminal Court; a full report appeared in the *Pharmaceutical Journal*. It is mentioned here more particularly to put Superintendents of the Preliminary examinations on their guard, and to show the necessity of identifying the candidates.

It will be remembered that some difficulty arose last year respecting the preparation of belladonna and aconite liniments with methylated spirit. The Board of Inland Revenue issued an interdict against that practice, and it was felt to be the duty of the Council to memorialize them on the matter. The memorial being couched in terms to show that the Council would in no way encourage or connive at any infringement of the Methylated Spirit Act, or any substitution of methylated for rectified spirit in the composition of medicines for internal use, met with that courteous consideration which has always been accorded to the Council by the authorities at Somerset House, and the previous decision of the Board was reversed.

The operations of the Benevolent Fund during the past year have been satisfactory. Four fresh annuitants were elected in October last, making twenty-four annuitants up to Christmas, representing an annual charge on the fund of £720. The casual grants to applicants amounted to £470. It is gratifying to observe that the annual subscriptions have exceeded those of 1875, by about £200, and the number of subscribers has increased from 1706 to 2347, showing a more widely spread interest in this important fund.

Before the official publication of this report, although after its preparation, an important gathering in aid of the Benevolent Fund will have been held. The Council decided on announcing a dinner at the present time for various reasons.

It is now ten years since the last dinner, which proved eminently successful, was held for a similar purpose. Ten years is the period allotted to firms as the limit of their privilege of voting in consideration of their respective donations, and many will doubtless be glad to renew that privilege as well as to extend aid in so good a cause. Another very important point is that the annuities, *which must never be jeopardized*, now exceed considerably the interest on invested capital, and although the Council would not for a moment anticipate any diminution of the annual subscriptions, they cannot as prudent guardians of the fund omit putting this question prominently forward.

By a new regulation which will come into operation in 1878, a provision is made to give votes, in proportion to his previous subscriptions or donations, to any person who may at some future time be under the necessity of seeking aid from the Benevolent Fund and be placed on the list of Candidates for an annuity.

FREDERICK BARRON,
WILLIAM HODGKINSON,
EDWARD HORNER,
HENRY AYSCOUGH THOMPSON,
WILLIAM SQUIRE,
Auditors.

March 26, 1877.

Mr. Jones (Leamington) said he was pleased to meet so many old friends in the room, and especially pleased, as the President of the Trade Association, to hear the kind remarks which had fallen from the President. That gentleman had also given a practical proof of good feeling towards the Association by a handsome donation from his firm. That donation was received with great pleasure, and on the part of the members of the Association he could thoroughly reciprocate his kind feeling, and say that they had no antagonism whatever towards the Society, their object being to work hand in hand with the Council to promote the general interests of chemists throughout the country. They felt there were matters which might fairly be considered as strictly trade matters, which the Trade Association could take up, and if they were at any time at a loss he was sure the Council would assist them with its advice. He was pleased to see that the financial statement of the Council showed that the funds were in a flourishing state. As regarded the number of candidates for examination it was a matter for congratulation to see that for the Preliminary they had increased from 824 to 1054; Minor, from 285 to 468; and the Major from 82 to 101; and it was especially pleasing to see the increase in the number of Major examinations, particularly to the Council, which was anxious that the number of members of the Society should increase. As a local secretary he might be allowed to say a word or two on the Preliminary examination. He considered, from some experience, the examination to be a very fair one. It was just such a one as a young man who had been fairly educated ought to pass, and he had always contended that when any candidates were plucked it had arisen, not from the fault of the Council or those who undertook the examination, but from their own fault in not passing it immediately they left school. No doubt many of those present, if set to work a very difficult sum in arithmetic or decimals, or to construe a long page of Cæsar, might find a difficulty, and so with these young men after they had left school some time. But when any such case happened within his experience he always recommended the parties to apply to a competent schoolmaster for instruction, and on the next occasion he found they passed a very good examination. He should recommend all his friends who took apprentices to insist on their passing the Preliminary examination immediately they left school. The examination was not by any means too severe, especially if taken at that time. The next point in the report referred to employers giving facilities to their assistants for study, and he was pleased to say that he knew a great many who took apprentices were now in the habit of giving them time to improve their minds and increase their knowledge. Then the report referred to the satisfactory condition of the North British Branch and to the fact of their having engaged a paid secretary. Of course that was only what they might expect from their Scotch friends, they knew how extremely well they managed all business matters, and with Mr. Mackay and the other Scotch members at the head he doubted not that the North British Branch would continue to flourish. Then a reference was made to the donation from the late Mr. Hanbury, and he could not pass that over without saying a word or two, because he had had the pleasure of enjoying Mr. Hanbury's society and friendship, and it was indeed a great blow to him when he was removed. He was glad to find the evening meetings had been pretty well attended, and he hoped the numbers would increase. It was a very great advantage to young men living in London to be able to attend those lectures and obtain information which could not fail to be of advantage to them. Then the report stated that no measure had been introduced into Parliament affecting the interests of the trade since the last meeting. He was sorry to say that one was now introduced which would require their very careful consideration, and perhaps they might hear from the Solicitor later on what interpretation the judges would probably put upon the most important clause in it. Then the report referred to prosecutions for illegal trading, and the next point was one with respect to the Benevolent Fund. The great gathering on the previous evening must have been very gratifying to the Council, especially as there was such a considerable increase in the funds. He wished every member would give according to his means, and in fact that every chemist throughout the country would give a small amount and then it would in the aggregate realize a large sum. They knew that chemists were not wealthy men; they generally managed to live quietly and comfortably, but their pockets did not get very full, and they were not able to leave large sums to those whom they left behind them. Sometimes misfortunes overtook people, and if a man felt that he had £30 a year to live upon, although it was not much, still it would keep him from the workhouse, or from starvation. He, therefore, hoped that not only donations but subscriptions would continue to increase from year to year. They must all be of one opinion with regard to the efforts made by the Council to encourage education and business-like habits amongst young men, and he was pleased to see that one of the examinations had become more practical, because that was what they wanted. They required not only a young man who was well up in chemistry and atomic weights, but one who knew the practical parts of the business. He had great pleasure in moving—

"That the report of the Council as now read be received, adopted, and printed in the Society's Journal and Transactions."

Mr. Slipper seconded the resolution with great pleasure, and said he felt it a great privilege to do so, and to follow Mr. Jones, who was so active and useful a member of the trade, and altogether a man of whom any society might be proud. He agreed with him very much in his remarks about education, especially about the education of those coming into the Society. He had always felt considerable interest in that point, and he was glad to find that the handing over of the examination to the College of Preceptors had been successful. He also sympathized with Mr. Jones's remark about tradesmen in the country insisting on parents and guardians seeing that those who were about to be apprenticed in this business should pass the Preliminary examination before the premium was paid. Any one who took apprentices would feel it much more pleasant to undertake the training of a youth who was properly prepared for the business in which he was going to be employed; and, therefore, he thought their country friends, who were more accustomed than those in London to take apprentices, should almost insist, if they took an apprentice, that he should be able to read a passage in Cæsar if it were put before him, and do certain other things, which forty years ago he himself might have been able to manage, but which he did not know that he could do so well now. He was glad to see that the number of Minors had increased, and he should like much to see the Majors increase also, because he thought it was very desirable that those who had got their Minor creditably should pass on to the higher examination. If a man thought at all about the interest of his order, he should feel that he had not attained his proper position until he was able to make use of the title, "pharmaceutical chemist." He was surprised to see so many young men go into business as chemists and druggists and remain so when a very little time given for the work would enable them to get through the Major examination creditably. He agreed with Mr. Jones that theirs was not a money-making business; but there was a satisfaction in feeling that wherever they were placed, they held a reputable position. He knew some of their friends spoke of themselves as professional men; but he must say he ignored that altogether unless they went in for the higher branches. He called himself a tradesman, and he thought most of them were tradesmen who dealt with the kind of things that came in their way. For any one to call himself a professional man who dealt in patent medicines and so forth appeared to him a misnomer. But still they might consider themselves as members of one of the most reputable trades that could be followed, and into which no one could enter unless he had received a respectable and something like a classical education. If they did not get very rich they ought to endeavour to uphold their position, and that might be considered almost a recompense for not making much money. With regard to the sale of methylated spirit he was very glad to see the good results which had followed the action of the Council, because it did seem a most anomalous thing that the distinction should be made between one liniment and another. It was quite absurd that they should be allowed to make soap liniment with methylated spirit, and not belladonna, which was a preparation that it was specially desirable they should make as reasonable as possible; and it was, therefore, very gratifying to find that the attention of the Council had been called to the matter, and that the Board of Inland Revenue had acceded to its request. He had been much pleased to be at the Benevolent Fund dinner on the previous evening, and hoped the Fund would be still more helped in the following year. He had been much struck with the figures stated by the President, showing how much would be produced if every chemist in the country subscribed 2*s.* 6*d.* per annum; and it did seem marvellous that there should be a chemist or druggist who did not subscribe. No one could tell what might happen to him, and the amount required was so small that he was surprised to find that any one did not subscribe at least 2*s.* 6*d.*, if not 5*s.*, to the Fund. He therefore trusted the remarks made by the President would receive attention, and that the Fund would be better supported in future.

Mr. Vizer (Brighton) said he was sorry he was too late to hear the address of the President, and with regard to the report he was also sorry that he could not enter into it with so much gusto as the last speaker. He did not regard it as quite so satisfactory; on the contrary, he thought it one of the most unsatisfactory ones he had read for a long time. He would not touch on many points on which observation might be made, as, for instance, on the decline in the number of members, which was a question that he had often spoken upon before, but he did wish to say a few words upon some points in it. He opened this report with some feelings of anxiety, being particularly desirous to know what the Society was doing in reference to subjects which were occupying a very prominent place in the minds of all their brethren. He read it carefully through paragraph by paragraph, and was astounded to find that not one single word was said upon the points on which he wanted information, and which he knew were uppermost in the mind of the trade. A very important decision which had been lately arrived at, with reference to the *lac sulphuris* question, was entirely absent, and the question of co-operative stores had failed entirely to stir the equanimity of their worthy brethren the Council. Again, he was astounded to find that the Nottingham case was not even alluded to. Was it the fact that the Council could sit there quietly and see a chemist fined £20, with a knowledge that the same thing might happen to any of themselves any day of the week, and yet not be disturbed about it? It had not only not been alluded to, but he found it stated that no measure affecting the interests of chemists and druggists had been proposed in Parliament since the last meeting of the Society. Now, he did not want to say anything harsh, but yet, as one engaged in the business, he must say that if the Council could not see clouds casting their shadows before them, it would be a very peculiar thing to his mind. Who could not foresee, from what was found in the *Lancet* of only Saturday last, that some day or other steps would be taken to settle this all important question with reference to prescribing over the counter? The paragraph to which he referred was on the 12th page of the *Lancet*, where it said that a Bill promoted by the East London Medical Defence Association had been introduced and read a first time on the 2nd May, bearing the names of Dr. Lush and other persons in high position, the object of which was that "any person not already registered or not qualified at the time of the passing of this Act to be registered under the said recited Act, who shall make, fill up, or sign any medical certificate for the purpose of an Act of Parliament, or who shall practise medicine or surgery for gain, unless such person has a duly registered qualification or qualifications in both medicine and surgery, shall likewise on summary conviction for any such offence pay the sum of £20." He was perfectly aware that in touching on a subject of this kind they stood in a most delicate position. Far be it from him to say one syllable that would compromise their position as dispensing chemists. He felt that the medical profession was an honourable one, and one which would not desire to unduly harass them. And from the intercourse he had had on the subject with different medical men, he was satisfied that it was not against the legitimate chemist that the medical profession was embittered, but it was against a class which he was quite confident the majority of chemists would equally deprecate. He would not advocate indiscriminate unlimited prescribing, for such was not their vocation; but whilst he maintained that, he also maintained that it would be a perfect impossibility, if this Act were carried through the House, for them to carry on business from day to day without incurring the liability which he had mentioned. Under these circumstances he was sorry to see the subject was not referred to in the report. Whether the President had touched upon it in his address he could not say, but he would impress upon the meeting most earnestly that the Council ought to put their shoulders to the wheel and face the difficulty which met them. He rejoiced to know that another organization was in existence, from which he believed, material help might be obtained, and he sincerely hoped that the two associations might work harmoniously together. He saw no reason why the trade association should not become instead of a very powerful opponent, as it might easily be, a very valuable support to the Society, and as such he hoped the Society would countenance it. Co-operative trading action was a very important question which no doubt they were all tired of hearing about, but at the same time they were equally tired of experiencing it, and he did say on mature consideration that the trade had a right to demand of the Council an absolute settlement of that question. Whether it was right or wrong they ought to know the fact. He was quite aware of what would be said about it, but if it were right that the Pharmacy Act was to protect them, and that persons had been prosecuted for carrying on business with qualified assistants, he did maintain that what was good for an individual must hold good in the case of multitudes of individuals, and therefore he thought they had a right to demand of the Council that this question should not be delegated to other parties. He admitted that the Society had carried on a great work with reference to education, but he did not think that was all it had to do; whereas in looking through the report, what did he find? Out of twenty-two paragraphs, eight were devoted to educational subjects, four to the Benevolent Fund, one to the infringement of the Pharmacy Act, but not one to any subject really touching their trade interests. With regard to this medical question, he held in his hand a resolution which was moved by a gentleman highly respected by all the older members of the association, Jacob Bell, in 1841, with reference to a Bill then before Parliament,—"That the provisions of this Bill deeply injure the interests and lessen the usefulness of chemists and druggists as well as affect the comfort and resources of the poorer classes of society, whilst the immediate and pressing wants of individuals would create a liability to informations which would be a source of increasing vexation."

He thought that was a good example for the Council to look at and carry out. They knew that such an Act as he had referred to would be highly injurious and detrimental, not to themselves only but to the public, and he believed that if a memorial were got up the public, as well as the trade, would sign it in great numbers. He therefore commended this subject to the attention of the Council, as it seemed to have been forgotten, and hoped it would receive careful attention.

Mr. YOUNG said he also was astonished at the apparent apathy of the Council with regard to the impending action of the medical profession as it influenced the trade. They had certain rights, and they ought to look to the Council to maintain those rights, so that they might hand them down intact to their successors. But speaking for himself, he must say, that if such an Act became law, he might close his shop. No doubt the medical profession was a very honourable one, but he did not give the members of it credit for having quite such good intentions as some gentlemen did towards chemists. That profession was already in possession of the Apothecaries Act of 1815, which gave them abundant power to prosecute medical nonconformists, and it was hardly likely they would go to Parliament for powers to prosecute medical eclectics, botanists and the like; they might depend upon it that chemists and druggists were really aimed at. Now he believed that chemists and druggists were a very important wheel in the social fabric, and that they ought to be supported. On a similar occasion some years ago, when a Bill was being brought in for the special aggrandizement of the medical profession, Sir Francis Burdett remarked in the House of Commons that they ought to be cautious lest they fell into pernicious error; they had not the power in England of compelling people to submit to medical prescriptions and surgical operations as was the case in some foreign countries, but only to the laws of the land. But if they did not look out they would have to submit to physicians' prescriptions and the operations of surgeons, because it was clear that chemists would not be able to afford any relief to the poor. He therefore hoped that the Council would take up the matter and he felt sure that the public would willingly sign in thousands any petition which might be prepared.

The PRESIDENT remarked that this Bill had been only published on the previous day, and that the Parliamentary Committee which met in the afternoon had had it under serious consideration, but it was impossible it could have appeared in the report which was printed a week previously.

Mr. URWICK was sorry he could not quite follow what had been said by a previous speaker as to the great advantage and gain to the Society from the increase in the number of persons examined. It was quite true there was a slight increase over the numbers in 1875, but if they went back to 1874 there was a decrease in all the classes except the one in which he was most pleased to see an increase, namely the Major examinations. The principal suggestion he had to make was as to the Shepperley case. No doubt the Council thought it was acting rightly in having nothing to do with it, but he could not forget that when the Society was formed the charter set out as its main objects not only education, but the protection of chemists and druggists, not of pharmaceutical chemists alone; and in the Shepperley case there were many things which affected their interests. He had never given himself to prescribing, because he did not like it, but still they were bound sometimes to prescribe. He always liked to keep within the law, and he should like to know what the law really was, and no doubt many others were in the same position; and while appreciating what the Society had done for education, he thought it ought also to have done something in this case. The Council might have good reasons for not taking it up, because there were many things known to the Council which were not known outside, and therefore he was quite prepared to believe that it had acted conscientiously. But there was another course which he thought might have been taken with advantage to the trade at large. The case might have been watched by the Solicitor, because very often in those cases, if the circumstances did not come exactly within the Act, there were principles involved, which rendered it important to know what was done, and to render assistance to the magistrates, especially with a view to dealing with future cases. He therefore thought it would be a great advantage if the Society appeared to watch the case, and no doubt the judge would have sanctioned it. Another serious matter was the co-operative trading. That was a very difficult question, and he was afraid many of the trade did not know all the difficulties. He believed many of these associations really came under the Benefit Societies Act, and that where men were associated together in supplying themselves they came within that Act, and had a right to be supplied with any articles at whatever risk or prices they could supply themselves at.

Mr. BULLEN (Westrup) supported the resolution, and in doing so said he did not propose to offer any criticism on the action of the Council, because his voice had been so rarely heard on pharmaceutical politics that he should consider it impertinent to offer any comments of his own. He only wished to make a suggestion, and to raise, if possible, a discussion on a point which had been more than once mooted there, namely, the administration of the Benevolent Fund. The President in his excellent address on the previous evening had alluded to the desirability that all annuitants on the Fund should have their income dependent on money absolutely invested and not on current subscriptions; but while he bowed readily to any opinion of the President, he thought that such a policy, although eminently safe, was not a wise one, and that a bolder and more liberal course would be more desirable. The gentleman who seconded the adoption of the report had remarked on the comparatively few subscribers to the Fund. It appeared that there were about 8000 chemists in business, of whom only about 2300 subscribed to it, and although he could not easily account for this fact, he thought it might to some extent be explained by the fact that they did not feel that personal interest in the matter which they would if there were a larger number of annuitants, and if they felt a closer association with the Fund. He thought it would be much wiser to throw themselves on the liberality of pharmaceutical benevolence rather than to invest all the money. A country chemist looked at 5*s.*, and, taking the time and labour into consideration, there was probably no money earned more hardly than that earned by chemists and druggists in the country. He looked at this 5*s.*, and though he would be glad to give it towards an annuity to an old friend who had broken down in business or fallen into distress, he did not feel inclined to hand it over to the Pharmaceutical Council to be invested in the 3 per cents., which would produce only 1½*d.* per annum out of the 5*s.* If the governors of the various orphan asylums and other charitable institutions were all to determine that no child at school and no poor person in the asylum should receive any benefit except what was derived from the interest of invested money, it would be a great calamity and a great reflection on the benevolence of the British public. But it would be a libel to suppose that the benevolence of chemists was not equal to that of the ordinary British public, and if they were to throw a little greater strain on these current subscriptions, he believed they would still bear it, and that the pulse of this pharmaceutical benevolence, which was healthy if not very robust, would throb with much greater power than it had hitherto done. He would, therefore, suggest that ten more annuitants should be added so as to charge an additional £300 on the current subscriptions, and he believed that if this were done it would give local secretaries a much stronger interest in the matter, that they would readily respond to the call, that the Benevolent Fund would be made much more useful, and that they would be more than recouped the extra £300 required. It need not be feared that the money would not be forthcoming in all future years, because there was no reason why succeeding chemists and druggists should be any less benevolent than they were at present. The experience of last year was a strong warrant for being more liberal in the disposal of this Fund, since £1359 had been received against £1145 in the previous year. One other item he should like to allude to, namely, the action of the Pharmacy Act with regard to one particular class of persons connected with the trade, and it seemed to him it was in that direction it was likely to throw upon the Benevolent Fund more candidates than would otherwise make claims upon it, namely, the widows of deceased chemists. He believed the Act did not allow a widow to carry on business in her own name even with a qualified assistant. It struck him it was rather oppressive in that respect. He had always been anxious that the Act should be carried out fairly and that no unqualified person should carry on business whose name was not on the register; but if a poor woman whose husband was just dead, had a son of 17 or 18 likely to succeed to the business, or if she herself by the aid of a competent assistant could carry it on for the rest of her life, so as to obtain a living, he thought it extremely desirable, and it seemed somewhat of an oversight on the part of those who drew the Act that some special exemption in favour of a *bonâ fide* widow of a chemist was not made. He hoped, therefore, the Council would be very careful in applying the Act and not allow it to be made in any way oppressive in that direction.

Mr. Fitch (Hackney) said that whilst he fully endorsed all that had been said by the President he must say there was one part he had passed over very cursorily, and that was the question of co-operative stores. He had always considered that the stores did not protect themselves by having a qualified assistant to manage, and that probably there was something in the Act which would show that they were not exempt, and upon looking into the Act he had been confirmed in that opinion. But feeling some doubts upon the subject, he wrote to the Editor of the Journal, desiring to ventilate the question amongst his brethren, but his letter was not answered. That was in December, 1876. In that letter, he referred to the Pharmacy Act, 1868, and especially to clauses 1 and 17, which seemed directly to meet the case of co-operative stores dealing with the public, and asked him if any one could take proceedings under the Act, or if they must be taken by the Registrar of the Society, adding that if he received an answer to the effect that any one could prosecute, he was prepared to do it, because, when he joined the Society, he understood that a certain amount of education was required from its members, and that the Society would protect them and see that no one outside robbed them of their just privileges. Receiving no answer, he waited until January, and then thinking his letter might have miscarried,* he sent a subscription by a crossed cheque to the Secretary and enclosed it in the letter so as to be able to prove delivery, —that was on January 17, 1877. In it he referred to his former letter and asked if it had been received, for that he had taken legal advice and was informed that co-operative stores could be prosecuted. To that letter, as to any letter addressed to the Secretary, he received a polite reply, saying that if he would furnish him with the names of any persons who were infringing the Act he would take proceedings. He accordingly furnished him with the names, but he was not aware that any proceedings had been taken. He then proceeded to state in detail the steps which he had taken to prove the infringement of the Act by the dispensing of a prescription containing poison, and also the sale of tincture of aconite not properly labelled, at a place of business professing to be a co-operative store, the prescription being labelled, not with the name of the man who served it, or with the name of the establishment where it was served, but with the name of a Mr. Flowers, of 112, Victoria Street, which was a considerable distance off the place where he purchased it. When he got home he took the trouble to inquire of a friend if Mr. Flowers was alive, and heard that he died the day before. This was going on continuously,—he did not say at the civil service stores, because he believed they were conducted respectably—but at these Brummagem stores. He had a son, twelve years old, whom he thought of making a chemist, but he wanted to know if he might forego his education and the cost of passing the examination and buy a big shop and put a qualified assistant in it, and whether that would protect him the same as it did the stores. Legislation to be just must be fair and equal. If the stores were allowed to do it individuals were allowed to do it, and if a chemist were prosecuted for selling syrup of poppies without a label, as took place only recently, why was it that he could take up the price list of many of these stores, as for instance, the Provident Supply Association, which was recently defunct, and find poisons publicly advertised for sale? Was that to be allowed to go on or not? The last remark he had to make was with regard to widows. Could it be right that if any one of their number died his widow might not carry on the business by means of a qualified assistant, and yet the same business might be conducted by a co-operative store? He had not yet joined the new association, because he thought the work ought to have been done by the Council, and if the Society wanted more subscriptions it ought to appeal to the trade, and he, for one, would readily respond. In two years time they might have some other society coming forward and saying the Trade Association did not do the work properly, and that it was going to do it. His idea was, that in that Society they ought to be welded together in one body to give a superior class of education for the benefit of the public, and to shut out outsiders. Two years ago it was his misfortune to prescribe for a man—he could not help himself; a fortnight afterwards he called again, when he was out and asked for two ounces of laudanum. His assistant asked Mrs. Fitch what he should do, and she said he seemed a respectable man, he had better let him have it. However, his assistant had more sense than his wife, and only gave one ounce, and that he took home, and immediately tried to poison his whole family; fortunately he did not succeed, and but only managed to cut his own throat and one of his children's. He afterwards saw him at Horsemonger Lane gaol, when he wanted to know if he would speak for him at the trial and he said he would do so if properly subpœnaed. The trial in due time came on, but it was not reported, because the trial of Colonel Baker, which had much more interest for the public, happened to be on the same day; the gaol surgeon gave evidence, also a surgeon from Penge, and a mad doctor or medical expert was also called, and he himself also gave evidence. When Justice Brett came to sum up he said with regard to the medical evidence it was as usual; they seemed to come there more to air their theories than to enlighten the court on the facts of the case, and the first direct evidence they got was from the chemist at Hackney who clearly told them what the symptoms were and what he prescribed. Those were the words of one of the judges who might on another occasion have fined him £20 under like circumstances. He thought some resolution ought to be come to that the incoming Council be urged by every means in their power take up the prosecution of the stores as long as the secretary and directors were not on the register.

Mr. Humpage said his impression with regard to cooperative trading had been only confirmed by the statement of the last speaker; but at the same time the question struck him whether at a meeting of that kind

* This statement is hardly correct, nor was the inference justified. On the 6th of December last, a letter, which we suppose to be the one referred to, was received from Mr. Fitch, signed "M. P. S. G. B.," and its receipt was acknowledged under that signature on p. 488 of the Journal for December 9.—Ed. Ph. J.

it was a question which they could go into and decide. He agreed most fully with what had been said to a certain point, that they ought to know distinctly their real position, and if by the arrangements which these stores adopted the Act could be defied, it was well it should be known, and they must pocket the affront; but to go to a meeting like that, and point out the unfairness and the dishonesty and the disgrace of those who carried on the stores,—and he would add equally of those who encouraged their being carried on,—was of very little use. There was no law to prevent a person who called himself a gentleman from cleaning his own boots; and in the same way if a squire drove up to town, he might buy what he liked, and take it home in his carriage, and they could not prevent it. If they had the power to prevent these stores from selling poison, let them put it in operation; but he would not say a word against the action of the Council, because he believed they had on that Council gentlemen, not deficient in brains, who were desirous of doing all they could for the Society. If they found that the Council would willingly take up such cases if it had the power, but not having the power it did not do so, it was mere folly to come to the meeting and complain. He had been struck with the very few friends who had ever read or seemed to know anything of the extremely interesting pamphlet which was published in 1841 by Jacob Bell on the progress of pharmacy. There the case was stated most distinctly, how the apothecaries acted towards them in 1813 and 1814, and how the trade acted in reference to that attack. Finding their interests were about to be interfered with, they met together —all the leading men in London taking part—and said they could not assent to this Act of the apothecaries, which would virtually crush them. The meetings were carried on for more than a year, and at last a resolution was drawn up and agreed to by the Apothecaries' Company, that a certain clause should be inserted in the Act to leave chemists exactly as they then were, and that their successors should not be interfered with in the future. The apothecaries did not like it, as was clearly shown in this pamphlet, but they could not do better; therefore they accepted that clause, which was referred to counsel before it was agreed to, in order to prevent any mistake. From the year 1815 up to the year 1841 that clause did seem to protect chemists and druggists, for it was not upon record that any one had been prosecuted for the period of twenty-six years. Now, if the Apothecaries' Company, having the desire to interfere, took no action for twenty-six years, it was manifest it felt it could not. In 1841 Mr. Hawes brought forward a Bill, and there was then an attempt made to interfere with the rights of chemists. Their action was then repeated; the trade were called together and an arrangement was again come to, that a clause should be inserted so that the rights of chemists should not be interfered with in any shape or form. It was sometimes said that they must not use any of the money of the Society for legal purposes in defending actions and so on; that it was not their business to go to law. Now he was an enemy of law as much as any one, because he thought that the clients generally got the shells and the lawyers the oysters; but still occasion might arise when it was necessary, and he wished here to refer to what was done in 1841. After having obtained a second victory in that year, Jacob Bell, with his usual sagacity, said here was a valuable association of the trade,—why should it be dissolved? And the result was that the Pharmaceutical Society was founded, and £500 which had been invested by the consent of a meeting in 1815, as a fund for future proceedings, and which had accumulated to £800 in 1841, was handed over to the newly formed Society for the purpose of defence, and for promoting education. He therefore thought they had some claim on these funds for defending their rights, when they were attacked. With that clause, which had protected him for thirty-five years, he did not feel inclined now to submit to its being said that he was infringing the law and acting unfairly towards the medical profession. His father was one of the old apothecaries; after being two years in his surgery he was sent to one of the first houses in Bristol, and when he went there he found in that establishment prescribing was constantly practised by the principal who never thought if he asked a man to open his mouth that he would be prosecuted for it. He had travelled all over the kingdom and he never knew a chemist's shop where prescribing was not more or less carried on; but still it was a question of degree. While he would denounce any man who went beyond a fair line or represented himself as a medical man, he contended that chemists had their rights, which seemed now being nibbled away; and they ought to stand up for them. He thought that it would be well if the Council would say directly or indirectly that it was prepared to defend those rights. Reticence might be carried too far, and he was quite sure it would be very beneficial if their friends outside were to know that the Council was as much interested and as much disposed to do what it could in the matter as any outsider.

Mr. CHURCHILL (Birmingham), said he was surprised beyond measure to see that no reference was made in the report to this burning question of counter prescribing. As many of his friends knew, he was not at all in favour of counter prescribing, and in his shop there was as little of it as possible, and he believed that was the case with a great many of those who were present. He hoped the day would come when doctors would do all the prescribing and chemists all the dispensing; but he was afraid that day was still far distant, and until it came, when by mutual agreement or by parliamentary interference such a solution of the difficulty could be arrived at, it would be unwise for the guardians of the trade to budge an inch from the present position taken by the trade—namely that they claimed the right to prescribe in simple cases. Possibly the difficulty would some day be solved on this basis, that the medical man should be prevented from dispensing if there were a chemist within a certain distance, and that the chemist should be prevented from prescribing more than a single dose of medicine—that would get over all the difficulty of the chemist being called upon to precribe in a case of emergency. He was happy to know that the interests of the trade were now being well looked after by an association which took trading matters under its particular cognizance, and which would spare no expense in fighting out this matter of counter prescribing. Nevertheless, he was surprised that no allusion whatever was made to it in the report. With regard to co-operative trading, perhaps some had gone a little further in this matter than others, and those who had gone into it knew that the Council of the Society had in past years given attention to it and had found it surrounded with great difficulty. He did not think when the trade knew all the circumstances,—and there were some which it was very difficult to lay fully before the trade, because that would be equivalent to laying them before the public,—it would be seen that the Council, if it had acted weakly had very good reason for so doing. But he could not believe that the Council would now allow the matter to go entirely unheeded when such evidence was placed before it as had been offered by Mr. Fitch. It was very often said that it was difficult to lay hold of these societies, because they had a right to dispense for one another, but here was a case of one of the outside public going and obtaining such a poison as tincture of aconite.

The PRESIDENT asked if Mr. Fitch was a member of the co-operative association.

Mr. FITCH: No.

Mr. URWICK suggested that the particulars of the case should not be published and that the Council should take it up.

Mr. CHURCHILL asked how long ago this occurred.

Mr. FITCH replied on the 5th of April. The place referred to had used the label of a store which had become bankrupt and closed.

Mr. CHURCHILL said he hoped the particulars would not go beyond that room, that the Council would be able to institute proceedings. In another place on the previous day he had heard one gentlemen complain that the Council did not prevent co-operative stores selling Mrs. Allen's Hair Restorer for less than six shillings a bottle. Of course they knew the Society could not interfere with such matters as that, but when all the rising generation of chemists were educated at great trouble and expense in order to qualify themselves, it seemed to him from their point of view, to say nothing of the public point of view, it was their duty to look into such a flagrant case as that which had been described. There was another aspect of the question in regard to which he had heard of a great many complaints although he personally had not suffered from it. There were, to his knowledge, in Birmingham three cases, and in the surrounding districts many others, of young men opening what were to all intents and purposes chemists' shops, dispensing medicines, probably containing poisons, who had not passed the examinations. Very often these were young men who had tried to pass the examination but had failed, and it seemed to him that the Society was bound, seeing it received fees to qualify men, to prosecute those who set up in business without passing its examination. He did not wish to confound with such cases those of persons selling patent medicines, because he knew they could not be interfered with; but there were numerous instances of illegal trading, and in such cases the Society had not done its duty in not looking more actively after them. There was a strong feeling amongst some chemists that the habit of the officers of the Society of giving warning when information had been obtained acted very detrimentally in preventing the obtaining of similar evidence on a future occasion. If he went into a strange town where he knew illegal trading went on, and bought some laudanum or oxalic acid, and the matter were laid before the Council and the Secretary wrote a letter warning that man, it was not likely if he went to that town again that he should be able to obtain the poison, although the same person might continually supply his customers illegally. He was certain that that was done in many instances. But he was very happy to see the recent decision of the Treasury in reference to the fees, and he hoped it would encourage the Council to go on prosecuting many of those cases. But apart from that he considered it its duty to prosecute. Another matter he had greatly at heart was the Benevolent Fund. He would not say anything about the management because he thought they all felt that the Council managed the Fund economically and well; but on looking through the list he could not help seeing what a small list of donors there was in his own town and in the country generally. He also thought that many men who were well off threw 10*s.* 6*d.* to this Fund as they would 6*d.* to a railway porter. The proper way was not to give under a momentary impulse but to look into one's income and see how much one could afford to give. He might mention that two chemists in Birmingham determined to go into the matter and canvass the town thoroughly, and the result was that three-fourths of the trade in that town contributed to the Fund and he had no doubt would continue to do so in years to come. He mentioned that in the hope that others would do the same in their neighbourhood.

The PRESIDENT said he was astonished at one statement which had just been made, that cases of known infringement of the Act of Parliament existed in Birmingham to a large extent, which the Council had neglected to prosecute, because he might say that every case brought before the Council was attended to carefully. It was quite true that hitherto offenders had been warned before proceedings were taken, because it was not wished to carry out the Act in a vindictive manner, and it was thought to be advisable to warn offenders before proceeding further. He might appeal to the Solicitor whether he was not constantly required to get proper evidence for proceeding, and however painful it might be to some members of the Parliamentary Committee who had to examine these questions, still the Council never hesitated in going on with the prosecution if it was thought to be a just and proper thing to do.

Mr. CHURCHILL hoped that before the meeting closed the Secretary would be able to tell them how many cases had been prosecuted during last year.

Mr. FLUX (Solicitor) said he might state broadly that no proved case of any offence against the Act of Parliament had gone unpunished; and, with regard to the remarks of Mr. Churchill, he might add that if within his own knowledge there were numerous offenders who went unpunished, that was attributable not to any failure of duty on the part of the Council, but on the part of gentlemen who had the requisite knowledge, and did not carry it to the right quarter.

Mr. JONES said they had been disappointed at one or two meetings at Birmingham, when cases had been sent up, which they believed to be flagrant cases of breach of the law, on receiving letters afterwards from the Secretary stating that the parties had been cautioned. He suggested that such a letter of caution should not be written where the information was considered sufficient to warrant a prosecution, but that the parties should be at once proceeded against.

Mr. FLUX said cases, as they were sent up to London, were not sent generally in such a shape as could be used for the purpose of prosecution. A gentleman got some one else to make a purchase of the article, which passed through various hands, and in a general way came by post to London, and if he were to proceed on that case he should have to bring, at great expense, a number of witnesses into the witness box, all of whom would be reluctant, and scarcely one of whom but would prefer that his name should not be associated in any way with the case. The evidence thus brought forward was generally received as evidence that there was mischief going on. But the wishes of those resident in the district were, for the most part, respected so far as this, that a new process for acquiring evidence by some short and inexpensive mode was entered upon, and in the majority of cases they succeeded, more especially if gentlemen resident in the district would give the willing assistance which they could privately, and he did not know of any instance in which this confidence had been broken. He believed in all cases where gentlemen had given information, and desired that their names should not be disclosed, that had been accomplished.

Mr. JONES said he was not quite clear yet whether, if they sent up evidence which would be considered sufficient by the Solicitor, he would at once proceed without sending the written letter. They were ready to employ their secretary to collect evidence, presuming that, if sent up, such evidence as was considered satisfactory, and which their secretary would swear to the truth of, the Society would at once proceed against the party. But he wished to know whether this was so, or whether they would still consider it their duty to write him a letter first.

Mr. FLUX said no case came before him otherwise than through the Council, and when it came through him it was a case for a civil action. Now, in all cases of civil action, it was the right of the defendant not to come into court; he might pay the money into court, any day, or any minute, before the judge heard the case; and it was the common courtesy of the profession to send a man a letter before action, and charge him with it. In by far the larger number of cases the penalty came back with the costs of the letter. If he were to institute proceedings in the County Court, instead of writing a letter, it would just amount to this—that the 10*s.* he paid on taking out the summons would have to be paid by the defendant, instead of the 3*s.* 6*d.* which he charged for the letter. But to make a man feel the weight of the Act of Parliament, which was done when he was made to pay the penalty without the process of the Court, was what seemed to him the proper course of proceeding.

Mr. JONES said he was referring to the letter sent by the Secretary.

The PRESIDENT said he must state most clearly that the Council considered it its duty to consider every case on its merits, and in doing so it directed the Secretary to write to the supposed offenders, if they were not on the register, to know why they were carrying on business, and warning them against doing so. These persons then either proved that they had a right to be carrying on business, as had occurred in some cases that had been sent up from Birmingham, or, if not, a prosecution was commenced.

Mr. FRAZER said he could mention a case which occurred in Scotland, where, owing to some misunderstanding, proceedings were commenced immediately without a letter of warning having been sent, and he had been very much called to task by Mr. Giles, of Clifton, for having done so. This showed how difficult it was to meet the views of everybody.

Mr. CHURCHILL hoped Mr. Flux did not suppose that he or Mr. Jones wished in any way to teach him his business. The point they wished to be clear upon was whether the Registrar's letter would be sent, not as to how the matter was conducted by the Solicitor after it came into his hands.

Mr. FAIRLIE said there were several things in the report which he thought worthy of attention. The first point he would remark upon was that he had recently read an editorial statement that the Journal had become a profitable speculation. He had looked to see how this was made out, but he could not see anything on the receipts which would lead to any profit whatever, though he found on the expenditure side the Journal cost the Society upward of £600. He also saw in the same column the expenditure of the North British Branch, but there was no statement as to whether that branch contributed anything to the Society. It would be an advantage to the Scotch members particularly to know whether it was really a loss or profit to the Society; but on the whole he thought the report was satisfactory. It was well to know that the funds were increasing, although it was to be regretted that membership had been of late on the decrease. Some people had been of opinion that the institution of the Trade Association had done the Society some harm,—that it might have kept some others from sending up subscriptions or from joining it, but personally he should say that it had been the reverse. He knew the secretary of the Trade Association had taken the opportunity, when people spoke against the Pharmaceutical Society, of telling them that they ought to become members, and then they would have a voice in the management. At the last meeting of the Association held in Scotland, three gentlemen had been introduced to the Society. With respect to the Benevolent Fund, he somehow sympathized with the remarks made by one gentleman, that they ought not to hoard up so much money as they appeared to be doing. He saw that £600 had been invested during the last year; and though certainly a good deal had been given away in small sums besides the annuities, which showed that the committee in charge of the Fund had a great deal of work to do, yet the interest might be much increased if a general appeal were made to the entire trade. If the suggestion made by one speaker were adopted, and each district were to take in hand to subscribe as much money as would provide an annuity for one person, he thought a great deal nore money might be raised. He must say he had been much surprised at reading in the report of a recent meeting of the Council that that body was opposed to the use of the room to young men connected with the trade for holding their meetings. Possibly he might not have understood the exact terms in which they applied for it, but he thought the Council ought to encourage young men connected with the trade as much as they could in meeting together for mutual benefit and instruction. So far as Glasgow was concerned, unless they gave young men encouragement they could not get them to study as they ought to do, and he hoped, if a future application were made, with the omission of any statement which might not be conformable to the feeling of some of the Council, it would be granted. Possibly there might have been some other reason which did not appear; but if it was in the power of the Council to grant the use of the room he did not see why they should not have it. There was a students' association meeting in that building, but that was confined to those who attended the classes there. In connection with the Glasgow Association, they some years ago formed an assistants' section, which met monthly, and had been the means of doing a great deal of good, one of the members having since become secretary of the local association. He was very pleased to hear the remarks of the President with regard to local associations, because it was no doubt the fact that in all large centres, where such bodies exist, the great burden of the work rested on a few individuals, and he did not see why this should be. He hoped the members of the trade would interest themselves in local matters, and that this branch of operations would be further developed. He was sorry to see that only £40 had been spent throughout the year in grants to local societies, and though this might be the fault of the local societies, in not applying, he must say he regretted that the scheme which Mr. Schacht brought forward some time ago had fallen to the ground. He should have been glad to see it brought forward year by year until it was adopted. They all knew that in the House of Commons, when a member took up a particular measure, he generally laid it on the table year after year, and although he did not get much support at first, he ultimately carried his point, and, therefore, he regretted that Mr. Schacht did not persevere with this matter of provincial education. There was a great deal of money spent in that house on education, but they could not expect all young men to come up to London and study there. He sympathized with the remarks made about the Preliminary examination, and the desirability of young men passing it before they were apprenticed. But they could not carry that out in Scotland; in fact, he had given up taking apprentices altogether, because he could not get boys to pass the Preliminary examination before entering the trade. He looked forward to the time when, in addition to passing the examination, young men would be required to present a certificate that they had attended recognized classes in connection with their business. But before that was done some more perfect system of provincial education would have to be organized.

The PRESIDENT said it was quite true there was a balance against the Journal as shown by the balance sheet, but if credit were given for something like 5000 numbers a week, which were distributed to members of the Society, the balance would be on the other side, and they really had a right to credit themselves with something on that account.

Mr. FAIRLIE said he understood that, but he thought it would be well if the Journal account were more plainly stated.

Mr. CARTEIGHE said this question of the Journal was a most important one, and he agreed with Mr. Fairlie that the statement of it was not put quite so clearly as it might be. Perhaps the Secretary could inform him what was the annual cost of postage of the Journal.

THE SECRETARY said he could not say off hand; but about 300,000 copies were sent out in the year.

Mr. CARTEIGHE said that would come to at least £625, so that whereas the Journal appeared in the balance sheet as costing £629, the truth was the Journal cost the Society nothing, and the members received it free, having only to pay for the postage.

The PRESIDENT said, with regard to the North British Branch, that the receipts included both subscriptions and fees derived from the examinations. The whole receipts were paid into the common fund, and did not appear in the balance sheet as a separate item. As a matter of fact there was derived from the North British Branch a balance of about £100 towards the general expenses of the Society.

Mr. REYNOLDS (Leeds) said, with regard to the retiring members of the Council, the time was gone by when it could profit by any advice which had been given by preceding speakers; but, with regard to the incoming Council, he conceived that the meeting to-day had a most valuable and important office. Whether the Council had a policy or not, the speakers at that meeting showed that the Society itself had a policy, and that on the matter of the protection of trade interests it did require greater activity to be shown than had sometimes been thought necessary by the Council. It was evident that difficult questions were thickening around them, and he hoped before the meeting closed some assurance would be given of what measures were likely to be taken, or at least that active measures would be taken in the matter of Dr. Lush's Bill. On that point at any rate he imagined there would be no difficulty in the Society taking its position in the front of the opposition, rather than standing aside and leaving it to the Trade Association to undertake the defence of the trade, for that would be defeating the object of chemists throughout the country when they formed the Association. It would be seen that the matter of trade interests as compared with other subjects was placed very much in the background in the report, the principal portion being devoted to education and the operations of the Benevolent Fund. He must say he could not see why they had left the Trade Association to score a victory on the milk of sulphur case. When one of those prosecutions occurred in his own town he, as local secretary, applied to the Society when the case was pending and asked, if the verdict were adverse, that he might be authorized to apply for a case, but this was refused. He thought the Society made a great mistake in not empowering him to take such steps as would have given it the credit which now attached to the Trade Defence Association. However, he did not wish to complain of the past. He trusted that in the future the policy of the Society might be one of greater activity in defence of their interests, and that they might not treat them as the gentleman who said to the waiter after dinner—"What is the smallest possible coin I can give you without being thought mean?"

The PRESIDENT said the second reading of Dr. Lush's Bill was put down for the first of June; and he could assure the meeting it would be closely watched. It appeared to him they had no ground to oppose to the Bill as a bill. He should rather try to get introduced into it a clause defining the legitimate and right position which chemists ought to hold. It appeared to him there was an opportunity here for getting legislation which would be of great importance in settling a public question, and if that were so, he could not understand how they could oppose the Bill as a whole.

Mr. YOUNG said he had been informed that there was no chance of the Bill coming on this Session.

Mr. FAIRLIE said the Act of Parliament which this Bill was to amend said, in the 68th clause, that nothing in it should affect the interests of chemists and druggists; but if some such clause as had been indicated, defining precisely the position of chemists and druggists, were inserted, it would be a great advantage.

Mr. ANDREWS said he had been astonished at the absence from the report of any mention of the Nottingham prescribing case. He had felt great anxiety as to what the action of the Council would be in the case of any one of them being attacked by the Medical Defence Association. It was not only at the east end, but he was informed that before long the same thing would be tried at the west end, and that some of them would be summoned for counter prescribing. Now, if they were to be summoned, and put to great expense and anxiety, and perhaps fined £20 for doing what had been done from time immemorial, he thought it was high time some steps should be taken, and he should like to know whether, if he were summoned, the Council would defend him in a case of that sort. He was aware that such a resolution was passed at the Council some time ago, and he believed it was originally decided that Mr. Shepperley's case should be defended. He should like to know how it was that that had not been done, and that the case had been taken up by another association. In common with Mr. Churchill, he discouraged prescribing as much as possible; he much preferred dispensing, because it was more profitable, and he understood it better. But it was absolutely impossible to refuse to prescribe, and he maintained it was not only a privilege, but that they had a right to do so by long usage and regard for the public convenience. If a customer asked him the action of a certain drug, how could he refuse to say what it was? whether, in his opinion, it was suited to the particular case for which he was going to use it? A man would be branded as a fool if he could not answer such a question. Twelve or fourteen years ago, in that room, he had urged the claims of education for those about to become pharmacists; and any one who took apprentices must know how difficult it had always been to obtain those who had received such an education at school as prepared them for the business. He was glad to see that a little while ago, some remarks fell from one of the members of the Council with regard to education, and if they undertook this matter, he thought it should not only be for the very poorest members of the trade, but that it should be such an education as those might take advantage of who were in a respectable position, but who could not afford to spend very much on the education of their sons. It might be said that if they provided a special education, and the boys did not afterwards become pharmacists, the education would be thrown away; but it appeared to him that an education which would make a good pharmacist, would send a young man out into the world fit for almost any occupation.

The PRESIDENT said he believed from what he had heard from a very high authority in the medical profession, that it was the general desire of that body that, after a time, when all chemists throughout the country were really up to the mark, dispensing on the part of medical men should come to an end, and be entirely handed over to chemists and druggists.

Mr. FRAZER said he should have felt inclined, as a retired member of the Council, to reply to a great many of the strictures which had been put forward at that meeting, but he had already expressed his views in a paper read before the Glasgow Association, which would appear in print in the Journal of the following Saturday, to which he begged leave to refer.*

Mr. FLUX said if gentlemen would refer to the earliest records of the Society they would not find the word "prescribing" in the resolution which had reference to this counter practice. There was a great deal in a cry, and if they let medical men set up a cry on the word "prescribing," they would leave the game very much in their hands. If, however, they took their stand on "counter practice," as a necessity of the case for chemists and druggists, and for public convenience, he had no moral doubt whatever that the judges would go with them, as well as the Legislature.

Mr. WATTS said the word "advising" would be much better than "prescribing."

Mr. FLUX said the phrase for which the fight was made at the Crown and Anchor, as recorded in the early history of the Society, was "counter practice."

Mr. FAIRLIE remarked that the new Bill which had been referred to was intented to amend the Act of 1858.

* We are compelled, by the length of the report of the official proceedings, to defer the publication of this paper until next week.

Now, that Act was under the supervision of the Medical Council, and he should like to know whether it had received the assent of that body.

Mr. ATKINS said he had had an opportunity of seeing Dr. Lush, and asked him if the Bill had any reference to the position of chemists—if it would in any sense infringe on their rights; when he said it would not, as far as he knew. Dr. Lush was a medical man out of practice, a man of the broadest possible sympathies, who had not an atom of undue *esprit de corps*, or narrow prejudices, and he was perfectly sure that if this Bill did contain anything injurious to their interests, it only needed an intelligent and respectful representation to him for him to at once disown any connection with it.

Mr. HUMPAGE said this was very satisfactory; but he wished to go a little further, and to have it distinctly understood whether they were acting illegally or not in counter practice—whether they were, in fact, simply allowed to prescribe on sufferance; because to that he entirely demurred. He thought it was the duty of the Council, if an addition could be made to that Bill, to introduce a clause drawing the line of their privileges; and then if any one went beyond that they might leave him to get out of the difficulty as best he could, but if any of those who kept within it were attacked, they might take up the case jointly with the Association and fight it out to the last.

Mr. FLUX said he might once again interpose to state his most thorough and honest conviction that if there were a well conducted manly fight on that subject no chemist or druggist who kept within his own doors had anything to fear.

Mr. JONES, on behalf of the Trade Association desired to thank Mr. Flux very sincerely for the remarks he had made.

The resolution for the adoption of the report was then put and carried unanimously.

Mr. FITCH then moved—

"That it is the opinion of this meeting that it is expedient that the Council should at once take legal proceedings against the proprietors of one of the co-operative stores, in order that the legality of their action shall be finally settled."

Mr. VIZER seconded the resolution, as he had often urged it before, and there now appeared to be evidence very clearly brought forward.

Mr. URWICK said he was glad to hear that such evidence had been obtained, for he himself had tried in numerous instances to obtain poisons, and had not been able to do so. He could only get them through members of the stores and not personally.

The PRESIDENT said there had been great difficulty on several occasions in getting the legal evidence necessary, and he thought it very likely that the stores so-called, now referred to, was not a co-operative store at all, but simply a shop under another name, which was breaking the law, and, therefore, amenable to a penalty.

Mr. FITCH said he believed it was a limited company, the promoters of which had each taken one share of £1.

Mr. VIZER remarked that the resolution referred to co-operative stores generally.

Mr. W. WATTS suggested that counsel's opinion should be taken, whether any stores selling poisons and dispensing prescriptions containing poisons was not contrary to the Pharmacy Act?

Mr. VIZER said counsel's opinion had been taken over and over again.

Mr. SANDFORD wished, as a member of the new Council by lot to ask the meeting whether they intended to tie the Council hand and foot to prosecute against their judgment or against counsel's opinion, and against all the policy of the question.

Mr. HUMPAGE said certainly not.

Mr. SANDFORD said if they thought this question had not been agitated in the Council, they were very much mistaken, for it had occupied its attention a great deal during the last twelve months. One gentleman said they ought to take counsel's opinion, but if counsel's opinion were against them, what then? The gentleman seemed anxious to be told everything which was said in the council room, but if they knew what the Council did, and declined to do, as matter of judgment, he thought they should be satisfied. Proof had been given that day that it was watching these matters carefully. He would not go back to speak of the counter practice, but he might say he had recently had a conversation with a very eminent physician and mentioned that particular subject to him, and his opinion was that more or less druggists must prescribe. You could not fix a hard and fast line. What Baron Bramwell said was a most important point in their favour, namely, that taking the Act of 1815, a man who gave a draught for a headache did, according to the strict letter of the law, infringe it, but the Apothecaries' Company would be very absurd to prosecute such a man. He took that as the feeling of the highest authority on the law, and he knew it to be the feeling of the highest authority in the medical profession. He believed that by treating the question temperately and quietly they would do better than by violent declamation. There was an opportunity now in this Bill, which to-day came before them for the first time, which might be very serviceable because they could get a clause inserted to protect their rights, and it would be very important to take advantage of this opportunity to get a clause inserted which would more clearly define the existing privileges of chemists. It was not the interest of members of the Council to let co-operative stores take away their custom; they were injured in the same way as other people; but if the meeting tied the Council to a certain course, whether it deemed it right or not to take it, they would utterly destroy the good work which the Council might do. The Council knew the wish of the meeting, with which a great many of its members thoroughly agreed, and therefore he hoped they would leave it free to act for the best.

Mr. FITCH said he could mention cases where medical men told their patients to go to the stores because they could get the prescriptions made up cheaper.

Mr. HAMPSON said he occupied the position of not knowing whether he was going to be a councillor next year or not, and therefore he could speak somewhat freely, but at the same time he should do so with the utmost caution with regard to those whom he had worked with. He had strong views upon this co-operative trading question, and believed that it must be considered and settled. It stood in their path, and he thought going round it and looking at it as if it were a great bugbear that could not be removed was an entire mistake. He believed it was their duty to face it in spite of counsel's opinion or any other opinion. He believed that the Pharmacy Act, if it were allowed to be tampered with and destroyed in this manner, might as well be repealed. He held that the law ought to be applied with equality to all persons, but in this case it was not. The stores were doing an incalculable mischief. He did not mean in the sale of miscellaneous articles, but with regard to legitimate pharmaceutical business, by bringing discredit on their ordinary remunerative charges. He spoke now simply for himself, but if he were elected he should certainly feel bound to face the difficulty and should be ashamed of a seat on the Council if he did not. It must be faced in the interest of the Society, and especially in the interest of the public. The Pharmacy Act was passed in the interest of the public and he maintained they were not taking care of that interest by simply doing nothing. He admitted they had considered the question, and it had caused a deal of trouble and anxiety, but still that would try and settle the question. He believed if they took it in hand with proper resolution to solve it, they could solve it within the walls of the Act, but if they could not do so it was their duty to go for further powers.

Mr. LINFORD said there was a very old adage which some speakers seemed to forget, viz.: "That it was bad policy to bark when you could not bite." To send the new Council to their duties with an order that they must bark whether they could bite or not seemed to him the most foolish thing they could do.

Mr. WATTS said after the remarks of Mr. Sandford he would ask the mover of the resolution to withdraw it, and leave the matter in the hands of the Council.

Mr. FITCH said he should not consent to the withdrawal of the motion.

Mr. CARTEIGHE said he should move that they proceed to the next business.

Mr. VIZER said he was quite prepared to ask the mover to withdraw the motion. He was satisfied that the Council would be thoroughly impressed with its importance and would fairly consider it. Mr. Sandford spoke of dealing with the question temperately and quietly, but it appeared to him they had been dealing with it temperately so long that it was time they should now take it up in a stronger way.

The PRESIDENT said the strong opinion expressed at that meeting would have full weight with the Council in any consideration of this question.

Mr. FITCH, in deference to the opinion expressed, then withdrew his motion.

Mr. GOSTLING (Diss) remarked that he thought the usefulness of the Pharmaceutical Journal might be increased. There was a great deal in it which was very interesting to some of the more scientific members of the Society, but not so much so to a large proportion of their body and they thought it a pity when subjects affecting the trade were being discussed and when correspondence was sent, such as had been referred to, it was not inserted. It seemed as if there was a tendency to neglect and ignore the feelings and wishes of the members. He had recently seen an announcement that some gentleman of the name of Giles had been honoured with a Fellowship of some Geographical Society in Australia, but as far as he could see his only connection with the Society was a very indirect one, he being the cousin of Mr. Giles of Clifton. It seemed to him rather curious that space should be found for such matters when correspondence was excluded. He hoped more room would be allotted to this feature.

The PRESIDENT said he should be very sorry to see the Editor giving legal opinions, and when letters came, as he had sometimes seen, asking legal questions, the express desire of the Council was that the Editor should simply acknowledge the receipt.

Mr. FITCH said all he asked in his letter was in whom was the power vested for suing for penalties.

Mr. GOSTLING added that he should be sorry to oblige the Editor to print all the correspondence he received, but he thought he might give more space to it.

The PRESIDENT said he thought they would be very sorry to read very much of the correspondence with which the Editor had to deal.

Mr. CHURCHILL said he had frequently heard it remarked in country places, where pharmaceutical chemists were few and far between, that the Journal was about ten years a-head of the trade. He himself endeavoured to keep *au courant* with what occurred in chemistry, but still he was a tradesman, and he did not like to have new preparations such as guarana—he did not allude to the patent preparations—brought under his notice by wholesale druggists; he thought they should be brought before him first of all in the Pharmaceutical Journal. It was sometimes said to men who asked what they would get for their guinea if they joined the Society, that they would have the Journal, but he feared that a great many would not appreciate it very highly, and he held that, side by side with the scientific matter there should be a large infusion of trade subjects, which would be interesting to a large portion of the trade; in fact they were very similarly placed, with regard to trade information, to the Conservatives in Birmingham who got the Conservative paper for their politics and the Liberal one for their news.

The PRESIDENT said it might be interesting to know that over and above the circulation of nearly six thousand copies to the members, there was also a very large sale for the Journal, amounting to nearly one thousand copies a week.

The following Registers were placed before the Meeting by the Registrar in compliance with the provisions of the Pharmacy Acts, 1852 and 1868.

Register of Members, Associates and Apprentices of the Society.
Register of Pharmaceutical Chemists.
Register of Assistants.
Register of Apprentices and Students under the Pharmacy Act, 1852.
Register of Chemists and Druggists under the Pharmacy Act, 1868.

Scrutineers were then appointed to examine the voting papers, and after a vote of thanks to the President, the meeting was adjourned until Friday, at eleven o'clock, to receive the Scrutineers' report.

ADJOURNED MEETING.

Friday, May 18, 1877.

MR. JOHN WILLIAMS IN THE CHAIR.

The Scrutineers brought up their report as follows:—

SCRUTINEERS' REPORT.

We, the undersigned Scrutineers, appointed at the Thirty-sixth Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us and report the following:—

Voting papers received		1462
Disallowed from informality	23	
Received by post too late	106	
Unsigned by Voters on envelope	14	
		143
Votes Registered		1319

Hanbury	1000	Gostling	700
Bottle	989	Cracknell	682
Greenish	961		
Hampson	936	Deane	674
Atherton	920	Vizer	590
Shaw	895	Stacey	587
Williams	881	Baildon	546
Rimmington	845	Cubley	546
Betty	842	Richardson	496
Churchill	829	Wills	456
Robbins	789	Bulgin	455
Brown	772	Guyer	439

E. N. BUTT, *Chairman*.

W. K. HOPKIN.	JAMES M. FAIRLIE.
CHARLES CROYDEN.	FREDERICK TIBBS.
MATTHEW POUND.	HORACE DAVENPORT.
THOMAS E. GREENISH.	THOMAS BULLEN.
CHARLES SHAPLEY.	CHARLES E. TURNER.
HENRY GEORGE STACEY.	WILLIAM GULLIVER.
ROBERT ROWE.	MAURICE HOWELL.
WALTER HILLS.	JOHN J. MATTHIAS.

Mr. GREENISH drew attention to the large number of informal votes, amounting to about ten per cent. on the whole number. He also remarked on the small number of votes given as compared with the number of voting papers issued.

The Chairman of the Scrutineers (Mr. BUTT) said, in addition to the small number of votes given, it was remarkable that some districts appeared to be entirely unrepresented.

The New Council.

The Chairman then declared that the following gentlemen would constitute the Council for the ensuing twelve months:—

Atherton, John Henry, Long Row, Nottingham.
Atkins, Samuel Ralph, Market Place, Salisbury.
Betty, Samuel Chapman, 6, Park Street, Camden Town, N.W.
Bottle, Alexander, 37, Townwall Street, Dover.
Brown, William Scott, 113, Market Street, Manchester.
Churchill, Walter John, 46, New Street, Birmingham.
Cracknell, Charles, 217, Edgware Road, W.
Gostling, Thomas Preston, Diss.
Greenish, Thomas, 20, New Street, Dorset Square, N.W.
Hampson, Robert, 205, St. John Street Road, E.C.
Hanbury, Cornelius, Plough Court, Lombard Street, E.C.
Hills, Thomas Hyde, 338, Oxford Street, W.
Mackay, John, 119, George Street, Edinburgh.
Owen, John, 51, Holloway Road, N.
Rimmington, Felix M., 9, Bridge Street, Bradford, Yorks.
Robbins, John, 372, Oxford Street, W.
Sandford, George Webb, 47, Piccadilly, W.
Savage, William Dawson, 4, Park Road East, Brighton.
Schacht, George Frederick, 7, Regent Street, Clifton, Bristol.
Shaw, John, 24, Great George Place, Liverpool.
Williams, John, 16, Cross Street, Hatton Garden, E.C,

Auditors.

There being only the requisite number of Candidates (five) for the office of Auditors, the Chairman declared the following duly elected for the ensuing twelve months:—

Andrews, Frederick, 23, Leinster Ter., Hyde Park, W.
Barron, Frederick, 2, Bush Lane, Cannon Street, E.C.
Hodgkinson, William, 127, Aldersgate Street, E.C.
Horner, Edward, 20, Bucklersbury, E.C.
Squire, William, 5, Coleman Street, E.C.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

The annual meeting of the members of this Association was held on Tuesday last, at the Freemasons' Tavern, Great Queen Street; Mr. Jones, of Leamington, President of the Association, in the chair.

The Secretary having read the notice convening the meeting,

The Chairman expressed the very great pleasure he had in meeting his fellow chemists in the metropolis at a time when they wanted to form a strong bond of union among themselves. During the past year the executive had had some very difficult subjects to deal with, and had been attacked on various subjects by different parties. One or two questions had been settled, but it had one still under consideration which was one of the most serious it had had to contend with. He alluded to the prescribing question. But he referred to those members of the trade who simply prescribed in their own shops, behind their own counters, who did not visit persons out of doors, except in cases of humanity, where exceptions should be made, and he trusted none of them would shrink from attending such cases. Only a short time ago he had been called out of his shop to attend an old gentleman in the street, whose lips were pale and his pulse almost gone, and if he had not received speedy assistance he must undoubtedly have perished. In such cases of humanity they must not shrink from doing their duty; but such things as a room at the back of their shops, to give the semblance of medical consultation, they must avoid, if they did not wish to bring themselves within the meshes of the law. If, however, they were to be prosecuted for prescribing for a man who came into the shop with a sore throat, half the chemists in the country might as well shut up shops. A great deal had been made of looking at a man's throat; but there were two sides to that question. No right-minded man would undertake a case if it were at all serious, and, in the case referred to, if Mr. Shepperley had seen that the person calling on him had ulceration in progress, or ulcers already formed, he would no doubt have told him to go to a medical man for advice. The Executive Committee was unanimously of opinion that it should get the best counsel they could to argue this case and to get a decision in the High Court of Justice upon the point whether chemists were to be prohibited from simply prescribing behind their own counters and using simple remedies. If this should unfortunately prove unsuccessful, it would then have to take another course and appeal to Parliament, in which course he had no doubt it would be supported by the whole of the trade throughout the country. During the past year the members of the executive had had anxious duties to perform, but if their efforts were appreciated they would be well repaid.

The report and accounts, of which we gave a short *résumé* last week, having been taken as read,

Mr. Bell (Hull) moved their adoption. He thought the executive ought to be highly complimented on the success which had followed the endeavours to form this Association. He trusted it would go on progressing favourably, and that every chemist and druggist would join it and support it, not only by subscriptions but also by donations. They all knew a war could not be continued without funds, and there was a great battle looming in the distance, for the purpose of which the Committee would require substantial support, but he felt that if prescribing were stopped most of them would have to close their shops, and look after some other trade less harassed than that of the chemist and druggist.

Mr. Vizer (Brighton) seconded the resolution. He regarded the Association as wonderful, considering the apathy which they knew existed to so large an extent throughout the trade. He thought the report now presented showed that to a large extent that apathy had been shaken off, since there were nearly 3000 members, and close on £2000 had been subscribed. When the Society was first mentioned, some people said it was a mere trade speculation, but that idea was now quite abandoned. Some one must originate these things; and those who had the power of judging what was going on in the trade, and who came forward to meet the circumstances of the moment, and to start such an organization, ought to receive the gratitude of the whole body. The question was sometimes raised whether the Association was antagonistic to the Pharmaceutical Society. His opinion was that it was not in any way; and he should be very sorry if it were so. The Pharmaceutical Society, in its origin, was really and truly much the same as that Association: it was strictly a protective society, originated for the special object of defending the trade against legislation which was then proposed, by which chemists were to be brought under the auspices of the medical profession, licensed annually to carry on their business, and put under the control of a body composed of medical men. Under that proposed Act he believed a chemist would have been liable to a penalty for prescribing in any way over the counter. In those days, the difficulty raised by the medical profession was that of education: that the body of men then existing were not properly qualified to carry on their business satisfactorily. The Pharmaceutical Society then stepped forward to meet that difficulty and provide educational appliances, and, to cut a long story short, a Bill was ultimately carried by which it was deputed to look after the educational qualifications of the whole body. So far as its educational function was concerned, therefore, the object of the Pharmaceutical Society was attained. But then came the question whether it had carried out its protective function: and many of the members, he believed, were of opinion that it had not. Now, this organization, he believed, would be of the utmost value in days to come in protecting the interests of the trade. Looking through the report, he found abundant evidence of that fact. As page 9, it referred to the *lac sulphuris* question, which had been one in dispute for many years—in fact, since the days of his apprenticeship. Again, on page 8, there was another benefit obtained in the fact that there was now a body prepared to protect and defend in cases of informers going and purchasing drugs for analysis. When this was the case, the informer lost half his terror to the mind of the chemist. At page 10, there was another important question referred to, and it was said that no expense would be spared, or effort wanted on the part of the Committee to provide the very best obtainable talent for the purpose of the case with regard to prescribing. Now, that was most satisfactory. It was a very delicate question, because they all felt they were apparently in antagonism with those on whom most of them depended for a living. It might be absolutely detrimental to their interest to be contesting this matter, but where duty called they ought not to shrink. He was pleased to find a resolution had been passed by the Committee to the effect that the solicitor would defend cases of charges for prescribing, though at the same time it discouraged indiscriminate prescribing. There was a broad line to be drawn in this matter. He did not hold the idea that they were qualified to become medical men, though he knew there were some chemists who laid themselves out especially for prescribing business. He, himself, confessed he did not consider that was their vocation; but, at the same time, it was a physical and moral impossibility to carry on business unless they were allowed to express an opinion as to what was good for this or that trifling ailment. Only the previous week a lady came into his shop, and insisted upon having information given her as to the way in which she should take something which had been ordered, and what she should mix it with, although he repeatedly advised her to consult her physician. Since he entered the room he had heard that a Bill had been just brought in to make it penal for any one not registered to practise medicine or surgery; and if that passed he supposed he would have been held to be a transgressor for having given that simple information. Lastly, there was the question of co-operative stores, which was every day becoming more pressing, as they found to their cost. He was delighted to see that a case was being prepared to go before counsel. And here he could not but say that the Pharmaceutical Society had lacked woefully. But he looked upon that society as their guardians to a great extent. At any rate, it had the power of carrying out the Act of Parliament. This Act was passed with the idea of protecting the trade against illegal tradesmen, and he had heard an instance mentioned by the secretary in which a widow had been compelled to sell her business at a great sacrifice because she was unable to carry it on under the charge of a qualified assistant; and he believed there were many other cases of the same sort. Therefore, when co-operative stores came into existence he maintained that it was the imperative duty of the Society to have "taken the bull by the horns" at the time, and not allowed these stores to carry on business with impunity under the support of aristocratic tradespeople, simply putting in a qualified man to manage the dispensing, who might perhaps be a member of the Pharmaceutical Society, and put its arms upon his label. A case ought to have been tried, if for nothing else but that would be a satisfactory settlement of the question. It was possible that these stores might evade the law; but it ought to be proved clearly whether they were legal or not.

Mr. Andrews (London) remarked that it was stated in the *Lancet* of last Saturday that there was a great profusion of medical Bills just now, three of which were mentioned. One had been introduced and read a first time, containing this clause: "Any person who shall practise medicine or surgery for gain, unless such person holds the duly registered qualification, shall likewise pay £20." It occurred to him that that was carrying the matter far beyond anything which had been hitherto attempted.

Mr. Slipper (London) supported the resolution. With regard to the Bill just referred to, he might remark that taking out a tooth was a surgical operation, and some druggists could do it as well as many surgeons. But he was glad to find this Association had been formed, and he thought they owed their thanks to their country friends for the hearty manner in which they had taken it up, and the energy with which they had carried it on.

Mr. Bulgin (Gravesend) also supported the resolution. He said the Association was very badly wanted, as was shown by these new Bills referred to in the *Lancet*. He thought it would be their own fault if such a Bill were allowed to pass, for he did not believe Parliament would interfere with the chemist pursuing his vocation in a proper manner if the truth were properly put forward. He was no advocate for a chemist going out to prescribe; but if a man, woman, or child, came into his shop with a sore throat or a cut finger, or a bilious attack, he maintained that he was within his right by prescribing for them. If he could not do so, he could only say he would sell his business to the first man who offered him £10 for it, and go to Canada or Australia.

Mr. Preston said that although gentlemen representing the retail trade only had spoken hitherto, he thought it his duty to say that he believed the Association deserved the support of the whole trade. One great benefit had already been effected by it. The analysts had been more on their guard since it was known that a society was formed for the protection of those whom they might assail. No one who had regarded the action of the analysts in the past but must be aware that charges of the most frivolous nature were frequently brought against the retail trader, and carried on in a very litigious and oppressive manner. But he had noticed of late that analysts had taken a different position, and the prosecutions had not been so frivolous. An Act of Parliament having been passed enforcing a greater surveillance over articles sold by retail traders, it was quite clear that those who were appointed to look after the interests of the public had a perfect right to see that the things that were sold were genuine, and therefore he did not object to the action of analysts if they had fair ground to go upon; but he did object to their taking hold of articles about which there might be some little doubt, but the absolute purity of which was of very little consequence to the persons who bought them. It was evident that some of the cases which had been brought into court were more for the purpose of bringing the name of the analyst forward than for the protection of the public. But, with reference to the question of prescribing, he knew from his own experience, from having travelled for many years through the country, that it was impossible for a chemist to carry on his business if he were not to give advice to his customers. Was he to be told that a gentleman who had passed the examinations now prescribed by law was only to show his intelligence and knowledge by telling his customers, "I can give you no information whatever"? He knew many cases himself, especially in large country towns, where surgeons actually told their patients, if it were but a slight ailment, to go to Mr. So-and-So, the chemist, who could deal with it as well as he could. There was a large number of chemists in the trade who, from the long experience they had gained in the trifling ailments of human nature were far better qualified to act than the medical men; and medical men of real intelligence recognized that fact. In the case of tooth-drawing there were a number of chemists and druggists who drew teeth better than medical men; in fact, as a rule, surgeons did not like to draw teeth. In conclusion, he would say that if the society were to succeed, it must be supported by those who were principally interested in its success, for he did not believe in any society being founded substantially which relied on extraneous assistance.

Mr. Elwood (Leominster) said this matter of counter prescribing was of great importance to country chemists. If they were to be prohibited from so doing, or from the smaller acts of surgery, such as patching up a cut finger, they would have to leave the trade. It was a small country town where he resided, and he was sorry to say the four other druggists who were there did not support the Association. In that town they had a large country district to depend upon, and tooth extraction and minor operations of surgery became very important items. He had long since ceased to subscribe to the Pharmaceutical Society, because he felt that it had ceased to represent the interests of provincial chemists and druggists, and was now merely the representative of metropolitan chemists and druggists. He had not only ceased to subscribe, but he declined to pay the fee necessary to pass the Major examination, because he did not feel he could give that support to the Society which some members of the trade appeared to think it deserved. He supported this Association because he felt sure that it would, if energetically worked, make a better future for the trade.

Mr. Dean (Bow) did not believe in a chemist setting up to give advice gratis, or imitating surgeons' labels by saying he was at home at certain hours; but still they were able to prescribe for small complaints, and there were very few of them but what did. If a chemist at the east end depended on dispensing he would very soon go to the wall, and it was utterly impossible to carry on business in a poor neighbourhood without prescribing in simple cases. He had been in business for about twelve years, and had been able to do a little prescribing, but he had always been very careful in avoiding any serious cases, and he was on very friendly terms with a large number of surgeons in his neighbourhood. He did not see how the line was to be drawn, because it occurred to him that if it were legal to put up a cough mixture with a patent medicine stamp upon it, and sell it, it could be no greater offence to tell a person you could make him up something to suit him, and label it, "One sixth part to be taken every four hours."

Mr. Mellin (Wimbledon) said if the Pharmaceutical Society had done as it ought some years ago, there would have been no necessity for this Association at the present time. He lived in a neighbourhood where there was no necessity for counter prescribing, but he had had a shop previously in a country district, where two-thirds of the business was done in that way; and, in fact, through leaving it some time in the hands of an assistant who could not prescribe, the business fell off very considerably. He felt very strongly on the question of co-operative stores, for nineteen-twentieths of the people dealt at these places, and he found his business most prejudicially affected.

Another gentleman remarked that he was quite sure if they were pressed hard on this matter of counter prescribing they would be supported by the public, because it really affected them.

Mr. Churchill (Birmingham), as a member of the Finance Committee, wished to enforce the observations of Mr. Preston with regard to subscriptions, and at the same time to thank many of the large wholesale houses who had assisted them during the last year with donations. But still he was sensible of the fact that these donations could not be expected to continue, and that they must look in future to their own members, and he should therefore hope that gentlemen would not only join the society and subscribe, but would give donations as well.

The resolution was then put and carried unanimously.

Mr. John Owen moved the re-election of the President, Vice-President, Honorary Treasurer, and Honorary Secretary, and in doing so took occasion to protest against some few words of antagonism to the Pharmaceutical Society which had been expressed. He assured the meeting that a great deal of business took place at the Council which did not appear in public, and on some of the delicate questions which had been mentioned the Council felt great difficulty in acting. He hoped there would be nothing but the most friendly relations between the two bodies.

Mr. Croyden seconded the resolution, which was carried unanimously, and briefly responded to by the President.

Mr. Urwick moved the re-election of the Executive Committee. He did so with great pleasure, especially as he knew that none of those gentlemen were at all unfriendly to the great institution at Bloomsbury Square, in whose prosperity he felt the deepest interest.

Mr. Shepperley seconded the resolution. He said he had of course suffered some uneasiness from the legal proceedings with which his name was connected, but he was reassured by the support he had met with from the Trade Association. He always endeavoured to be as careful as possible in prescribing. He should have preferred it if his defence had been taken up by the Pharmaceutical Society, but it had not seen fit to do so, for some reasons which he could not of course divine; and he was therefore very grateful to the Birmingham Association for coming forward to support him.

The resolution was put and carried unanimously.

Mr. Horncastle, in moving the next resolution, said he was much pleased to think that there was the greatest harmony existing between this Association and the Pharmaceutical Society. He then moved the re-election of the General Committee, with the addition of a long list of additional names.

Mr. Fairlie seconded the resolution. He said the election of this committee was the grand feature of the Association, as it would lead men in the various localities to know one another better and take interest in matters affecting their business. Referring to the milk of sulphur case, he regretted that the costs were not allowed when the decision was in their favour.

Mr. R. Hampson moved that Mr. Glaisyer be reappointed solicitor to the Association, on the same terms as before, in doing which he paid a tribute to the ability and courtesy with which he had discharged his duties.

Mr. Churchill (Birmingham) seconded the resolution, which was carried unanimously.

Mr. Thomas Barclay (Birmingham) moved the re-election of Mr. Haydon, as secretary, which was seconded by Mr. Shaw, and carried unanimously.

Professor Attfield was then unanimously re-elected analytical referee, on the motion of Mr. Rimmington, seconded by Mr. Atherton. The auditors and bankers were also reappointed.

A vote of thanks was then passed to the London Committee for its exertions in connection with the meeting, and a vote of thanks to the chairman terminated the proceedings.

The Public Meeting.

A public meeting of the trade was held immediately at the conclusion of the annual meeting, when there was a very good attendance. Mr. Preston was voted to the chair.

The Chairman, in opening the proceedings, said he felt that somebody connected with the retail trade would have better occupied his position, but at the same time he did not shrink from coming forward to do what he could to enforce the claims of the Association. He had attended the meeting at Glasgow with very great pleasure, and since then a great deal of good work had been done. Their object now was to enlist the sympathy of all in the trade, more especially in London, in order that they should be prepared to work heartily and generously with those who had borne the burden of the day so far. Their object was to form a strong and useful Association in connection with the trade; and if they could not efficiently protect their own interests under the existing law, to apply to Parliament that they might have the same protection as was extended to those connected with the professions. He owned that of late he thought there had been a little too much the idea of thinking of chemists and druggists as professional men. They should not lose sight of the fact that they were connected with a trade, and their trade interests they were bound to protect. The trade of the chemist and druggist was one of the most important which could be carried on? The public generally recognized that they were men of ability and intelligence, and if an Act of Parliament were brought forward to show the necessity of protecting their rights, there would be no difficulty in enlisting the sympathy of the press, and he felt sure that they might, if they were determined, fully protect themselves against all attacks.

Mr. Pound (London) moved the first resolution:—"That this meeting of pharmaceutical chemists, and chemists and druggists, heartily approves of the formation of the Chemists and Druggists' Trade Association, and pledges itself to support the same by every means in its power." Something had been said at the previous meeting about an antagonistic feeling between the Pharmaceutical Society and that Association; but his opinion was, and that had induced him to subscribe to it, that each had its function, and that there were many things the Pharmaceutical Society could not do which this Association could; he felt very much pleased, therefore, that it had been formed.

Mr. Wiggington seconded the resolution.

Mr. Thomas Barclay (Birmingham) said the work set before the Executive Committee at the conference at Birmingham was the protection of the legitimate interests of chemists and druggists from unfair attacks and encroachments, and the protection of their common welfare; and as one of the Executive Council he was obliged to the meeting for the confidence it had shown in them by re-electing them. Perhaps a brief review of what had been done during the year might be of interest to the meeting. The first way in which the executive had to carry out the programme was the defence of members from vexatious and unjust prosecution under the Adulteration and Medical Acts. Allusion had been made that morning to the milk of sulphur case, which had caused a great amount of labour and anxiety. Several members of the Association objected to use the lime sulphur, and that difficulty had to be faced; but it was known, on the other hand, that there were medical men who thought that the lime preparation was the only one which ought to be supplied as milk of sulphur. The great question was this, however,—should a chemist who had never been in a police court or accused of any offence be branded as an adulterator, or one who broke the law, for selling a recognized preparation? Before this Association was formed, the chemists were put down all over the country; in some cases the verdict was in their favour; in others, against them. But now all members might feel secure, if they were doing their business legitimately, that they would have the whole force of the Association at their back to protect them. Now, instead of having ridiculous prosecutions here, there and everywhere, analysts were apparently reviewing their position, for they were doing next to nothing, and chemists were already feeling the benefit by not having to face these paltry prosecutions; in fact, the chemist might now say "*Nemo me impune lacessit.*" The next point was the defence of the members from unjust prosecutions under the Medical Act; and they were not long without an opportunity of showing that they were ready to carry out that part of the programme, and some good work had been already done. At Birmingham something of the kind had been attempted, for after Shepperley's case was heard, a Medical Defence Association was started, in that town. A secretary was appointed, and a circular was sent round, saying that Mr. Oliver Pemberton would become the president. The solicitor to the Defence Association brought actions against herbalists, and also against a chemist and druggist, who, however, had not yet been before the Police Court owing to some technicality. In the meantime, however, the local press got hold of the fact that a public officer had been used for the getting up of the evidence, and having drawn attention to this fact, the result was, the Watch Committee washed their hands of the whole affair, and said if the Medical Trade Union wished to do such work it must use its own officers. A considerable discussion ensued in the local newspapers, and the result was that Mr. Pemberton, who was supposed to be the president, wrote a strong letter, stating that he was thoroughly opposed to the spirit in which these prosecutions were undertaken, and that he would have no connection with them whatever. The secretary also wrote, saying it was quite clear the association was not wanted in Birmingham, and he begged to withdraw; and, following on, the solicitors wrote to say they never intended to prosecute chemists and druggists, it was only quacks and herbalists. But he mentioned this to show that even if they were beaten in the Queen's Bench, they would have the public and the press with them, and if they united in one strong body they would be able to insist on their rights and not be put down by any class whatever. The next point was the amendment of the Pharmacy Act to prevent the sale of poisons by unregistered men. This had been before the executive but it had not yet been able to do anything. Next was the exemption of all registered chemists and druggists from serving on juries, and probably some Bill would shortly come before Parliament in which they might co-operate with the Pharmaceutical Society in obtaining that exemption. The next point was the defence of the trade from encroachment by unauthorized dealers in drugs. There were a great many of these men carrying on business as chemists and druggists all over the country who were not authorized; but the Secretary had been hitherto so much engaged with the organization and general work, that he had not had opportunity to procure the necessary evidence. He believed, however, the Pharmaceutical Society would be ready to assist them in putting down illicit trading. The question of co-operative trading had already been mentioned, and it was a very vexed question. From all quarters there were all kinds of suggestions as to the way in which this could be put down. There was a universal outcry that the co-operative trading was unjust, and was working injuriously to the qualified chemist; and a conference, after a considerable amount of discussion, declared that it was wrong, and that it should be put down. This question was now in the hands of two of the most able and experienced of the Executive Council, who were getting all the information that they could, and endeavouring to put the solicitor in the position to go forward, and he hoped in some way or other they would be successful, or if the present law were not strong enough to get it altered, so that this very unjust and unfair method of competition should be put a stop to. If he could not take a partner, who was not a qualified chemist, into his business it was unfair that thousands of men all through the country should be sharing the profits of a large business. It was not like dealing in groceries or many other things. When a man had spent a deal of time and money in becoming properly qualified, it was unjust that those who had undergone no such preparation should compete with him to the detriment of the public. The last object placed before the members of the executive was to watch the proceedings of Parliament, with a view of preventing any injurious legislation. They had not had much to do in that direction, for although last session Sir William Frazer proposed to bring in a Bill, when they got one of his constituents to write and ask him the nature of it, he did not seem to have any clear views upon the matter, and nothing came of it eventually. They were now told that two or three Bills were likely to be before the House, and they might depend on the Committee doing everything in its power to protect the interests of chemists and druggists throughout the country. He thought the coming year would be the test of their success. Something like 3000 members had enrolled themselves during the last ten months, which was a success of which they were all proud; something like

£1000—besides subscriptions—had been given in money, of which about £300 had been contributed in donations of five or ten guineas, showing that something like £700 had come in smaller sums, which was very satisfactory, as showing the interest taken by chemists at large. But they had a great work before them and must not flag in their efforts. He hoped every gentleman present not already a member would give his subscription before leaving the room, in order to save the secretary the time and expense of collection. They had in Birmingham a motto, "Forward!", which he hoped they might adopt as the motto of that Association, and thoroughly act up to it.

Mr. Hampson said that, occupying a seat at the Council of the Pharmaceutical Society, he felt a considerable hesitancy at first in joining this Association, but after carefully considering the position of the trade and a man's independence in respect of his calling and connections, he felt it was the only step he could take, and that he ought to join the Association and support it as far as possible. Its success depended on the number of its subscribers and the energy of its members; and if they did not come forward and support it they did not deserve support at all. The matter was entirely in their own hands; of course, if they felt that their interests were not of any importance, they would not support the Association, but the evidence which had already appeared, namely, that 3000 members had already joined, was almost a sufficient answer to that idea, and a good augury for the future. With regard to the attitude of the Pharmaceutical Society towards that Association, he wished to say one word. He did not see there was any necessity for any antagonism whatever between the two. On the contrary, he thought every man should join that Assosiation, and that every one who was eligible should also join the Pharmaceutical Society, for they both had important work to do in the future. The Pharmaceutical Society had this important work to do, that it had to set the law in motion, and he must add that it rested with the members of the trade whether the law should be set in motion or whether it should be amended. He had taken considerable interest in one or two questions which had come before them, and particularly in the one with regard to co-operative stores. That subject had been looked upon as a great bugbear, which ought to be hidden rather than faced; but he believed in facing a thing, and they must face it in future. If he had a seat in the next Council, he should endeavour to face the question, and he hoped the Trade Association would also do its work well with respect to it. With regard to the Pharmaceutical Society, he had no doubt that it also would do its duty if the members expressed their opinion, for he must repeat, they had the matter in their own hands. If necessary, they could alter the character of the Council, though he did not wish that any undue pressure should be exercised, or that any wholesale change in the Council should take place; on the contrary, the men should be fairly tried, fairly judged; but still the same remark applied to the Pharmaceutical Society, as to that—it entirely rested with the members as to what the action should be. If there was a want of energy in the Council, there must be a want of energy in the members; and the same with them; if there was a want of energy in the Executive Committee, it must be from a similar want in the members at large. But he supported the resolution with much pleasure, and he almost hoped the London chemists would form a committee among themselves to give extra help to this Association. This was an age of over legislation; every year produced some kind of stupid Bill before the House, which, if carried into law, invaded somebody's rights and privileges. They had already had evidence that some persons were bringing forward a Bill to amend the Medical Act; and if it passed they would be simply prevented from carrying on a legitimate part of their business. The question of prescribing was a very delicate subject; but if they were simply apathetic and quiescent they would not only lose their independence, but would find that the aggressive spirit would be stronger. He did not believe in being trampled upon. Chemists and druggists were an important body, and could exercise great power over the legislature, and he believed that in case of an aggressive measure being introduced, they had sufficient power, if they were united, to prevent it passing. But they could never exercise that power unless they supported an organization which would bring it to bear when needed.

Mr. Mackenzie (Edinburgh) supported the resolution, because he felt the Association was needed. There seemed to be an organization on the part of some medical men to interfere with them, but he must say that things seemed much changed in the medical profession to what they used to be. A medical man's education was now in many cases little more than a farce, and he thought they ought, in fairness, to be a little more considerate towards chemists and druggists. He knew one medical man of high position, a professor, who told him that after he had been licensed from one of the first universities to practise medicine, he was afraid for some years to write a prescription, lest the intelligent dispensing chemist would have occasion to laugh at some inaccuracy: and he believed the same thing was pretty general, although not always so honestly confessed. Mr. Barclay had mentioned one motto, and just before he spoke of it he had been thinking of another, which he carried for some years as a volunteer, namely, "Defence, not Defiance"; but they were able, he hoped, to defend themselves, and when aroused by insult after insult, he thought it was time for them to stand up for themselves, and he was sure the country would support them. He might also say that as a member of the Pharmaceutical Society, he went in heartily for this Association. It was only in accordance with human nature to be somewhat supine in the hour of prosperity, and that might apply in some respects to the Council of the latter body, and, therefore, he though there was room for another Association. It was an old adage in Scotland, that an ill beginning oftentimes had a good ending. They had made a good beginning, but sometimes a good beginning was a misfortune, because people were flushed with victory, and thought themselves stronger than they really were, and this gave the enemy an advantage, and they must therefore be on their guard. If the thousands at present on the list would each one endeavour to bring an additional member in the year to come, their numbers would be doubled, and in that way they might secure the whole names on the register. That would not do the Pharmaceutical Society any harm, and would do an immense deal of good, whilst it would show all aggressors that they were in earnest in defending themselves.

Mr. Holdsworth (Hon. Sec.) said he hoped those gentlemen who had not already joined would not let idle sympathy take the place of efficient expression, and that no one would think it did not matter whether he joined the society or not. The balance sheet showed that the expenses were very heavy, even for a part of one year, and that the subscriptions were not sufficient of themselves to keep the society in successful operation. They had been largely dependent on donations from members of the wholesale trade, which they could not expect would be repeated. The subscription had been fixed at five shillings in the hope that every chemist in the kingdom would join; and he trusted that that hope would to a large extent be realized. The Association had won the milk of sulphur case, but had done so at a great cost; and as other cases were constantly coming up—for instance, this great case of counter prescribing—it was evident that it wanted continuous and hearty support. In dealing with a body of 8000 men every act was an expensive one, for they could not even send out a post-card at a less expense than £20. But he would ask every gentleman present who had subscribed whether he had not been amply paid by what he had received, whether he was not money in pocket, to say nothing of the peace of mind he obtained. In fact, he believed they would all agree that it was the best investment of five shillings they had ever made.

Mr. Wade, as a London member who had recently joined, said he felt satisfied that a great many others in London had abstained for the same reason as had operated with himself. He would not say anything about the jealousy shown in some quarters when the Association first started, on account of its being originated in a provincial town; but there was another feeling among the London members, and that was that one of the objects of the Association was to foster and encourage adulteration and the sale of inferior drugs. Many of them also thought that there was nothing particular to be got out of any action against co-operative stores, and those two feelings had kept a great many aloof. But a question was now brought forward which affected the whole trade—that of counter prescribing. It was also said, that if the Council of the Pharmaceutical Society represented the trade where was the necessity for this new Association? But his contention was that that Council did not fairly represent the whole trade, nor even the members of the Society, and therefore it became a necessity that a new society should be formed. They wished to uphold the law, not to infringe the law. When the Act of 1815 was passed, he considered it was a line distinctly drawn between the medical practitioner and the chemist and druggist, and it had been invariably understood ever since that chemists had a perfect right to prescribe for simple ailments over the counter, while they should in no way attempt to visit patients out of doors or prescribe for severe cases. If that was the case, why was it now impugned? Why, after sixty years of practice, should they be called upon for the first time to give up that right? He took it for granted there were none present who did not regret that the question had been raised, because it was a mistake for them to be put in antagonism with the medical profession, with whom they ought to work, if possible, harmoniously. But he did not believe medical men at large would interfere with them in any way. There were, no doubt, some chemists who had overstepped the mark, and with them they had no sympathy; but why should the whole of them be put down because of those men? They were, in fact, no more numerous than these prosecuting surgeons were amongst their own body. For he believed it was only some few pettifogging little surgeons with no practice of their own who were jealous of chemists who possessed the confidence of the public. Every man who had been in business for a number of years knew what he was about, and there were even chemists and druggists who had had experience in almost every branch, both in chemistry and surgery. Many of them might have held important positions in years gone by as assistants to surgeons, and were then considered qualified to perform all the duties of the surgeon in the business of their masters; yet, after years of experience, they were not now considered qualified to look at a man's tongue. He did not think they ought to go beyond simple prescribing; but he did say they were far better qualified in many respects than a young practitioner just coming from the hospitals, with nothing but his diploma to show, and that was often obtained with "crammed" knowledge. That was a strong argument, but not the one that they ought to stand upon. It was in reality a matter of public interest. If they went to Parliament, it should be on behalf of the public, that it should not be dragooned into going to medical men, and be forced to pay five shillings for what it could get at a chemist's for a few pence. He believed they were none of them desirous of fostering a prescribing trade, but it was really forced upon them by the public. It had been said that at the east end of the town there was very little done in the way of dispensing prescriptions, but he might add that within a stone's throw of Buckingham Palace there were shops that did not see a prescription once a day. It was not altogether because it was a place where prescriptions were not written, but because they were surrounded by medical men who sent out their own medicines. How, then, was a chemist to get a living, if he were not allowed to prescribe himself nor dispense a medical man's prescription? But if a chemist were not to prescribe, it would be only fair that surgeons should not send out their own medicines; but they not only did so, but sent out dietetics, instruments, and sundries as well.

The resolution was then put, and carried unanimously.

Mr. Reinhardt (Leeds), as one of the founders of the Pharmaceutical Society, wished to remind his fellow-members that if the Council did not represent them it was because they did not take the trouble to inquire into the merits of the persons coming forward. He was glad to find that there seemed now a prospect of candidates for office setting forth a programme of their views and showing what their ideas were, and he trusted that this plan would be followed in future. The trade in the west of London was conducted on very different principles from what it was in the country. The special question now before them was counter prescribing, and it ought to be taken up from one end of the country to the other. When they had been accustomed to this for sixty years, how was it that this mine was now sprung upon them in 1877? They could only meet force by force, and it was through Parliament they must gain their true position. On the one side they were attacked by co-operative stores, and on the other side by lower ranks of the medical profession. He said "lower ranks," because he had known men who had flourished for years as physicians recommend persons to go to his shop for advice in simple cases. He had written a letter to the editor of the *Pharmaceutical Journal*, which was not inserted, but which appeared in the *Chemist and Druggist*, saying, as his time was now at his own disposal, he would be willing to go all over the country, and try to influence the trade to make a stand on this important question, charging only his hotel and travelling expenses; that offer he begged now to repeat, because he felt it was necessary to rouse the feeling of the trade.

Mr. Jones said, as President of the Association, he could not but thank Mr. Reinhardt most heartily for the kind offer he had made.

Mr. Corey said the question of counter prescribing was one much more important to country chemists than to those in London, since they had not so many prescriptions to dispense. At the same time he did not think they had so many enemies amongst the medical men as in some larger centres. After giving an instance which had come under his own notice of the ignorance of two eminent physicians with regard to the proper dose of a powerful poison, he suggested that it would be a good plan for some one member in a country town to undertake the collection of subscriptions from the surrounding districts, and forward them to the secretary. He should be very happy to take this duty in his own neighbourhood; and he thought it would also be worthy of consideration whether the amount of subscriptions should be increased, or whether they should seek for small donations in addition.

Mr. Young said he had just purchased for a halfpenny, which was more than it was worth, the Medical Bill which had just been introduced in the House, and which, if passed, would entirely take away their power of prescribing. But he thought it would be very desirable if post-cards were sent to all in the trade asking them to write to their representatives in Parliament, requesting them to oppose this Bill, as being a violation of the rights of chemists and druggists.

Mr. Gostling (Diss) said if it was necessary for London tradesmen to speak out on behalf of counter prescribing, it was far more important for those in the country, for if this proposed Bill were passed, they would nearly all have to close their shops and train up their sons to be apothecaries instead of chemists and druggists. Having spoken at some length with reference to the universal practice of counter prescribing, he concluded by supporting the suggestion that petitions against the proposed Bill should be sent in.

Mr. Jones then moved a vote of thanks to the chairman, which was seconded by Mr. Greenish, and carried unanimously, and the proceedings terminated.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A special meeting was held on Friday, the 27th ult., to bring to a conclusion the winter classes. Mr. Townsend, Secretary, mentioned that the classes, having been only held once a week, had been much better attended than in the previous year. The dispensing class especially had been well taken up, and he hoped that next year still better results would follow. Financially, the Association was in a prosperous condition, but from the fewer available members in the town than when the Association started, of course the number of members would be comparatively small.

The President, Mr. G. C. Druce, gave a short address, in which he suggested that the new laboratories of the Science and Art Department should be utilized at least for the chemistry classes of the Association in future; he also proposed that during the summer months a botany class should be held weekly, starting at 6 A.M. into the country, and then a night could be occasionally employed in looking over recent specimens. He referred to Mr. Hanbury's proposed alterations in reference to the herbarium prize, and thought they were excellent, though he considered the age should not exceed twenty-one. Having noticed recent legal matters connected with the trade, he concluded by hoping all would try to keep the Association in a flourishing condition.

Specimens of equisitum spores were shown under one of Swift's binocular microscopes. The thanks of the society were passed to various donors, including the Science and Art Department, for the loan of an analytical balance; to the Pharmaceutical Society for Journal; Mr. Saul for framed chemical chart; and Mr. Maxwell for some chemical apparatus.

Parliamentary and Law Proceedings.

A Bill to Amend the Medical Act of 1858.

The following Bill has been introduced into the House of Commons by Dr. Lush:—

Whereas an Act was passed in the twenty-first and twenty-second years of the reign of Her Majesty "to regulate the qualifications of practitioners in medicine and surgery;" and whereas it is expedient to amend the said Act:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. Section forty of the said recited Act shall be repealed, and in lieu thereof it is enacted: Any person who for the purpose of any Act of Parliament, or for the purpose of gain, shall take or use any medical or surgical name, title, or description, unless such person's qualification or qualifications entitle such person to take or use such name, title, or description, and such qualification or qualifications be also registered, shall, upon summary conviction for either or any such offence, pay a sum of *twenty pounds*: And it is further enacted, that any person not already registered or not qualified at the time of the passing of this Act to be registered under the said recited Act, who shall make, fill up, or sign any medical certificate for the purpose of any Act of Parliament, or who shall practise medicine or surgery for gain, unless such person holds a duly registered qualification or qualifications in both medicine and surgery, shall likewise, upon summary conviction for either or any such offence, pay a sum of *twenty pounds*.

2. Section forty-two of the said recited Act shall be repealed, and in lieu thereof it is enacted: Any sum or sums of money arising from conviction and recovery of penalties as aforesaid shall be paid to the treasurer of the General Medical Council, anything to the contrary contained in any Act passed before the passing of this Act notwithstanding.

3. To Schedule A. of the said recited Act it is enacted that this section shall be added: Doctor of Medicine, or Bachelor of Medicine, of any foreign or colonial university, whose examination is proved to the satisfaction of the General Medical Council by such university to be equal to that required, for the time being, by the College of Physicians of London for their qualification of membership, or to such other examination as may be fixed upon for the purpose by the said Council.

4. This Act to be read with and form part of the said recited Act.

5. This Act may be cited for all purposes as the Medical Acts Amendment Act, 1877.

Singular Charge of Adulteration against a Chemist and Druggise.

At the Sheffield Town Hall on Wednesday, a curious case, under the Sale of Food and Drugs Act, came before Mr. Webster and Mr. Stephenson. Mr. John Henry Dixon Jenkinson, chemist and druggist, of Duke Street, Park, was summoned under the 6th section of the Sale of Food and Drugs Act, 1865, "for that he, on the 28th April, did unlawfully sell to one William Brammer, the purchaser thereof, to his prejudice, a certain drug, to wit, half an ounce of jalap, which was not of the nature, substance, and quality of the article demanded by the purchaser." The Town Clerk appeared in support of the information, and Mr. Barker, barrister, appeared for the defendant.

The Town Clerk, having referred to the section under which the proceedings were taken, stated that a man named Richard Gillott, who lived in the Park, had two valuable dogs, and on the 27th ultimo he wished to administer to them a purgative. He sent to the defendant's shop, and purchased what he thought to be a pennyworth of jalap, which was given to the dogs. They both died within twenty minutes, and as they were of such value, the owner felt that he should like to have an analysis of the drug. Accordingly word was conveyed to Mr. Allen, the borough analyst, and one of the inspectors, William Brammer, was sent to the defendant's shop to purchase some jalap. The sample thus obtained was analysed by Mr. Allen, and was found to contain nux vomica or strychnine, a very deadly poison. Mr. Allen had given a certificate which he would hand to the bench, and he believed that Mr. Barker, on the part of the defendant, would plead guilty.

Mr. Webster asked what object the defendant could have in mixing jalap and nux vomica.

The Town Clerk said there could be no object whatever.

Mr. Webster said he believed there would be no pecuniary gain. If the jalap as bought had been administered to a human being instead of to dogs the consequences would have been very serious to Mr. Jenkinson. He would have been committed for manslaughter.

The Town Clerk said that was the case.

Mr. Baker said he would like to ask Mr. Allen a question or two. He would plead guilty on behalf of his client.

Mr. Allen, in reply to Mr. Barker, said in colour nux vomica and jalap were very much alike, and in price they were about the same. There could be no object in mixing the two powders.

Mr. Barker said he could not deny that his client had laid himself open to a penalty, but he was at a loss to know how the mistake had occurred. The drug was sold at a branch shop, and was part of a lot which was bought fifteen months ago. There was no nux vomica in the shop, and how it had got into the jalap his client did not know. Large quantities of it had been sold and no evil consequences had ensued, as must have been the case if the medicine sold had contained nux vomica. Mr. Jenkinson could have no possible object in mixing the powders.

Mr. Webster: There must have been great carelessness.

Mr. Barker said the case was not one in which any fraudulent intent was alleged, and he asked the bench to impose a nominal fine. The defendant was already threatened with an action by the owner of the dogs, who laid his damages at £30, and when the defendant had paid that amount he would have been sufficiently punished for his carelessness.

A fine of £2 and costs was imposed, Mr. Webster remarking that he thought that druggists ought not to keep branch shops unless they could personally attend to them.—*Sheffield Independent.*

Review.

THE HISTORY, PRODUCTS, AND PROCESSES OF THE ALKALI TRADE; including the most recent Improvements. By CHARLES THOMAS KINGZETT, F.C.S. With twenty-three Illustrations. London: Longmans, Green and Co., 1877.

To the many historical works already extant that have been written for our enjoyment and instruction, concerning history, *par excellence,* or men, or philosophy, there has been added a volume which, while dealing with none of these subjects especially, lays claim to be ranked in the same category. Under the title of the 'History, Products, and Processes of the Alkali Trade,' Mr. Kingzett gives us a most interesting account of a special branch of chemical industry, which, since it forms the largest chemical industry of this country, is one of the mainsprings of our boasted national wealth. This is the first time that it has been attempted to bring a work of so special a kind before the public, and we need scarcely say that the task has fallen into good hands, the practical experience and scientific reputation of the author being a sufficient guarantee of its value.

But the history before us does not confine itself to the mere narration of bygone circumstances; it deals not alone with the past, but treats of the all-important present and uncertain future of the alkali trade. It further differs from most histories in that it offers, unlike these, a scientific explanation of its related facts. The work indeed is, though essentially historical, by no means wholly so, but constitutes, as Mr. Kingzett tells us in his preface, a treatise in which much stress has been laid on matters of history interesting as these are in showing how gradually knowledge is perfected. To quote the author's own words: "It will, for instance, be seen that at no time in the history of the alkali trade has an inventor brought into use an entirely new process; so-called new processes are but the perfected forms of old ones, and are based upon previously known facts. Moreover, the greatest commercial successes have been achieved, not by the practical application of new ideas, but in the development of old ones." In urging strongly that scientific investigation must necessarily precede industry, Mr. Kingzett assures us that those who discuss the value of such scientific work "must be further prepared to discuss the good, for humanity, of all progress, not only in industry and commerce, but in every direction of civilization." These passages from the preface are well illustrative of the philosophical spirit which pervades the volume.

It will we feel sure be not uninteresting in again turning over the leaves of a volume which has caused us so much pleasure in its perusal to afford our readers some account of its scope and tendency.

In an opening chapter of much interest the author sketches briefly the early history of the trade and manufacturing industries generally, and points out in a general summary the products which go to form its basis.

In Chapter II., we have some most interesting details relating to pyrites, sulphur, and nitre; and in Chapter III. a masterly description of the manufacture of sulphuric acid. The illustration here and throughout the volume intensify exceedingly the value of the text. Among the more modern improvements, Dr. Sprengel's water spray apparatus is fully entered into. Mr. Kingzett next proceeds to consider the treatment of burnt pyrites, the extraction from these of copper, silver, and gold, and the manufacture of sulphate of copper. The chapter which follows forms a historical sketch of alkali manufacture, and the curious traditions and striking statistics which the author has brought to bear on his subject here find their most fascinating expression. We are next led to contemplate the manufacture of salt, and in connection with this that of sulphate of soda and hydrochloric acid. Leaving these matters we proceed to be instructed as to the making of carbonate and bicarbonate of soda from *black ash* or crude carbonate. Much space is here devoted to a consideration of the advantages of "revolving furnaces" and the chapter is admirably illustrated. This and the following chapters on caustic soda, alkali waste, regeneration of sulphur, etc., are of special interest and importance. Chapter X. includes the description of other soda processes than Leblanc's, and particular attention is drawn in it to the "ammonia process." Chapter XI. deals with soap making. The author defines soap commercially, as a "body which on treatment with water liberates alkali," a definition which includes the silicated soaps so lately introduced into general use by Mr. Gossage. Chapters XII. to XVI. deal with the bleaching industry. They rival the foregoing in interest and clear exposition, and form a most complete *résumé* of the practical industrial application of chlorine as a bleaching agent. The author brings his treatise to a gradual close with some general considerations relating to the trade, and some remarks on chemical climatology, and finally most fitly concludes with a chapter on statistics.

In treating of products and processes, Mr. Kingzett does not forget to remind his readers of the duties of those to whom these products and processes are a source of income and affluence, as the following eloquent passage shows:—"Manufacturers would do well to appreciate more fully than they do at present, that science is slow to progress, and that on that progress all improvement in industrial applications depends. Let them, therefore, encourage its development by employing competent chemists; and not only so, but rather aid research than war against it as they have too often done in the past. They cannot hinder the current of knowledge in its advance, but they can help to increase its rate of movement. In another direction they can also benefit humanity by creating the means whereby their workmen may elevate themselves, and train their children in a better way than is to be witnessed now. Men have other relations one to the other than those included in the commercial world of capital and labour, and this better side of life cannot be hidden even by the shadow of the Stock Exchange and the marts. Indeed, life may be compared to a spectrum with its bright and dark lines." (p. 241).

It is the duty of all impartial critics according to certain tenets to find fault, and if the faults of a work do not lie on the surface, to dive deeply in search of them. Perhaps the greatest fault that can be found with the present volume is its brevity, and yet many may consider this an advantage. Mr. Kingzett has, however, undertaken to give us an account of the alkali trade from an historical, an industrial, and a commercial point of view; in our opinion he has done this in a most able manner, and all must agree that the incorporation of the author's own researches in most important directions lend a particular value to the work.

We regret exceedingly that the nature of the subject matter of the volume necessarily precludes disjointed quotation. It may be said, however, without prejudice, that many of the more scientific and descriptive passages remind one not a little in their succinct conciseness of the terse manner of Rolleston, in his 'Forms of Animal Life.'

We have no doubt the volume will enjoy the welcome reception it merits both at the hands of those more particularly interested in these matters and from the general public. It is with this conviction and hope that we linger over its last page.

Notes and Queries.

[545]. LOGWOOD.—Can you tell me the process which logwood chips undergo to develop a good colour—what I believe is called "liquoring down?"—A Subscriber.

[546]. DALE'S PLASTER.—Will any one kindly give the formula for "Dale's Plaster," as prepared and sold by chemists in the North of England?—J. P.

SALICYLIC ACID AND BORAX.—It may be interesting and perhaps useful for some readers of the Journal to know, that while a solution containing 10 grains of salicylic acid and 10 grains of borax in 1 ounce of water, has a very bitter taste and an acid reaction; a solution containing 10 grains of salicylic acid, and 15 grains of borax, has no disagreeable taste, and is nearly neutral. This solution appears to possess all the valuable properties of salicylic acid, and forms an agreeable means of using the acid internally or as a gargle.—S. N.

Obituary.

Notice has been received of the death of the following:—

On the 13th of April, 1877, Mr. Charles Morgan, Chemist and Druggist, Ross. Aged 57 years.

On the 13th of April, 1877, Mr. William Wilson, Chemist and Druggist, Oldham. Aged 51 years.

On the 18th of April, 1877, Mr. Joseph Farnell, Chemist and Druggist, Laisterdyke, Bradford. Aged 69 years.

On the 23rd of April, 1877, Mr. James Hood, Chemist and Druggist, Morpeth, Northumberland. Aged 60 years.

On the 6th of May, 1877, Mr. William Hancock Balkwill, Chemist and Druggist, Kingsbridge, Devon. Aged 66 years.

On the 8th of May, 1877, Mr. John Lockley Whitfield, Pharmaceutical Chemist, Worcester. Aged 82 years. Mr. Whitfield had been a Member of the Pharmaceutical Society since 1842.

Correspondence.

*** No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Meaning of the Word "Dispense."

Sir,—I have (with many of your readers, I daresay) been on the look out for disquisitions on the meaning of the word "dispense" from the more prominent of your correspondents.

It appears certain that the result of the appeal in the case of the Apothecaries' Company *v.* Shepperley turns entirely upon the definition of this word.

It may, I think, be fairly argued to involve all that is implied in the words "dispensary" and "dispensatory." These terms are to be found in dictionaries long anterior to the passing of the Apothecaries Act in 1815.

In my copy of Bailey's 'Dictionary,' 1770, to "administer" is one of the meanings given to the term "dispense."

I hope that this now important word will receive in your columns the scrutinizing analysis it so well deserves.

J. W.

York, May 12, 1877.

H. S. Newzand.—Cochineal, ½ oz.; boiling water, 1 gallon; digest, strain, add ½ oz. sulphuric acid, and water to make up 2 gallons (Beasley).

F. G.—*Valerianella* sp., probably *elitoria;* the fruit is not well developed.

L. Thompson.—*Lathræa squamaria.*

A. R. T.—We believe the method is sometimes adopted of preserving the skin in the neighbourhood of the hair from the action of the dye by covering it with grease.

T. R. E.—The regular meetings of the Council are held on the first Wednesday in each month.

"*Anxious.*"—The "Ebert Prize" had its origin in a donation of 500 dollars, made in 1873, to the American Pharmaceutical Association, by Mr. A. E. Ebert. The annual interest on this sum was to have been given as a prize yearly "for the best essay or written contribution containing an original investigation of a medicinal substance or information respecting improved methods for the preparation of chemical or pharmaceutical products."

"*Trouvant.*"—"Aqua Toffana" was the name given to a poison prepared by an Italian woman living in the 17th century. Its composition is not known with certainty, but it was probably an arsenical solution.

Communications, Letters, etc., have been received from Professor Dymock, Mr. Taylor, Professor Bentley, Mr. Roberts, Mr. Bates, Mr. Cragg, Mr. Haldon, Mr. Rivers, Mr. Benger, Mr. Chipperfield, Mr. Ingham, A. P. S., J. P., Dictionary, Beginner, Novice.

"THE MONTH."

An old writer well says of May—

"Of all the moneths in the year
To mirthful May there is no peer."

May is, as it were, the childhood of the year, and it is only during this period that the freshness of foliage and profusion of flowers which characterize it are seen in full perfection. But this year the season is at least three weeks behind its usual time. "May blossom" is only just appearing, and the lily of the valley has not until this week ventured to put forth its fragrant bells. Instead of the flowers of May we have been presented with the sunshine and showers of April. Ere long, however, we may hope to see the London streets decked in their best, and the golden racemes of the laburnum, the lovely blossoms of the pink "may," the handsome white panicles of the horse-chestnut, and the fragrant lilac, vying with each other in vindicating the title of May to be considered the most charming month of the year.

Many forest trees and shrubs may be found in flower this month—more, perhaps, than in any other of the year. Among these the oak, willow, juniper, larch, and Scotch fir are of pharmaceutical interest. The Oak (*Quercus robur*, L.) is a very variable species, of which two comparatively distinct varieties are recognized by most botanists, and are sometimes even elevated into species. One of these is *Quercus pedunculata*, Ehrh., distinguished by having the pistillate flowers stalked, and the leaf-stalk very short. The other is *Quercus sessiliflora*, Salisb., which has the pistillate flowers sessile, and the leaf-stalk longer. The latter is usually a larger, taller, and handsomer tree, with longer leaves. Of these two varieties no less than thirty-two forms in all have been described by De Candolle. The flowers are monœcious, the staminate flowers being arranged in loose, slender, pendulous spikes (catkins), each flower consisting of six or eight short stamens surrounded by a calyx, deeply divided into six or eight strap-shaped toothed segments. The pistillate flowers are not so readily noticed, being very small, but may be found in the axils of the uppermost leaves, and are either solitary and stalkless, or two or three together on a stalk. The ovary is hidden in what looks like a scaly bud, but which is really an involucre of imbricated bracts, which afterwards forms the acorn cup, the 3-lobed stigma protruding above the cupule. The ovary, when young, is 3-celled, and each cell contains two ovules; but of these six ovules only one is ultimately developed and fills the whole of the ovary. The oak is perhaps more infested by gall insects than any other British tree; the leaves, buds, inflorescence, and roots all harbouring different species. The common round hard gall produced by *Cynips Kollari*, Gir., on coppice oak, contains, if gathered in August, 17 per cent. of tannin, and might perhaps be available if the Turkish war diminishes our supply of Aleppo galls.

Of the Willow several species are used in preparing salicin. The structure in all is very similar. The flowers are arranged in catkins, and are diœcious; the pistillate flower consists of a single ovary, having a hairy scale and a minute gland at its base. The ovary is one-celled, but is composed of two carpels, and contains hairy seeds; the staminate flower consists of two, three, or five stamens in different species, and has also a small scaly bract and a gland or nectary at its base. These glands may be seen on the side of the flower next to the axis of the catkin; they are very small and yellow, and serve to attract insects. The species said to contain most salicin is the *Salix Russelliana*, Sm., or Bedford willow. It has smooth long lanceolate serrate leaves, which are glaucous underneath, lateral stalked catkins, two distinct stamens in each flower, and a stalked lanceolate capsule which has a style as long as the forked stigma.

The Larch (*Pinus Larix*, L.) may be readily known from the other fir trees common in this country by its pale green leaves falling off in winter, and by their being arranged in tufts along the branches. Its small bright crimson catkins form very pretty objects in spring. The tufts of leaves are evidently only condensed branches, for the terminal tuft may frequently be found elongated into a slender twig, in which the leaves are distinctly alternate. The staminate flowers are arranged in small cones, and the anthers are almost sessile upon the thick central axis. The scales of the cones are flat, and somewhat irregular at the margin; hence the larch is sometimes placed in a separate genus. The Scotch fir, or *Pinus sylvestris*, has the leaves arranged in pairs, and the cones are ovate, conical, and acute, and when young are as long as the leaves, stalked and recurved. The essential oil of this plant has lately been used for throat complaints in the form of inhalation. The commercial article is, however, rarely pure, and is very different in taste to the pure article. A good idea of the purity of the oil may be obtained by comparing its taste with that of the leaves of the Scotch fir, which have a rather pleasant taste, somewhat resembling that of blackberries.

The Norway Spruce (*Pinus Abies*, L.), also commonly cultivated in plantations, parks, and shrubberies, often used for Christmas decorations, and known to pharmacists as the tree which should furnish the Burgundy pitch of commerce, is easily recognized by its very short four-cornered leaves, not growing in pairs, but close together in an irregular manner all round the branches, which nevertheless present a somewhat flattened appearance. The cones are long and cylindrical, and the scales flattened like those of the larch cone. Several other species, used medicinally, may be seen at Kew, but as they are all labelled, and the trees are more easily recognized by habit, the comparative length of the leaves and their arrangement, we will only mention the names of those which are of pharmaceutical interest; they are as follows: *Pinus Tæda*, L. and *P. palustris*, Mill, yielding American turpentine; *P. maritima*, Poir, from which Bordeaux turpentine is obtained; *P. picea*, L., the tree yielding Strassburg turpentine; *P. pumilio*, Hanke, from which an essential oil is distilled, and used for inhalation; *P. balsamea*, L., the Canada balsam tree; and *P. Canadensis*, Ait., the tree yielding the Canada pitch, or hemlock pitch, of the United States Pharmacopœia.

All the above flower in May; the larch, the Norway spruce, and the mountain pine (*P. Pumilio*) being the earliest to open.

Another plant of this family (*Juniperus communis*, L.), may now be found on chalky downs. The staminate flowers are arranged in small catkins about one eighth of an inch long, on separate plants, each scale of the catkin having three or four anther cells attached to its under surface. The cone consists, when young, of twelve to sixteen scales, all of which, except the three uppermost, are empty. The three topmost scales are thinner than the others, and of a pinkish tint; they surround three naked ovules. These three scales ultimately enlarge, become fleshy, and unite to form the small fleshy galbulus, commonly called a juniper berry, on the apex of which the junction of the three scales may be easily seen.

In the Chelsea Garden, the *Lobelia inflata* may now be seen in blossom in the hothouse. It is by no means the prettiest of the genus, the flowers being of a very dull pale lilac colour. It receives its name from the inflated ovary, which is large for the size of the flower. The ovary is inferior, and the very minute seeds, which are brown when ripe, are singularly reticulated, by which character they are easily recognized in cases of poisoning. The corolla is split on the upper side quite down to the base, and does not readily fall off, but withers on the calyx. The anthers and filaments are all united together around the style, and the stigma is furnished with a small tuft of hair. The seeds are often given by herbalists in large quantities, sometimes as much as a teaspoonful for a dose, as an emetic; and were it not that they usualy administer heroic doses of cayenne pepper with the lobelia seed, there would probably be many more cases of poisoning by this drug than are now recorded.

The labdanum plant, *Cistus creticus*, is also still in flower, and the rice, *Oryza sativa*, is just coming into flower in the water tank. The tips of the paleæ are of a black colour, which give the flowers the appearence of being smitten with mildew. The ligule, or appendage at the top of the leaf sheath, is very well developed in this plant. In the open ground several species of rhubarb are coming into flower. The Polygonaceæ, to which rhubarb belongs, and the Valerianaceæ, will be well represented in fields and gardens during the next month, and may be studied with advantage.

The *Actæa racemosa*, L., which of late years has been recommended in acute rheumatism, is now coming into blossom. Both in foliage and in flower it is very similar to the rare British species, *A. spicata*, L., which is found on a few limestone tracts in the north of England. The raceme of flowers is, however, longer than in *A. spicata*. The fruit in the two species is very different in appearance, *A. racemosa* having dry dehiscent follicles, and *A. spicata* a red juicy baccate fruit. On this account the former is sometimes placed in a distinct genus, *Cimicifuga*. The carraway, asarabacca and *Geranium maculatum* are also still to be seen in flower. *Ferula Tingitana*, the plant which yields African ammoniacum, will also shortly be in blossom, both in the Chelsea Gardens and at Kew. We are glad to see also that there are two small plants of *Euryangium Sumbul* growing at Chelsea.

At Kew there are only two plants of interest at present in blossom in the economic house. These are the chick pea, which is rarely seen in botanical gardens, and the ipecacuanha. The latter is by no means a showy plant, having a few small dense cymes of white flowers arising from the axils of the upper leaves. The leaves are dark green and oval in outline. The flowers are very small, and are so crowded together as to appear like a dense umbel or small capitulum. The ovary is inferior and crowned with a roundish disk, surrounding which is a small membranous ring, representing the limb of the calyx. The leaves, as in most Cinchonaceæ, are furnished with interpetiolar stipules. The flowers are dimorphic, some having long styles and short stamens, and others short styles and long stamens. The plant appears to be endowed with remarkable vitality, for it has been found that portions of the annulated root only one-sixteenth of an inch in thickness will grow into a perfect plant, and that even the petiole of the leaf is capable of producing young plants. Nevertheless, it does not seem to flourish well in the botanical gardens in this country. It is fortunate that the plant is so prolific in its native habitat, for from its slow growth and from being collected nearly all the year round, it would otherwise have become extinct.

In the herbaceous ground at Kew, there are many curious plants now in blossom. *Podophyllum peltatum* will shortly be in full bloom, and *Sarracenia purpurea* is already in bud. The Ranunculaceæ present many genera for observation by the botanist—*Trollius*, with about fifteen sepals and small linear petals, hidden under the stamens; *Aquilegia*, with its spurred petals, often exhibiting anthers turning into petals; *Peonia*, with its well marked disk, and persistent sepals; *Anemone*, with corolla wanting; and various species of *Clematis*, differing from nearly all the other ranunculaceous plants in having opposite leaves and a shrubby habit.

In the Papaveraceæ a curious plant is now to be seen in blossom in which the carpels are scarcely coherent even when young, appearing to hang together, without any real union, thus approaching the ovary of the Ranunculaceæ in structure. The stamens also are petaloid, whence its name *Platystemon Californicum*. Several rare British plants may also now be seen in flower at Kew, of which *Urtica pilulifera*, *Euphorbia hiberna*, *E. pilosa*, *Allium triquetrum* and *Scrophularia vernalis* are especially noticeable; the Violaceæ and Boraginaceæ are also in good condition for examination.

The broom, *Sarothamnus scoparius* is, however, almost the only medicinal plant, except the rhubarbs, which especially requires notice. The Spanish broom, *Spartium junceum*, which blossoms in July, when the common broom has ceased to flower, is often mistaken for it, being a common plant in shrubberies and parks; it may, however, be easily distinguished by its larger flowers and by the branches being quite round and smooth, like the leaves of the common rush. The true broom has branches which are more slender and very angular. The flowers are curiously constructed. The stamens are of two lengths, but the filaments are all united into a single tube surrounding the pistil. The pistil itself has a very long style which is concealed within the lower petal or keel. If a bee alights on the keel of a recently opened flower the shorter stamens only emerge and dust the under part of the bee; but if the flower be a day or two old the keel gives way suddenly and the longer stamens and pistil spring out with a jerk, the pistil being thus dusted over with pollen, which by virtue of its position the stigma deposits on the back of the bee. The pistil then curls into a kind of circle so that its stigma is presented to the under surface of any bee which may afterwards visit the flower. Thus, as Mr. Darwin observes, both the upper and under surface of the bee get dusted with pollen, which will be transferred to the stigma at two different periods.

Of the rhubarbs, *Rheum rhaponticum*, L., *R. compactum*, L., and *R. undulatum*, L., are very similar in general habit, but are distinguished chiefly by the character of the leaf-stalk and fruit-stalk.

In *R. undulatum* the petiole is channelled above, rounded at the back and not furrowed, and the pedicels are jointed near the base. In *R. rhaponticum* the leaf-stalk is flat above and rounded and furrowed beneath and the fruit-stalks are jointed near the middle. In *R. compactum* the leaf-stalks are furrowed and flat above and the margins of the leaves denticulate. *R. palmatum* is easily distinguished by its deeply divided palmate leaves, but it does not appear to thrive well in either of the botanical gardens, and we have not seen it in flower. The above species are those which have been chiefly cultivated as sources of rhubarb root in Europe. A little, however, has been produced in Silesia, by *R. australe*, Don., which is easily distinguished by its rounded soft looking leaves, the blood-red colour of the whole inflorescence, and the scabrous surface of all parts of the plant. But the king of all the species is *Rheum officinale*, Baill., with which in point of size and beauty of foliage none of the others will bear comparison. The petiole in this species is not channelled on the upper surface, and is covered throughout with a pale pubescence, and the leaves are hairy underneath; the flower spikes are long, tapering, and drooping. In the Regent's Park Botanical Gardens, the Barbadoes aloes, and the *Aloe plicatilis*, may be seen in blossom; also the *Cypripedium pubescens*, or American valerian, which has a showy yellow flower, furnished like most of this genus with two stamens, one on each side of the column. The root somewhat resembles that of valerian in appearance, but is more slender, wavy, and of a brighter brown colour. It is used by the eclectics in America and by herbalists in this country as a nervine tonic.

At the Edinburgh Botanical Gardens the following medicinal plants are in flower:—*Anemone Pulsatilla, Cochlearia officinalis, Sanguinaria Canadensis, Arctostaphylos Uva-ursi, Amygdalus communis, Rosmarinus officinalis, Asarum Europæum*, and *Coptis trifoliata*, all in the open ground, and *Aloe plicatilis* in the greenhouse. Two species of *Iris* which yield orris root, *I. Florentina* and *I. germanica*, are just coming into blossom. In the gardens at Glasnevin, Dublin, only one plant, not hitherto mentioned, is in flower, and that is the *Curcuma longa*. There is yet one more plant which will probably be over by the end of June, and should, therefore, be noticed now. This is the *Arum maculatum*, which yields a starch formerly prepared under the name of Portland arrowroot, and the corm of which has been occasionally taken in small doses for gout. The flowering spike or spadix has near its base a ring of ovaries, and above these again a ring of anthers, and above these again a ring of abortive ovaries with long hair-like styles, which point downwards, and which are exactly level with the contracted portion of the spathe that they serve to close. The stigmas mature first, and by the time the anthers shed their pollen the stigmas are no longer fit to receive it. It, therefore, drops to the bottom of the spathe, and is carried from thence to fertilize other flowers of the same species by minute insects that can enter the spathe at any time, but cannot get out until the hair-like styles have withered, which takes place soon after the shedding of the pollen.

In the drug market we have noticed several spurious drugs, among which were copalchi bark offered as angostura bark; Para bark, a worthless bark containing no alkaloid, but closely resembling quilled Calisaya in appearance; and *Stenostomum acutatum*, a spurious cinchona in long grey smooth quills very different in appearance from any other bark. Black or striated ipecacuanha (*Psychotria emetica*) has also been offered at a price a little below that of true ipecacuanha. The gum described by Guibourt as *Gomme pelliculée*, which has a thin layer of papery bark here and there on its surface, has also been seen. Indian dill seeds (*Anethum Sowa*, Roxb.) have been offered as Sowa seed. These closely resemble the ordinary dill seed in appearance, but are narrower and more oval. Japanese isinglass in square sticks, made from various species of seaweed, and consisting chiefly of gelose, has also figured in the sales. Large quantities of East Indian cinchona have appeared during the month, but do not seem to have had any influence upon the high price of quinine. It may naturally be expected that such drugs as are obtained from Turkey and Russia will now rise in value. Opium, Aleppo galls, otto of rose, and linseed, as well as a few other drugs, may be expected to be much dearer before the year is expired, and are already showing signs of a rise in price.

We are glad to see that there is a tendency abroad to make Materia Medica collections available for students at the medical schools of a better character than hitherto. Dr. Phillips, of Westminister Hospital, has lately presented the school there with a very handsome and complete set of specimens, which is undoubtedly the best and most complete in any of the London hospitals.

Since the mention of Casca bark in the report in the *British Medical Journal* of the excellent lectures by Dr. Lauder Brunton,* inquiries have been made concerning it from various parts of the country, and our readers may be interested to know that it is identical with the sassy bark described several years ago in the *Pharmaceutical Journal* as the ordeal bark of Liberia on the Western Coast of Africa.† Although not at present a commercial article, it is probable that some of this bark will shortly be on it way to this country.

Curaçoa aloes, which has lately come over in large quantities, deserves chemical investigation, its aloin, we believe, not having yet been examined.

If the number of remedies lately brought into notice be any criterion, skin diseases must cease, ere long, to be an opprobrium to the medical profession. The latest new specific of this class hails from China, and is known by the sonorous name of Tong pang chong, and is said to be the product of *Akebia quinata*, Decaisne, a berberidaceous plant. It is said, by Dr. Murray, to produce wonderful effects in some cases of tinea and eczema.‡

Euonymin and Iridin have been highly spoken of as cholagogues, by Dr. Rutherford and M. Vignal, in their late report to the scientific grants committee of the British Medical Association. Of the former they say, that it is "worthy of receiving far greater attention in practical medicine than it has done hitherto,"

* *British Medical Journal*, March 24, p. 345.
† *Pharm. Journ.*, 1st ser., vol. xvi. p. 233.
‡ *British Medical Journal*, May 19, p. 609.

and of the latter, "there seems every reason why it should be removed from its present obscurity, and placed in a prominent position in practical medicine."

Coca leaves, of which much was at one time expected, have at last received a practical application. Dr. S. McBean has found them of service in typhoid fever, and other febrile diseases.*

Macaulay once wrote "we know no spectacle so ridiculous as the British public in one of its periodical fits of morality. In general, elopements, divorces, and family quarrels, pass with little notice. We read the scandal, talk about it for a day, and forget it. But once in six or seven years our virtue becomes outrageous. We cannot suffer the laws of religion and decency to be violated. We must make a stand against vice."

The truth of these words cannot be disputed; the British virtue unmistakably breaks out at times in excessive forms and constitutes the only revolutionary phase of the national character. The English people as a rule progress by evolutionary changes, but when they depart from this standard the consequences are ridiculous. Witness for instance the recent anti-vivisection movement; what could possibly be more absurd than the dying phases of this, in which disgusting placards are circulated throughout our towns setting forth the tortures inflicted by vivisectional experiments? What better things can be expected of a nation estimated by Carlyle to contain so many fools?

Unfortunately it must be admitted that in the matter of which we have just spoken, there has existed and still exists, if not here at least elsewhere, too much ground for the objections raised by the outraged people against the practice of vivisection. It is quite true that the agitators have ignored the good that has resulted, and may still result to the human race from properly organized and studied methods of research. Had this branch of science produced no other result than the discovery of the circulation of the blood, its employment would stand justified; on the other hand the results have been many, various, and of the highest importance. Yet it must be confessed that through the exercise of uncerebrated research, much unnecessary pain has been inflicted upon animals, and a large percentage indeed of the total amount of vivisectional experiments have been worse than useless, having been carried out in an empirical unstudied manner, and yielding results not worth the paper upon which they have been recorded.

In former articles we have adverted to several instances which may fairly be included among such results, and now again another instance is before us. MM. Dujardin-Beaumetz and Audigé have found that 245 grams of glycerine, when injected under the skin of a dog with an equal quantity of water, kill the animal in forty-five minutes. It had been well for the dog to have died more quickly; it had been better that the experiment—stupid as it was—had never been performed. Imagine the effect of injecting nearly a pint of any liquid subcutaneously; death must be the inevitable result of such a rude experiment and a proceeding running counter to the conditions upon which life depends.

The other results obtained by these investigators are equally worthless. They found that death always follows the injection of ·8 of the animal's body-weight of glycerine, and that 1·25 gives rise to tetanic convulsions; the body temperature rises to 109°, and congestion of the cerebro-spinal meninges is seen.

Such experiments as these, having reference to no primary idea, and the attainment of no definite object, are as indefensible as another, quite as repugnant, of which information reached us some time since. It was this. The specific gravity of the urine of a dog was first taken, the bladder of the animal was then kept tied during a protracted period, after which the ligature was removed, and a second specific gravity determination effected. The professed object of this experiment was to ascertain whether under these conditions an increase in the density of the urine was caused by means of the absorption of water by the walls of the bladder. Surely the walls of the bladder were no more designed to absorb the water it is destined to store, than the pirate was erratic in putting forth to sea and breaking the eighth commandment. In observing the moral, the pirate would lose sight of his profession to steal.

As already stated, we are by no means at one with the anti-vivisectionists; public opinion, however, should not effect results by fits and starts; it should be well instructed, and uniformly exercised.

In regarding the physiological action of glycerine, we may compare the results obtained by M. Catillon* against those just commented upon. He finds that considerable doses decidedly lessen the decomposition both of the fatty and azotised constituents of the body, and that under its influence animals increase in weight and excrete less urea. That the urea is not stored in the system is proved by the fact that the proportion existing in the blood is not augmented by the glycerine administration. In moderate doses glycerine acts as a mild laxative and improves both the appetite and the digestive powers and all that enters the stomach is absorbed. This absorptive faculty, however, is limited, and if the limit be overstepped glycerine appears in the urine; it begins to be eliminated in less than an hour by the kidneys when the dose exceeds twenty grams. When a very large quantity, for instance, fifteen grams per kilo of body weight, is taken in one dose, death usually takes place, and the *post mortem* lesions are found to be similar to those effected by acute alcoholic poisoning.

With these remarks let us pass on to consider other matter relating to the month.

Quite recently the eighth report (new series) of the medical officer of the Privy Council and Local Government Board has been issued. This is the last one with which Mr. John Simon will be officially connected, and it is one of peculiar interest and importance. Dr. Sanderson contributes to it a further study of morbific ferments, and shows that the common ferment of putrid infusions is removed by filtration through porous porcelain. That this is so, is shown by the fact that the filtrate will not now undergo any further zymotic process in itself, and if introduced into the living body will not exercise any morbific influence (fever) on it. These results are important because they signify the particulate nature of such ferments, and no field of research could be more productive of good to humanity than a study

* *British Medical Journal*, March 10, p. 291.

* *Archives de Physiologie* (Janvier-Février, 1877).

of the ferment matter itself conducted upon chemical and mathematical principles. Indeed, it must be admitted that such a study is the one most urgently called for at the present time in chemico-physiological science.

The questions to be solved may be expressed as follows:—

(1) The chemical constitution of infusions which are liable to putrefaction.

(2) The alteration in constitution induced by putrefaction.

(3) The chemical constitution of the particulate matter removable by porcelain.

(4) The chemical constitution of the filtrate.

With the solution of these problems would come an insight into the nature of these particular ferments, the processes by which they are developed, and the conditions necessary for their existence. After this there would be some reasonable hope of finding an explanation of zymotic disease—at present there is not one.

Dr. Klein gives a report on the minute anatomy of scarlatina, and one on the so-called enteric fever of the pig; but elaborate as they are in detail they admit of no conclusions respecting contagium. It is true that specific changes are described, changes associated more or less with the development of micrococci and so forth; but there is no evidence to show how far these low forms of life—germs, in fact—are concerned with the cause of the disease. From certain important evidences it would seem that they are mere attributes of disease, while the causes depend for their existence upon ferments and upon chemical changes.

Dr. Creighton's report on the Infectiveness of Cancerous Tumours, contained in the blue book before us, lends weight to this view and supports an opinion which has been somewhat abandoned of late years. It would appear that such acts of infection are due to a specific ferment-power possessed by the elements of the primarily diseased parts; these changed matters have the power to cause new parts to desert their own former textural type, and as Mr. Simon puts it, "grow in a new way with new endowments, so as to become in form and ferment-power a repetition of the parent tumour."

The last report is by Dr. Thudichum on the Chemical Constitution of the Brain, and contains also the summarized substance of certain researches conducted conjointly with Mr. Kingzett. Some of these matters have already been noticed in this Journal, but other points may conveniently be referred to here. The further investigations regarding the constitution and nature of the phosphorized principles in brain substance, show that they all yield their phosphorus in decomposition by hydration, as glycerophosphoric acid ($C_3H_9PO_6$); they all yield their nitrogen in one form, but from certain chemical considerations the exact formula of the free base is a little doubtful. More probably it is $C_5H_{13}NO$, but perhaps it may be $C_5H_{15}NO_2$; this, however, is certain, that the platinic chloride combinations with the hydrochloride of the base have invariably a composition represented by $(C_5H_{13}NO)_2$, $2\,HCl,PtCl_4$. Sometimes, however, apparently by secondary decompositions, two other bases are obtained, but only as additions to the one already described as forming the chief amount. One of the salts has the empirical formula, $C_5H_{14}N_2O$, HCl, $PtCl_4$; and the other $(C_2H_7NO)_2$, 2HCl, $PtCl_4$.

The phosphorized principles of the brain therefore differ one from the other only in the nature of the fatty acids which they yield on decomposition. Lecithine yields margaric and oleic acids; kephaline yields one known (but not yet published), and one unknown acid; myeline is a general name for a number of substances of a type common to the foregoing, but differing from them apparently in being derived from a condensed (perhaps double) glycerine type, and yielding at least part of their nitrogen as amidated fatty acids. One of the fatty acids yielded by myeline is palmitic. All these principles need yet further study; but one point discovered by Thudihcum and Kingzett is particularly striking, viz., the identity of that peculiar phosphorized matter associated with blood corpuscles with one of the forms of brain myeline. The chemical constitution of cerebrine and certain allied principles yet remains to a large extent undetermined experimentally. A reasonable view, however, results from the observation that they yield sugar when boiled or heated in sealed tubes with hydrating agents, such as sulphuric acid. On this Mr. Simon remarks, that "it is highly suggestive in relation to the familiar occurrence of so-called "amyloid bodies" in the diseased nerve centres of persons who have suffered certain sorts of paralysis, and perhaps, also (in a different way), in relation to one interesting section in the obscure etiology of diabetes."

Space alone prevents us from following further the investigations detailed so fully in this report.

Among matters of more passing interest there is little calling for special attention.

Galippe* has recently communicated to the French Academy of Sciences some results having regard to the alleged poisonous effects of copper salts. He has found that the administration of large doses causes vomiting, but that the same compounds may be taken in increasing amounts for prolonged periods of time without the attendance of any painful symptoms. After referring to the experiments of Burq and Ducom, in which dogs were fed with food that had been cooked and cooled in vessels made of copper and previously exposed to the action of vinegar and salt, without experiencing poisonous effects, he proceeds to describe how he himself has lived on food similarly prepared. The various dishes thus partaken of, although often tinted green with the verdigris, gave rise to no dangerous or even unpleasant symptoms either in Galippe or his family.

These experiences support the opinion we have consistently expressed in these columns of the innocuous nature of traces of copper in foods, notably preserved peas and pickles. No matter how introduced, copper in minute quantity is a normal constituent of many animal tissues, although we admit it to be another question, and not an unimportant one either, as to the extent to which copper should be allowed to accumulate in the system. Speaking of the metallic constituents of the body, this forms a fitting place to notice a paper by Lechartier and Bellamy, which is printed in the same number of the *Comptes Rendus* as Galippe's research.

Lechartier and Bellamy state that they have found appreciable quantities of zinc in the liver of man and other animals, such as the calf, ox, and dog; and pursuing their investigations yet further, they also demonstrated the presence of zinc in hen's eggs, wheat, barley, maize, and haricot beans. Consider-

* *Comptes Rendus*, April 9, 1877.

ing the important bearing these results have on certain medico-legal questions, it is extremely desirable that they should be confirmed by other investigators before they receive acceptance.

Dr. Alford, the medical officer of health for Taunton, has reported to the local sanitary authority an outbreak of lead poisoning in his district, arising from the method of grinding flour adopted there. Some difficulty was experienced in ascertaining the source of the lead, but it was eventually found that all the persons affected had sent their corn to be ground at the same mill, and on examining this, Dr. Alford observed that a number of holes which had appeared in the mill stones had been repaired by pouring in molten lead. He therefore regards this as explanatory of the cases referred to. These were of a very decided nature, in which the blue lines on the gums, the cholic and other symptoms were plainly evinced. The mill had been repaired by means of lead, as described, during an illness of the owner, but it came out in the course of an examination, that what is more ordinarily used is a mixture of red-lead and borax, or alum and borax. The use of the first of these mixtures one might imagine to be rather more injurious than lead itself, but it is to be hoped that its employment is not extended and may be abolished.

Mendelejeff has recently communicated to the Russian Chemical Society the conclusions arrived at from an examination of the deposits of mineral oil in the Caucasus and in Pennsylvania. He disputes the correctness of the view that these are derived from the decomposition of fossil remains of organisms and concludes that they have their origin in a series of changes to which carbon and iron in the presence of water are liable under certain conditions, such as high temperature and great pressure. Under these influences Mendelejeff opines that metallic oxides and saturated hydrocarbons would be formed, and that the latter by permeation of the porous sand-stones of higher levels condense there, or undergo further change and become unsaturated hydrocarbons.

Kolbe* has described an improved method of preparing hydriodic acid. It consists in adding to ten parts of iodine contained in an atmosphere of carbonic anhydride one part of phosphorus little by little, slowly; on the mixture of di- and tri-iodide is poured four parts of water. From such a preparation abundance of hydriodic acid is generated on the application of a gentle heat, and it is not contaminated with free iodine. Everyone who has prepared hydriodic acid must be aware of the truth of Kolbe's statement to the effect that the methods given in most text-books give much water and little hydriodic acid; this arises from the general employment of too much iodine and water in proportion to the phosphorus used.

Radziszewski† has found that formic aldehyde and grape sugar, mixed with an alcoholic solution of caustic potash, and warmed in the presence of air, becomes phosphorescent. From this it is suggested that the burning sensation experienced on the skin and produced by *Noctiluca milicris*, owing to the secretion of formic aldehyde, which undergoes oxidation into formic acid. The phosphorescence above alluded to lends small weight to the view that grape sugar is an aldehyde in constitution.

* *Journ. Prakt. Chem.*, 1877, *xv.*, 1672.
† *Beiblatter Ann. Physik und Chemie*, 1877, *i.*, 242.

In the *Canadian Pharmaceutical Journal* for May, E. B. Shuttleworth contributes an interesting note, setting forth the advantages presented by the use of impermeable paper boxes in pharmacy. He points out that the Chinese, to whom we are indebted among other discoveries, for that of paper making, have long been familiar with the mode of waterproofing tissues of vegetable fibres, so that they could be employed for even containing liquids. Recently paper of a thick character has been employed to construct barrels which are cheaper and lighter than those made of wood. Mr. Shuttleworth described several methods of rendering paper boxes, etc., tight at the joints and impermeable, according to the nature of the substances to be contained in them. Thus they may be dipped into melted paraffin or an alcoholic solution of shellac; or another composition which may be used is silicate of calcium, obtained by dipping first in a bath of potassium or sodium silicate, and then in one of calcic chloride.

The Chinese use, as is well known, liquid blood albumen, with lime and alum, for rendering waterproof, articles made of paper and straw; and such a preparation does its work remarkably well.

The hints furnished by Mr. Shuttleworth are valuable, and there can be no doubt of the advantage to be gained by the use of such a cheap material as paper as against china or porcelain or even stoneware. Articles of semi-fluid or pillular consistence, such as extracts, confections, honey, ointments, for instance might be packed in impervious paper boxes.

Under the Sale of Food Act, a grocer of Freshwater in the Isle of Wight has been fined for the sale of mustard containing, according to the analyst's certificate, 30 per cent. of wheaten flour and a small quantity of turmeric employed to heighten the colour.

In conclusion we may note an important point which the Rev. W. H. Dallinger has established in the course of the researches which formed the topic of his discourse at the Royal Institution on the 11th inst. After describing the process of sporing by which monads appear to reproduce themselves, the lecturer stated that he had found the spores capable of resisting a temperature of above 300° F. for ten minutes, whereas the adults were readily killed by exposing them to a temperature of 140° F.

The importance of this fact lies in the explanation it affords of several matters which have recently formed the object of vehement discussion between Bastian on the one hand, and Pastem and Tyndall on the other hand. It will be remembered that the latter observers have contended that the temperature of boiling water is sufficient to destroy germs, whereas Bastian asserts that germ life often reveals itself, even in infusions which have been subjected to a higher temperature. From Mr. Dallinger's results it would seem that both sides were right, but that neither of them knew the whole truth. While, however, the bone of contention is thus removed, Bastian's assertion of spontaneous generation is involved in yet graver doubt, for, as we have seen, monad spores resist the critical temperature which even he has viewed as destructive of previously existing life. Before their spontaneous generation can be asserted as true it is essential to ascertain particularly when matter is absolutely dead and the conditions necessary for perfect isolation from living matter.

SATURDAY, MAY 26, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, *17, Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary, 17, Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE OUTBREAK OF SCURVY IN THE RECENT ARCTIC EXPEDITION.

REGARDING the outbreak of scurvy in the recent Arctic Expedition, the Commission appointed by the Lords of the Admiralty has just issued a voluminous Report which will meet on most sides with the fate that many blue books of as great and much greater value experience, viz., comparative obscurity. And yet there is much important matter in these volumes whose burial is almost simultaneous with their birth. From the nature of the subject the present one is of peculiar interest, affecting as it does a disease continually appearing in the naval service, and treatment of which is so imperfectly understood.

In the Report before us, the early outbreak of scurvy in the spring sledging parties of the expedition is attributed to the absence of lime juice from the sledge dietaries, and the opinion is expressed that the winter of 142 days, involving absence of sunlight, confinement during the greater part of the twenty-four hours to a lower deck of necessity not free from damp and a comparatively vitiated atmosphere, and the deprivation of fresh meat, were circumstances which constituted predisposing causes of scurvy. It is further supposed that the severe cold and arduous labour encountered by the sledging parties aggravated the causes which led to the outbreak.

The adequacy of the provision made by the Admiralty in the way of food, medicines, and medical comforts, was in every respect good, and even more complete than that made for any previous expedition of a like nature. But the propriety of the orders given by the commander of the expedition for provisioning the sledge parties is strongly commented upon, as they did not include lime juice, thereby deviating from the 11th article of the Memorandum of Recommendations and Suggestions of the Medical Director-General.

In the early part of the Report there is a valuable paper, contributed by Dr. DONNET and Dr. FRASER, on the symptoms, pathology, and causes of scurvy, and it is seen that the medical evidence is almost unanimous as regards the direct causes of the disease. Here it is unnecessary to enter at all into the symptoms of the disease, but in relation to its pathology we may note that the characters may be regarded as representing the deterioration of the blood that exists as a result of depraved nutrition.

Mr. BUSK considered scurvy to be essentially a consequence of defective not deficient nutrition; in fact, a kind of starvation due to the want of "a particular element of the nature of which we are entirely ignorant." This element is apparently afforded by raw vegetable juices, and some are of opinion that fresh animal meat, notably in the raw state, and milk, are also possessed of powerful antiscorbutic properties.

There are, however, other medical men whose views do not quite coincide with those of the mass. Thus, Sir ROBERT CHRISTISON believes that a deficiency of the nitrogenous principles of food, and especially of albumen and casein, is a cause of scurvy. The reason however for this statement is not so satisfactory as might be wished, and if true at all, it must be taken as meaning albumen and casein of a particular character, for in certain more or less dry forms there was evidently abundance of these substances. Dr. GARROD refers the appearance of the disease mainly to the absence of potash, and Dr. ALDRIDGE assigns the greatest influence in the production of the disease to the absence or deficiency of phosphorus, sulphur lime, potash, and soda. It will be seen that these substances are contained in the ashes of vegetable and animal foods, and are present equally in dry as in fresh foods, and therefore the Commissioners report that the arguments in support of these opinions are not sufficient to lead to the general adoption of any of them. These may then for the present be left out of further consideration; they are not widely adopted, and are not based on sound chemical views.

In the present aspect of affairs it is somewhat difficult to perceive the cause of the ulcerations that occur in the advanced stages of scurvy—ulcers which sailors graphically term "bullock's liver," and which emit a very offensive odour. In this advanced condition, "every slight scratch degenerates into an ulcer, old scars break out afresh, and hæmorrhages are now frequent from different parts of the body." The only explanation is that the economy is so weak and reduced, by reason of a deficiency in some vital and necessary element, that it is no longer able to maintain by its food—such as it is—the conditions upon which health depends. The slightest causes are now able to disturb the balance, and with their appearance the purely chemical changes set in and overthrow the chemico-physiological concatenation of influences upon which health and even life depends. In good health the body lives by virtue of a predisposing cause apparently inherent in its protoplasm, and life is maintained so long as that protoplasm can, from the food properly presented to it, reproduce the various tissues and parts of which the body is constituted. But if that food be deficient in any vital particular, then, although reproduction of tissues may go on in a measure, the influences which hold them parts of a harmonious whole are disturbed, and outside agencies are powerful to still further disturb the equilibrium. The question then that has to be solved before the nature of scurvy is comprehended, relates to the missing element in the food by the partaking of which the disease is caused—that element, in short, of which we know nothing. And in tracing out the mystery we must begin at the beginning, and ascertain in what respects dry and preserved meat and vegetables differ from fresh foods.

Even at the onset we are baffled; these differences are unknown, but there is knowledge to hand from which some sort of insight may be obtained. Fresh meat or vegetables, or their juices, contain ferments which would in all probability lose their original form, and with it their power, by drying. It seems as if these ferments are extremely active in the wet, original state, but that their power is only associated with what we may call this nascent form, and that if at all present in dry or preserved nitrogenous foods they exist in a deteriorated condition, or so changed that they have lost their power to bring about those changes upon the matters associated with them and other foods in the stomach, through which digestive fluids are reproduced, and by means of which life and health are sustained.

The deficit in the supply of fresh meat to the crews of the vessels attached to the Arctic Expedition is exemplified by the fact that whilst the crew of the "Discovery" was able to obtain a sufficient supply of large game to permit of fresh meat being issued on fifty-three days, the crew of the "Alert" was restricted during the same period to an issue of fresh meat on only fourteen days.

Of the seventy men who wintered in the "Alert," forty-five (or 64 per cent.) were affected with scurvy; whereas only fifteen men (or 29 per cent.) out of the fifty-two who wintered in the "Discovery" were attacked. This disparity in numbers is explained as due to the more prolonged absence of sun-light, and the much greater deficiency of fresh meat experienced by the men on the "Alert." From the reports of the commanding officers of the two ships it is gathered that the dietary was quite sufficient as regards quantity, and was supplemented by the daily issue of at least one ounce of lime juice, the preserved and salted meat being substituted at times by fresh meat. From the analyses to which the various articles of food and lime juice were subjected by chemists employed by the Commission, these appear to have been of an ordinary good quality, except the salt beef, which was somewhat oversalted. The dry vegetables, represented by compressed cabbage and compressed mixed vegetables, were found to be somewhat deficient in saline constituents, but it is thought by the Commissioners that no deleterious effects can be traced to this deficiency.

The preserved vegetables, including moist tinned carrots and dry preserved potatoes, were ascertained, so it is said, to have maintained their quality and nutritive value a character the more important on account of the antiscorbutic reputation of vegetables—especially potatoes—which has been so well established. This matter is, in our opinion, a most important one, and we submit that whereas in all probability the antiscorbutic value of vegetables is a property directly connected with what may be called their living juice, it cannot be accepted as absolutely proved that preserved vegetables, in spite of the pressure and partial loss of moisture incidental to their storage, retain unaffected the nutritive qualities originally possessed by them. Indeed, there is considerable evidence to show that although preserved vegetables constitute valuable food matter, they are not nearly so nutritious as fresh ones.

From the nature and requirements of sledge travelling, especially in extended journeys, it is essential to carry as little weight as possible, and on the assumption that foods are not impaired by partial loss of their natural water and preserving; the sledge expeditions in the recent attempt to reach the Pole were largely supplied with these condensed forms of pabulum.

The Northern sledge party, consisting of two officers and fifteen men, were all affected with scurvy during the journey; and out of the Western sledge party, which altogether numbered fourteen men, only one man escaped. With the Eastern sledge party twenty-four men were connected, and among these seventeen cases of scurvy occurred.

It is unnecessary to go further into figures, but from the evidence contained in the Report it is seen that the great majority of cases of the disease occurred during the sledging expeditions. Insufficient nutrition cannot be regarded as the main cause of this outbreak, although most of the medical men examined were of opinion that the amount of preserved potato served out daily on the sledging expeditions was an insufficient one. But what is held accountable for this serious outbreak of scurvy is the omission of lime juice from the sledge dietary; lime juice being considered to have an established character of supplementing the deficiency in the vegetable element presented by the dietary among Arctic Expedition.

As for the exact action of lime juice, it is known that it is not sufficient to swallow it merely, "but the function" served by it "during the process of nutrition must be accomplished," and this is a function to secure which a definite plan must be adopted. In proof of this, it may be stated that alcoholic indulgence and other causes are sufficient to prevent this antiscorbutic action of lime juice, owing to the disturbing influence they exert upon the process in which lime juice plays its part—that of stomachic nutrition.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, W.C., on Thursday evening next, May 31, when a paper will be read by Mr A. G. RICKARBY, on "Poisons."

Transactions of the Pharmaceutical Society.

DINNER IN AID OF THE

BENEVOLENT FUND.

The following Donations and Annual Subscriptions have been received or promised. Further contributions are solicited, and should be made payable to,

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Annual General Meeting.

The annual business meeting of this Association was held in the Manager's Library, of Anderson's College, on Monday evening, 7th inst.; Mr. Daniel Frazer, President, in the chair. After the usual preliminary business had been disposed of, the Hon. Sec. (Mr. James M. Fairlie) was called upon to read the Annual Report of the Council, of which the following is an abstract:

This document referred, in the first place, to the visit of the Pharmaceutical Conference and the arrangements connected therewith. It stated that upwards of £200 was expended by the local pharmacists in furtherance of the meetings in connection with it, and that the balance of the subscriptions had been handed over to the Association, and would be expended in books for the library. On account of the Conference, the scientific meetings had commenced later than usual, but there had been eight held during the session, three of which had been addressed by Dr. Machattie. The other work of the Association had been chiefly connected with the classes. Fifteen students were enrolled for the practical chemistry class, conducted at the laboratory, 88, Hope Street, by Dr. Machattie and assistants, and several of the students who attended that class had since passed their examination. An examination had been held at the end of the session, when a competition took place for two prizes offered by the Council. Mr. John Macnicol obtained the first prize, and Mr. George William Watt the second. Thirty-one members had been enrolled for the tutorial class, conducted by Mr. Archibald Fairlie, C.M., who had also reported favourably regarding the attendance and progress of the class. An examination was held at the close of the session, to decide the recipients of the Council's prizes. Mr. William Blain was entitled to the first prize in the senior division, and Mr. Hugh Campbell second; Mr. Alexander Skirving being first in the junior division, and Mr. John Lawrence jun., second. Twenty members had been enrolled for the botany class, conducted by Professor Keddie, F.R.S.E., in the Science Class Room of the Free Church College, and Professor Keddie had spoken very highly of this class. An examination would be held at the close of the session in June, and the Council's prizes would then be competed for and presented. The Library of the Association had been greatly taken advantage of this session as in past years. Ninety-five exchanges had taken place during the session, and twenty-five of the volumes were then in circulation. The best thanks of the members were due to Mr. James Murdoch, who had had the whole management of the books in his hands. The microscope had been put to good service by the numerous interesting objects supplied from time to time by Mr. John C. Hunter and Mr. John Edmond Fairlie, both of whom had done much to render the microscope a popular study among the students. The materia medica cabinet, or rather cabinets (a second one having been handsomely presented to the Association in course of the session by Mr. S. M. Frazer), had also been eagerly inspected from time to time by the students preparing for their examinations. The Price List Committee had been at work during the winter, and a new edition had been issued with a dispensing card attached, at the usual price of one shilling. The old edition was entirely sold out, and many were anxious for a new list. The increase made on the prices of many of the things, particularly the dispensing scale, had met with a little opposition at first, but it was believed it was being gradually adopted as a whole, with advantage to the chemist, and no complaints on the part of the public. The formation of the Chemists and Druggists' Trade Association was referred to, and the Scottish branch with head quarters at Glasgow. The earlier closing question had come to the front again, and an opinion was expressed that the assistants must certainly get more leisure for their studies, and the masters would benefit perhaps both in pocket and in health if a complete understanding could be come to on the subject. The Financial Statement showed that the number of members had slightly decreased from last year, which was acounted for by a number of country chemists enrolling themselves last session in connection with the special effort made in anticipation of the Conference meetings, but who had not renewed their subscription. It was understood that the University authorities had made an application to the proper quarter for the appointments of a Professor of Pharmacy at Gilmorehill. If the government give their consent, it would behove the Association to see that a thoroughly qualified person was appointed, one who, while upholding the dignity of the University, would also assist in placing the Profession of Pharmacy in the place it should be amongst the sciences.

The Treasurer read his Financial Statement, which showed that while there was an apparent cash deficit, there was a stock of price lists on hand which would soon realize as much as would clear it off.

On the motion of Mr. John Currie, sen., seconded by Mr. William Whyte (of Brown Brothers and Co.), the reports were unanimously adopted as read, and the hearty thanks of the Association given to Messrs. Fairlie and Mackenzie for their arduous labours connected with the Association for so many years.

The Chairman (Mr. Frazer) thereupon read his valedictory address, as follows

The President's Address.

Gentlemen,—The closing words—the last word itself—of many a speech, and of, I fear, many a sermon, is not unfrequently the most welcomed by the hearers of both. So with "the closing address of the session," by the chairmen of all sorts of educational associations. In such cases, and quite irrespective of the length or quality of the address itself, the mere fact of its being delivered tells of a longer or of a shorter term of work—alike by the teacher and the taught—being brought to a close, and of a holiday being about to be entered upon by both. Thus will it be with the present address. It will be welcomed by the students and scholars who have worked, many of them under great disadvantages, the hardest, as giving them a well-earned respite from the toil and moil of a laborious session; and it will be doubly welcomed by those who have *not* worked hard, as telling them that now, whatever it may have been in the past, they will no longer have to furbish up the wonted excuse for the ill-prepared task, or for the frequent absence. At the same time I trust that though the compulsory attendances at the class or lecture is over for the season, the long summer holidays on which we are entering will not pass without recording much voluntary and, therefore, pleasant work done. Hugh Miller, in one of his famous leading articles, told how he laboured hard at his task in the long summer days, and saved the half of his wages that he might have the long winter nights, "all to himself," to prosecute the study of science and of literature. How well Mr. Miller succeeded in this is known to all. What he did so well on the chosen field of his labours I trust not a few of you will do on yours. If so, pharmacy will, by and by, be the gainer, and you yourselves all the richer—richer in knowledge at all events, and I hope also in even the meaner riches that, no doubt, form the first stimulus to study and hard work with most of us. As I do not wish you to weary too keenly for the "last word" of this address, as I fear I gave you cause for doing at the opening of the session, in the few remarks that I propose now to make on two or three matters that have somewhat exercised the pharmaceutical world for some months back, I will content myself with doing little more than give the headings of the different subjects to be mentioned, and upon which, but for sparing your time and my own, I could quite easily have written pretty largely. The first of these is the milk of sulphur question. Every dog has his day, and the dog of the pharmacists during the last few months has certainly been the said milk of sulphur question. In letters, lectures, speeches, and articles in the *Pharmaceutical Journal*, and in the *Chemist and Druggist*, and discussions in the law courts, this has been the burning question of the season. Many men, many minds—and as men, happily, are not automatons—this diversity of opinion is not only natural in itself, but is at once inevitable and right. Where there is life there is animation. Where there is death there is only stagnation. In the present case, Tom swears by the "genuine old milk of sulphur," and Dick by the "sulph. præcip., B. P.," while Harry goes in for both. Well, I suppose I better be out with it; I go in with Dick for the B. P. article. Doing this myself I am quite sure you will not wonder that I think everyone who does not is just as far wrong as they are bound to believe I am. My reasons are very simply stated. Sulphur is sulphur: it is not sulphur and lime. Sulphur is prescribed by medical men, and the public ask for sulphur, or for milk of sulphur. Unquestionably, ninety-nine medical men out of one hundred mean the pure article, and just as large a portion, I believe, of the chemically ignorant public mean the same. When they ask for the milk of thing—be it what it may—surely common sense tells that something better is meant than the article without the prefix is in itself. The cream that rises upon the surface of new milk does not gather up any foreign substance to it; it is the richest part of the milk. Such, I am quite sure, is the idea the average purchasers of milk of sulphur have when they purchase it rather than the flower of sulphur. Will any pharmacist tell me that if he frankly told his customers that the milk of sulphur he was selling contained a large percentage of lime, whereas the flower of sulphur was comparatively a pure article, and only a half or a third of the price, he has so low an opinion of the intelligence of his customers as to say he would, after such an honest statement of fact, give a preference to the mixed article? I am told that in some districts in England some druggists sell a hundredweight or more of the milk of sulphur in a month. I am extremely curious to know this, if these druggists could purchase the sulph. præcip. for 5*d.* and have to pay 8*d.* for the said milk, would they continue to supply the lime article, merely because the public had been, as is alleged, accustomed to it and found it so much easier to mix? Would they not do, as I had to do some thirty years ago, when introducing pure linseed meal and genuine brown mustard, and ponderous magnesia instead of the light—instruct the public that the new articles were better than the old? I believe they would, and with the same success as I had with these articles. I confess that it took an immense amount of persuasion to induce the public to substitute the pure articles for the adulterated ones, but I would give them nothing else, and now they come to me from all quarters to get them. Besides, I believe it is all a bugbear about the public insisting upon getting the mixed article. The much-abused public, as a rule, know nothing whatever of the composition of the article sold. And most delighted am I to record it here; it was brought out in the famous Runcorn trial, that out of fifty samples of milk of sulphur examined by the public analyst, forty-five were found by him to be pure! Surely this thoroughly disposes of the question as to the difficulty of inducing the public to purchase a genuine article. Another question that has caused some, as I think quite needless, discussion, is the tea, dessert, and table-spoon measure, one. I have a strong impression that if every body would be content to attend to their own business, the world would be none the worse, but all the better for it. As to the bearing of this very trite remark in the present case, it is simply this, our business is not to prescribe, but to dispense, and in dispensing we have but to "do as the doctor orders." He knows quite as well as we do how much the spoons in domestic use vary, and we are bound to believe him intelligent enough to take this variation into calculation when writing out his prescriptions. I was very glad to see this view advocated in one of the last letters on the subject that appeared in the *Journal*, but was, I confess, surprised that so very able and experienced a pharmacist as Mr. Proctor, of Newcastle, should have put himself to so much trouble in a matter that, for the life of me, I cannot see pharmacists have anything to do with. When speaking of prescribing, I wish to say here that I was surprised last year at a discussion that occupied the columns of the *Journal* for some time—viz., as to the dispenser retaining the prescriptions from the patient, and charging for copies of it. I maintain that the prescription is as much the property of the patient, and as little that of the dispenser of it, as are his spectacles, or his household furniture, or anything that is his—his by purchase or by inheritance. As to prescribing by pharmacists, I remain of precisely the same opinion as I was when I referred to the subject in my opening address. As long as we honestly seek to confine ourselves to our own legitimate field, and do not encroach upon the proper domains of the medical practitioner by making a trade, if I may so term it, of prescribing, no respectable body of men will interfere with us, and no law will be put in force against us. Regarding the famous Nottingham case, it is true that the actual case selected for trial does appear to bear hard on the pharmacists, but it is at least equally true that the party in the particular case tried was reported to be regularly in the habit of trespassing, and trespassing very largely, on.

the domain of medical men of the town, and doing so in a manner to bring great gains to himself. As for the Trade Association, I will not rediscuss this question. Suffice it to say, I abide absolutely by all I stated on the subject in my opening address. Indeed, I confess all that has happened since has only strengthened my views on the subject. Notably amongst others things that have strengthened me in my views, were its defence of the sale of the lime milk of sulphur, and of the prescribing Nottingham pharmacist. I still maintain that in a law-governed country such as ours, the common law of the country is amply sufficient to protect every man in it in the honest and lawful prosecution of his own legitimate business, and so, if the two chemists involved in the above cases had not trangressed that law, they would have needed no defence society and no lawyers to defend them, any more than I should have needed their assistance had I not sold wine without a wine licence. I have only one more general topic to mention: it is as to the mode of sending representatives to the London Council. At this hour the whole country is called upon to elect fourteen councillors to supply that number of vacancies. You, in Glasgow, are asked to record your vote for men you never saw and never heard of—at least, there are not a few names of whom I have never heard, and whom, to my knowledge, I have never seen. I felt this to be an anomaly the first time I sat at the Council table, when every face but that of Mr. Mackay was strange to me, and our Vice-President came all the way from Dartford, in the extreme South of England. I said to him then he could know nothing of me, as I could know as little of him. I then suggested territorial representation: that the country should be divided into districts—London of course, getting the lion's share in the representation—each sending a man known to it. Scotland, I suggested, should have two, one for the east, and one for the west half, or for the north and south halves, as might be arranged, etc. I broached this subject frequently in private, and would have brought it before the Council by a motion, could I have got any support to warrant me; but failing this, I left the matter over. This is one point in which I agree with the Trade Association, territorial representation; and if they take this topic up as it bears upon the London Council, I, for one, will wish it every success in it. It only remains that I should thank you most heartily for the kind expression of feeling exhibited towards me in the unanimous vote of thanks passed in my favour at your last meeting; for your thanks for what services I have been able to render to you on the London Council during the last six years; and for the very kind expression of regret at my retiring from it at this time. I assure you I value this expression greatly, but I confess that it, with similar expressions of feeling of regret for the same step conveyed to me by my friends in the Council itself, has only greatly deepened my own intense regret at having felt myself shut up, from family reasons, to take the step I did. Your loss you can repair by sending such a man as Mr. Bailton, who in many respects is better able to fill the seat I occupied at the Council Board than I can pretend to be, but my own loss cannot be made up, for though the friendships made in London, with Londoners and London visitors, will, I believe, remain; the opportunities of exhibiting the ties made must now be of the rarest. I think it is right in all frankness here to add, that though the first thoughts of retiring from the Council arose in my mind from great disappointment felt at the *unanimity* with which my views of the Trade Association were condemned at a meeting held for discussing these views as well as from other representations made to me privately as to my views on the vexed milk of sulphur questions: it was not upon these my retirement ultimately turned. All that irritation had passed away, and my resolution to retire turned upon the questions of the intended removal of my house to a place where I should be some two miles from the nearest neighbour, save the villagers of Cumbernauld, and my desire to get a few days a month to myself there. Now, though I cannot go there, I am even more shut up in the step I took, for I as yet do not know where my house is to be situated. I have now only to thank you for your kind attention, and the patience shown in listening to this much too hastily prepared address.

The President then presented some of the prizes to the successful competitors amidst applause.

The following motion was proposed by Mr. J. A. Clarke, and seconded by Mr. J. Fenwick, viz.:

"That the Association impresses upon all connected with the trade the importance of adhering, as far as possible, to the retail price list, published by a commitee of the trade, under the auspices of the Association; that each prescription be marked distinctly when first dispensed; and that the trade mark attached to the list alone be used."

After some discussion the motion was put to the meeting, and unanimously agreed to.

Mr. Davidson then proposed, and Mr. Whyte seconded, the following, viz.:

"That in order to permit of the young men connected with the trade to obtain the full advantages of the classes organised by the Association, all employers are respectfully requested to assist the earlier closing movement by putting up their shutters, and relieving their assistants, at eight o'clock *prompt*."

The motion on being put to the meeting was also agreed to unanimously.

The election of officers and council was then proceeded with, the result being as follows:—

President, Mr. Daniel Frazer; Vice-President, Mr. James M. Fairlie; Treasurer, Mr. Joseph A. Clarke; Secretary, Mr. James L. Macmillan (Globe Manufacturing Company); Council, Messrs. John Currie, senr., A. Kinninmont, T. Davison, W. Whyte, W. Greig, R. M'Adam, A. Paul, J. W. Pettigrew, R. Brodie, W. Mackenzie, J. C. Steele, and R. MacDonald; Auditors, Messrs. John Jaap and J. L. Hatrick; Librarian Mr. James Murdoch.

A hearty vote of thanks to the chairman brought the proceedings to a close.

MANCHESTER CHEMISTS AND DRUGGISTS ASSOCIATION AND SCHOOL OF PHARMACY

The concluding meeting of the Session was held at the Memorial Hall, Albert Square, on Friday evening, May 11th; Mr. J. T. Slugg, F.R.A.S., Vice-President, occupied the chair. The minutes of the previous meeting having been read by one of the Secretaries (Mr. Benger), and confirmed, the Chairman called on Mr. Louis Siebold, F.C.S., to read his annual report of the classes as follows:

In presenting to you the Fifth Annual Report of the Manchester School of Pharmacy, I have much pleasure in stating that the session now terminating has been a very prosperous and successful one, and that the favourable expectations I ventured to express at the last annual meeting have been fully realized. Four courses of lectures were delivered during the session, viz., thirty-three lectures on pharmaceutical chemistry, on Fridays from 7.30 to 9 p.m.; twenty-seven lectures on materia medica and pharmacy, on Tuesdays from 7.30 to 8.45 pm.; fifteen lectures on botany, on Fridays from 9 to 10 p.m.; and twenty lectures on qualitative analysis, on Tuesdays from 8.45 to 9.45 p.m. Twenty-five students entered for the chemistry course, twenty-three for materia medica and pharmacy, nineteen for botany, and seventeen for the course on analytical chemistry, making a total of eighty-four entries or thirty-two more than in the previous year. The botany lectures were delivered by Mr. Leo H. Grindon, whose able and most lucid instructions were highly appreciated by all attending his class. The fees were 30*s*. for the chemistry course, 25*s*. for the materia medica and pharmacy, 20*s*. for the analytical course, or £3 5*s*. for the three; and 15*s*. for that on botany. The total amount of fees received was £91 10*s*., or £29 in excess of those of last session. The attendance throughout the session was very good indeed, and the interest and attention on the part of the great majority of the students was all that could be desired. Competitive examinations were held at the close of the session and prizes awarded to the successful competitors. Eleven candidates competed for the chemistry prizes, nine for the materia medica, and the same number for the botany prizes. The awards are as follows:

Chemistry.

1st prize to Mr. C. Challinor; 2nd prize to Mr. Frederic Percy Wood.

Materia Medica and Pharmacy.

1st prize to Mr. Frederic Percy Wood; 2nd prize to Mr. T. C. Blaymire.

Botany.

1st prize to Mr. C. Challinor; 2nd prize to Mr. J. C. Crompton.

Mr. Grindon expresses himself very well satisfied with the progress of his students. The majority of papers in these examinations were very satisfactory, and proved that their authors had made good use of the opportunities afforded to them. The result of the session, both as regards numbers of students and the quality of their work, is highly encouraging, and goes far to prove that the Manchester School of Pharmacy may henceforth be regarded as a self-supporting institution.

The following are the questions given in the competitive examination:

Chemistry.

1. Explain by equations the action of sulphuric acid, nitric acid, and hydrochloric acid upon metallic copper.
2. How is potassium cyanide prepared?
3. Describe and explain various processes for the preparation of potassium chlorate.
4. How would you prove that the correct formula for free cyanogen is C_2N_2 and not CN?
5. Explain the action of boiling hydrochloric acid on calomel.
6. How would you show the presence of mercury (mercuric), bismuth, and copper in a solution containing no other metals?
7. Explain the terms alcohol and aldehyde, and give examples of each.
8. Give the distinguishing tests for arsenites and arseniates.
9. Briefly explain the officinal processes for the preparation of potassium permanganate, sodium arseniate, and spirit of nitrous ether.
10. How would you prove heavy spar to be a sulphate?
11. How are the three oxides of lead obtained? Mention their composition and chemical properties.
12. Give the formula of the following preparations:—Ammonium phosphate, potassium ferricyanide, bismuth subcarbonate, borax, acetic ether, nitro-benzol, oil of bitter almonds, and salicylic acid.

Materia Medica and Pharmacy.

1. Name the different kinds of rhatany met with in commerce, and state how they may be distinguished; also give the botanical source of each.
2. Name and describe the various drugs known as Pareira brava.
3. Describe the processes of maceration and percolation.
4. Recognize the eight specimens of drugs placed before you, and assign to each its botanical source, natural order and habitat.
5. Classify the officinal extracts according to their mode of preparation.
6. How would you ascertain the purity of copaiba.
7. Give a short description of the roots of belladonna, scammony and gentian.
8. Describe a convenient process for rapid filtration.
9. Name and describe the principal kinds of aloes.
10. Write about a dozen lines on the chemical composition of essential oils.

Botany (by Mr. Leo H. Grindon).

1. Enumerate the organs found in a complete flower; say which are essential and which are non-essential, and describe the functions of the former.
2. How are plants primarily classified? Give the names of the great primary classes.
3. How many natural orders are there? Say what you understand by a natural order.

BY MR. LEO H. GRINDON.

4. What are the characters of the Ranunculaceæ? In what particulars do the Rosaceæ differ from the Ranunculaceæ?
5. What are the leading features of the natural order Umbelliferæ? Mention the names of several important plants of this order.
6. To what natural orders do the following belong:—Hyoscyamus, Calumbo, Mustard, Irish Moss, Peruvian Bark, Chamomile, Balsam of Peru, Turpentine?
7. Describe the Foxglove (*Digitalis purpurea*) in botanical terms as nearly as you can.

The Chairman and other members having spoken on the very encouraging report just read, Mr. George S. Woolley took the chair, and Mr. J. T. Slugg delivered a short lecture on—

THE CHEMISTRY OF THE SUN,

of which the following is a brief report:

Mr. Slugg said that previous to the invention of the telescope nothing was known as to the physical constitution of the sun. In 1769 Dr. A. Wilson as the result of careful observation, discovered that sun-spots were cavities in a luminous atmosphere surrounding a darker body. Sir W. Herschell afterwards assumed that there are three concentric coverings of the sun, first a vaporous, then a luminous, and lastly, a cloudy and imperfectly transparent atmosphere. It was not till 1842 that attention was directed to the existence of the red prominences which are noticed surrounding the black disk seen in the sky during a total eclipse of the sun. The first question asked was, "Do they belong to the sun or to the moon?" This question was not answered till 1851, when a total eclipse of the sun took place, and when the Astronomer Royal produced evidence that they belonged to the sun. In 1860 this was confirmed by the application of photography during the eclipse of that year. Still the question, "What are they?" remained unsolved. In 1868 a total eclipse occurred which was visible in India, when for the first time that marvellous instrument, destined to rival the telescope in the importance of its discoveries—the spectroscope—was applied. It was discovered that these flames principally consist of hydrogen gas. Up to this point, owing to the glare of the sun, they could only be observed during a total eclipse of the sun. Astronomers, however, never rested until they discovered a method of observing them whenever the sun is visible. The spectroscope has revealed to us the existence in the sun of iron, nickel, zinc, copper, chromium, magnesium, calcium, sodium, potassium, barium, strontium, manganese, lead, cobalt, and one or two new elements, as well as hydrogen. After describing the great solar storm witnessed by Professor Young in 1871, the lecturer expressed his admiration of the able and devoted labours of such men as Huggins and Lockyer in this field of science, and stated his belief that before long, we shall be in possession of further important information respecting the physical constitution of the sun.

A cordial vote of thanks to Mr. Slugg, for his interesting lecture, was carried by acclamation.

LEEDS CHEMISTS' ASSOCIATION.

The Seventh General Meeting of this Association for the session 1876-77, was held in the Library on Wednesday evening, Apil 11; the President, Mr. Yewdall, occupying the chair.

The minutes of the previous meeting having been read and confirmed, letters were read by the Secretary, from Mr. F. Reynolds, expressing his regret that in future he would be unable to attend the evening meetings; from Mr. Bremridge, to the effect that a gift of a copy each of the 'Calendar' of the Pharmaceutical Society, and of the 'Register' for the present year had been made to the Association by the Council of the Pharmaceutical Society; and from Mr. Henry Pocklington, stating that owing to his having been unexpectedly summoned to attend a police inquiry that evening, he would be unable to read his promised paper on "The Physics of Pharmacy."

On the motion of Mr. Pick, seconded by Mr. Highmoor, "The best thanks of the Association were tendered to the Council of the Pharmaceutical Society for the gift of the Calendar and Register."

The Chairman said he was very sorry the meeting would be deprived of the pleasure of hearing Mr. Pocklington that evening, and he was sure that nothing but the force of circumstances would have prevented that gentleman from keeping his engagement; but was glad to find from the tenor of his note that the delivery of the paper was only postponed. In the meantime, he would suggest that a conversation take place amongst those present respecting the recent prosecution of a chemist at Nottingham for prescribing.

A free discussion ensued: the unanimous opinion being that should the decission in the Court of Queen's Bench in this case be adverse, the Chemists and Druggists' Trade Association should be encouraged and assisted to carry the case to the House of Lords, and should its decission be against the trade, an appeal to Parliament supported by public petition should be made for an alteration of the law.

The Fourteenth Annual Meeting was held in the Library on Wednesday afternoon, May 9; the President, Mr. Yewdall, in the chair.

After the minutes of the previous meeting had as usual been read and confirmed, the Report was read by the Secretary.

The Report stated that in accordance with a resolution passed at a special general meeting of the Association, held on the 18th of October last, whereby that part of Rule 5 providing for the holding of the annual general meeting in October was so altered that that meeting was now to be held in May, the committee had called the meeting that afternoon, in order that the Officers and Committee for the ensuing year might be elected, and afford an opportunity of discussing the proceedings of the Association, of which the following is a report for the last eighteen months. The Association consisted of forty-three members and thirty-nine Associates, being an increase in the number of members of two, and a decrease in that of Associates of four, upon the members of 1875-76; and an increase of three members and a decrease of seven Associates since the last report was presented. The financial condition of the Association as shown by the balance sheet might be said to be sound; the subscriptions being slightly on the increase, and the reserve fund in the hands of the Treasurer remaining untouched. The Library table had been supplied with the usual periodical literature, but an addition had been made during the present year of an extra copy each of the two representative Journals, and cases for holding the current numbers of periodicals provided. The 'Calendar' of the Pharmaceutical Society, the 'Register of Chemists and Druggists' for the present year, and one copy weekly of the *Pharmaceutical Journal*, have been presented to the Association by the Council of the Pharmaceutical Society, and the 'Year Book of Pharmacy' by the Executive Committee of the Pharmaceutical Conference. Owing to the amount spent in binding, the Committee had not had much cash to spare for the purchase of new books. It was however resolved a short time ago, that the new editions of Fownes' 'Manual of Chemistry,' in two vols., Squire's 'Pharmacopœias of the London Hospitals,' and Squire's 'Companion to the British Pharmacopœia,' should be added to the Library. During the eighteen months past there have been held nineteen general meetings, namely, twelve during the year 1875-76, and eight during the session just over. The Committee reports that perhaps the greatest discouragement it had had to contend with had been the miserably poor attendance at these meetings. Unless there was an improvement in this matter, it would be absolutely impossible ere long for the Committee to get a good man to read a paper before the Association, as it was ridiculous, if not actually insulting, to ask a gentleman to take the trouble of getting up a paper, and then when he came to read it, salute him with an array of empty benches. Besides which it was a complete waste of funds, the amount expended in getting up these meetings being very considerable. During the two past sessions classes in botany, under Mr. Abbott, and in chemistry, under Mr. Ward, both in connection with the Science and Art Department, had been held for the benefit of the Associates. Six students attended the former in the session 1875-76, three of whom went up for examination, one obtaining a second-class certificate in the elementary stage. This year the number of students is sixteen, seven of whom are going in for examination in the elementary stage. Nine of the Associates attended Mr. Ward's Chemistry Classes in 1875-76; two of whom obtained second-class certificates in Elementary Inorganic Chemistry; one a second-class Elementary, and one a first advanced Inorganic Chemistry, with laboratory practice, and a first Elementary Organic, with laboratory practice. The results of the present year were not yet known. Two prizes had been offered by the Committee, of the respective value of 15*s.* and 7*s.* 6*d.* to be competed for in each of these classes of the last session. There was yet £20 of the Pharmaceutical Society's grant for educational purposes in the possession of the Association, and no doubt the Committee to be elected that day would expend it judiciously in assisting the studies of the Associates, in response to the slightest wish on the part of the latter to be assisted. The report concluded with a reference to the part the Association had taken in respect to the discussion on the establishment of a museum of apparatus at Bloomsbury Square, the Sale of Food and Drugs Act, the use of methylated spirit in liniments, and the establishment of the Chemists and Druggists' Trade Association.

The adoption of the report was moved by Mr. Richard Reynolds, seconded by Mr. Edward Brown, and carried.

The following gentlemen were then, by ballot, elected to serve on the Committee and act as Auditors during the ensuing year, viz.:—President, Mr. Peter Jefferson; Vice-President, Mr. Richard Pick; Secretary, Mr. Samuel Taylor; Committee, Messrs. Joseph Beedle, John Bowman, Edward Brown, John Hellowell, T. B. Stead, and Edwin Yewdall; Auditors, Messrs. F. Reynolds and James Abbott.

A vote of thanks to the retiring officers for the manner in which they had conducted the affairs of the Association during the past eighteen months was passed on the motion of Mr. Richard Reynolds, seconded by Mr. Abbott.

The thanks of the Association were also tendered to the Council of the Pharmaceutical Society for the weekly copy of the *Journal* supplied gratuitously last year, and to the Executive Committee of the Pharmaceutical Conference for the gift of the 'Year Book of Pharmacy' for the present year.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, May 1, a meeting of this Association was held in the rooms, Halford Street, when a lecture on the "Codex Française" was given by Mr. E. Jones.

The Lecturer spoke of the report to the Emperor from the Ministers of Agriculture and Public Instruction, regarding the necessity for such a work as the Codex to guard against quackery and roguery, as well as to be the guide of the doctor and pharmacien. The dates of the former Pharmacopœias were given, and various parts of the preface referring to the densities and thermometers explained, and the fact was pointed out that in France medicines are not measured, but weighed. The lecturer named the substances, together with many of their properties, which are contained in the Codex but which are not mentioned in the British Pharmacopœia. He stated the laws which govern chemists, and which did not allow any but chemists to deal in drugs. He also referred to the stringency of the examination which a chemist is required to pass before able to commence business for himself. In concluding, the lecturer mentioned that the chemists in Paris opened their shops late in the morning and closed about eleven and twelve at night.

At the close of the lecture a hearty vote of thanks was accorded to Mr. Jones, which was duly responded to.

A vote of thanks to the Chairman (Mr. H. Cooper) concluded the meeting.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, May 17th; W. Crookes, F.R.S., Vice-President, in the chair. The minutes of the previous meeting having been read and confirmed, the Chairman announced that the extraordinary general meeting would be held on May 31, at 8 p.m., in the Society's room.

Mr. Tribe gave notice that at this meeting he would move the following resolution: "That this Society is of opinion that the present system of election to its fellowship does not promote its interests or sustain its dignity, and that in place of this system, the Council of the Society should recommend to the Fellows annually not more than twenty of the more meritorious candidates for election to its fellowship."

The following certificate was read for the first time: F. H. T. Allan.

The following papers were then read by the Secretary, Dr. Armstrong:

1. *On a Slight Modification of Hofmann's Vapour Density Apparatus.* By M. M. P. Muir and S. Suguira.—The original apparatus consisted (*Deut. Chem. Ges. Ber.* ix. 1304) of an ungraduated barometer tube which could be closed under mercury at its lower end by a caoutchouc plate, when the level of the mercury, which is of course depressed until the whole of the liquid under examination is converted into vapour, remains constant; the apparatus is then allowed to cool, and the height of the mercury marked by a slip of gummed paper. The tube is now displaced, and the amount of mercury necessary to fill the tube to the paper mark weighed. The authors propose to omit the closing with the indiarubber plate and to read off the height of the mercury by a cathetometer. When the tube has cooled sufficiently, by means of the cathetometer a piece of gummed paper is placed at the exact level at which the meniscus stood. The authors do not claim absolute accuracy, but quickness and facility for the method; thus with isoneptane the theoretical number is 50 by experiment, 48·3 was obtained, and with terpene from sage oil, 68 theory, and 67·5 experiment.

2. *Note on the Fluid contained in a Cavity in Fluorspar.* By J. W. Mallet, Virginia.—The author possessed a specimen of green fluor from Alston Moor, containing a cavity of considerable size with fluid contents, and a readily mobile bubble. The largest crystal was 14 m.m. on the side; the cavity is irregular and flattened about 6 m.m. by 2·5 m.m., and 1 m.m. deep. On gradually heating the mass to 150° C. the bubble increased in size and lost its mobility. On cooling the bubble required a sharp jerk to make it change its place. Under the microscope the crystal, after heating, showed signs of incipient splitting. No viscidity was observed in the liquid after heating—in all probability the liquid was water.

Professor Church remarked that he had examined a crystal of fluorspar resembling very much the one mentioned in the paper; in it there was a cavity containing some liquid and a mobile bubble. On heating it, below 100° C., the bubble enlarged, filled the cavity, and the liquid disappeared; on cooling the crystal was evidently fissured, and the liquid had vanished. No evidence could be obtained of the presence of carbonic anhydride.

Mr. Crookes suggested the examination of the enclosed gas in a vacuum by the induction spark-spectroscope, after fracturing the crystal by heat.

3. *Examination of Substances by the Time Method.* By J. B. Hannay.—The author has determined with great care the loss of weight sustained by various hydrates in equal and successive intervals of time when submitted in a Liebig's drying tube to a current of air forced over them at various temperatures. He finds by this method that a hydrate usually begins to lose water more or less rapidly up to a certain point when the rate of loss becomes suddenly less rapid, up to another point when the rate of loss is again decreased, and so on. These alterations in the rate of loss indicate the formation of other and lower hydrates which lose water less rapidly, and so evidence of the existence of hitherto unknown hydrates has been obtained. Thus magnesium sulphate at 100° C. lost in five minutes 8·36 per cent. = $MgSO_4 6H_2O$, the loss is then pretty regular until about 29 to 30 per cent. has been lost in forty-five minutes, leaving $MgSO_4 3H_2O$ when the rate falls; the weight then diminishes slowly till $MgSO_4 2H_2O$ is left when the loss becomes suddenly very slow until $MgSO_4 H_2O$ remains. Sodium sulphate, zinc sulphate (which presents some anomalies), ferrous sulphate, calcium and strontium chlorides were examined. Numerous tables and graphic curves illustrate this paper.

4. *On the Dehydration of Hydrates by the Time Method.* By W. Ramsay, Ph.D. Part I., Iron and Aluminum Hydrates.—The method employed was similar to that used by Mr. Hannay. The substances first examined were the hydrates of aluminum and iron. The author considers that hydrates such as $Al_2O_3 4H_2O$ $Al_2O_3 3H_2O$, etc. (excepting $Fe_2O_3 H_2O$) have no existence, or that a very large number of hydrates exist, the vapour tensions of which are very slightly different from each other; the hydrates of copper and lead were also examined and evidence obtained of the existence of $3PbOH_2O$ and $2PbOH_2O$.

Mr. Groves said that the author seemed only to have determined the loss at one pressure, viz., that of the atmosphere; it would be interesting to know what would happen if the pressure as well as the temperature were varied.

Professor Church suggested the name of baro-hydrates for substances whose water of hydration varies with pressure, and hydro-hydrates for those which vary with the moisture of the atmosphere.

Dr. Armstrong considered Mr. Hannay's method valuable and likely to give important information, but thought on the whole it would be preferable to determine the vapour tension directly.

Mr. Crookes called attention to the fact that small quantities of hygroscopic moisture would not come off from glass surfaces for weeks in a vacuum with strong sulphuric acid, but required the aid of heat.

5. *On the Transformation of Aurin into Rosaniline.* By R. S. Dale, B.A. and C. Schorlemmer, F.R.S.—By the action of ammonia on aurin, peonin, or red aurin is formed; by heating peonin to 150° C. for several days

with alcoholic ammonia the red colour disappears and a yellow liquid is obtained; on adding water a white crystalline precipitate is deposited which presents all the characteristic properties of rosaniline. It is soluble in acetic acid with a splendid crimson colour, etc. The reaction by which the rosaniline is formed is $C_{20}H_{14}O_3 + 3NH_3 = C_{20}H_{17}N_3 + 3H_2O$. According to Hofmann the formula of rosaniline is $C_{20}H_{19}N_3$; on this point the authors promise a careful investigation of the base and its salts. The authors believe aurin and rosolic acid to be identical; pure aurin is prepared without difficulty by heating a mixture of sulphuric acid and pure phenol on a water-bath and adding oxalic acid gradually, leaving always an excess of phenol.

6. *On certain Bismuth Compounds.* Part IV. By M. M. P. Muir.—After an historical sketch of the attempts made to prepare hypobismuthous oxide the author describes its preparation by Schneider's method, viz., dissolving stannous chloride and bismuthous oxide in hydrochloric acid, pouring the solution into strong potash and washing the black precipitate with weak potash. By heating to 180° C. hypobismuthous oxide (Bi_2O_2) is oxidized; it readily parts with its oxygen to reducing agents. By subliming bismuthous chloride or by the action of nitrogen trioxide on fused bismuthous chloride an oxychloride ($Bi_3Cl_3O_2$ or $Bi_4Cl_4O_3$), is produced; by a similar reaction on oxybromide $Bi_8Br_6O_{15}$ can be formed. Bromide of bismuth is more readily oxidized than the chloride. The author compares phosphorus with bismuthous chloride. By the action of sulphur on bismuthous chloride sulphbismuthyl chloride BiSCl is prepared; $BiSCl_3$ could not be obtained. The author also failed to prepare a bromochloride containing five atoms of bromine and chlorine. By acting on metallic bismuth or bismuthous oxide suspended in strong potash with bromine bismuthic hydrate is very readily produced.

7. *On the Theory of the Luminous and Non-Luminous Flame.* By J. Philippson. In this paper the author merely states what he considers to be the causes of luminosity or non-luminosity of flames.

After the thanks of the Society had been returned to the authors of the above papers it was announced that the present volume of the 'Royal Society's Proceedings,' was nearly completed, and that any Fellow of the Society wishing to have the next volume was requested to send his subscription (10*s.*) forthwith to Mr. Hall or to Messrs. Taylor and Francis.

The Society then adjourned till June 7, when the following papers will be read:—

1. "On the Gases Enclosed in Lignite," by J. W. Thomas. 2. "On Narcotine, Cotarnine, and Hydrocotarnine," by Dr. Wright. 3. "On Otto of Limes," by C. H. Piesse and Dr. Wright.

A general meeting will be held on Thursday, May 31, at 8 p.m.

Correspondence.

Meaning of the Word "Dispense."

Sir,—I observe in your last issue a correspondent points out that Bailey's Dictionary (1770) gives "to administer" as among the meanings of the above word.

It may be interesting to know that it still holds the same meaning, as I find it appears so in Boag's 'Imperial Lexicon' (A. Fullarton and Co., publishers, Edinburgh and London).

Probably these facts can be further corroborated, and will prove serviceable in the next hearing of the Shepperley case.

Derby, May 22, 1877. Forward.

The Election of the Council.

Sir,—Mr. Greenish has done an excellent service in calling attention to the circumstance that in the annual election for the Council, only a small number of the voting papers issued to the members are actually used and returned.

There may be several reasons for this apparent indifference, but one I know to be that many of the voters have so imperfect a knowledge of the views and purposes of the candidates, that they instinctively abstain from voting at all, fearing to promote the election of one opposed to their own views, or to hinder one in favour of them—in either case a matter of chance.

To remove all doubt and hesitation, it is much to be desired that on all future occasions, the candidates should abandon their un-English silence, and manfully give full publicity to their opinions and intentions.

R. H.

May 21, 1877.

Sir,—The difficulty in voting for the members of the Council, alluded to by Mr. Frazer, at Glasgow, must have been felt by many, if not all, country chemists. As he says, we are annually "called upon to record our votes for men we never saw and never heard of." Mr. Frazer suggests, as an improvement, "territorial representation," but there would be many difficulties in arranging such a scheme. Why not take a hint from School Board elections, and adopt the "cumulative vote?" While avoiding the difficulties of any territorial arrangements, such a mode would secure, to a great extent, its practical advantages, and enable all or most chemists to vote with discrimination, instead of (as must now be too often the case) obliterating a certain number of names on the list at random.

W. Symons.

Barnstaple, May 18, 1877.

A New Form of Commission.

Sir,—Some time ago the *Times* called public attention to the abuse of "commissions," and more recently the *Examiner* in one of its "Variorum Notes," referred to a rumour that some medical men received fees or commissions from undertakers. Your own columns have contained some severe strictures upon private arrangements between members of the faculty and chemists. The following indicates a new form (to me) of this Protean evil. I suppress names and would only say that the first letter is from a person absolutely unknown to me at the time, but I have been since informed that he holds a responsible position. The letter was written upon the official stationery of a well-known firm, who publish advertisements in their monthly price list, etc.

"———, 9th May, 1877.

"Mr. Pollard, High Street, Ryde.

"Dear Sir,—Your name has been given to me by Mr. ———, of ———, as likely to want an apprentice, I can introduce one to you on good terms (and should, of course, look for a £20 commission), if you would give me full particulars. Waiting reply,

"Yours faithfully,

"Private" "———.

To this I replied:

"May 10, 1877.

"Mr. ———, Sir,—I am in receipt of yours of yesterday, offering to introduce an apprentice to me for £20 commission. I shall be happy to negotiate on condition that you will make your charge direct to the parties who would have to pay it; from which course the double advantage would issue that your clients would learn the great value of your services, and being willing to pay such a sum for the mention of my name would doubtless be also willing to give me an exceedingly handsome premium for the very much greater trouble I should have. As the course you propose is the ramification of a crying evil, I must decline to regard any part of your note private except the signature.

"I am, etc.,

"———."

Withholding the name of the writer, I sent copies to the firm, expressing the opinion that such a proposal was an insult to an honourable man, and unless disowned, a reflection upon the house whence it emanated. I received the following:

"We thank you for your letter of the 10th, and shall give the matter our immediate attention,

"Yours faithfully,

"———."

It will be observed that no opinion is expressed as to the policy I condemned. I am not able to say whether this is accounted for by the fact which has subsequently come to my knowledge, that my name was not originally given to the writer of the first letter, but to a member of the firm in whose service he appears to be engaged. I am not able to appraise the expression "of course" in the above, but if it indicates a custom at all prevalent, I think the unsophisticated should be put upon their guard. I do not feel called upon to determine whether a charge should be made for introducing apprentices such as we pay at registry offices for servants. I know of no such custom amongst wholesale houses, and if it existed, the transaction, whether at 5 or 50 per cent., should be as open in one case as the other; but the form of this proposition removes it altogether from such a category. The proposed apprentice may be *eximiâ spe, summæ virtutis adolescens*, and worth £20 to anybody, or self-conceit might insinuate that such a recommendation was worth the addition of that sum to the premium secretly; but common sense would suspect that the youth was for sale to any man who would pay the price or purloin the additional premium, and honour forbids the bargain. Instead of the satisfaction with which business used to be done, every tenth customer grumbles because the tariff of the "stores" is not adopted; surely it is not desirable (were it honest) to be further embarrassed with "wire-pulling" commissions and secret understandings, in which one knows not which is the more sold, men or things.

HENRY H. POLLARD.

140, *High Street, Ryde, May* 21, 1877.

UNG. PLUMBI SUBACET. CO.

Sir,—As the formula for the above, which we have in the Pharmacopœia, at present is rather an unsatisfactory one, owing to the difficulty of its keeping, I have made several experiments, and one which seems to be very satisfactory I wish to bring before your notice, under the name of "Ung. Plumbi Subacet. Co. c. Vaselin." By substituting the vaselin for the almond oil, we have an ointment of a good colour, and one that will keep, I may say, for any ordinary length of time. I have some by me now that has been made six weeks, and still is perfectly fresh and good colour; whereas, as is well known, the B. P. preparation becomes rancid in a short time, and through that is to be found in very few pharmacies ready when a prescription is presented for it. The formula I introduce is as follows:

Cera Alba	℥j.
Vaseline	℥vss.
Liq. Plumbi Subacet.	℥iss.
Camphor	gr.xv.

Melt the wax on a water bath, liquefy the vaseline, and add it to the wax; take from the fire, add the camphor, and when it begins to thicken, gradually add the liq. plumbi, stirring constantly.

J. MUNDAY.

14, *Rue de la Paix, Paris.*

SUNDAY CLOSING.

Sir,—Permit me to say a few words in reply to your correspondent, "Eusebius," on the above subject. I will trespass but very little upon your valuable space.

I must inform him that I entirely indorse what he says, in a religious point of view, and I endeavour (as much as the nature of the business will allow me) to keep the Sabbath day holy, and I close my shop more from principle than anything else, and nothing but medicine is supplied on that day.

When I first broached the subject, I did not consider it prudent to disclose religious controversy in my letter.

No doubt that "Eusebius" will agree with me in this, that if you interrogate a man as to "Why he opens his shop on Sunday," he will make the following excuses:

1st. That if he did not, it would decrease his cash returns.

2nd. That he is obliged to, as he dispenses for two or three surgeons.

3rd. That he must do it, as Mr. So-and-So, lower down, does it

Poor excuses these! and, as I have said before, principle would not allow me to open upon any account. And, I will say in conclusion, that if any business is dependent, directly or indirectly, upon what little there is to do on Sunday, the sooner it is shut up the better.

I am happy to say we have moved in the right direction of early closing, and I trust it will soon become universal throughout London.

A BEGINNER.

Highbury Park, May 14, 1877.

Corrections.—On p. 939, at bottom of first column, instead of the passage in Mr. Vizer's speech, commencing "As one engaged in the business," read,—"As one engaged in business, I must say that if the Council could not see clouds casting their shadows before them, it was to my mind most peculiar. Who could not have foreseen that some day or other steps would be taken to settle this all-important question with reference to counter prescribing? What do we now find in the *Lancet* of last Saturday? The paragraph to which I refer is in the *Lancet* of the 12th instant, where it is said," etc.

We have received from Mr. Mackenzie, of Edinburgh, a letter, in which he explains with respect to the phrase in his speech, as reported on p. 952, that he referred only to the pharmaceutical portion of "a medical man's education," when he said "it was now in many cases little more than a farce."

We are informed by Mr. Mumby, of Gosport, that he spoke the words on p. 940, attributed to Mr. Bullen, of Westrup, and take the opportunity of saying that it is sometimes extremely difficult to arrive at the name of a speaker who may not happen to be well-known, unless the chairman is enabled to announce it before he commences to speak.

In reference to our editorial remarks last week, we have received a letter from Mr. M. J. Ellwood, of Leominster, in which he states that he subscribed for four years to the Pharmaceutical Society. We are happy to make this correction, but we think it does not affect our argument that his better plan would have been to have remained a subscriber, and, if he thought it necessary, followed a course of action similar to that adopted by the members of whose conduct he speaks with approval in his letter.

"*Williams.*"—(1) *Mercurialis perennis*; (2) *Arum maculatum*; (3) *Chœrophyllum temulum*; (4) *Scolopendrium vulgare*; (5) *Sarothamnus scoparius*; (6) *Lychnis diurna*; (7) *Digitalis purpurea.*

F. B. Marchant.—*Stellaria Holostea.*

J. D. Jenkinson.—We do not think the paragraph sent adds in any way to the information given in the report last week.

J. A. Barrett.—We shall be glad to assist you, provided that the specimens be sent in as perfect a state as possible, and that you first make an effort to name them yourself.

"*An Associate.*"—A solution of peroxide of hydrogen is generally used.

W. L.—Neutral carbonate of ammonium.

E. E. R.—Apply at Apothecaries' Hall, Blackfriars, E.C.

"*Novice.*"—We are not aware that any stains would be left that could not be removed by soap and hot water.

"*Dictionary.*"—Maynes' 'Medical Vocabulary' (Churchill), price 10*s.*

"*Manduell.*"—Aq. Menth. Vir. should be used.

A. F. F.—Dissolve the chlorate of potash in the water, and add the syrup. To the tinct. camph. co. add the tinct. tolu, and throw these upon the above solution contained in a bottle, and shake briskly. It is impossible to prevent some separation of tolu resin.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Haydon, Mr. Brain, Mr. Barrett, Mr. Bailey, Mr. Towler, R. H., B. M. S.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 731.)

(*Continued from page* 731.)

CASSIA ALATA.—*Local name,* DADMURDUN.

This shrub is only found in gardens in this part of India. The leaves are two feet long or more, and consist of a triangular petiole with from 8—14 pairs of leaflets. The first pairare the smallest and are placed near the branch and separated from the second pair by a longer interval than there is between the other pairs. The terminal leaflets are as much as 5—6 inches in length. They are all obovate-oblong, obtuse, mucronate, and glabrous on both sides; and taste like senna, but less nauseous; their properties are fully described in the 'Pharmacopœia of India.'

CASSIA AURICULATA.—*Local name,* TURWAR or AWUL.

The bark as generally met with is about as thick as cinnamon, nearly smooth, externally reddish-brown, internally olive-green; it occurs in small strips or quills. Taste sweetish, and moderately astringent. Sections examined under the microscope show a deposit of crystals arranged like rows of beads in the course of the vessels, otherwise there is nothing remarkable. Turwar bark is astringent, but not nearly so powerfully so as many other common Indian barks. The small flat heart-shaped seeds are administered by the native doctors as a cooling medicine; their use as an application to the eyes is noticed in the 'Pharmacopœia of India.'

DÆMIA EXTENSA.—*Local name,* OOTERNEE.

The leaves of this climbing plant are roundish, cordate, acuminated, acute, auricled at the base, downy, glaucous beneath. They vary in size, but are generally from one to two inches in diameter. The peduncles are long, slender, and hoary; odour mousey, and peculiar. Examined with a lens both the upper and under sides of the dry leaf present a green mossy surface, thickly studded with short white hairs. The taste is faintly bitter and somewhat nauseous. This drug has a general reputation in Western India as an expectorant and emetic. In Goa, and probably elsewhere, the juice of the leaves is applied to rheumatic swellings. Ainslie mentions its use as an anthelmintic.

AILANTHUS EXCELSA.—*Local name,* MAHAROOK.

Bark light coloured, very thick and granular; externally hoary, rough from the presence of numerous longitudinal scabrous ridges; internal surface yellowish-white, and finely fibrous; when soaked in water it swells greatly and becomes glutinous on the surface; odour when moist acrid and disagreeable; taste very bitter. Sections for the microscope show that a great portion of the bark consists of large stony cells collected together in groups. There are also many conglomerate raphides. Maharook is as bitter as quassia, and is a promising drug. Its bitter principle does not appear to have been examined. Ainslie's description of the bark as pleasant tasted and somewhat aromatic is hardly correct; it is intensely bitter. The name Maharook is also applied to the *Cinnamomum Tamala*, by the

Concanist gardeners of Bombay. The large pinnate leaves of *A. excelsa* are in great repute as a tonic, especially in debility after childbirth.

DILIVARIA ILICIFOLIA.—*Local name,* MORANNA.

A shrub, common in salt marshes, with elliptic-sinuate, dentate-spinous waved leaves, just like those of our common holly. It is used at Goa as a fomentation in rheumatic and neuralgic pains; it is mucilaginous.

ABUTILON INDICUM, var. *carpels not acute; plant very tomentose, hoary.*—*Local name of seed,* BULBIJ.

A shrubby plant, having a hoary appearance, covered all over with a dense silky tomentum of simple hairs; leaves cordate, unequally and sharply serrated; calyx five-cleft; pedicels axillary, jointed near the flowers, which are of an orange colour, and open in the evening; capsules truncated, longer than the calyx; carpels about twenty, not awned, hairy on the dorsum; seeds reniform, about $\frac{1}{10}$th of an inch long, and nearly as broad at the larger end, three in each carpel; testa very hard, dull brown, covered with simple hairs, rising from a conical base, which is attached to the testa by several radiating processes like roots. The seeds are mucilaginous, and like many others having this property are supposed to be restoratives of the virile powers; they are kept in all the shops. The plant described was obtained by sowing the bazaar seed.

CORCHORUS FASCICULARIS.—*Local name,* HIRUNKHOREE.

A small procumbent woody plant with oblong or lanceolate serrated leaves; peduncles 2—5 flowered, opposite to the leaves; capsules linear-oblong, nearly terete, rostrate, three-celled, about half an inch long ('Bombay Flora,' p. 24). The capsules are clothed with simple hairs; they contain a number of small dark-brown angular seeds. The plant is very mucilaginous and somewhat astringent; it is valued on this account as a restorative. Hirunkhoree is the name given to it by the country people and means deer's hoof; many of the capsules are in pairs and somewhat resemble the hoof of a deer. In the Bombay shops it is called Bhauphulli, which must not be confounded with Bhaphulli, the Mahratta name of *Pastinaca grandis*.

INDIGOFERA, Sp. ?—*Local name,* WEKARIA.

The plant raised from bazaar seed very nearly resembles *I. glandulosa*, but the legumes are longer and six-seeded. Wékaria seeds are oblong, less than $\frac{1}{16}$th of an inch in length, polished, yellowish, and marked with dull red blotches; they taste like dried beans or peas, and are prescribed along with various mucilaginous drugs as a restorative.

BRACHYRAMPHUS SONCHIFOLIUS.—*Local name,* VOONDRACHA KAN.

Rats' ear, or Goa Taraxacum, is a glabrous plant: stem erect, leafy at the base, naked at the top, sparingly branched; leaves membranaceous, stem-clasping, obovate, somewhat runcinate and waved, bristle-ciliated on the margins; capitula remotely spicato-racemose; pedicels a little scaly, short; achenia oblong, sub-compressed, transversely muricated, attenuated into a short beak; pappus white, soft ('Bombay Flora,' p. 132). The whole plant is used as a substitute for Taraxacum, at Goa, and called by the Portuguese Taraxaco.

BOERHAVIA DIFFUSA.—*Local name,* PUNANARVA.

A common creeping weed on waste ground and road sides; stalks numerous, about two feet long, slender, procumbent; leaves cordate, ovate, unequal, opposite, edges waved; flowers small, pink, sessile on the apex of the pedicel; peduncles from the axils and ends of the branches; fruit oblong, dull green, or brownish, viscid, about the size of a carraway seed, longitudinally five-grooved, studded all over with glandular hairs; root twisted, often as thick as the finger, when fresh; whitish, fleshy, two or three branched, a foot long or more; taste bitterish, nauseous. A microscopic section shows that the structure is loaded with needle-shaped crystals, otherwise there is nothing peculiar. The dried herb without the root is met with in the shops. Its properties as an expectorant are noticed in the 'Pharmacopœia of India.' In Goa it is esteemed as a diuretic in gonorrhœa. In Peru, *B. scandens* is used for the same purpose ('Flora Peruviana,' vol. iv., p. 4). Ainslie mentions the use of the dry root in doses of a teaspoonful of the powder twice daily as a laxative.

MIMUSOPS ELENGI.—*Local name,* WOWLEE.

The bark is red, woody, and fibrous, and has a thin grey epidermis studded with lichens; its general appearance when dry reminds one of red cinchona, but the inner surface is marked with whitish stains as if it were mildewed. On breaking the bark these stains are seen to penetrate the substance to some depth; they are caused by the drying of the milky juice with which the tree abounds. Upon soaking a piece of dry bark in water it becomes coated with mucilage, and a milky fluid can be squeezed out from its freshly cut surface. Microscopic examination discovers no distinctive characteristics. Wowlee bark is bitter and astringent. I have no experience of its use. *Mimusops Kauki,* the Adam's fruit of Goa, has much the same properties. The olive-shaped berries of both trees are edible.

SALIX TETRASPERMA.—*Local name,* WALLOONJ.

The bark of this tree is noticed in the 'Pharmacopœia of India'; it is a thick red bark, very light and corky, deeply fissured longitudinally and cracked transversely on the outer surface. Microscopic sections show that the greater portion of the bark consists of a corky parenchyma, much charged with red colouring matter. Walloonj bark is insipid and stains the saliva red; it is probably quite inert.

SHOREA ROBUSTA. VATERIA INDICA. CANARIUM STRICTUM. *Trees producing Dammar.*

European and American resins are in Bombay so much cheaper and better than the produce of these trees that they are practically of little importance for medicinal or commercial purposes.

SOYMIDA FEBRIFUGA—*Local name,* ROHUN.

As the authors of the 'Pharmacographia' have only described very young bark, I may mention that old bark has a ragged dry suber, quarter of an inch thick, and of a rusty blackish-brown colour, deeply fissured longitudinally, and minutely cracked transversely; the small corky warts described by Hanbury on young bark are still visible here and there between the fissures. Old bark is generally in half quills, the total thickness being about half an inch; its colour is a rich red brown; its substance when soaked in water becomes very compact. The microscopic appearances are the same as described in the 'Pharmacographia,' except that the corky outer part of the bark is much more developed. Rohun is rarely to be met with in the Bombay shops; my specimen was obtained from the Botanical Gardens, Poonah. The tree grows wild in the northern parts of this Presidency.

HEYDOTIS HEYNEI.—*Local name,* POPATO and KAZURI.

A small plant common in cultivated ground. It is erect, about one foot high, dichotomous, glabrous; stem acutely four-angled; leaves linear-lanceolate; pedicels one-flowered, axillary; capsule nearly round, opening at the apex; root small and fibrous. The plant turns black when dry. It is kept in the druggists' shops at Goa, and is in use there as an alterative in low forms of fever. It is administered in combination with *Adiantum lunulatum* and *Hydrocotyle asiatica.* I have never seen it in the Bombay shops.

GARUGA PINNATA.—*Local name,* KOORAK.

The gum of this tree is greenish-yellow, translucent, in small mamilliform masses, having a mild terebinthinate odour and taste. Only a very small part of it is soluble in rectified spirit, causing a slight turbidity; in water it rapidly disintegrates, forming a tolerably thick mucilage, in which globules of oleoresin (?) may be seen with the microscope; the insoluble portion is amorphous, flaky, and white. The mucilage is precipitated milk-white by rectified spirit. I am not aware of this gum having been used for any purpose. The tree is nowhere very abundant; my specimen came from North Canara.

LASIOSIPHON SPECIOSUS.—*Local Name,* RAMETA.

A hard brittle bark, in flat pieces or half quills from $\frac{1}{10}$th to $\frac{2}{10}$ths of an inch thick; external surface marked by numerous slightly elevated longitudinal ridges of a dull brown colour, with a pinkish tinge; internal surface striated of a dull red or dirty pink colour. The epidermis has generally been removed, but a small patch of a dirty white colour is occasionally met with. The bark when soaked in water becomes very friable, and coated with thick mucilage; it has a mildly astringent mucilaginous taste with a faint aroma. The microscope shows numerous bundles of needle-shaped crystals and of large liber cells thickly scattered throughout its substance. There is also much colouring matter, but no specially remarkable character. Rameta is one of the mucilaginous barks which find so much favour with native doctors, from their supposed restorative properties.

RHAMNUS WIGHTII.—*Local Name,* RUGTRORA.

The bark as met with in the shops is in irregular pieces or half quills about $\frac{1}{4}$ of an inch thick; texture fibrous; external surface decorticated, dull red, nearly smooth; internal surface dull red, faintly striated. A transverse section shows numerous waved medullary rays of a darker colour than the rest of the bark. Under the microscope many dotted vessels and cells are seen; most of the cells contain red colouring matter. There are no distinctive characters. Portions of the grey epidermis may often be found adhering to the bark. Rugtrora is in considerable repute among the natives as a tonic and astringent. The tree grows upon the highest hills in the northern parts of this Presidency.

ERYTHRÆA ROXBURGHII.—*Local Name*, CHOTA CHIRAYTA.

A very delicate little plant, from 4—10 inches high, appearing in cultivated ground after the rains. This year, owing to want of rain, it is very scarce. The root is small and fibrous, sparingly branched; the stem quadrangular and winged; lower leaves obovate-oblong, obtuse, those on the stem linear-acuminate; cymes dichotomous; flowers bright pink, starlike; capsules oblong, mucronate, ¼ of an inch long, dehiscing, 2 celled, covered by the long sepals, and the inflated silver-paper like tube of the corolla. The plant is a good bitter, and may be found useful occasionally when Chiretta is scarce or dear, but from its small size, it is not likely to compete with that drug as a commercial article.

(*To be continued.*)

THE SUPPOSED MERCURIAL POISONING BY COLOURED VULCANITE.

The interest excited by the publication of a statement by Dr. Bathurst Woodman, to the effect that he had met with several cases where patients had shown symptoms of mercurial poisoning for which he could find no other explanation than that they were wearing artificial gums or palates coloured with vermilion,* led the Odontological Society to appoint a committee to collect evidence and report upon the subject.

The report, which has just appeared in the *Transactions of the Odontological Society*, for April, is made under two heads:—(1) Evidence derived from the observation of cases occurring in practice; (2) Evidence as to the *à priori* probability or possibility of the supposed poisonous effects. In order to collect evidence under the first head a number of circulars containing a series of questions were issued. Of these, 96 were filled in and returned. The answers in 66 cases gave a decided negative as to having seen any symptoms which they attributed to the use of coloured vulcanite; 30 replied that they had seen local symptoms, but in the opinion of the committee 21 of these answers were inconclusive; and in no single instance were such symptoms related as would lead the committee to infer that the effect was due to mercury rather than to other and more direct causes.

Under the second the committee includes a report by Professor Attfield, which had been placed at their disposal by Messrs. Ash and Sons, to the following effect:—

"In accordance with your instructions, I have made 'an investigation of the influence, if any, of saliva and the other fluids of the human body on the pink and red varieties of vulcanite used by dentists in making artificial teeth-plates, gums, and palates'; and I now report results.

"I understand from you that these tinted varieties of vulcanite are made by heating pink or red 'dental rubber,' under pressure, to a temperature of 310° to 315° F. (154° to 157° C.), and that this 'dental rubber' is prepared by incorporating sulphur and vermilion with pure india-rubber.

"The innocuous nature of two of the three components of tinted vulcanite is admitted by everybody; sulphur and the india-rubber of vulcanite, as exposed in the mouths of persons wearing artificial teeth, are perfectly harmless. Vermilion, however, demands detailed notice from me. I will afterwards describe my experiments on the completed vulcanite made from these three substances.

"Vermilion, sometimes termed cinnabar or red sulphide of mercury, has been celebrated from the earliest recorded times for its beautiful scarlet-red colour, both Jeremiah and Ezekiel alluding to it as a paint or pigment. As a medicinal agent it has always been found to be inactive and useless. It is true that until recent years the medical colleges of most countries gave, in their Pharmacopœias, directions for its preparation. But it was recognized medicinally only as a fumigating agent in certain affections of the mouth and throat, being, for this purpose, sprinkled freely on a hot iron shovel and the fumes inhaled. Even under these circumstances any medicinal action that was produced was not due to the vermilion as vermilion, but to other compounds of mercury as well as to certain sulphurous gases into which the vermilion was converted by the heat. Vermilion itself, according to the experiments and observations of the greatest French authority on such matters, Orfila, is inert, for he found that 'no effects were produced on dogs by half an ounce, either when applied to wounds or when taken into the stomach.' In America it appears to be used rarely even in fumigation. In the 'United States Dispensatory,' however (twelfth edition, 1865), there is a statement which shows that if given internally the dose may be from ten to thirty grains in electuary or bolus. From this, by the way, an inference may fairly be drawn that if the wearer of a tinted vulcanite teeth-plate swallowed the whole of it, the vermilion in it, even if unprotected by the india-rubber, could not do him any harm. In Great Britain, vermilion or cinnabar is not now recognized as a medicinal agent. Taylor ('On Poisons,' second edition, page 475) says:—'Cinnabar . . is well known as a red pigment, and is often employed in colouring confectionery and wafers. I have not,' he says, 'been able to find any instance of its having acted as a poison on man. . . . . Cinnabar is sometimes used for giving a red colour to ointments—*e. g.*, the sulphur ointment. In such cases,' he continues, 'the quantity is very small, and can do no injury even if swallowed.'

"In short, vermilion is obviously so harmless a substance,—that is to say, its action on the human system is so insignificant,—as to be unworthy the notice of medical men, and, therefore, of the public generally.

"Combined with sulphur and india-rubber, vermilion might, with reason, be expected to be even still less likely to be affected by, or to affect, the fluids of the human frame. For india-rubber and the hardened india-rubber termed vulcanite are each of so insoluble and inactive a nature that either would probably retard rather than accelerate any action between a substance mixed with it and the saliva or gastric fluids. Then no soluble chemical compound of vermilion and indiarubber is known or is likely to exist, or ever to be found. Nevertheless, the importance of the question now under investigation, on account of the wide-spread use of tinted vulcanite, demands that actual experiments shall decide on the inaction or action, if any, of saliva, and even of stronger saline acid and alkaline fluids on pink and red vermilion-coloured artificial gums, palates, and teeth-plates.

"In the experiments about to be described the influence of various liquids both on pink and on red vulcanite was first examined. Secondly, the effect of the fluids on an unvulcanized mixture of the ingredients of tinted vulcanite,—that is to say, their action on

* See *Pharm. Journ.* [3], vol. v., p. 484.

'dental rubber,'—was investigated. Thirdly, the question was decided as to whether or not any compound of mercury soluble in saliva, etc., is set free when the metallic pins and braces used by dentists are heated with dental rubber in the process of vulcanization.

"*Experiments on Tinted Vulcanite.*—The vulcanite was finely shredded and a small teaspoonful of the shreds placed in the respective fluids. Thirteen fluids were selected, representing the liquids of the mouth and stomach, solutions of salts, acids, alkalies, and spirits. The pink and red varieties of the vulcanite were separately treated. One set of twenty-six vessels containing the shreds and solvents was placed in a chamber carefully and continuously warmed to 98° F. (37° C.); that is to say, the mixtures were kept at about the natural temperature of the mouth. The temperature of other vessels and their contents varied with the temperature of the air in January, February, and March. Each mixture was frequently stirred or shaken, so that each was freely exposed to atmospheric influences. The experiments were continued from day to day for one, two, three, and four weeks, and each fluid was tested from time to time for mercury by sulphuretted hydrogen, by electrolysis, and, in short, by the most delicate tests known to chemists.

"1. *Saliva.*—At ordinary temperatures there was no action on the first day, nor on the second day. After another day or two the mixtures smelled sour, and after two or three days had the smell of decaying beef; no action. At the end of a fortnight no action.

"Other mixtures of the pink shreds and saliva, and of the red shreds and saliva, were exposed at the temperature of the mouth for six hours daily for several weeks. The fluids were frequently tested for mercury, but no trace of that metal was detected.

"2, 3, 4. *Solutions of* (2) *sulpho-cyanide of potassium, two parts in one thousand parts of water;* (3) *of chloride of sodium, of similar strength; and* (4) *of the sulpho-cyanide one part, the chloride one part, and water one thousand parts.* In these respective liquids the different shreds of vulcanite were exposed as already described. During the first week of treatment no action occurred; at the end of the second week, no action; at the end of a month, no action.

5. *Pepsin.*—The influence of pepsin was next investigated. Ten parts of pepsin and one thousand of water, containing fifteen of strong hydrochloric acid, were mixed. Such a mixture, kept at 98° Fahr. for a few hours, will, as is well known, dissolve solid food in the manner in which solid food is dissolved in the stomach; indeed, it may be regarded, for all experimental digestive purposes, as the actual digestive fluid of the healthy sheep, pig, or calf, from which pepsin itself is obtained. Portions of the tinted vulcanite shreds were placed in different quantities of this pepsin fluid at the temperature of the body, treated as before mentioned, and occasionally tested for mercury. No action occurred after one day, two days, a week, two weeks, four weeks.

"6, 7, 8. *Alkaline Liquids.*—In aqueous solutions of (6) caustic potash, (7) hydrate of sodium, and (8) ammonia, each having a strength of about five per cent., the shreds were soaked, at the temperature of the body, for days and weeks. Not the slightest trace of mercury was dissolved.

"9, 10, 11, 12. *Acids.*—The vulcanite shreds, pink and red separately, were also soaked, under the conditions just described, in (9) vinegar containing about five per cent. of acetic acid; in (10) a mixture of nitric acid one part to water five parts; in (11) sulphuric acid and water, one to seven; and (12) in diluted hydrochloric acid, one to nine. The digestion was continued as before for six hours daily for three weeks. The hydrochloric acid, when tested, yielded faint traces of a metal, so slight that by no reagent could it be proved to be due to mercury. The other acid liquids afforded not the slightest evidence of the presence of mercury.

"13. *Alcohol.*—Spirit of wine one part to water three parts did not extract a trace of mercury from the vulcanites at any temperature.

"*Experiments on 'Dental Rubber.'*—The object of these experiments was the determination of the action, if any, of the thirteen solvents previously described, not only on imperfectly vulcanized materials, but on the actual raw material of vulcanite. A description of these experiments is unnecessary; they were conducted as before for ten days or a fortnight. The dental rubber was also cut into shreds so as to expose as great a surface to the fluid as possible, and thus to make the experiments fully as severe as the former set. The results may be summed up in one sentence. Neither saliva, acids, alkalies, saline solutions, nor spirits, affected the dental rubber.

"*Experiments on the Action of Metals on 'Dental Rubber,' at the Temperature of Vulcanization, and on the Influence, if any, of Saliva, etc., on Vulcanite containing such Metals.*—The metals employed in these experiments were those commonly used for fastening artificial teeth into vulcanite, and for bracing and strengthening the different parts of the teeth-plate, namely, sixteen-carat gold, hard platinum (iridio-platinum), and 'dental alloy' (platinum one, silver three parts). Some other metals, stated to have been found embedded in vulcanite teeth-plates, were also experimented upon, namely, nine-carat gold, German silver (copper, zinc, and nickel), brass (copper and zinc), iron, steel, copper, tin, and lead. Two wires of each metal were imbedded in a tablet of dental rubber tinted with vermilion; indeed, there were prepared two such red tablets for each metal. The twenty-two tablets were then vulcanized in the usual way by heating to the proper temperature, and under the proper pressure, for the proper length of time. One of each couple of tablets was then physically and chemically examined, the other being kept for future reference. A smart blow of a hammer on a chisel laid bare a wire and its bed. After a careful scrutiny, both with the naked eye and with the aid of the microscope, the wire and vulcanite fragments were gently warmed with nitric acid and water (one to eight) the resulting liquid evaporated to dryness, the residue moistened with strong hydrochloric acid, again evaporated to dryness, and the latter treatment repeated. The last residue was finally diluted with water, and tested for mercury. Besides this severe process, some milder methods were employed in appropriate cases.

"The sixteen-carat gold and the nine-carat gold, when chiselled out of the vulcanite were found to be slightly tarnished, and the channel which the wire had occupied had a dull metallic appearance, but neither the wire nor the fragments of vulcanite yielded the slightest trace of mercury to the acids or any of the many solvents already mentioned.

"The platinum, the dental alloy, the tin, and the German silver, were not altered in appearance. No evidence of the occurrence of free mercury or any soluble compound of mercury could be obtained from the wires or from the beds they had occupied.

"The steel had scarcely been affected by the vulcanizing operation, and had not produced any mercury or, as proved by experiments with solvents, any soluble compound of mercury.

"The iron was superficially converted into sulphide of iron, doubtless by the free sulphur of the 'dental rubber,' for no mercury could be extracted by the solvents.

"The lead had similarly affected and been affected by the dental rubber, but no soluble form of mercury could be detected.

"The copper and the brass were somewhat deeply corroded by the sulphur of the prepared rubber; but the cinnabar of the mixture was not degraded. In both cases the corrosion was proved to be due to the formation of a thick coat of sulphide of copper, which crumbled readily between the fingers; but no trace of mercury was detected, and even moderately strong acids failed to extract mercury in any form.

"*Conclusions.*—1. So far as any action on man is concerned, vermilion is a harmless substance.

"2. So far as any effect or influence of the vermilion is concerned, the mixture of vermilion, sulphur, and india-rubber, commonly termed 'dental rubber,' is also a perfectly innocuous substance.

"3. Pink or red dental vulcanite, even when placed under the severest conditions of experiment, does not yield any trace of mercury to saliva or indeed to other far more powerful solvents.

"4. The metallic pins and braces in dental vulcanite do not displace mercury, or induce the formation of any compound of mercury soluble in saliva or in more powerful solvents.

"5. The results of this investigation are such as would be anticipated by chemists. For, first, vermilion is well known to be of the most repellent or sluggish nature as regards any action on it by ordinary solvents, or even by corrosive fluids. Secondly, india-rubber, or the sulphurized or hardened india-rubber termed vulcanite, is, as regards resistance to corrosion or solution, one of the most chemically obstinate of substances, and would well play the part, if necessary, of protector from chemical attack of any material well mixed in it. Thirdly, even if metals extracted sulphur from vermilion, at the low temperature of vulcanization, as they do at a far higher temperature, they would do so because of their great affinity for sulphur; hence would properly be expected to combine with the free sulphur mixed with the vermilion and india-rubber in preference to the sulphur already intimately chemically combined with the mercury.

"6. The harmlessness of vermilion vulcanite should also be anticipated by medical practitioners; for it has been extensively used for the last fifteen years, and during that time hundreds of thousands of persons in Europe and America have worn, and are now wearing, pink and red vulcanite teeth-plates, and it is inconceivable that any wide-spread or even occasional harm resulting therefrom could elude the trained powers of observation of physicians and surgeons. The medical records, extending over many years, show that only three writers have ever suspected or regarded vermilion vulcanite as liable, in extremely rare cases, to be somewhat mischievous, and in these case that the fault lay with the vermilion was not conclusively proved.

"7. Though, however, chemistry and medicine would concur in forecasting the innocuous nature of vermilion vulcanite, experimental evidence of its harmlessness should be most acceptable; for the integrity of a substance worn within the mouths of men and women in all civilized countries must be beyond suspicion.

"8. I am of opinion that vermilion vulcanite teeth-plates are practically unaffected by saliva, or by any substance which ever gains access to the mouth; and, in short, that the pink and red vulcanite artificial gums and palates now so generally worn are absolutely harmless."

In concluding this section of their report the committee call attention to a fact which bears upon the *à priori* probility of deleterious results following prolonged contact with vermilion, even when not locked up in the interstices of vulcanized rubber—namely, that men employed in vermilion-works, who are constantly red from head to foot while engaged in their occupation, do not suffer from any local or constitutional symptom of mercurial poisoning.

The committee, however, are of opinion that in a certain small percentage of cases vulcanite may exercise some irritating effects upon the tissue with which it is in immediate contact; but there is not the smallest evidence that these effects are due to its chemical composition, or, at all events, to the vermilion which it contains, inasmuch as precisely similar results are recorded as occurring in connection with the use of the uncoloured vulcanite.

AN EASTER HOLIDAY IN LIGURIA.*

BY PROFESSOR FLUCKIGER.

(*Continued from p.* 853.)

But especially the lemon trees occur in this district in such large numbers that their light shining leaves stand out in most conspicuous contrast to the seriousness of the olive. The lemon tree is throughout almost the entire year favoured simultaneously with its red-tipped flowers and with fruit, but the principal harvest is obtained about the middle of May. The fruit requires more shelter than most of the other allied *agrumi* (acid fruits), as the entire genus is here called, so that not even in the Riviera di Ponente is there a large quantity of lemons available for exportation. Indeed, the position of Nizza is too cold, although an abundance of oranges are to be found there. The lemons are much more profitable, and the plant is therefore preferred everywhere in this country, where it can be tolerably well cultivated. The greatest enemy of the lemon tree is probably the wind, which will sometimes strip the branches clean of leaves, through which the activity of the tree is frequently injured for a time. On the heights east of Mentone, close to the Italian frontier, where the south-west storms have freer access than in Mentone even, the most beautiful lemons utter their moan, for there they hang until they perish upon the naked boughs. It is remarkable how small a quantity of fallen fruit is met with in these lemon gardens, certainly far less than is usual in a German orchard.

The lemons of the Riviera are the fruit known in Germany and France as citrons: they are more juicy and richer in citric acid than the true citron, although both fruits may have been developed from the same species. The Italian botanists separate entirely the lemon tree (*Citrus limonum*, Risso) from the citron tree (*C. medica*, Risso), the *cédratier* of the French, and the fruits are so different as to serve quite different purposes. The lemon is used on account of the considerable amount of acid it contains and in the production of the essential oil; the usually much larger citron is used only in the preparation of candied peel: the lemon has so thin a rind as not to be suitable for the latter purpose. In the citron the white inner tissue of the rind is generally preponderant in weight, and so little juice is present, and that so slightly acid, that these true citrons cannot render the same service as lemons in the pharmacy and kitchen.

As an article of commerce the lemon is the most valued of all the *agrumi*, and is also probably the least perishable among these fruits. From the Riviera di Ponente they are carried off at good prices by ships from New York and Boston, and the absence of the Americans in any future year might lead to a very disagreeable disenchantment.

The sweet or China oranges are in this country cultivated only here and there. At Nizza they predominate. Still more limited is the culture of the other *agrumi*, such as the bitter fruited orange (*Citrus vulgaris*, Risso), and the citron (*C. medica*, Risso). Savona has some repute on account of its mandarins, the fine fruit of *C. myrtifolia* and *C. sinensis*. Here and there, but only as a curiosity, one meets with the bergamot, a graft on the *C. vulgaris*; an insignificant pale yellow orange, with an aroma as fine as its taste is abominably bitter. This fruit appears to have been first produced in cultivation in the seventeenth century, but whether it stands in any relation to the state of Bergamo is not known. The oil of bergamot was known in Germany at the end of that century; for instance, in a pharmacy in Giessen. The so-called Adam's apple, which is in this country insipid and remarkable only for its size, is seen occasionally in the gardens, but hardly perhaps in memory of the crusaders who brought information respecting this large fruit to Europe. In fact, it was first mentioned at the commencement of the thirteenth century by Jacques de Vitry (Jacobus de

* From the *N. Repertorium f. Pharmacie*, vol. xxv. 1876

Vitriaco), Bishop of Accon, the St. Jean d'Acre of the present day, in his 'Historia Hierosolymitana;' and in the sixteenth century the *poma Adami* appears to have been obtainable in German pharmacies.

Consequently, of the essential oils to be obtained from the *agrumi* only the oil of lemon is dealt in the Riviera, and even that is prepared in but limited quantity, when the fruit no longer finds a good market. At Mentone, however, there is a well-regulated and beautifully situated establishment, belonging to M. Médecin, where two kinds of oil of lemon are prepared: the "essence de citron au zeste," and the "essence de citron distillée," the name oil of lemon being unknown in the trade. The former sort is obtained by rupturing the oil cells, which are situated in the outermost layer of the rind of all these fruits. For this purpose are used *écuelles à piquer*, which are tin basins supported upon a hollow stem and provided with numerous upright brass needles. Each *ecuelle* is fastened by its stem into a depression in the table, and a workman rubs the lemons upon the upright needles, turning and pressing them so that the contents of the largest possible number of oil vessels may escape. This essential oil mixes with the watery juice from the neighbouring parenchyma cells, and collects in the hollow stem, from which it is empted into a clarifying vessel. Here, after a short time, a layer of clear oil rises to the top, which after filtration is at once sent to market. This oil therefore comes directly from the vessel in which it is formed, and is of much greater value than the other. Those oil cells that escape puncture in the *écuelle à piquer* are afterwards emptied by distillation. The rind is removed from the punctured lemons, and there is thus obtained a second quality oil which is an instructive instance of the change that may be produced in an oil by distillation alone, as in their aroma the two kinds differ very much. The whole residue of the lemons is finally eaten with avidity by cattle, and appears to be a not unsatisfactory substitute for the fodder roots which are absent from the south.

Eau de fleurs d'oranger, the German *aqua naphæ*, is another leading article of the manufactory of M. Médecin, for which the flowers of the bitter-fruited orange tree are chiefly used. In Nizza, also, is distilled the oil of these flowers, the oil of neroli, of a magnificent blue colour with a red fluorescence. This oil is never brought pure into commerce in consequence of its high price. The same oil is obtained in smaller quantity at Nervi, near Genoa.

The Riviera indeed presents only an imperfect view of the entire industry that is based upon the *agrumi*; probably the separate branches have always been limited to certain points. This oil of bergamot is manufactured only at Reggio, Messina, and near Palermo; oil of neroli only in South France. Other districts again are occupied in the preservation of the peel of citrons, oranges, mandarins, etc. The pharmaceutical world in the Riviera appears to be far removed from these branches of industry. In a curious pharmacy in Ventimiglia there was neither any information relative to them, nor perhaps at any time a distillatory appatatus to be found. This establishment, however, is truly classical through the wonderful prospect over the Roia valley, the lofty maritime alps and the sea. The shop vessels and a portion of their paltry contents originated in the earlier decades of the last century, and probably also some of the dust and dirt.

Let the eye rove over those olive groves that border the coast, the animated hill slopes, and the valleys filled with pleasant shadows. The question rises, What might have been the appearance of this land at a time when the olive was not yet introduced, when the *agrumi* did not ripen here their odoriferous fruit, and even the fig and the vine were absent? Covered with needle-leaved trees and evergreens, probably mountain and valley looked no less charming. But what would the future of the people of the Riviera be should the olive commerce be menaced with a more strenuous competition? At the present time the revenue laboriously wrung from the olive tree remunerates the small cultivator very moderately. The only advantage possessed by olive oil over other fat oils is in its fine flavour; for other purposes than as food it can be replaced by other fats, so that a considerable portion of the "olive oil" exported from Italy even consists principally of cotton seed oil which has been pressed in Marseilles. Were olive oil, either in this underhand way or more openly, gradually excluded from the world's market, what reaction would it produce upon the Riviera? To what plant would the sober olive give place?

One tree of the future, at least—one of hope for the poorly wooded districts of Italy,—may to a certain extent be recognized in the *Eucalyptus globulus*, Labill. This tree is sufficiently heterogeneous to give, in the event of its extensive cultivation, an entirely altered appearance to the landscape. For this, however, the Riviera has yet a long time to wait; for of systematic forest cultivation of the eucalyptus nothing is yet known, and scarcely anything of the cultivation of forestry itself. But there is sufficient opportunity of seeing fine specimens of this tree everywhere, from Genoa to Cannes. Many entire lengths of road are planted with it, and in very many gardens these Australian citizens already tower boldly above their surroundings, and warrant the expectation that in this country they will not remain far below the height of 100 metres that they attain in Tasmania. The tree was discovered in the south of that island on the 6th of May, 1792, in the neighbourhood of the Entrecasteaux Channel, by Jacques Jules Labillardière, when botanist to an expedition, consisting of the "Recherché" and the "Espérance," fitted out by order of the French National Assembly to search for La Pérouse, who had disappeared since 1788. But a less learned collector might well have been attracted by this striking gigantic tree. In the first place, the entirely different appearance of the full-grown tree is remarkable. In the young tree the quandrangular branches are furnished with broad opposite amplexicaul leaves; but instead of these, while still quite in its early years, on the new shoots, and afterwards on all the subsequent ones, there are formed small long-stalked pointed leaves, which often take a sickle-like form. The latter form alone is shown by La Billardière in his great work, together with the fruit, which he compared to the fashionable button of the day, and on that account he named the new species *Eucalyptus globulus*. The broad ovate leaves and the young shoots are covered with wax, imparting to the quite young trees a dull grey green colour, which is not so much the case with the small later leaves. These hang loosely downwards from the long rather horizontal branches, and are swayed by the wind like aspen leaves, notwithstanding their thick coriaceous texture. It is known that the chemical properties of a leaf hanging perpendicularly differ from those of a leaf occurring in the ordinary nearly horizontal direction. Robert Brown noticed, for instance, that in respect to the stomata in the eucalyptus leaves an important difference exists. The broad sessile leaves have stomata only on the under side; but the pendent stalked leaves are provided with them on both sides. The action of the sun's rays upon the two kinds of leaf must likewise be very different. Most probably even the oils occurring in the two leaf-forms do not correspond.

The trunk of the *E. globulus* (and other species) throws off very long strips of brown bark in a similar manner as the plane scales off its shorter but much wider pieces of bark. The entire family of *Myrtaceæ* is distinguished by its richness in essential oils, and the genus *Eucalyptus*, which belongs to it, is not an exception. When a leaf is held against the light numberless oil glands can be seen; even the bark torn off by the wind is still aromatic; that collected in Australia far more so then that of this country. This essential oil has procured for the tree a considerable reputation during the short period of its naturalization in Italy, South France, Algeria, Spain, and Portugal. In pharmaceutical literature it has been a standing subject since about 1866, and it has become not less important in the horticulture of the South.

With respect to the essential oil no definite conclusion has yet been arrived at. It appears probable that it is essentially a mixture of cymol, $C_{10}H_{14}$, and terebene, $C_{10}H_{16}$, with an oxygenated oil, $C_{10}H_{14}O$; that is to say, these constituents were recognized in commercial eucalyptus oil, which was probably distilled from *E. amygdalina*, Labill., in Australia; but without further investigation this could be scarcely identified. Ferdinand Müller, the honoured botanist of the colony of Victoria, enumerates about sixty species of *Eucalyptus* in his 'Fragmenta Phytographiæ Australiæ,' and a glance at the names alone would awaken the expectation of considerable chemical variations. Amongst them are found such designations as *citriodora, elæophora, eudesmoides, odorata, oleosa, piperita*. This fact allows the conclusion that there are important differences in the smell of the oil of the aromatic leaves, and that nearly as the species may stand in botanical relation to each other, they still produce chemically different oils. Moreover, judging by the odour, the *E. globulus* contains in the large and numerous oil cells of its fruit a different oil from that in its leaves and bark. In the garden of the Palazzo Orengo, besides some fine specimens of *E. globulus*, there are some very young trees of *E. eugenioides*, Sieb. (referred by Müller to *E. hæmostoma*, Smith), the leaves of which upon being rubbed give off a very remarkable smell of butyric acid, exactly resembling St. John's bread. The work upon the only eucalyptus oil at present examined is not yet finished, and of the oils of the other species we have no knowledge, so that these trees still present an immense field for chemical research.

Whether the final judgment of medicine upon the eucalyptus leaf be favourable or unfavourable, gardeners and foresters are probably perfectly right in advocating the propagation of this tree in the South. Febrifuge or not, its greater diffusion will naturally make the district healthier by intercepting the scorching rays and contributing to the more active distribution of atmospheric moisture. Such expectations will be doubtless quickly fulfilled where regular woods of eucalyptus are planted, as in Algeria, the Campagna di Roma, and the Delta of the Var, near Nizza. For these inestimable services eucalyptus trees are preeminently suited by their remarkably rapid growth. Throughout this district the *E. globulus* alone has been planted. Next to *E. amygdalina* this species attains the greatest height and it probably owes its more frequent cultivation in Europe to its having been the first introduced. But it is a question whether other species also, both the shrubby and tree forms, would not be equally well adapted to the South European climate. In the gardens of South France, the *E. globulus* occurred as a curiosity as early as 1822, and in Algeria in 1854; but real cultural experiments were not undertaken till 1863. At present, a tree fifteen years old, about 28 metres high, with numerous enormous branches, stands in the public gardens at Antibes, and at a man's height is 2·25 metres in circumference. Another in the garden of the Palazzo di Orengo, near Mentone, only seven years old, has a circumference of 1·30 metre, and is 19 metres high. This is a development which is not attained by any other indigenous or introduced tree in Southern Europe. The olive, chestnut, walnut, and ceratonia grow much more slowly, and do not present so tall, straight, and columnar a trunk. Labillardière called attention to the extraordinary hardness of the wood. It is evident how valuable such a tree would be in this woodless land; but in the Riviera the reign of indolence is not yet broken by the eucalyptus. In Algeria and the Roman Campagna, on the other hand, very promising and extensive plantations appears to be in full development. Separately and in small groups the *E. globulus* is sufficiently frequent in the Riviera de Ponente to compel closer consideration. As to whether it is to be described as a beautiful tree opinions are much divided, and on account of its peculiarity it is difficult to form a definite judgment in the matter, because at different stages of its growth it changes far more in respect to its branching and foliage than any European tree. When it bears the small sickle-formed leaves, their great mobility introduces a very pleasant liveliness among the surrounding stiff-leaved olive, ceratonia, and lemon trees. However, the foliage of the eucalyptus cannot on the whole be called particularly rich; in this respect, and also as to the pendent leaves, it might be compared to the birch. But this tree is much more branched, and fine specimens therefore make a far more striking impresion.

What the effect as to appearance in the Riviera will be at some future time of a tall straight-stemmed wood of *E. globulus*, the foliage of which would probably not amount to much before the trees attained a height of 30 metres, must remain undecided. However, it can scarcely be expected that trees 100 metres high, a height to which this species attains in Tasmania, will afford a really beautiful prospect. The species which grows to the greatest height, *E. amygdalina*, the stems of which, 145 metres high, exceed that of the tower of Strassburg Minster (142 metres), or the present height of the Cheops Pyramid (137 metres), appears not to be yet cultivated in Europe; but probably some of the smaller partially bushy species might become rivals to *E. globulus* as to appearance. Obviously, the climate of the Riviera, and the still more favourably situated district of central and southern Italy, not too far removed from the coast, suits the *E. globulus* as well as that of Algeria, Andalusia or Portugal. It prospers also near the north Italian lakes; on the other hand, its success in Lombardy, Istria, and in South France westward of Cannes is as yet doubtful; neither has Pisa proved favourable. It sounds, therefore surprising that a specimen should have survived the winters of 1873 and 1874, in the Marly Garden, near Sans Souci. Possibly species might be found that would not suffer from the mild winter of southern England.

The juices of several eucalyptus trees correspond with the kino from *Pterocarpus Marsupium*, Roxb., especially those of *E. citriodora*, Hook., *E. corymbosa*, Sm., *E. vostrata*, Schlecht., and *E. resinifera*, Sm. The last named is represented by some young trees in the grounds of the Palazzo Orengo. It can only be hoped, therefore, that in the near future the vigorous group of the eucalypti may produce a picturesque alteration in the olive groves of the Riviera. In the public grounds a similar part has hitherto been played by the handsome *Schinus Molle*, L., of the family Anacardiaceæ. But this small South American tree, with its somewhat pungent red berries—known on that account in Italy as the "pepper tree"—is much less vigorous than the eucalypti, and up to the present time no special interest has attached to the *Schinus*.

The date palm, also (*Phœnix dactylifera*, L.), which from a practical point of view is scarcely of so high importance as the eucalyptus, occupies in the landscape of this district a prominent place, and produces illusions that could not emanate from the Australian tree which has no history. Indeed, the palm form has a much more remarkable appearance, especially to the northener. To Europe belongs only the dwarf palm, *Chamærops humilis*, L., a very ordinary ornament in our plant houses; but the date palm is a much more imposing representative of this family, and is most generally the tree meant when the palm is spoken of in Germany. Involuntarily upon the bare mention of the word "palm," there is associated with it pictures of oriental peculiarities in nature, history, and customs, with a fulness dependent upon the extent and depth of the imagination of the thinker; whilst the history of the eucalyptus, begun under our eyes, carries us indeed farther away to the Antipodes, but not into the cradle lands of the oldest cultivators, where the palm is particularly at home. Here in the Riviera the palm tops are sufficiently frequent for their light shadows to favour the impression. Already the form of the stem with the remarkable traces of numerous preliminary rosettes of leaves, is thoroughly different in appearance from the trees of Central Europe, and still more from the mature state of the palm, with its wide-spreading tufts of leaves. Whilst the gentlest breadth of wind sways the loosely hanging sickle-shaped leaves of the eucalyptus, the great palm fronds remain in undisturbed peace until startled by a much rougher shock, and even the storm only seldom overcomes the strong mutually supporting petioles. Many trunks deviate in different ways from the exact perpendicular, and such deviation occurs especially in groups of palms up which the ivy and smilax have climbed. Bunches of fruit also, shining with nearly ripe berries, give at least an indication of the blessings which the date palm confers upon its native country, although its fruit in this country cannot compete either in size or flavour with the North African fruit.

Five degrees further south, at a short distance from the Spanish coast, in the province of Alicante, is Elché, famed for its palms. The date woods there number about 100,000 trees, yielding a considerable quantity of palatable fruit, a result that has not yet been attained in the Riviera. But except Elché, this is the only district in Europe where palms can be seen in such numbers as to warrant the designation palm groves. This is limited, however, to Bordighera and San Remo, as even the vigorous palms of Nizza only form a boundary, certainly a very picturesque one, to the Paglione, which, when it has any water, flows through the town. Throughout the whole of the Riviera di Ponente the gardens are adorned with isolated palms, making altogether a very large number, of which many are a foot in diameter and exceed 10 to 20 metres in height; but they occur in thousands only in Bordighera. They are used here, as also in Elché, in the ceremonies of the Catholic Church at Easter time, especially on Palm Sunday. The preparation and forwarding of palm leaves for this purpose form, in the Bordighera and San Remo, a very fluctuating occupation, as there is a similar requirement for the Jewish services. Well-informed persons estimate the palm trees in the Bordighera at 10,000, and this number is continually increased by the plantation of Egyptian seeds. Many of the trees are wretchedly maltreated, the elegant outspreading tufts of fronds being in summer time bound together and covered with straw, so that the formation of chlorophyll in the innermost fronds is stayed. These more delicate and paler fronds, as a symbol of purity, are at Easter time valued doubly as high as the ordinary ones. Of less importance is the plaiting of beautiful small mats and hats from the split palm leaves.

Although the planting of the palm in Italy dates from ancient times, its more general distribution through Sicily, Southern Italy, Southern Spain, and Sardinia was the work of the Arabs. Whether the trees of the Riviera are to be referred back to those times may remain undecided. The fanciful inhabitants of this district, justly proud of their Paradise, appear to be of this opinion, and reckon the age of their largest date palms by centuries, if not at a thousand years and more. But it appears that, in general, the *Phœnix dactylifera* does not attain any great age, and if the opinion be taken of unprejuced observers of mature age as to the age of date palms sown by themselves, the conclusion will be arrived at that only a few of the trees could have seen the next previous century. Palms seem, however, to have long been used for ecclesiastical purposes in San Remo, since Pope Sixtus V., in the year 1584, is said to have bestowed on Captain Brescia, of San Remo, the important privilege exclusively to provide the palm leaves required for the *casa apostolica* every Easter.

At the points of the Riviera where most frequently the foreign traveller stays longest the *Eucalyptus globulus* and *Phœnix dactylifera* are at present sufficiently numerous to be considered well-settled and indeed very prominent members of the flora. They are indications of the meteorological conditions of this strip of coast, which render possible the success of a flora, that is only again to to found several degrees farther south. These two trees proclaim, more clearly than all the thermometer observations in the land, the true south, where belated winter nights in May no longer pinch the promising shoots. Occasional shortness of water and violent storms are, however, enemies to be reckoned with here, which sometimes cause very perceptible damage. The shortness of water is confined within certain limits by the industry of the cultivators, and even the storm does not penetrate everywhere. At any rate these two evils do not act upon the vegetation so definitely as regularly recurring spring frosts.

OSTRUTHIN.*

BY E. VON GORUP-BESANEZ.

This body was discovered by the author in 1874, in the root of *Imperatoria ostruthium*. The following is an outline of the process by which the largest yield has been obtained:—

The young roots of masterwort, one to two years old, are cut and digested with 90 per cent. alcohol at 50 to 60° C. until the liquid ceases to become coloured; the mixed tinctures are distilled to one-third, and this then evaporated until on cooling a thick liquid remains. This residue is exhausted by a mixture of three parts of ether and one of ligroin, of low boiling point, until a firm plaster-like mass remains. The solution is mixed with more ligroin, which separates a brown sticky mass, and the decanted liquor is evaporated spontaneously from flat dishes, and if necessary decanted from the oily sediment forming. Yellow crystals are afterwards deposited, which are freed from adhering resinous matter by spreading them upon porous plaster tiles. The crystals are then dissolved in ether, the solution again mixed with some ligroin, freed from the deposited oily matter, and evaporated spontaneously. Repeated recrystallization from ether yields larger but still yellow crystals, which are obtained white by dissolving them in alcohol and adding water until a permanent precipitate begins to appear.

Ostruthin crystallizes from ether in the triclinic system, the crystals resembling rhombohedrons. It fuses at 115° C. and congeals at 91° C. to a wax-like mass, becoming crystalline; it is inodorous, tasteless, burns with a bright smoky flame, and yields by dry distillation a thick yellowish oil, with an odour resembling Canada balsam. It is insoluble in cold water, sparingly soluble in benzol and petroleum benzin and freely soluble in alcohol and ether. The alcoholic solution has a faint blue fluorescence, which becomes magnificently blue on the addition of water; more water precipitates it. All its solutions are neutral and optically inactive. Its composition is $C_{14}H_{17}O_2$.

Ostruthin Hydrochlorate, $C_{14}H_{17}O_2HCl$, is obtained by passing muriatic acid gas into a not very dilute alcoholic solution of ostruthin, which congeals; the mass is then washed with water and crystallized from ether. It forms white, tasteless and inodorous needles, soluble in alcohol, ether, benzol and chloroform, less so in petroleum benzin.

Ostruthin Hydrobromate is prepared in the same way, but on attempting to crystallize from ether it was decomposed, bromine being liberated.

A combination with hydriodic acid could not be obtained, owing to the liberation of iodine.

Among the products of decomposition obtained by adding ostruthin to fusing potassa, *resorcin* was found. Treated with strong nitric acid, it is first converted into a resinous body and finally into *oxalic* acid; but when boiled for a long time with nitric acid, diluted with three parts of water, it yields *styphnic* and a little *oxalic acid*.

Chlorine yields with difficulty, bromine more readily, substitution compounds.

* Liebig's *Ann. d. Chem.*, clxxxiii., p. 321-343. From the *American Journal of Pharmacy*, for May, 1877.

The Pharmaceutical Journal.

SATURDAY, JUNE 2, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MEDICAL ACTS AMENDMENT BILL.

WITH the utmost satisfaction we are able to announce that the action of the Council of the Pharmaceutical Society in relation to the clause in the Medical Acts Amendment Bill which recently gave such reasonable cause for alarm to chemists and druggists has been entirely successful, and that the objectionable words are virtually abandoned by the promoters of the Bill. On the 17th of May,—the second day after the printing of the Bill,—a deputation appointed by the late Council had an interview with Dr. LUSH at the House of Commons and laid before him arguments against the Bill passing as it stood. On the 19th, Mr. ATKINS, who was a member of the deputation, received an intimation from Dr. LUSH that at the proper time he would move the omission of the words, "or who shall practise medicine or surgery for gain," from the first clause of the Bill. Although, in consequence of the Whitsuntide recess having intervened, notice of the proposed erasure has not yet appeared on the Parliamentary papers, there is little doubt that this arrangement will be carried out, and there is nothing else in the Bill which would interest chemists and druggists in its ultimate fate.

The opinion expressed by Mr. ATKINS at the Annual Meeting, that it would only require an intelligent and respectful representation to Dr. LUSH as to the injurious nature of the Bill to lead him to modify it, has therefore been justified. Indeed, we are informed that Dr. LUSH has stated that it was not until he had received a deputation from the Council of the Pharmaceutical Society that he had any idea his Bill would interfere with the counter business of druggists. Further, in a published extract from a letter received by Mr. BALKWILL, of Plymouth, Dr. LUSH says, "The Pharmacy Act is so "much more stringent as regards the exclusion of "unfit and unlicensed persons from your business "than the present Medical Act is with regard to "quacks and pretenders in mine, that I in no way "intend to interfere with it."

But although this is the opinion of one of the more conspicuous promoters of the Bill now before Parliament, it would be idle to pretend that it probably represents the views of all its advocates, for there is reason to believe that chemists and druggists were not wrong in the construction they put upon the presence in the Bill of the words now to be omitted. As, therefore, it is possible that the attempt may be renewed, it will be well to refer here to an important expression of opinion by the Medical Council in respect to such legislation. The question came up on the presentation of a report from the Committee appointed by the Medical Council to consider legislation now before Parliament affecting medicine. The Committee reported that it could not recommend the Medical Council to give approval to Clause 1 of Dr. LUSH's Bill as it stood, and stated that it did not believe that a clause of such stringency, even if it could be recommended by the Council, would have any chance of being accepted by the legislature. The Committee also suggested that endeavours to strengthen the Medical Acts "in their penal relations "to medical imposture" would probably be best postponed until those Acts shall have received all essential amendments in relation to the profession itself. Discussion upon this report was initiated by Mr. SIMON, who moved that the consideration of the question of introducing more stringent penal clauses into the Medical Acts should be postponed till such time as those Acts shall have received all essential amendments in the provisions relative to the profession itself. This motion it will be seen was merely an echo of the report. Dr. WOOD considered that its adoption would be "deferring *ad Græcas Kalendas* "the consideration of a very important subject," but Mr. SIMON pointed out that the members of the Council could not conveniently consider the question of trespassers upon their province until they knew what were the limits of their profession as fixed by law. In this the other members of the Council appear to have concurred, for the motion was carried.

Reverting to the withdrawal of the obnoxious words, we think it may be claimed that the Council of the Pharmaceutical Society has thus proved its willingness and ability to defend the interests of the trade from unjust attack. It will be seen also by a report on another page, that the executive of the Chemists and Druggists' Trade Association has been making active preparations for the parliamentary campaign which fortunately has become no longer necessary, and we are glad to notice that it was only the assumed urgency of the occasion that led to these steps being taken last Friday independently of the Pharmaceutical Society. Of course, the dispute upon which the proposed legislation turned is by no means settled, and the time may yet come when the joint efforts of the Society and Association will be required. But the important evidence evolved by the recent movement, that the most influential portion of the medical profession has no sympathy with the recent attempt to disturb chemists and druggists in the exercise of long-established rights is a clear gain in the struggle.

LONDON MILK SUPPLY.

A REPRESENTATION has been made to us on behalf of The Aylesbury Dairy Company, Limited, purporting that the remarks on "Milk Supply," which appeared in our number of the 28th of April, are understood to convey an attack upon that company or the article supplied by it, and asking us to give insertion to a lengthy letter detailing sundry precautions, said to be enforced by the company. It is difficult to trace in those remarks anything which can properly be so understood, and we cannot comply with the request to insert the letter which has been received, unless on the usual terms of an advertisement; but we do not hesitate to disclaim any intention to make an attack on the company or the article supplied by it, and we may repeat by way of quotation a sentence from our remarks: "We are assured that "the Aylesbury Dairy Company do their best to give "their customers the best and safest article they can "command. Doubtless this is so, and it is equally "true of many other companies and individuals."

A SUPPOSED REMEDY FOR RABIES AND LEPROSY FROM COCHIN CHINA.

So far back as 1875, an account appeared in some scientific notes in *Les Missions Catholiques*, of the discovery in Tonquin of a sure remedy against hydrophobia and leprosy. This discovery was made by the Roman Catholic Missionaries, prominent amongst whom was a Monsignor GAUTHIER. The remedy was known as the "Hoâng-nan" and was referred to a red scurf covering the bark of a climbing shrubby plant having some analogy with the ivy. The plant is described as being found on the mountains, particularly in calcareous soils. In some provinces it is more abundant than in others and the quality also varies apparently according to soil and climate.

Large quantities of the powder are in constant use, and it is said to have been employed with success in the cure of ulcers, cancerous and syphilitic affections, leprosy, snake bites and hydrophobia. With a remedy having such a reputation it was most important, if there was really anything in it, that the plant should be known that produced it. On this point, however, little has been said until the appearance of M. BERNARDIN's little pamphlet on the commercial products of Central Africa, where under the head of *Drugs* we are told that the Hoâng-nan of Tonquin has been described by M. PIERRE, Director of the Botanic Garden at Saigon, as a species of Strychnos under the name of *S. gautheriana*. The reason of its being referred to amongst African products is, M. BERNARDIN says, that the *Strychnos* of the Gabon is also covered with a similar reddish powder which may have properties analogous to that referred to above.

THE SANITARY INFLUENCE OF THE EUCALYPTUS.

WE learn from the *Meteorological Magazine*, that at the Easter réunion at the Sorbonne, some information was given by Dr. DE PIETRA SANTRA, a delegate from the Climatological Society of Algiers, as to the results of an investigation made in Algeria to ascertain the importance and value of the *Eucalyptus globulus* in relation to public health. It appears that reports were received from fifty localities where the aggregate number of blue gum trees is nearly one million, and from these reports the following conclusions have been drawn:—(1) It is incontestably proved that the Eucalyptus possesses sanitary influence; for (2) wherever it has been cultivated intermittent fever has considerably decreased both in intensity and in frequency; and (3) marshy and uncultivated lands have thus been rendered healthy and quite transformed. Similar results have been obtained in Corsica, where it is computed that at the end of the present year there will be upwards of 600,000 plants of eucalyptus in full growth.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening next, June 7th, at eight o'clock, when papers will be read by Mr. E. RICHARDSON, on "The Conditions attending the Production of a Current of Voltaic Electricity;" and by Mr. S. HARDWICKE, on "ILES's New Test for Boracic Acid."

THE COLLECTION OF MASTERWORT AND OTHER ROOTS ON THE CONTINENT.

A RECENT communication to the *Pharmaceutische Zeitung* is of interest in connection with some admixtures that have been the subject of recent papers in this Journal. The writer says were it once seen how the root diggers in the Alps proceed in the collection and drying of the roots, it would no longer be wondered at that all roots from that source contain numerous admixtures. These people principally go out to dig gentian, the collection of gentian being farmed out in many districts of the Alps, but they also take the opportunity of collecting anything else that is valuable. The gatherings are afterwards dried in their houses, heaped pell mell upon hurdles, or on large stone hearths, or sometimes in the sun. The sorting is not carried out so carefully but that something is overlooked or thrown upon the wrong heap. In this respect special reference is made to the rhizoma imperatoriæ, which, the writer says, always contains foreign, and generally poisonous admixtures. In many districts rhizoma imperatoriæ is a favourite popular remedy, sold under the name of "masterwort," and usually taken in brandy. For several years he has obtained supplies from different drug houses, but never found them free from admixture. Veratrum rhizomes and aconite roots were scarcely ever absent, although not present in very large quantity.

The admixture thus pointed out is just the reverse of that recently described in this Journal by Mr. HOLMES, and is, of course, much more dangerous. It is fresh evidence, were it required, of the necessity, in the absence of any provision for the inspection of imported drugs, that the pharmacist himself should exercise a vigilant and intelligent supervision over such articles before placing them in stock.

Provincial Transactions.

CHEMISTS AND DRUGGISTS OF PLYMOUTH.

At a large and influential Meeting of the Chemists and Druggists of Plymouth, Devonport, and Stonehouse, held at the Exmouth Hall, Manor Street, Stonehouse, on the 25th May, 1877:—

The following resolutions were unanimously passed:

Moved by Mr. Chas. Rowe, J.P., seconded by Mr. J. H. Filmer, and resolved—

"That in the opinion of this meeting the Bill now before Parliament entitled 'The Medical Acts Amendment Act, 1877,' if passed, will make it illegal for chemists aud druggists to give advice to their customers in their own shops respecting the use of medicines, or to continue their counter practice according to their long established usage."

Moved by Mr. S. B. Turney, seconded by Mr. J. Allen, and resolved—

"That this would be a most unjust interference with the existing rights and customs of the trade, and injurious to the best interests of the public."

Moved by Mr. S. Maitland, seconded by Mr. J. Burdwood, and resolved—

"That this meeting therefore considers it a duty to the public and themselves, to use every effort to obtain such an amendment of the first clause, as shall secure the long established usages of the trade."

Moved by Mr. W. Wilson, seconded by Mr S. Daymond, and resolved—

"That a copy of the foregoing resolutions, be sent to the Home Secretary, and to each of the local Members of Parliament."

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The Annual Meeting of this Association was held at the room of the Association, Britannia Chambers, Pelham Street, on Friday, May 25th, the chair being occupied by the President, Mr. J. H. Atherton, F.C.S. After the transaction of some preliminary business, the Hon. Secretary, Mr. Roberts Jackson, read the following

Annual Report of the Council.

The Council have pleasure in presenting their Annual Report to the members of the Nottingham and Notts Chemists' Association, and in congratulating them on the general and financial success of the Society during the past year.

Four monthly meetings have been held, at which interesting papers and lectures were given, and discussions ensued, besides which two open meetings of the trade have been called for the consideration of matters of importance not properly within the legal limits of discussion by the Association.

The attendance at the former has been very limited, while the latter were largely attended. Your Council have again to express their regret at the want of interest shown in the educational work of the Association as exemplified by the poor attendance of the members at the general meetings. On the other hand, it is gratifying to find that most of the chemists in the town are members of the Association. The number of members is 55 (51 town and 4 country) being an increase of five on the number recorded last year, while the number of associates is only 20 against 27 the previous session. The number of associates must necessarily vary very considerably owing to frequent changes, but your Council would earnestly urge the members to use their influence with the young men in their employ to avail themselves of the advantages offered to the associates.

The Council, at the commencement of the session, arranged a course of lectures on pharmaceutical chemistry, to which 18 associates subscribed, besides which, as an inducement to the practical study of chemistry, 16 associates were presented with tickets for laboratory practice at the Mechanics' Institution.

In connection with the former class the Council offered two prizes for competition, but only five students presented themselves for the examination. The names of the successful candidates will be announced and the prizes delivered at the next meeting.

The room of the Association has been open every Friday night during the session for the use of the associates; twenty-one meetings have been held with very variable attendance, numerous at the commencement, with the usual dwindling down of numbers afterwards, giving the poor average of 6 during the whole session. The principal work done by this improvement class has been pharmacy, materia medica, examination of specimens in the museum, microscopic examination and practice in the use of the instrument. The use of the library is still limited, but the report shows an increase in the demand for books as compared with last session.

A good workable microscope was purchased at the commencement of the session for the use of members and associates, an addition to the educational resources of the Society which has been much appreciated by the associates.

Your Council have to acknowledge with gratitude the handsome donation of £10 from Mr. F. J. Clarke of Lincoln, which very materially augments the balance in the Treasurer's hands, and your Council would be glad to see so good an example followed by others of a similar or even less amounts.

The annual supper was held in January, at the Flying Horse Hotel, and it is almost needless to say proved by far the most successful meeting of the year.

It is very gratifying to find that the Society has this year a balance in hand of £25 5*s.* 1*d.*, and it will be for the incoming Council to determine in what manner a portion of that sum can be most effectively used to promote the educational objects of the Association.

The Council now retiring would suggest to their successors that a portion should be used to purchase books to increase the museum.

A matter of considerable importance to the trade has occurred during the past session, which was thought would materially interfere with the ordinary conduct of the business of a chemist and druggist, and although trade matters cannot (according to present rules) be discussed by the Association, a general meeting of the trade was called by the Secretary at the instigation of the Council to take the matter of "counter prescribing" into consideration. Considerable alarm was naturally felt and expressed at this meeting, and it was considered utterly impossible to carry on business unless allowed either by sanction or law to give simple medicines for simple ailments.

Your Council have given the matter their serious consideration and feel they are justified in expressing a decided opinion that even if the law is at present against such practice, the moderate use of the privilege of counter prescribing is too much a public convenience to be interfered with.

A bill has been read the first time in Parliament to amend the Medical Acts, and it is satisfactory to note that the Council of the Pharmaceutical Society has already taken steps to try and effect an alteration in the objectionable clauses in the Apothecaries Act, and to define the relative positions of medicine and pharmacy.

Mr. H. Shippam and Mr. M. H. Humphreys were appointed auditors of treasurer's accounts, which showed a balance in hand of £25 5*s.* 1*d.* After a long discussion on various points, both reports were unanimously passed. The following officers were then re-elected:—President, Mr. J. H. Atherton, F.C.S.; Vice-President, Mr. R. Fitzhugh, F.C.S.; Treasurer, Mr. J. Rayner; Hon. Secretary, Mr. Roberts Jackson. Council, Messrs. C. A. Bolton, T. B. Fletcher, J. T. Jenkins, J. Lewis, J. Lomas, W. Smith, F. White, and J. Wilford.

A vote of thanks to the officers and council for their past services brought the proceeedings to a conclusion.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

A meeting of the Executive Committee was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on the 25th of May.

Mr. S. U. Jones, President, in the chair; Mr. Thomas Barclay, Vice-President.

Present,—Messrs. Andrews (London), Arblaster (Birmingham), Brevitt (Wolverhampton), Churchill (Birmingham), Cross (Shrewsbury), Greaves (Chesterfield), Greenish (London), Hampson (London), Jervis (Sheffield), Laird (Dundee), Southall (Birmingham), Shaw (Liverpool), Walker (Birmingham), and the Solicitor of the Association.

Letters were read from Messrs Delves, Holdsworth, Johnson, Mackenzie and Fairlie, regretting their inability to attend.

The minutes of the previous meeting were read and approved.

The President said they would now proceed to consider the "Medical Acts Amendment Bill," a portion of the first clause of which he considered required their serious attention.

Mr. Hampson said he had looked through the bill and no doubt they ought all to consider it as a very serious question. They had to determine as to what practical steps should be taken, and as to what method they should adopt either to oppose the bill or to amend it. They ought to regard it as a deliberate intention on the part of the medical men to put a stop to counter practice. The matter, then, came before them in a form which led them to consider whether they should oppose the bill, or endeavour to amend it. His view was that they ought distinctly to oppose the bill. If they did not oppose it they would have to alter it, and on the face of it he held that it would not be acceptable without such alterations as they could not hope to obtain from the promoters of the bill. The object of the promoters was undoubtedly to cripple the chemists and druggists. He therefore thought the best policy would be that of opposition. He should wish that the bill should be discussed in the House of Commons, and to that end it was necessary that there should be formal opposition. If an attempt was made to frame a clause which would satisfy all parties it would be found to be an almost impossible task. They ought to impress upon medical men that they were not to be put down, and that they would defend their rights as much as possible. He thought that the first step should be to get some member of parliament to move the rejection of the bill. The next step would be for them to present a petition against the bill. The Pharmaceutical Society were active in the matter, but they seemed to think that the Medical Association might possibly be induced to frame an amendment or rather a clause that would guarantee the rights of the chemists. He however, did not think this possible. They ought to move forward in a straightforward way to reassert their rights. They should argue for their right of giving simple remedies over the counter in simple cases.

Some little discussion then took place. A strong feeling was expressed that it would be very desirable to act with the Pharmaceutical Society in this matter, but it was felt that the time was too short (the second reading of the bill coming on within a week) for the Association to take any effective action after the delay such a course would involve.

It was moved by the President: "That this Association take immediate steps to oppose 'A Bill to amend the Medical Act of 1858,' now before the House of Commons on its second reading."

Mr. Brevitt seconded the resolution. He said it would strengthen the case for the Association to go forward independently. He thought they would find no difficulty in getting petitions signed.

Mr. Hampson supported the resolution.

Mr. Greenish thought that they should move at once as there was no time to be lost, and said he had great pleasure in supporting the resolution.

Mr. Shaw said he did not think there could be the least expectation of their being successful in any attempt they might make to have the bill amended. He thought they should at once look round for some honourable member who would look at the public interests involved in that bill, and take up the opposition from a public point of view. Whatever action the Pharmaceutical Society might take, and he had no doubt they would take action, they would be in a position to unite.

The resolution was then put to the meeting and carried unanimously.

It was moved by Mr. Andrews, seconded by Mr. Arblaster, that steps be taken to invite members of parliament to oppose the Medical Bill now before the House of Commons, on its second reading.

Mr. Southall said they should take care that the opposition was brought forward at the second reading. It would be well also that the Secretary should address letters to well known friends in important towns, asking them to communicate with their representatives, setting forth the views of the druggists upon the matter. The question would be more weightily considered if they could get a number of members imbued with similar views.

Mr. Barclay said he had been informed that Dr. Lush, who had introduced the obnoxious bill, was in reality friendly towards the chemists and had no intention to injure them; if this was the case Dr. Lush would no doubt be ready to meet the wishes of the chemists as far as possible. Whatever was to be done he agreed ought to be done immediately. Let them do what they could and no doubt the Pharmaceutical Society would gladly come forward and join in opposing the bill. He had no doubt that Mr. Chamberlain, one of their local members, would be willing to help them. They ought then to address circulars to the members of the trade asking or advising them to consult their members.

Mr. Andrews said he had received some information of which he could not very well give the source, and it was corroborative of the views expressed by Mr. Hampson.

Mr. Glaisyer said that he believed that Dr. Lush did not know the intention of the bill, and therefore it would be but courteous for the committee to appoint a deputation to see that gentleman.

The following form of petition was then adopted:—

"To the Honourable the Commons of Great Britain and Ireland, in Parliament assembled."

"The Humble Petition of Pharmaceutical Chemists and Chemists and Druggists residing at

____

in the County of ______________

"Sheweth,

"That your petitioners desire to call your attention to a Bill now before your Honourable House, intituled 'A Bill to Amend the Medical Act of 1858,' which bill, if passed into law, would act prejudicially to Her Majesty's subjects by creating a monopoly, and preventing the public obtaining relief for simple complaints, and in cases of emergency, from chemists and druggists and all other persons other than medical practitioners.

"Your petitioners would direct attention to the fact that one of the clauses of the said bill renders it a penal offence for any person to supply the simplest remedy, or perform the most trivial surgical operation for gain, unless he be a medical man. This enactment would press with extreme harshness and severity upon the poor and others who have hitherto been able to obtain simple remedies from chemists and druggists without being compelled in all cases to consult a physician or surgeon.

"Your petitioners respectfully urge that the provisions of this bill, if it obtains the sanction of your honourable house, would also deprive them of a right which they have exercised from time immemorial, and which they maintain has not been detrimental to the community, but, on the contrary, of the greatest public advantage.

"And your petitioners will every pray, etc."

The Secretary was instructed to forward a copy of a circular with a written copy of the petition to prominent members of the trade in 150 of the principal towns in Great Britain, asking them to obtain the signatures of local chemists to the petition, and forward the same to one of their members of parliament.

It was moved by Mr. Barclay, seconded by Mr. Brevitt, and unanimously resolved:—"That a deputation, consisting of the officers of the Association, together with Messrs. Arblaster, Churchill and the Solicitor of the Association, be hereby empowered to wait upon Joseph Chamberlain, Esq., M.P. for Birmingham, to invite him to give formal notice of opposition to the Medical Acts Amendment Bill now before the House of Commons."

Moved by Mr. Greaves, seconded by Mr. Walker, and unanimously resolved:—"That the deputation appointed to wait on Mr. Chamberlain be empowered to secure some other Member of Parliament to give notice of opposition to the Bill if Mr. Chamberlain declined."

Law, Finance, and General Purposes Committees were then appointed.

A vote of thanks to the President for presiding terminated the proceedings.

The deputation had an interview with J. Chamberlain, Esq., M.P., on the 28th ult., when he said he should have been pleased to have moved the rejection of the bill, but local business of an important nature, connected with Mr. Gladstone's visit to the town, would prevent his being present in the House on the 1st of June, when the bill would be called on for second reading. The deputation subsequently waited upon Sampson S. Lloyd, Esq., M.P., who consented to oppose the bill on its second reading.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

A meeting of this College was held on the 17th of April, Mr. A. P. Brown in the chair.

A specimen was exhibited of the so-called "cream of tartar fruit," from the Orange Free State. Professor Maisch stated that it belonged to the genus *Adansonia*, and probably to *A. Gregorii*, which is stated to be a native of Northern Australia. The fruit is smaller, and the taste of the acidulous pulp differs from that of *A. digitata*, the baobab, of which handsome specimens had been on exhibition from Jamaica. In answer to a question he stated that he had not had the time yet to ascertain the composition of the pulp. He also called attention to the Latin names by which some Japanese chemicals exhibited were designated, and which were similar to those used in Germany and Holland; for instance, *Zincum oxydatum sulfuricum*.

Professor Remington read a paper on "Aromatic Elixir of Licorice," and its effectiveness for disguising the bitter taste of sulphate of quinia. Mr. Brown stated that he made such an elixir by dissolving 8 grains of ammoniacal glycyrrhizin in one fluid ounce of simple elixir. Inquiry having been made about a *compound elixir of eucalyptus*, which has been recently introduced for the same purpose, it was stated to owe its effects likewise to glycyrrhizin, but appeared to be flavoured with oil of eucalyptus, besides other aromatics.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held at 17, Bloomsbury Square, on Thursday, May 10, Mr. C. Hutchinson in the chair.

The first paper was by Mr. Harold Senier, on the Luminosity of Flame, of which the following is an abstract:—

Flame may be defined as the luminous envelope which marks, in some cases, the limit of union between a combustible and a supporter of combustion. The colour of all flames is due to incandescence, but all incandescence is not flame. There are four kinds of incandescence: (1) of solids by their own oxidation; (2) of gases by their own oxidation; (3) of solids by external heat; and (4) of gases by external heat. Flames can be divided into two classes: luminous, which give a continuous spectrum, and non-luminous, which give a non-continuous spectrum. The luminous class, to which by far the greater number of flames belong, may be subdivided into those (1) in which at the temperature necessary for their existence solid particles are present, and those in (2) which at that temperature solid particles can no longer exist. Davy's theory of the structure of some luminous flames and Frankland's theory of the second class of luminous flames were explained and illustrated by experiment, a candle flame being taken as the type of the former and arsenicum burning in oxygen as a type of the latter. Several experiments were also shown which appeared to point to the conclusion that compressed air retards combustion of gases and rarefied air renders it more complete. Frankland's theory in explanation is that the particles of oxygen in a rarefied atmosphere have greater freedom of motion and consequently have more ready access to the luminous cone of the flame and more completely prevent the separation of carbon. The paper concluded with an account of the latest researches on the Bunsen flame and of an experiment made by the author to ascertain in what relation this flame stood in regard to its heating power when burning in common air to one burning in CO_2. A Bunsen burning a fixed quantity of coal gas, to which air was admitted freely, was allowed to play against the bottom of a flask containing 500 c.c. of water, the flame being protected from all draughts and other varying influences. When the water had been heated to 80°, the time taken to heat it 20° more was accurately taken, and found to be 1 min. 32 secs. When CO_2 was substituted for air, under precisely similar conditions, the time taken was 2 minutes, showing that the relation was as 3 to 4.

A vote of thanks to the author was passed unanimously.

The next paper read was entitled—

TABLES FOR THE QUALITATIVE ANALYSIS OF THE MORE COMMONLY OCCURRING SCALE PREPARATIONS, ALKALOIDS, ETC.

BY DR. A. SENIER, F.C.S.

In presenting to you these tables, which have been used with satisfactory results in the laboratories of the Pharmaceutical Society, I must, in the first place, disclaim all intention of giving you original matter, for although I have never seen such tables in print I am aware that similar ones have been used from time to time by teachers in our laboratories, as well as in other schools.

Like all charts which have been constructed to facilitate analysis, they may be used both properly and improperly. I would draw special attention to this. In the laboratories of the Pharmaceutical Society, where these charts have been used, it has always been required that the student should have previously prepared one or more alkaloids and scale preparations, and should have made himself familiar with their behaviour towards reagents and solvents. He is then in a position to use these tables intelligently and correctly. For students who have not done this they are not intended and will be found in practice to be of little use.

TABLE FOR THE QUALITATIVE ANALYSIS OF ORDINARY SCALE COMPOUNDS.

ALKALOIDS.

Quinia. Quinidia. Beberia. Cinchonia. Cinchonidia. Strychnia.

Dissolve a portion in H_2O, and add NH_4HO cautiously (Precipitate=Alkaloids (except Strychnia) and sometimes $Fe_2 6 HO$). Add NH_4HO in excess (insoluble Precipitate=Cinchonia or Cinchonidia, or perhaps $Fe_2 6 HO$). Agitate the mixture with Ether and separate, by means of a pipette, the ethereal solution, aqueous solution and insoluble precipitate.

Ethereal Solution.

May contain quinia, quinidia, or beberia. To solution in a test-tube add H_2O, acidulated with $HC_2H_3O_2$ and boil, burning off the ether. To a portion of the acetic solution, add Cl water and afterwards NH_4HO.

Green Colour (thalleioquin.)

Solution is fluorescent, and contains either quinia or quinidia. Concentrate the remainder of the solution and divide into two parts. To one add KI, and to the other add $(NH_4)_2C_2O_4$. KI precipitates *quinidia*, not quinia. $(NH_4)_2C_2O_4$ precipitates *quinia*, not quinidia.

No Green.

To a portion of the acetic solution add KHO, a yellow precipitate = *beberia.*

Insoluble Precipitate.

Is cinchonia, cinchonidia, or $Fe_2 6 HO$. Benzole may be employed to separate the cinchonia or cinchonidia, it being afterwards removed by heat. Dissolve in dilute $HC_2H_3O_2$, and to part of the solution add $Na_2C_4H_4O_6$, when a precipitate occurs in the case of *cinchonidia*, and no precipitate in that of *cinchonia.*

The solution in $HC_2H_3O_2$ is not fluorescent, and gives no thalleioquin.

Aqueous Solution.

May contain strychnia. Agitate with $CHCl_3$ and separate chloroformic solution. Evaporate chloroformic solution and moisten residue with concentrated H_2SO_4. Draw across the acid film a small moistened crystal of $K_2Cr_2O_7$ when a transient play of colours—violet to red = *strychnia.* No colours = no strychnia. In case of doubt add NH_4HO to original solution. Agitate with chloroform, and proceed as before.

ACIDS.

Pyrophosphoric. Hypophosphorous (generally converted into pyrophosphoric.) Sulphuric. Hydrochloric (as a contamination.) Tartaric. Citric.

Dissolve in H_2O, add KHO, in slight excess, and warm. Note here whether NH_3 is evolved by action upon litmus paper (*Ammonium*). Filter (reserve precipitate), boil a portion of the filtrate with HNO_3 in slight excess and add a few drops of the acid solution to excess of molybdate of ammonium and again boil.

A Yellow Precipitate.

Pyrophosphoric or hypophosphorous acid. To another portion of the filtrate from KHO, neutralized, add $AgNO_3$.

- White precip. soluble in nitric acid = *pyrophosphoric acid.*
- White to black precipitate, soluble in nitric acid = *hypophosphorous acid.*

No Yellow Precipitate.

To another portion of the filtrate from KHO add HNO_3 to acid reaction and divide into two parts. To one add $BaCl_2$ (precipitate = *sulphuric acid*). To the other add $AgNO_3$ (precipitate = *hydrochloric acid*). Neutralize another portion of the KHO filtrate and add $AgNO_3$.

Precipitate Grey to Black.

Add very little NH_4HO (not sufficient to dissolve the whole precipitate) and heat. A silver mirror=*tartaric acid.*

$CaCl_2$ and $Ca 2HO$ precipitate neutral solution (if concentrated) in the cold the precip. redissolving on boiling.

Precipitate White.

Citric acid gives no mirror. $CaCl_2$ and $Ca 2 HO$ do not precipitate citric acid in the cold, but upon boiling (if solution be sufficiently concentrated) precipitation occurs.

Confirm tartaric or citric acid.—To slightly acidified KHO filtrate, add NH_4HO in slight excess and considerable quantity of NH_4Cl and $CaCl_2$. *Tartrates* are precipitated completely in the cold with agitation and rest for about ten minutes. To the solution (or filtrate, if tartrates are present) add three volumes of spirits of wine when *Citrates* are precipitated. If sulphates have been found disregard slight precipitate with spirits of wine.

INORGANIC BASES.

Ammonium (often as a contamination.) Ferric Iron. Potassium. Sodium (rare).

Ammonium — already sought. *Iron*—precipitate by KHO (previously reserved) may be dissolved in HCl, and the solution tested for iron by K_4FeCy_6, KCyS, etc.

Potassium and Sodium. Ignite a small quantity of the scale, and moisten the residue with water. Test moistened residue with litmus paper. If alkaline examine for potassium and sodium by the colour imparted to flame, and for potassium by HCl and $PtCl_4$.

TABLE FOR THE IDENTIFICATION OF THE FOLLOWING ALKALOIDS, ACIDS, ALOINS, ETC.

ALKALOIDS, ETC. { MORPHIA. QUINIA. SALICIN.		STRYCHNIA. BRUCIA. QUINIDIA.		CINCHONIA. CINCHONIDIA.		ACIDS. { SULPHURIC. HYDROCHLORIC. PHOSPHORIC.			ACETIC. MECONIC CITRIC.		ALOINS { SOCALOIN. NATALOIN. BARBALOIN.	
To a small quantity on a porcelain plate add conc. HNO_3.		If no Morphia or Brucia, moisten a small quantity on a porcelain plate with conc. H_2SO_4.		If Morphia, Brucia, Salicin, and Strychnia, are absent, make a solution—using a little acid if necessary—and add NH_4HO in excess.		Make a solution with a slight excess of HNO_3, divide it into three portions, and test as follows:—			Make a neutral solution, divide it into two portions, and test as follows:—		To Aloin, or powdered aloes—on a porcelain plate—add concentrated HNO_3.	
An Orange Colour, decolorized by $SnCl_2$, $Na_2S_2H_2O_4$, or $NaHS$ = *Morphia.** Confirm by— Fe_2Cl_6 (neut.), which gives with morphia or its salts a blue colour. HIO_3 is decomposed by morphia or its compounds, with liberation of iodine which may be recognized by starch.	*A red colour*, changed to violet by $SnCl_2$ $Na_2S_2H_2O_4$ or $NaHS$ = *Brucia.*	*A deep red colour* = *Salicin.* Confirm by boiling the substance with water to which has been added a few drops of dilute H_2SO_4. Then neutralize the acid and examine for glucose.	*No colour, or only a slight colour.* Draw a moistened crystal of $K_2Cr_2O_7$ across the acid film when a transient play of colours, violet to red, = *Strychnia.*	*Precipitate dissolves with difficulty in excess* = Quinia or Quinidia. Confirm— Solution fluorescent. Sol. with chlorine water and NH_4HO gives a green colour (thalleioquin). Alkaloids soluble in ether. Distinguish— Make a concentrated, slightly acetic, solution, divide into two portions; to one add conc. sol. of KI, and to the other add conc. sol. $(NH_4)_2C_2O_4$. *Quinidia* is precipitated by KI and not by $(NH_4)_2C_2O_4$. *Quinia* is precipitated by $(NH_4)_2C_2O_4$, and not by KI.	*Precipitate does not dissolve in excess* = Cinchonia or Cinchonidia. Confirm— No fluorescence. No thalleioquin. Alkaloids insoluble in ether (cinchonidia sol. 1 in 150). Distinguish— Make a concentrated slightly acetic solution, add $Na_2C_4H_4O_6$. Precipitate = *Cinchonidia.* No precipitate = *Cinchonia.*	*First portion.* Add $BaCl_2$ A precipitate = *Sulphuric Acid.*	*Second portion.* Add $AgNO_3$ A precipitate soluble in NH_4HO = *Hydrochloric Acid.*	*Third portion.* Boil for a time and then add a few drops to an excess of solution of molybdate of ammonium, and boil. A yellow precipitate = *Phosphoric Acid.*	*First portion.* Add neutral Fe_2Cl_6. A red color indicates acetic or meconic acid. Distinguish Decolorized by boiling = *Acetic Acid.* Not decolorized by boiling *Meconic Acid.*	*Second portion.* If no acetic or meconic acid, add $AgNO_3$. Precipitate (white, with a tendency to darken) soluble in HNO_3 = *Citric Acid.* Confirm by adding $CaCl_2$ to a neutral conc. solution and boiling, when a white precipitate of citrate of calcium separates.	*No colour* = *Socaloin.*	*Crimson colour.* Nataloin or Barbaloin. To another portion add concentrated H_2SO_4 and vapour of N_2O_4. *A blue colour* = Nataloin. *No blue colour* = Barbaloin.

* Strychnia of commerce often gives an orange or red colour, due to contamination with brucia.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE MOLECULE AND THE ATOM.*

BY PROFESSOR G. F. BARKER.

(*Concluded from p.* 866.)

The illustrations of this third law which are given by Berthelot, are numerous and interesting. Considering, in the first place, direct combinations, he shows that while the union of nitrogen dioxide with oxygen to form the trioxide evolves ten calories, its union with oxygen to form the tetroxide evolves seventeen. Hence, the latter is always formed in the presence of an excess of oxygen. Tin in forming stannous oxide evolves 36·9 calories, in forming stannic oxide 72·7; the latter is the body universally formed. Hydrogen sets free in forming water 34·5 calories; but in forming hydrogen dioxide, only 23·5; hence, it is the former which hydrogen gives on burning. In confirmation of this statement is the fact that the formation of the dioxide is attended with an absorption of heat, and hence, that it cannot be produced from water and oxygen without the intervention of foreign energy. On the other hand, the oxides of nitrogen and of chlorine, nitrous chloride, acetylene, and marsh gas are all formed from their elements with the absorption of heat. None of them can be formed by the aid of the energy contained in their elements alone; the assistance of foreign energy is required, electrical in the case of acetylene and marsh gas for example, and in the case of the oxides of chlorine, energy derived from the simultaneous formation of a metallic chloride which evolves heat. Chemical decompositions also furnish many striking illustrations of this law. If the formation of a body which absorbs heat cannot take place without the aid of foreign energy, so a body formed from its elements with the evolution of heat cannot decompose without the aid of foreign energy—either that of heat, light, electricity, chemism, or of physical disaggregation. If the compound has been formed with absorption of heat, however, it is either spontaneously decomposable—like the chlorine oxides and nitrogen chloride—or it is readily susceptible of undergoing changes attended with the evolution of heat—as acetylene, cyanogen, and nitrogen dioxide. In relation to the question of substitution, the law says if a body A, in uniting with a metal produces more heat than another B, then A will displace B. Because chlorine, in uniting with the metals, sets free more heat than bromine or iodine, it displaces these bodies from their metallic combinations. Whenever a metal displaces another from a compound, it is because the production of the new salt corresponds to an increased evolution of heat. The phenomena of double decomposition give rise to some curious applications of the law. Dry hydrochloric acid gas acting on dry mercuric cyanide decomposes it at once, since it evolves 5·3 calories. But in solution, hydrocyanic acid decomposes at once mercuric chloride, since in this reaction 15·5 calories are set free. So silver chloride and hydriodic acid give silver iodide and hydrochloric acid, a total decomposition, whether gaseous or in solution; while silver iodide and chlorine give at once silver chloride and iodine, an apparent reversal of attraction. But, on the one hand, chlorine evolves 15 calories more than iodine in uniting with silver; and on the other, hydriodic acid evolves 31·8 calories liquid, and 51·3 gaseous in acting on silver oxide, hydrochloric acid evolving only 20·6 and 38 calories respectively. We must not, however, extend this portion of our subject to any greater length. Enough has been said to show the controlling agency of thermo-chemical considerations in any theory we may orm of chemism.

It must be confessed, however, that notwithstanding all the assistance which physics has rendered chemistry in helping it to a rational conception of its fundamental attraction, the real underlying essence of this attraction remains as completely hidden as before. But this fact should by no means be considered a discouraging one when we remember that we know absolutely nothing of the cause of any other form of attraction, nor even whether the force resides in the attracting body itself, or is caused by outside agencies, as is now more than suspected. Indeed, the cause of the attraction of gravitation is itself unknown. But two modes of accounting for it, consistent with present ideas, are suggested: the one that it is due to differences of pressure in a substance continously filling all space, the other that it is due to the impact of particles. The latter hypothesis, suggested long ago by Le Sage of Geneva,* has received a large share of attention in recent times. It supposes that the particles of matter are subject to bombardment by an infinite number of still minuter particles which are darting about with inconceivably great velocities. As each material particle screens its fellow on one side from this rain of particles, the final effect is to force them together. It may be easily shown that the result of this action is an apparent attraction which follows exactly the law of gravitation, *i.e.*, varying as the inverse square of the distance, and—admitting the free passage of most of the particles through the matter—being directly as the product of their masses. Chemical and physical attraction are bound up in the same category with the attraction of gravitation; he who succeeds in explaining the one will have found the key to the whole.†

Finally, we have to ask: What is this atom about which we have said so much? Has science any conception of such a thing? This brings us to the most important atomic theory of the day, the theory of vortex-atoms of Helmholtz, as worked out by Thomson.‡ In his investigations upon the laws of fluid motion, Helmholtz§ examined exhaustively the equations of motion of an incompressible frictionless fluid, admitting that this motion could be rotational. He proved that any portions of such a fluid which possess rotation must possess it for ever, and are thus isolated particles; and that these portions must be arranged in filaments whose direction at each point is the axis of rotation, these filaments being endless, or terminating in the free surface of the fluid. Accepting these results, Thomson conceived the hypothesis that what we call matter may consist of the rotating portions of a perfect fluid which continuously fills space. If any portions of such a fluid have this vortex-motion communicated to them, they will retain it for ever, thus constituting what Thomson calls a vortex-atom. Moreover, since the only necessary condition of the existence of a vortex-atom is that the filament should rotate on its axis and should be endless, it is plain that there may be various kinds of such atoms according to the shapes of the vortices.|| The simplest form is a plain ring, like a smoke-ring. But the filament may undergo any number of knottings and twistings, and yet comply with the definition. As nothing short of creative power could annihilate such an atom, so nothing short of this could launch it into existence. Moreover, such an atom would have actually the properties of the metaphysical

* Deux traités de physique mécanique, publiés par Pierre Prévost. Génève et Paris, 1818.

† "If such heterogeneity (that of matter) were only pronounced enough, it appears that the law of gravitation would be capable of accounting for at least the greater number of effects at present attributed to the so-called molecular forces and the course of chemical affinity."—Stewart and Tait, loc. cit., 95.

‡ 'Trans. Roy. Soc. Ed.,' xxv., 217, 1868.

§ Ueber Integrale der hydrodynamischen Gleichungen welche dem Wirbelbewegungen entsprechen. Crelle Ann., 1858; *Phil. Mag.*, 1867, 1.

|| Tait. *Recent Advances*, 294. Since the number of possible forms is almost infinite, the explanation of the existence of only sixty-three elements is difficult.

atom; it cannot be cut, from its very nature. This marvellous hypothesis is as yet, of course, only a matter of speculation. Much more work must be done upon it before it can even be accepted as probable. But it is not too much to say of it now that it explains most satisfactorily many vexed problems in molecular and atomic science.

It only remains for me now, after this lengthy discussion, to ask what are the bearings of the facts and of the generalizations from them, which have now been stated, upon chemical science? What is the conception which we should now hold of the atom, and of the various changes in which it may perform a part? In the first place, it seems to be clear that, in the opinion of modern science, the atom has a real existence; that there is a fixed portion of matter, definite for each element, which is the smallest quantity of it capable of taking part in a chemical change. If this be true, then the restiveness shown in certain directions in using the word atom, and the attempts made to substitute some other idea for it, are entirely needless.

In the second place, it is evident that our equations representing chemical changes need to be more significant, by including in them the changes of energy involved.* The equations of Stahl, of phlogistic memory, did this. Thus the (metallic calx+phlogiston)=metallic calx+heat. This Lavoisier translated thus: metal+(oxygen+heat)=metallic oxide+free heat. To-day we should say: (metal+m units of energy)+(oxygen +n units of energy)=(metallic oxide+p units of energy)+(exterior energy represented by $m+n-p$ units). The power of prediction in chemistry, the power which characterizes an exact science, appears to lie in a clear comprehension of the transformations of energy which take place during chemical action.

Again, the real existence of atoms occupying space forbids the assumption too often based upon our present system of graphic formulas—but unfairly, as it seems to me—that the atoms in a molecule all lie in one plane; and thus gives rise to a chemistry of three dimensions. This idea was distinctly expressed by Kekulé in 1866, in his Lehrbuch,† where he gives perspective views of the constitution of the benzene atom. And in Clarke's paper, already referred to, the conditions under which solid molecules are possible are satisfactorily discussed. I by no means wish to imply that graphic formulas are useless. I would have the idea clearly held that they only express the mode in which the atoms are combined with each other, considered statically, and not the manner of their arrangement in space.

Lastly, the fact is clearly before us that the atoms are not at rest within the molecule, and therefore that they cannot occupy positions fixed in space. We have seen that it is the belief of eminent authority that they even exchange molecules in their rapid motion; moreover, this conception of atomic motion is strengthened by the fact observed by Hofmann,‡ that one isomeric form of an aromatic monamine may be converted into another by what he calls a wandering of the atoms within the molecule. Indeed, so obvious is this atomic motion, and so necessary is it to take account of it in chemical theory, that Kekulé has founded upon it his explanation of equivalence.§ According to him, the equivalence of any atom is the relative number of impacts which it receives from other atoms in a unit of time. The view of Michaelis is analogous to this.|| He supposes that during the vibration of the atom it attains certain positions, at each of which it is capable of exercising chemical action upon other atoms. The number of such positions constitutes the equivalence of the atom. If we suppose the total force unequally distributed, the atom will exert different amounts in its different positions, thus accounting for variable equivalence. And if the total force has no fixed ratio to the number of positions, the fact is accounted for that there is no necessary relation between chemism and equivalence.

The task which I have allotted to myself is now accomplished. I have attempted to set before you, as clearly as I was able, the conception which the science of to-day holds concerning the molecule and the atom. If I have contributed, in doing this, to make more precise the ideas which are commonly held upon this subject, I shall feel that an essential service has been rendered to a science which more than any other calls to its aid creative energy, and produces continually new forms of matter to astonish and delight mankind.

Parliamentary and Law Proceedings.

Poisoning by Laudanum.

On Monday an inquest was held at Portsmouth on the body of Fleet-Surgeon Dyas, of the *Warrior*, who was found in an insensible condition on board that ship, and died in a short time. The evidence showed that the deceased had suffered from rheumatism, but had otherwise enjoyed good health. He had been in the habit of taking tincture of opium as a sedative every night, and had also been in the habit of lying down after luncheon on a couch in the sick bay, which was in the dispensary. At ten o'clock on Saturday morning he went in to lie down, this being the first time he had done so in the morning, and at half-past one, as a man had to be examined, the door, being locked, was forced, and deceased was found lying on the couch. A glass was on the table in which were a few drops of laudanum.

Surgeon Collett, of the *Repulse*, said he was called, and found deceased perfectly insensible, with symptoms showing that he had taken a poisonous dose of opium. The stomach-pump was used, and deceased rallied for a short time, but soon collapsed. Remedies were applied, but deceased sank, and died at five o'clock. The cause of death was a poisonous dose of tincture of opium, commonly called laudanum.

Paymaster Penfold, of the *Warrior*, said he had cautioned deceased against taking opium, and he had promised not to do so.

The jury found that deceased died from an overdose of tincture of opium, but whether taken accidentally or otherwise there was no evidence to show.

Suicide of a Chemist and Druggist.

Last week Mr. Carter held an inquiry, at the Hope Tavern, Bird Street, Newington, into the circumstances attending the death of Mr. John Middleton, aged 36, a dispensing chemist, carrying on business at 6, Bird Street, who was found lying dead on the threshold of his premises by his wife on Tuesday morning.

From the evidence of Mrs. Elizabeth Middleton, it appeared that the deceased had been very much depressed of late through reading in the public and medical journals certain articles which had for their tendency an interference with the interests of chemists generally, and this much preyed upon his mind, as he had an apprehension that his trade would be taken from him. He had great fear that certain authorities would, to use his own words, "come down upon him." He was a remakably steady man. The deceased had two children, and said he was afraid lest his business might be interfered with. Witness sat up with him all night, though he wished her to retire to rest, but she sat up with him, because he appeared so strange, and it made her very nervous. Previously to this he had been under medical treatment. She had been advised to go to the authorities of Bedlam

Hospital, and he was to have been removed to that institution on the morning that he died. From the medical evidence there appeared to be no doubt that he died from the effects of prussic acid, and the jury returned a verdict of "Suicide while in an unsound state of mind."

Notes and Queries.

[547.] BLEACHING OF FERNS.—F. S. SEYMOUR WIMBORNE will be glad if any one will inform him how he may bleach ferns, without injuring the veins, causing them to have a whitish or transparent appearance.

[548]. MANGANESE BATTERY.—What is the composition of the plates, and how are they made, in the battery known as a Manganese Battery?—B. M. S.

Obituary.

JOSEPH-BIENAIME CAVENTOU.

In Joseph-Bienaimé Caventou, Honorary Professor in the Paris School of Pharmacy, who died a few days since in Paris, has passed away one whose name is indissolubly connected with the history of chemistry, especially in its relations to pharmacy. For the following sketch of his career we are indebted to *Le Mouvement medical.*

Joseph-Bienaimé Caventou was still an *interne* at the Pitié, when, in 1816, a note upon the properties of the narcissus drew towards him the attention of the scientific world. It was the first step in a road along which he advanced rapidly from success to success. In a short time, in fact, either alone, or with his colleague, Pelletier, he isolated a long series of alkaloids and active principles, with which his name will remain always associated. Veratrine was the first, in 1818, then, in 1820, quinine, the discovery of which alone would be sufficient to make a man famous; a little while afterwards, strychnine and brucine, and lastly, not to mention others, cafeine.

About the same time, Caventou demonstrated the existence of a special substance, chlorophyll, in the green parts of plants.

Such services claimed exceptional acknowledgment, and this explains the admission of Caventou to the Academy of Medicine, at its institution in 1823, although then scarcely twenty-seven years of age. When he died he was Dean of the Academy, and had had the satisfaction of seeing his son and his son-in-law take their seats by his side.

Entrusted in 1826 with the course of toxicology in the School of Pharmacy, he continued to act as Professor during thirty years with great success. In 1858, from a sentiment of exaggerated modesty, the eminent chemist imagined that the methods which he had instituted, and of which he had made such brilliant applications, were no longer *en rapport* with the progress recently realized; he desired to leave to younger men the care of continuing the teaching, and, still full of vigour and intelligence, he descended from his chair in spite of the representations of his colleagues and pupils.

Caventou's modesty became still more manifest after twenty years of retirement, and down to the time of his death. In accordance with his last wishes, no military honours were rendered to him, and no discourse was pronounced over his tomb. He could not, however, prevent those who had known and loved him from attending his obsequies, which took place on the 7th of May, in the church of Saint-Roch, in the midst of an immense concourse of relatives and friends. All the members of the Academy of Medicine and the Superior School of Pharmacie, headed by the Director, were there to render a last and solemn homage to this man, whom French science may claim as one of its most worthy representatives, and humanity can honour as one of its benefactors.

Notice has been received of the death of the following:—

On the 15th of April, 1877, Mr. Thomson Brown, Pharmaceutical Chemist, Trongate, Glasgow. Aged 48 years. Mr. Brown had been a Member of the Pharmaceutical Society since 1853.

On the 7th of May, 1877, Mr. Archibald James Herron, Chemist and Druggist, Margate. Aged 35 years. Mr. Herron had been an Associate of the Pharmaceutical Society since 1870.

On the 17th of May, 1877, Mr. Charles Miller Brown, Chemist and Druggist, Witney, Oxon. Aged 45 years.

On the 23rd of May, 1877, Mr. Henry Fairbairn, Chemist and Druggist, Alnwick. Aged 73 years.

Correspondence.

ELECTION OF COUNCIL.

Sir,—I perfectly agree with your correspondent R. H., that Mr. Greenish did well in calling attention to the small number of voting papers returned by members at the election of Council, but not entirely in his conclusion that an expression of the views of candidates on pharmaceutical politics would of itself secure a better result.

I think those who have taken an interest in these elections for any length of time are pretty unanimous in their conviction that at present little less than a panic on some vital question will arouse our brethren to anything like real action. That this apathetic indifference, together with the ultra-conservative principle of "leaving things as they are," might be largely removed were the Council to adopt means of drawing out the personal interest of the trade in matters directly relating to themselves, I feel satisfied, and that such would react again to the untold benefit of the Council and the Society I am equally convinced.

Hoping that the expressions of feelings at the last Annual Meeting may awaken the Council to more activity, I venture to throw out a few suggestions, which possibly may be considered worth a passing notice, as tending to produce a greater amount of interest among our friends in the general doings of the Society.

First and foremost I would say, let the report of Council meetings be more fully recorded than hitherto. There was a time when no report whatever was given; that barrier was ultimately broken down, thanks I believe to Mr. Hampson, but a still further advance is needed, by the admission of independent reporters from recognized organs of pharmaceutical lore, so that those journals may have the privilege of receiving their information without its first passing through official sieves. Again, the names of those voting on divisions at Council meetings were for a time, after the admission of the reporter, given monthly, but of late these records of actual fruit have become "finer by degrees and beautifully less," so that our knowledge of the representative qualities of our Council is reduced to comparatively nil. The admission of independent reporters would at once put aside this silence.

In reference to the election of Council, I would say, omit altogether that significant star affixed to the names of old councillors, by which an undue preference is inferred, and too often accepted by members, who instinctively erase all names against which such prefix is unseen. The result being that the same gentlemen, with rare exceptions, are elected year after year, perfectly regardless of personal merit, and unless an actual vacancy occurs through the retirement of a member, it is next to impossible to introduce new blood into the executive. In place of this official recognition I would suggest that together with the voting papers, an analysis of the actual work of the preceding year should be issued, showing the attendance of each member at the Council meetings, and also on committees. Members would then have before them distinct evidence of the active services of their representatives, which, together with the monthly reports, would enable them to judge pretty accurately as to their personal merits, and thus lead them to use their own judgment in giving their vote.

With regard to new candidates, the plan recently adopted by some of issuing an address is most desirable, in addition to which, the recommendation of provincial associations might profitably and legitimately be brought to bear in favour of representatives of known experience. The Council would by these means become increasingly a really representative body.

If some of our more active friends upon the Council would take up these and other suggestions, and persevere in them until they succeed, they would receive the hearty sympathy and approval of the trade.

May, 28, 1877. "OBSERVER."

COUNTER PRESCRIBING.

Sir,—To prohibit entirely the right, now threatened, of druggists prescribing at the counter, would have such a calamitous effect on the interests of many, that I for one regret exceedingly that the Council were not willing to undertake the defence of the case now pending. With co-operative stores, in almost every large town in the kingdom, selling every article considered to belong to a druggist's business, at little more than nominal profits,—with some selfish member of the trade in most of such towns acting similarly, seldom or never to his own aggrandisement, but greatly to the injury of those who decline to retaliate and so consummate the ruin of all, and with hucksters' and other shops supplying well nigh every drug and chemical in general requisition,—with all these enemies to their welfare to contend against, which did not exist in days of yore, if the right and privilege of counter prescribing, which they have enjoyed from time immemorial, were to be taken from them, one half the druggists who now manage to pay twenty shillings in the pound would cease to obtain a livelihood.

This is a matter not only of vital importance to the great majority of druggists, but of extreme importance to the great majority of the public, interference with whose rights and liberties it threatens. Poor people who have hitherto been accustomed when they or any of their children may be slightly ailing to obtain from some druggist in whom they have confidence the medicine needed, for perhaps a shilling or even a few pence, would be prevented from obtaining any, as they would be quite unable to pay the charges of a "doctor." Respectable practitioners too, throughout the length and breadth of the land, will be far from desiring the prohibition sought for. Imagine application being made to them in every case where "sixpenny worth of something for a cough" is required, or "something for worms" desired, when a like liberal outlay is the *maximum* expenditure meditated.

Again, in case of sudden illness, when possibly every "doctor" in the neighbourhood may be absent visiting his patients, and not expected home for some hours, what a boon it often is to the public to have an intelligent druggist to whom to have recourse. Suppose a case of colic or spasms or syncope suddenly occurring under such circumstances, is a druggist to tell any one so suffering, applying to him for relief, "I dare not prescribe for you but possibly the publican who keeps the neighbouring gin ship will"? The druggist is content to know that he possesses no *legal* qualification to prescribe, and therefore cannot sue for a debt incurred under such circumstances. But to interfere with the liberty of the public, and prevent them from obtaining from any druggist whom they desire to supply them, such remedies as the druggist deems they require, is an act of tyranny well nigh inconceivable—and more inconceivable, when it is considered that the education of druggists nowadays to fit them for such vocation is far in advance of that which obtained twenty years since. Nowadays there is scarcely one druggist in one hundred who is not too intelligent to prescribe himself the heterogeneous and incompatible mixtures which ever and anon he is called upon to dispense, ordered perhaps by a physician considered "one of the leading men of the day!" Striplings may occupy the twofold position of groom and dispenser to a surgeon, without the concurrence or even the cognizance of the patients who swallow the physic prepared by their skilful and careful hands, but my neighbour may not procure from me a bottle of medicine for his bilious attack, though I be willing to supply him, and he anxious to procure it from me. The thing is as I have said, monstrous. Again, any ignorant old woman may, by sticking a three-halfpenny government stamp on the bottle, distribute far and wide articles scheduled as poisons with impunity. I think the Chemists and Druggists' Trade Protection Society are much to be thanked for defending the case in question, and although I do not approve of their every act, I am of opinion that in this matter they merit the support of every druggist in the kingdom, and that on the strength of it each one should contribute a guinea to their funds.

ROBERT CHIPPERFIELD.

THE MEANING OF THE WORD "DISPENSE."

Sir,—As you have inserted two letters on "the meaning of the word 'dispense,'" perhaps you will not object to a third; though it seems almost absurd to write about the meaning of a word which every one ought to know. Of course the word "dispense" means to "administer," but what does administer mean? According to Webster, whose dictionary is made the standard of post office telegraphy, the word administer means to "afford, give, or furnish; as, to administer relief. Syn.: to manage; conduct; minister: supply; dispense; contribute." Consequently, counter prescribing is legal, and I do not think that it has ever been pronounced otherwise by any authority in the kingdom. But if Dr. Lush's Bill should become law, counter prescribing will be no longer legal. Why? Because the word "practise" in the said Bill means to "use medical methods or experiments," and as the Bill does not make a distinction between practice in a small way behind one's counter and the going out of one's shop to practise, we shall cease to be acting legally when we administer a "pick-me-up," or dose for a "belly-ache;" nor shall we be able to "strap up" a cut finger or attend an accident which has occurred in the street, nor extract a tooth, nor even apply a drop of laudanum, etc., to a painful nerve. All such acts will be unlawful!

It was well known when the Act of 1815 passed that chemists prescribed over the counter, and the word "dispensing" in that Act was, no doubt, put in to show that counter prescribing might be continued. For if counter prescribing was not intended why use the word at all, since in the same sentence occurs the word "preparing," which has reference to preparing physicians' prescriptions; and the word "dispensing" also occurs therein to allow the continuance of an immemorial custom of chemists to administer, to give, and to afford relief over the counter?

No additional Act of Parliament is necessary to define the duties of chemists and druggists, and if the words "or who shall practise medicine or surgery for gain," in Dr. Lush's Bill, be omitted, neither chemists nor the public, in my opinion, could object to the Bill becoming law. That simple omission would meet the whole case, and at the same time would not interfere with the rest of the Bill or its objects.

Dr. Lush's Bill must not pass in its present form.

GEORGE P. POND.

CHEMISTS' ASSISTANTS' ASSOCIATION.

Sir,—It has long been thought necessary that there should be something more sociable than the scientific meetings at the Square to promote good fellowship between chemists' assistants, and though much has been written and many suggestions offered I believe that it is only lately that a determined attempt to put them in actual practice has begun. The advantages of such an association are too obvious to need any comment, but I may suggest that the first and foremost place in the discussions that will result from its formation ought to be given to the subject of early closing. I suppose chemists must consider themselves as being public servants, but still let there be a limit to such servancy, and let those chemists who live in the West End, and can afford to lose a few small customers, initiate the movement. At the meeting held a few weeks ago in the lecture theatre there seemed a pretty general disposition amongst those present to endeavour to curtail the long hours of business; let us hope that we may hear some good come of the talk that took place.

Anent the Assistants' Association, I was sorry to observe a tendency on the part of some members of the trade to throw cold water on the scheme and to regard it in the light of a trade union. Now I do not see anything to justify that feeling, and should very deeply deplore a circumstance which I hope is improbable. With unanimity I think that the movement cannot fail to be successful, and I earnestly ask all those who have advocated the formation of an association to work hand-in-hand to secure the desired end.

Plumstead, Kent, May 26, 1877. AN ASSOCIATE.

THE SALE OF THE METHYLATED SPIRIT.

Sir,—In the Journal of November 25, 1876, a case is reported in which a dealer was fined for selling methylated spirit, which was afterwards used as a beverage. Wishing to know what retailers were liable to, I wrote to the Inland Revenue Office, and, after repeated applications, obtained the following answer to my questions, which is so curious that I think it may be well for retailers to be made acquainted with it.

The questions asked were:

1. Can methylated spirit be sold for any purpose apart from manufactures, or be used for domestic purposes?

2. Is a retail dealer required to ascertain what purpose methylated spirit is required for before selling?

H. GOODALL.

"Inland Revenue Office,
"Somerset House, London.
"January 20, 1877.

"Sir,—In reply to your communication, dated the 12th instant, I am directed by the Commissioners of Inland Revenue to inform you that,

"1. You can legally sell methylated spirit to be used for burning in lamps and for purposes not connected with manufacture.

"2. The law does not expressly bind you to know what purpose it is for before selling it, but if you sell methylated spirit and if it is afterwards used as a beverage you are thereby rendered liable to the penalty of £100, imposed by the Act 24 and 25 Vic., cap. 91, sec. 6, upon any person who 'shall sell any such spirit as and for a beverage.'

"WILLIAM ROSSETTI,
"*Assistant Secretary.*"

THE COPYING OF PRESCRIPTIONS.

Sir,—The now universal custom of copying prescriptions is felt by many chemists to be a vexatious expenditure of time. Just permit me, Mr. Editor, one or two remarks on the subject, in order to suggest how the evil may be remedied.

If prescriptions are to continue to be copied into books, as at present, it is absolutely necessary that some abbreviated method of copying be resorted to. If all were acquainted with phonetic shorthand we would have a ready means of economizing our labours, but the use of that system is in the meantime impracticable, since nine out of every ten are ignorant of it. Moreover, when the number of medico-pharmaceutical words is so very limited, it may be questioned whether it would be the best system to employ for the purpose. It would be very easy to invent a number of simple and appropriate signs representing prescription-language, which would economize time in a considerably greater degree than even phonetic shorthand.

But why should we copy our prescriptions at all? All the benefits arising from copying (which are neither numerous nor important) could be obtained in several ways in a much easier manner. What, for example, is to prevent chemists keeping the original prescriptions, numbering and filing them so as to be ready for immediate reference when required. This may not be the best conceivable system, but I venture to say it would be vastly preferable to that now in operation, even if for no other reason than that it would effect a saving of time in prescription-dispensing by nearly one-half. I hope pharmacists will take this subject into consideration.

And, by the bye, another source of lost time to chemists is the illegible manner in which prescriptions are frequently written; and if it be really an impossible thing for the busy practitioner to write in a human fashion, might not the medical profession, at the request of pharmacists, be induced to adopt some uniform style of penmanship, resembling, perhaps, the "engrossing hand" of lawyers? Clearness is doubtless an essential requisite of legal documents, but it is at least equally important that prescriptions should be written in a readily-read and unambiguous manner. R. HALDON.

AVOIRDUPOIS WEIGHTS AND FLUID MEASURES.

Sir,—In your next impression will you allow me space for a few remarks on the mode adopted by Mr. Squire in his 'Companion to the British Pharmacopœia' in expressing formulæ for preparations.

Throughout Mr. Squire's popular work the proportions of ingredients prescribed for pharmaceutical and other compounds are given in parts.

For example page 205, 10th edition, we read—

Ext. Opii 1; S. V. R. 16; Water 4.

In dispensing above it is customary to translate the parts as pounds, ounces, or drachms, as most convenient or required, and some dispensers I find, requiring a few ounces only of this preparation, weigh of the extract of opium one drachm (60 grains), and measure sixteen and four fluid drachms of the two other ingredients respectively, and thus commit an error, amounting to an excess of 5½ grains of opium extract.

This method of arranging formulæ, whilst being somewhat convenient, is, as I have endeavoured to point out, not without danger, and until we have a more perfect system of weights and measures should, I think, be discontinued, or accompanied with a few words of caution.

Newcastle-on-Tyne. JOSEPH ROBERTS.

Sir,—The enclosed has been sent me, and under the impression it is the same Mr. Fitch who spoke at the Annual Meeting, I enclose it to you, seeking to know if it be so, and whether his doctrine is like that animating some of our divines, Do as I say, not as I do.

BYAN WALKER.

26, *Clapham Road, May* 30, 1876.

Sir,—At the Annual Meeting of the Society there were many members who listened to the remarks of Mr. Fitch, of Hackney, with great attention, and thought, in him we have indeed a champion to fight co-operative societies and underselling chemists. Some unknown malicious person—no doubt connected with stores—has, I fear, perpetrated a cruel joke, by sending to me the enclosed handbill,* and a statement likewise that all drugs are sold at equally low prices, and refers me to the page of the Journal where Mr. Fitch's remarks appear. I can only look upon the matter as a shameful hoax and imposition.

May 29, 1877. JOHN WADE.

[*** We have received two other letters on this subject, but as it is to some extent a personal matter, and the writers do not sign their names, we think it will be sufficient to say that they are of the same purport as the foregoing.—ED. PHARM. JOURN.]

G. Dove.—(1) *Helleborus viridis.* (2) *Silene inflata.* (3) Apply to the Secretary for a copy of the Regulations.

"*Hexad.*"—Read the article on atomicity in Watts's 'Dictionary' or Fownes's 'Chemistry.'

W. M. Bates.—No doubt prescriptions are sometimes written that manifest a deficient knowledge of the chemical relations of the several ingredients, but we fail to see that this has any bearing upon the subject of counter practice.

"*Vincere.*"—(1) *Cardamine hirsuta.* (2) *Veronica serpyllifolia.* (3) *Cerastium glomeratum.* (4) *Sagina procumbens.*

"*Syrupus.*"—(1 *and* 2) *Weissia controversa.* (3) *Ceratodon purpureus.* (4) *Tortula vinealis.*

The Pharmaceutical Society and the Organization of the Chemical Profession.—We have received from Mr. Luff a letter in reference to this subject, but since his remarks are based on a misapprehension of the position of the Pharmaceutical Society we do not think its publication desirable.

Castor Oil Emulsion.—See before, p. 835. Also vol. v., p. 314.

Errata.—In the list of Donations to the Benevolent Fund published last week, for "Butler, Edward T.," *read* "Butler, Edmund T."; also in the address of Messrs. Silverlock, for 96, Blackfriars Road *read* 92.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Richardson, Mr. Pollard, Mr. Wilson, Mr Jackson, Mr. Patterson, Messrs. Newbery, Mr. Wilson, Mr. Churchill, Mr. Twelton, Justitia, Caryoph.

* This handbill is headed "Cooperative Stores and competition defied!!!" and it offers patent medicines at discount prices.

NOTES ON SOME OF THE PHARMACEUTICAL PRODUCTS EXHIBITED IN THE PHILADELPHIA EXHIBITION OF 1876.

BY JOHN R. JACKSON.

At the monster gathering at Philadelphia last year medicinal products seem to have been fairly represented, indeed in some individual countries they appear to have been made a special feature. From the catalogues of the Venezuelan and Mexican departments we may gather a fairly good notion of the extent of the pharmaceutical exhibits of these two countries. Taking those of Venezuela first, we find many that are not only well known, but that are also included in our own Pharmacopœia. Among such is the castor oil from the seeds of *Ricinus communis*, which, however, though one of the most common plants in Venezuela, does not supply the oil for medicinal use in the country, the preparation of it being too expensive; consequently the demand is furnished from Europe. Other well-known products are quassia wood (*Quassia amara*), the purgative pods of *Cassia fistula*, ginger (*Zingiber officinale*), turmeric (*Curcuma longa*), both of which are cultivated, the purgative oil of *Jatropha curcas*, and several others Of less known plants may be mentioned the Guacima, *Guazuma tomentosa*, H.B.K., and *G. ulmifolia*, Lam., the barks of which are mucilaginous and refreshing. Nutritive properties have been ascribed to the mucilage which abounds equally in the leaves and bark of the former species. It is readily extracted by water and has been used as a substitute for gelatine or albumen in clarifying sugar; an infusion of the bark has also been administered internally as a remedy in cutaneous diseases. Two or three species of *Aristolochia* are considered aromatic and antispasmodic. *A. barbata* is known as the Raiz de Mato, the latter name being that of a large lizard, and derived, it is said, from the popular belief that this reptile eats the roots after having been bitten by a venomous snake. *A. maxima*, Jacq., is known by the name of "Bejues de Santa Maria," and like the other species is used as an aromatic and antispasmodic. Chica, the red pigment prepared by the Indians of the Orinoco from the leaves of *Bignonia Chica*, H.B.K., has the reputation of being a remedy in erysipelas. To extract this pigment the leaves of the plant are left to macerate for some time, when the colouring matter separates and settles at the bottom of the vessels and is afterwards collected, dried, and formed into balls or cakes. Cola nuts, under the name of "Papas de Cola" (*Cola acuminata*, R. Br.), are cultivated, but are not common; the seeds are used in liver complaints. One of the most popular medicines for purifying the blood is known as the escorzonera (*Craniolaria annua*, L). The root is the part used in a dry state in medicine, and when fresh and fleshy it is sometimes preserved in sugar and eaten as a delicacy. From the seeds of *Mucuna pruriens*, which is known locally as the "Ojo de Zamuro," or eye of carrion vulture, an alcoholic extract is prepared which is reputed to be a remedy for asthma. The seeds of the tonquin bean (*Dipteryx odorata*) are included in these pharmaceutical products of Venezuela. In 1872–3, some 66,663 kilograms were exported from Ciudad Bolivar.

Leaving the Venezuelan collection and turning to that of Mexico, we find a very interesting series of chemical and pharmaceutical products. Amongst chemical products are first pipitzahoic acid and pipitzahuina, the extracts of a composite plant variously stated by different writers as *Perezia fruticosa*, *Acourtia rigida*, *Dumerilia Alamani*, and in the Mexican catalogue as *Trixis pipitzahoac*. The organic compounds extracted from this plant are described as interesting, not only because of their novelty but of their prospects of future usefulness. Pipitzahoic acid is of a "brilliant golden colour, and of a soft silky texture being contained either in an amorphous state or crystallized in small prisms and laminæ." At present, pipitzahoic acid is employed in medicine as a drastic purgative, and it can be used as a colouring matter. A fine sample of this substance, together with roots, foliage and flowers, is contained in the Kew museum. Its price in Mexico is 11 cents. a gram. Pipitzahuina is described as being white, fusible, and volatile at over 100° C.; when treated by sublimation it crystallizes in prismatic needles and when obtained by evaporation the crystals assume the laminar form. It is soluble in ether and chloroform, but insoluble in water. A substance known as Tebetosa or Tevetosin, which crystallizes in four-sided prisms, is inodorous, and very sour to the taste, likewise insoluble in water, but soluble in alcohol. It is a new product and is referred to hereafter under the order Apocynaceæ. In the section "medicine," a classified list of medicinal products of vegetable origin is given, sent by the Society of Natural History, and amongst which it is said there are specimens of great therapeutical interest. As comparatively few readers of the *Pharmaceutical Journal* will have had the opportunity of seeing this collection at Philadelphia, and as the circulation of the catalogue itself will necessarily be somewhat limited, a brief summary of the description of these products will no doubt prove interesting, more especially as comparatively little is really known about Mexican products. The arrangement in the catalogue is on a scientific basis, the plants being classified under each order, commencing with the cryptogams and ending with the magnoliaceæ. In many instances, most egregious mistakes occur in the spelling of the order, genera, species, or description of the plant and its uses. It will, we think, be more convenient for the readers of the Journal if we classify the products under the natural order as they occur in the 'Genera Plantarum,' so far as that work at present goes; the arrangement there adopted being that now most generally acknowledged. Reversing, then, the order of arrangement in the catalogue and commencing with—

MAGNOLIACEÆ.

Magnolia mexicana is the only plant mentioned. It is described as growing in the State of Morelos, and the flowers as containing "essential oil, green resin, quercitrine, tannin, extractive and salts." The infusion of the flowers is used as an antispasmodic, and the tincture as a tonic.

MALVACEÆ.

Malva angustifolia, Cav., "Yerba del Negro." Table land. Leaves and roots emollient.

ZYGOPHYLLEÆ.

Zygophyllum fabago, L. "Gobernadora." Leaves used in bathing to cure arthritic pains.

RUTACEÆ.

Zanthoxylum pentanome, D.C., "Palo mulato."

Valley of Mexico; wood and bark used as stimulant and tonic.

AMPELIDEÆ.

Cissus tiliacea, H. B. K. "Tripa de Judas." Table land. Decoction used in rheumatism.

ANACARDIACEÆ.

Amyris lignaloe, "Linaloe." Used chiefly as a perfume, which is extracted from the wood. This perfume was introduced into the English perfumery trade some few years since, and the wood was then said to be a species of *Bursera*. We can find no authenticity for the specific name *lignaloe*.

Schinus molle, L. Peru and Chili. This is a plant of some interest, both medicinally and botanically; medicinally on account of the uses of the roots and of the resin which is astringent. In Chili a kind of wine is prepared from the fruits, and the small twigs are used as toothpicks. The botanical interest is thus described in the *Botanical Register*. "The leaves of some of the species are so filled with a resinous fluid that the least degree of unusual repletion of the tissue causes it to be discharged; thus some of them fill the air with fragrance after rain, and *S. molle*, and some others expel their resin with such violence when immersed in water as to have the appearance of spontaneous motion in consequence of the recoil."

(*To be continued.*)

CRITICAL NOTES ON MUSCARINE, AND SOME ALLIED BASES.

BY CHARLES T. KINGZETT, F.C.S.

In a recent issue (p. 774) there appeared in this Journal an abstract of a paper by O. Schmiedeberg and E. Harnack,* on 'Muscarine,' a base which from its apparent connection with other bases of animal and vegetable origin, is possessed of much interest not only to the chemist, but to the physiologist. The authors of the paper in question appear, nevertheless, to entertain some erratic ideas regarding some of these bases and their sources. To render the subject clear it will be requisite to give some historical account of these nitrogenous substances.

O. Liebreich,† in his study of some brain principles, obtained by boiling them with baryta water a base soluble in alcohol, which he did not examine in any minuteness. But Diakonow‡ in a similar investigation, conducted on the same principles, examined this nitrogenous base more in detail, and gave to it the formula $C_5H_{15}NO_2$. He viewed it as *neurine*, or trimethyl-oxaethylammonium-hydroxide. Strecker§ obtained a like base by the decomposition of lecithine from eggs, with boiling baryta water. So far as the lecithine is concerned, it is sufficient for the present purpose to note here its identity with the lecithine prepared from brain matter. It should, however, be further stated that brain lecithine is one of a number of phosphorized principles built on a common type, and existing in the brains of men and oxen. None of these phosphorized principles are derived from albumin, nor have they any characters in common with that substance; they are conjugated compounds, which may be viewed as derived from glycerine by the replacement of hydroxyls by fatty acid radicles on the one hand, and by phosphoryl on the other hand: the phosphoryl, in its turn, has one hydroxyl replaced by an ammonium base, and that base is the one of which we have been treating. From all the phosphorized principles it is the same base which is obtained as a main product, but under certain conditions other bases may be obtained which exhibit a close relation to the main one, and which are probably by-products from a secondary decomposition of it.

The exact formula for this base is not absolutely established. We have seen that Diakonow and Strecker both regard it as $C_5H_{15}NO_2$, but in Thudichum's researches, with which the writer was associated for some years, the base obtained could scarcely be viewed as possessing such a composition. From kephaline, lecithine and certain forms of myeline there was obtained a base identical in all instances if judged by the empirical formula of its hydrochloride platinic chloride combination, which on analysis invariably gave figures corresponding to the formula $2(C_5H_{13}NO)\,2HCl.PtCl_4$; it should however be observed that different crystalline forms of the salt were obtained.

Writing of this compound Thudichum says,* "the formula of $C_5H_{15}NO_2$ is rather presumed than proved as regards the exact quantity of the hydrogen and oxygen, for if the HCl were like the $PtCl_4$ merely an addition, then the formula of the free base would be $C_5H_{13}NO$; but if the chloride were a product by substitution of hydroxyl by Cl, and expulsion of the hydroxyl as H_2O, then the larger formula for the free body would be correct."

In my opinion there is not the least reason for such a gratuitous assumption which the formula $C_5H_{15}NO_2$ necessitates according to the above observations. The base from brain sources has undoubtedly a formula of $C_5H_{13}NO$, although of course it is just possible that as a hydrate it would have the composition $C_5H_{13}NO.H_2O$.

The secondary by-products obtained in the above researches gave combinations which had the formula $2(C_2H_7NO)\,2HCl.PtCl_4$ and $C_5H_{14}N_2O.HCl.PtCl_4$. Viewing for the moment the main base as trimethyl-oxaethylammonium, then perhaps the first of these secondary substances may be regarded as oxethylamine,

$$\left.\begin{matrix}C_2H_5O\\H\\H\end{matrix}\right\}N\text{, or as dimethylamine hydroxide, }\left.\begin{matrix}CH_3\\CH_3\\HO\end{matrix}\right\}N$$

The relation of the other secondary product to the main base is not so clearly perceptible.

These lengthened observations are necessary in order to show that Schmiedeberg and Harnack are in error when they write of "lecithine from albumin." Lecithine may be obtained from many sources, including the brain, bile, eggs, the roe of certain fishes etc.; it is in no instance derived from the albumin, but constitutes in itself a principle, which on decomposition with baryta water splits up into glycerophosphoric acid, oleic and margaric acids, and a nitrogenous base.

Strecker gave the formula $C_{42}H_{84}NPO_9$ to egg lecithine, and showed its decomposition with baryta water, by the following equation:

$$C_{42}H_{84}NPO_9+3H_2O= \\ C_3H_9PO_6+C_{18}H_{34}O_2+C_{16}H_{32}O_2+C_5H_{15}NO_2$$

* *Archiv fur Experimentelle Pathologie u. Pharmakologie*, vol. vi. p. 101.
† *Ann. Chem.*, 134, 29.
‡ *Centr. bl.* No. 1, 1868, and *Centr. bl.* No. 7, 1868.
§ *Sitz. Ber. d. Acad. d. W. München*, 1869, 2, 269.

* *Rep. Med. Off.*, etc., New Series, No. VIII., p. 127.

Baeyer* produced this nitrogenized base, which is generally named choline by Liebreich's process, and purified it by combination with phosphowolframic acid and decomposition of the precipitate with baryta water. The free base thus obtained he converted into hydrochlorate, and from this he made the platinic chloride combinations. In his analyses of various preparations he obtained discordant results, which indicated the existence of the following three compounds:

(a) $2(C_5H_{13}N)2(HCl)PtCl_4$
(b) $2(C_5H_{11}N)2(HCl)PtCl_4$
(c) $2(C_5H_{13}NO)2(HCl)PtCl_4$

By heating in a sealed tube to 120—150°C. during some hours, a mixture of concentrated solution of the base, obtained as described, with concentrated hydriodic acid and phosphorus, Baeyer obtained large colourless prismatic crystals of the formula $(C_5H_{13}N)I_2$, from which, freshly precipitated chloride of silver removed one atom of iodine and gave up a chlorine in its place, thus furnishing a substance which combined with platinic chloride had the formula, $2((C_5H_{13}N)ICl)PtCl_4$.

When digested in the warm with silver oxide, the iodide lost both iodines, and yielded a base which when converted into hydrochlorate, and this combined with platinic chloride, etc., had the constant empiric composition, $C_{10}H_{24}N_2O2HClPtCl_4$. It is difficult to draw conclusions of a satisfactory nature from Baeyer's researches in this matter. In the first place he obtained from brain principles a mixture of allied bases, and among them the principal one which all other investigators before and since have obtained, and proceeding further he obtained bodies having here and there evident relations, which however disappear equally often.

To pass on to A. W. Hofmann's researches. He obtained a substance of the composition $(C_5H_{13}N)Br_2$ by treating an aqueous or alcoholic solution of trimethylamine with ethylene bromide; the product gave up to nitrate of silver one bromine, leaving a substance which, combined with platinic chloride, had the formula $2(C_5H_{13}N)Br_2Cl_2,PtCl_4$. Both bromines are removable by oxide of silver. Now from the compound which Baeyer obtained viz. $(C_5H_{13}N)I_2$, which is probably trimethyl-iodoethyl-ammonium iodide $(N(CH_3)_3\,(C_2H_4I)I)$ it becomes evident, that Baeyer's mixture may have contained either trimethylvinyl-ammonium-hydroxide, $(N(CH_3)_3\,(C_2H_3)HO)$, or trimethyl-oxethyl-ammonium-hydroxide, $(N(CH_3)_3\,(C_2H_4(HO)HO)$; it is probable that he had several bases in his hands under the name of neurine.

Summing up this evidence it will be seen that the substance represented by the formula $C_5H_{13}NO$ is the oxide of the base $C_5H_{13}N$, and that it is possible to obtain a large number of bases of allied characters, and referable to the one or to the other of these.

Von Babo and Huschbrunn,† obtained sinkaline as a product of decomposition of sinapine, an ingredient of mustard; and A. Clauss and C. Kessé‡ claim to have established the identity of sinkaline with choline (meaning probably $C_5H_{15}NO_2$).

Harnack (§) has found in the red fungus which yields muscarine (said to be isomeric with betaine), another alkaloid, said also to be isomeric with choline, which he names amanitine and regards as—

$$N\left\{\begin{array}{l}(CH_3)_3\\ CHOH{-}CH_3\\ OH\end{array}\right. \text{ or } C_5H_{15}NO_2$$

Now in the paper alluded to in commencing, Schmiedeberg and Harnack state that choline or neurine, sinkaline, and synthetically prepared hydrox-ethylentrimethyl-ammonium are identical, and all yield muscarine upon oxidation.

They regard muscarine as

$$N\left\{\begin{array}{l}(CH_3)_3\\ CHOH{-}CHO\\ OH\end{array}\right. \text{ or } C_5H_{13}NO_2 \text{ capable of}$$

forming the salt $C_5H_{13}NO_2\ HCl\ Pt\ Cl_4$, and the salt $C_5H_{13}NO_2\ 2HCl\ PtCl_4+2H_2O$. Muscarine is therefore said to be isomeric with betaine. By treatment of muscarine chloride with moist oxide of silver, the hydroxide is obtained.

$$N\left\{\begin{array}{l}(CH_3)_3\\ C_2H_5O_2\\ OH\end{array}\right. \text{ or } C_5H_{15}NO_3$$

The oxidation of choline and its so-called isomers into muscarine is not effected, according to Schmiedeberg and Harnack by means of such bodies as potassic permanganate and chromic acid, but requires strong nitric acid containing as little water as possible, and evaporation therewith to dryness.

The only difference between the two bodies is seen to be 2H.

$$\begin{array}{r}\text{Thus choline} = C_5H_{15}NO_2\\ \text{muscarine} = C_5H_{13}NO_2\\ \hline H_2\end{array}$$

and yet strong nitric acid and evaporation to dryness is required to remove these two hydrogens!

This and the various other facts stated, is sufficient to throw their conclusions into grave doubt; at least there is apparent a terrible confusion which is most bewildering in its effects upon those who have worked upon this subject, and which renders it impossible *pro tem.* to accept their results as entirely representing the truth.

Moreover, their reason for regarding muscarine as isomeric with betaine is not evident. This last-named substance has been built up synthetically by Peter Griess,* who regards it is trimethylglycocine $C_2H_2(CH_3)_3NO_2$ or $C_5H_{11}NO_2$. Griess obtained it by acting on glycocine in alkaline solution with methyl iodide, and although it may be identical with Scheibleis' betaine from beet-root, it is certainly not identical, as is stated, with oxyneurine or choline from brain sources.

It must be remembered that there are a series of betaines, or trebly substituted amido acids, the betaines, *par excellence*, being trimethyl and triethyl glycocine. (See paper by J. W. Brühl.†)

To conclude this article, it may be stated that most of the difficulty experienced in the study of these various bodies arises from the inability to determine accurately the percentage of hydrogen in them; it is almost impossible to do this to an atom of hydrogen, and yet the difference of an atom makes all the difference in the world to conclusions drawn from such work.

The method of analysis introduced by Liebig can yet do much towards completing our partial knowledge of these compounds; but it is futile to explain isomerism, the elucidation of which awaits the outburst of a new epoch in chemical science.

THE "STANDARD" ON THE PROPOSED AMENDMENT OF THE MEDICAL ACTS.

The following "editorial" which appeared in the *Standard* last Wednesday will be read with interest :—

"A deputation of medical men waited the other day upon the Home Secretary to complain of the inefficacy of the present administration of the laws intended to enforce the possession of proper qualifications by persons practising as surgeons and physicians. They pointed out in particular that a number of certificates of death are signed by unqualified persons; and inasmuch as in this case a legal requisition is in question, it would seem tolerably easy to deal with an obvious violation of the law. The practical mischief of the existing laxity was illustrated by Dr. Carpenter, who held a bundle of certificates all signed by the same person and all giving as the cause of death effusion on the brain—a form of fatal disease not common enough to render it possible that it should have occurred in so great a number of instances within the practice of a single "druggist's assistant." Now the purposes for which the law demands a certificate of the cause of death before a corpse is buried are very obvious. If nothing of the kind were required there would be very great probability of impunity in cases of manslaughter or murder not of a character to attract the notice of neighbours and provoke a coroner's inquest, especially among the poorer classes. But in order that the legal certificate may have any value as a security against malpractices it must evidently be signed by a qualified and responsible person, presumably capable of recognizing the distinctions between various forms of fatal disease, and of detecting the suspicious appearances which indicate poison, neglect, or ill-usage. If certificates are accepted indiscriminately from quacks or druggists' assistants, as well as from qualified surgeons and physicians, the object of the requirement is entirely defeated.

"The demand of the deputation for more stringent measures against "practising quacks" is not so easily to be satisfied. We have no sympathy whatever with any class of unqualified practitioners; nor will our readers suspect us of any lurking weakness in favour of any of those questionable therapeutic methods which occupy the border ground between regular medicine and downright imposture. But it is obvious that the existence of this latter class of practitioners, and the confidence reposed in them by a large number of persons who, however ignorant they may be of medicine, are not uneducated, and must be allowed to take their own way where their own health is concerned, interposes a serious difficulty in the way of any rigorous dealing with quackery. In order to punish or to put down quacks quackery must be legally defined, and we doubt whether any of the deputation, had Mr. Cross asked them for a definition, could have furnished one which a legal draughtsman would have ventured to embody in an Act of Parliament. Some of them might perhaps have given such a definition to their own satisfaction by insisting that no one not possessing a formal qualification either as a member of the College of Physicians or the College of Surgeons, or as a medical graduate of one of our own universities, should be allowed to practise the healing art in any form whatever. But it is obvious that so stringent a prohibition could not be obtained from Parliament, and could not be enforced against the convictions of a large number of persons firmly attached to practices which orthodox medical men regard as little better than quackery. No statesman, except perhaps Mr. Lowe, would venture on so high-handed an interference with personal liberty, or on the manifestation of so profound a contempt for the opinions of the numerous medical heretics to be found in all classes of society. We presume that, in the opinion of at least a majority of the deputation, the rules of homœopathy, formal and simple as they are, might be applied almost as safely by a druggist's assistant as by a qualified graduate of the University of London, if any such graduates believe in the theory of Hahnemann. It would not be easy to insist that no man not duly qualified as a medical practitioner should keep a hydropathic establishment. It might not even be possible either to forbid the employment of mesmerism in cases of serious illness, or to insist that every mesmerist should have the qualifications which Elliotson and one or two other almost equally celebrated mesmerists undoubtedly possessed. Even the suppression of herbalists would be felt as a practical grievance by a certain number of electors whose votes their Parliamentary representatives might not care to lose.

"Nor is it easy to see how homœopathists, hydropathists, mesmerists, and herbalists are to be legally distinguished from that most infamous class of quacks to whose malpractices the deputation especially referred. Morally, no doubt, there is the widest possible distinction between men, however weak their intellect, who believe in new-fangled methods of treatment, aquatic, vegetarian, or mystic, and designing advertisers who make fortunes out of the ignorance and the imprudences of youth. The latter are among the worst moral pests of the age. They not only poison the constitutions of thousands, but in many cases extort large sums by threatening to make known the secrets which have been professionally entrusted to them. The extreme rarity of the instances in in which such conduct is detected and punished affords no measure whatever of the frequency of its occurrence. It is obvious that not one in a thousand of those who find out that they have been imposed upon will tell their story in a court of justice. The very motive which sends them to these quacks—desire for secrecy—prevents them, however grossly wronged, from publishing their case. If the complaining physicians can afford us any satisfactory definition by which this class of quacks can be distinguished from merely preverse or heretical practitioners of unauthorized therapeutic systems we should heartily accept their proposal, and should think no punishment they might propose too severe for the class of offenders in question. But obviously it is impossible to forbid the use of any supposed curative process by persons not graduates of certain universities or licencees of certain professional bodies; and short of this we hardly see what measure could effectually reach the advertising quacks. Of course they can at present be punished for assuming qualifications they do not possess, and the punishment might be enhanced. But it is not necessary to them to call themselves physicians, surgeons, or even doctors; for now-a-days almost every one knows that many of the ablest regular practitioners do not bear the academic title of doctor. The quacks therefore could afford to drop this and every other recognized professional title, and could still carry on their practices as before.

"It is, moreover, impossible to prohibit chemists, who fill the place of the old apothecaries, from prescribing in apparently trivial cases for the poor. The latter cannot afford, whenever they or their children are ailing, even the smallest fee required by a regular practitioner, or the time necessary to obtain advice at an hospital. They go naturally to the person who can give them a rhubarb pill or a sedative powder over his counter; and we have no doubt that in nine cases out of ten the chemist's advice is good, and that his irregular practice of medicine and dentistry, though perhaps in strictness illegitimate, is indispensable to the respectable poor. All these considerations show how exceedingly delicate and difficult would be the task of a statesman who should undertake the repression of quackery by legislative measures; and we greatly doubt whether, except in the somewhat stricter enforcement of the regulations already existing, it be possible to put down by law the evils which have naturally excited the indignation of the profession. Common sense and the diffusion of education will no doubt greatly diminish the influence of medical delusions and the profits of imposture; and with this we fear that society and the doctors must for the present be content."

The Pharmaceutical Journal.

SATURDAY, JUNE 9, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, *17, Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary, 17, Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REPORTS OF THE GOVERNMENT VISITORS ON THE EXAMINATIONS.

"To see oursel's as others see us" was the aspiration of the Scotch bard, and, by the wisdom of Parliament and the courtesy of the Lords of the Privy Council, the Board of Examiners is from time to time provided with this safeguard against "blunders" and "foolish notions." But the reports of the Visitors to the Examinations on behalf of the Public have also a wider interest, extending to all who have the future welfare of pharmacy at heart, and one at least of those which were laid before the Council on Wednesday last is equal in importance to any that have preceded it.

Dr. MACLAGAN has given fresh proof that he exercises the important trust confided to him *con amore*, by the able and thorough way in which he discusses the results of the pharmaceutical examinations held in Edinburgh during the year 1876. Nor do we doubt that a perusal of the entire report from Dr. GREENHOW on the examinations in London would evidence the same spirit, but our knowledge of it is at present limited to the extremely satisfactory testimony that the examinations were conducted in such a manner as to "constitute an ample guarantee to the public of the practical competency of "persons admitted to register as Chemists and "Druggists under the Pharmacy Act of 1868."

The proportion of failures to pass the Major and Minor examinations in Edinburgh having been rather larger than in the previous year, Dr. MACLAGAN appears to think the satisfaction to be derived from the contemplation of this fact is confined to the evidence it affords that the examiners continue rigidly and impartially to discharge their duty in remitting candidates who are not up to the mark. It may be remarked, however, that the gross number of examinations in Scotland—Major, 2, and Minor, 84—was rather small for the purpose of an average, and that on the larger number examined in Great Britain the average of failures showed a considerable decrease. Moreover, the opinion that "these results certainly "show that there is no marked improvement in the "qualification of the bulk of the candidates" appears to require such qualification as is to be found in the increased stringency of the examinations instituted in 1876. A result of this increased stringency is perhaps to be traced in the greater correctness of answer to question and the more scientific style of answer noticed by Dr. MACLAGAN in the really good candidates.

One feature that will be sure to attract attention in Dr. MACLAGAN's report is the classified list of failures to obtain four tenths of the available marks. It is not very clear whether the figures given represent absolute or relative numbers, or what were the conditions under which they were obtained, for we presume that when a candidate has manifested a certain amount of incompetency he is remitted although he may not have been examined in all the subjects, and therefore the order in which the subjects were taken might have a decided influence on the figures. But even though it may be a somewhat rough indication of the comparative weakness of the unsuccessful candidates in the several subjects, there is a sharp contrast between the first three, prescription reading, practical dispensing, and materia medica, and the last three, pharmacy, chemistry and botany, that is very significant, the former each showing four failures, whilst the latter are respectively 12, 13 and 17. It may be that the explanation is to be found in the fact that many young pharmacists still receive during their apprenticeship solely empirical training, which is moreover of a very limited extent, affording little opportunity of acquiring chemical or botanical knowledge. The general success in detecting unusual doses and deciphering prescriptions, notwithstanding a manifest unfamiliarity with the Latin language, the ability to dispense, and the acquaintance with materia medica would allow of such a theory. Even the large number of failures in the important subject of pharmacy, involving not only the recognition of official preparations by their colour, smell and taste, but the knowledge of how these are prepared according to the Pharmacopœia, which was in fact the weak point, is due, probably, rather to the too frequent absence during apprenticeship of opportunities of becoming practically acquainted with the preparation of such compounds than to the neglect of opportunities. Such a deprivation, as Dr. MACLAGAN remarks, cannot be recovered by an attempt to commit the Pharmacopœia to memory.

The largest proportion of failures, as might be expected, was in the strictly scientific departments of chemistry and botany. Dr. MACLAGAN nevertheless urges the necessity of insisting on thorough knowledge of these branches as a means of raising the scientific character of the pharmaceutical profession, and in this he endorses the action of the Pharmaceutical Society since its foundation. As to the tendency to the display of chemical skill mentioned this may not be unaccountable from the impression the candidates may naturally acquire as to the character of the particular examination.

The careful consideration which Dr. MACLAGAN has evidently given to every part of this report makes doubly welcome the fact that he is found to be in accord with Dr. GREENHOW in stating his conviction that the various examiners, including those who have been added to the Board since his last Report, discharge their duties with a judicious combination of strictness, impartiality and consideration for candidates.

ELECTION OF ANNUITANTS ON THE BENEVOLENT FUND.

AMONGST the business that came before the new Pharmaceutical Council at its meeting last Wednesday, was the consideration of the expediency (financially) of electing annuitants on the Benevolent Fund, in October next. The decision to elect six fresh annuitants, a larger number than on any previous occasion, is one that will, we believe, meet with the approval of all the subscribers, and as it will represent an annual responsibility of £180 probably for several years, it cannot be said that the Council is lacking in confidence in the generosity of the trade. We regret, however, to learn from the Secretary's announcement that the ordinary annual subscriptions received during the present year are about £150 below the usual amount at this date.

We refer to this fact more particularly here, lest the long list of subscriptions, the first part of which appears in this week's Journal and which will be completed next week, might have a misleading effect.

THE MEDICAL ACT AMENDMENT BILL.

ON Friday, the 1st inst., Dr. LUSH carried out his promise to remove the objections of chemists and druggists, by withdrawing his Bill, and asking leave to introduce a fresh one. The new Bill was read a first time on Monday, June 4, and has since been printed. Upon comparison, it proves to be an exact counterpart of the previous Bill, with the exception that the words, "or who shall practise medicine or surgery for gain," are omitted. Chemists and druggists have therefore no further grounds for opposing the legislation proposed.

The wide-spread disfavour with which the manifest objects, of the extreme supporters of the late Bill was regarged is very significant. Not only did the Medical Council refuse to countenance it, but the medical press has not ventured to support it; in fact, one medical journal has gone so far as to express a regret that the original Bill was introduced at all, on the ground that it was little better than a chimera, and there was no advantage in the ventilation of impossible hopes. The subject has, however, attracted the attention of the public press generally, and there can be little doubt that the temperately written leader that appeared in the *Standard* on Wednesday, and which will be found on p. 1000, represents fairly the opinion of a very large section of the public on the question.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, June 6, 1877.

Present,—Messrs. Atherton, Atkins, Betty, Bottle, Churchill, Cracknell, Gostling, Greenish, Hampson, Hills, Owen, Rimmington, Robbins, Sandford, Savage, Schacht, Shaw, and Williams.

The chair having been taken by Mr. John Williams, the minutes of the previous meetings of May 2 and 16, were read and confirmed.

Mr. SCHACHT stated that owing to the liberality of the Council the Bristol Pharmaceutical Association had been able to purchase books to the value of £37, the first portion of which had just been placed on the shelves, and he had been complimented on the excellence of the selection. The arrangement of the materia medica museum had been entrusted to a small sub-committee, which had already received from the Curator of the Society's Museum a large proportion of the articles asked for, and the arrangement would soon be completed.

ELECTION OF PRESIDENT.

The first business was the election of President for the ensuing year, a ballot having been taken—

MR. JOHN WILLIAMS

was unanimously re-elected.

Mr. WILLIAMS thanked the Council for the honour done him, and for the support which he had received in carrying on the business of the Society during the past year.

ELECTION OF VICE-PRESIDENT.

On a ballot being taken—

MR. WILLIAM DAWSON SAVAGE

was re-elected Vice-President for the ensuing year.

Mr. SAVAGE briefly acknowledged his sense of the kindness of his colleagues in the expression of their confidence in him.

ELECTION OF TREASURER.

Mr. SANDFORD proposed that—

MR. CORNELIUS HANBURY

be re-elected Treasurer without the formality of a ballot.

The motion was agreed to.

APPOINTMENT OF SECRETARY AND ASSISTANT-SECRETARY.

Elias Bremridge was re-appointed Secretary and Registrar, and Richard Bremridge Assistant-Secretary and Deputy-Registrar for the ensuing year.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemist.

Marshall, Eli........................London.

Chemists and Druggists.

The following registered chemists and druggists were elected Members of the Society:—

Alexander, John Grieve ....Galashiels.
Lloyd, Thomas Howard .... Leicester.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Campbell, Colin ....Dumbarton.
Cartwright, William Adam......Astley Bridge.
Fox, Thomas Augustine ....St. Helens.

Geldart, William ....Boroughbridge.
Hall, Ralph ....Kingsland Road.
Holdcroft, George ....Victoria Park.
Hughes, Evan Grismond.........Gloucester.
Kimber, Benjamin Tindall......Tollington Park.
Martin, Henry Stephen ....East Grinstead.
Milton, Thomas, jun. ....Bristol.
Saville, George ....Wakefield.
Smith, Charles ....Heywood.
Spencer, James Hampson ......Chester.
Tripp, Zeno ....Stratford.

Modified.

Bedford, Christopher ....London.
Borthwick, Alexander John ...Selkirk.
Butcher, George Stephen ......Salford.
Daymond, Samuel ....Stonehouse.
Jagg, John Henry ....London.
Lincoln, Nathaniel ....Norwich.

ASSOCIATES.

The following having passed their respective examinations, and having tendered their subscriptions for the current year, or having paid the subscriptions of Apprentices or Students, were elected "Associates" of the Society:—

Minor.

Broadbent, John ....Manchester.
Capes, Howard Hawksley ......Epworth.
Dixon, Richard Dobson ....Sharrow.
Furness, Thomas ....Chesterfield.
Hall, Robert..........................Hartlepool.
Hulland, Charles Richard ......Bath.
Jones, Thomas ....Seacombe.
Simpkins, George Starr ....Minchinhampton.
Trood, Richard.......................Bath.
Wills, Vincent Andover ....Blaenavon.

Modified.

Davies, Charles Edward ....London.
Garrett, Thomas Philip ....London.
Hussey, Robert.......................London.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination, and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Andrew, Edward Oliver ....Welshpool.
Bowman, Edmund ....Leith.
Broadhead, Richard...............Levenshulme.
Brothwood, Harry Skarratt ...Shrewsbury.
Brown, Thomas Land ....Ripon.
Careless, John ....Birmingham.
Clarkson, Richard Bell ....Newark.
Crofts, John Ernest................Leicester.
Eaton, Charles Arthur ....Hull.
Evans, John Thomas Richard...Rhyl.
Fawcett, Christopher Airey ...Windermere.
Gascoigne, Charles ....Hurworth.
Hall, Charles.........................Leighton Buzzard.
Haward, Edgar.......................Darlington.
Heaton, John ....Burnley.
Jackson, William Edward ......Newark.
Jowett, Henry ....Leeds.
Morgan, George, jun. ....Market Drayton.
Owen, John Hart....................Bala.
Parkinson, William Armor......Preston.
Peat, Joseph ....Accrington.
Perry, John ....London.
Priestley, William Jepson ......Kingston-on-Thames
Richards, John Wesley ....Saltburn-by-the-Sea.
Riddle, James Pearson...........South Shields.
Spencer, George ....Bucklersbury.
Stanford, Frederick W............London.
Summerland, William Randle...Dudley.
Temple, Arthur William.........Thrapston.
Winch, John Miller.................Colchester.

Several individuals were restored to their former status in the Society, upon payment of the current year's subscriptions and a fine.

The names of the following persons were restored to the Register of Chemists and Druggists:—

Mary Jane Henderson, 4, Ferrier Street, Leith.
John Place, 24, King Street, Cambridge.
John Jonathan Goodlad, The Square, Isleworth.
William Boyd Johnstone, 2, Hilton Terrace, Shields Road, Byker, Newcastle-upon-Tyne.

APPOINTMENT OF COMMITTEES.

The Council next proceeded to appoint the Committees:—

General Purposes.—The whole of the Council; four to form a quorum, to meet as occasion may require.

Mr. SCHACHT suggested that if members residing in the country were appointed on Committees meeting in the middle of the month, their travelling expenses should be provided for. He would not move a resolution on the subject without notice, but if there were a general feeling that this should be done he would give notice of motion for next month.

Mr. BOTTLE reminded his country colleagues that they were now in a majority on the Council and must be prepared to take a fair share of Committee work.

Finance.—Messrs. Bottle, Cracknell, Greenish, Owen, Rimmington, and Robbins. The Committee to meet at three o'clock on the day preceding the Council Meeting.

Library, Museum, and Laboratory.—Messrs. Betty, Bottle, Gostling, Greenish, Hampson, Hanbury, Hills, Robbins, Sandford, and Schacht; to meet at eleven o'clock on the second Wednesday in each month except August and September.

House.—The same as the Library, Museum, and Laboratory Committee; to meet as occasion may require.

Benevolent Fund.—Mr. SHAW suggested that the whole of the Council should be appointed on this Committee.

The proposition was supported by Mr. Robbins and the President.

Mr. HAMPSON thought this would be a mistake, and that the work would not be done so well.

Mr. GOSTLING thought it would be well for all members to be on this Committee, as they all took a deep interest in the Fund.

Mr. CHURCHILL said he should be happy to serve upon it.

Mr. ATKINS thought it would be well to appoint the whole Council.

Mr. SCHACHT did not see the use of appointing Committees consisting of all the members of Council. The whole of the work might as well be done in Council. By having smaller Committees two could sit at one time.

After some further remarks from Mr. Hampson,

Mr. SANDFORD said though he saw the advantage of having gentlemen on that Committee from all parts of the country he still felt with Mr. Hampson that the work would be done better by a smaller Committee.

Ultimately the following names were agreed to as forming the Committee:—Messrs. Atherton, Betty, Bottle, Churchill, Gostling, Greenish, Owen, Rimmington, Robbins, Sandford and Shaw. The Committee to meet at four o'clock on the day before the Council Meeting.

Law and Parliamentary.—The whole of the Council; to meet on the Tuesday evening previous to the Council meeting, or as occasion may require.

THE EVENING MEETINGS.

Mr. GREENISH said it was usual to make arrangements for the evening meetings, but he begged leave on this occasion to move that the appointment of a Committee to make arrangements for the evening meetings for the ensuing session be referred to the Library, Museum and

Laboratory Committee, to report to the Council at the next meeting. He did so because he did not think the arrangements for the evening meetings had been everything that could be desired, and he had some suggestions to make which he could do better in the Committee than at the Council Board.

Mr. SCHACHT thought this motion was hardly regular. The Council was now appointing Committees, and he did not see how the desirability of appointing of one Committee could be referred to another. After some further conversation he said he would move as an amendment,

"That the President, the Vice-President, the Professors and the Editor be appointed a Committee to regulate the proceedings of the evening meetings."

Mr. BETTY seconded the amendment.

Mr. CHURCHILL said he should support Mr. Greenish's motion, because he felt anything which could improve the arrangements of the evening meetings should be supported.

Mr. HAMPSON asked if there were any record of the proceedings of the Committee for the past year.

The PRESIDENT said the Committee had in fact not acted.

The amendment was then negatived, and Mr. Greenish's motion carried by a large majority.

APPOINTMENT OF THE EDITOR AND SUB-EDITOR OF THE JOURNAL.

Dr. Paul was re-appointed Editor of the Society's Journal for the ensuing year, and Mr. F. Passmore Sub-Editor.

LOCAL SECRETARIES.

The SECRETARY suggested that the appointment of Local Secretaries should be deferred to next month, and that the Library, Museum, and Laboratory Committee should then present a revised list. He said the fact was that from 110 towns no returns had been received, and that the appointment of Local Secretaries appeared to be regarded with great apathy by members of the Society in the provinces. It was very important that the Local Secretaries should be carefully selected.

Mr. BOTTLE asked if the present Local Secretaries would remain in office until their successors were appointed, because there might be matters of legislation coming on with regard to which the co-operation of country members might be required.

The SECRETARY said there would be no difference on that score.

It was resolved that the matter be referred to the Committee as suggested.

THE CONVERSAZIONE.

Votes of thanks were passed to the Lords of the Committee of Council on Education for their kindness in allowing the use of the South Kensington Museum for the Annual Conversazione, and to the members of the official staff of the Museum for their services on the same occasion.

REPORTS OF COMMITTEES.

LIBRARY, MUSEUM, AND LABORATORY.

The Librarian had reported the average attendance in the library during the previous month to have been, day, 22; evening, 10. Circulation of books, in town, 160; country to 24 places, 42.

The Committee recommended the purchase for the Library of the 'Manchester Science Lectures' (continuation).

The Curator had reported the average attendance in the Museum to have been, morning, 15; evening, 5. Also that the whole of the chemical portion of the catalogue was now in print, and that the animal materia medica catalogue would be in the printer's hands immediately.

Professor Attfield had reported 83 entries in the Laboratory since the beginning of the session, 46 being now at work, and that the conduct of the students was satisfactory.

Professor Bentley had also reported satisfactorily of the progress of his class.

The report and recommendation of the Committee were received and adopted.

Mr. GREENISH suggested that it would be an assistance to the Librarian and Committee, if members who required any particular book which was not in the Library, would request the Librarian to enter it in his list to be brought before the Committee.

HOUSE.

The report of this Committee was received and adopted.

EXPENDITURE ON EDUCATION.

In accordance with a resolution passed at the last meeting the Secretary laid upon the table a return showing that during the past year the sum of £718 1*s*. 3*d*. had been expended by the Society on purposes in connection with education, including the endowment of the professorial chairs.

A further return was ordered, giving information as to the number of students attending the lectures of the professors and working in the laboratory during the year 1876; and also an apportionment of the rent and other charges not already included in the present return.

LAW AND PARLIAMENTARY.

The report of this Committee consisted mainly of the correspondence which had taken place with the Privy Council relative to the application of a proposed association of "professional chemists" to have their rules, etc., registered by the Board of Trade. The Solicitor had been requested to draft a letter to be sent in reply, which had been submitted to the Committee at a second meeting, and approved, and sent to the Privy Council. The purport of it was that though the Council was always glad to welcome any efforts for the advancement of chemical science it did not approve of powers being granted to any newly constituted body to grant certificates of competency, and objected to the proposed title of "professional chemists" as being vague and likely to lead to confusion. The Committee had also had under consideration the Medical Act Amendment Bill, which it was decided to oppose unless a clause were inserted to protect and define the existing rights of chemists and druggists.

The SECRETARY said that since the report was drawn up the Bill had been withdrawn and another one introduced, copies of which were now on the table.

Mr. SANDFORD suggested that the report of the Committee be received and adopted, and the Council could then discuss the state of affairs as now existing.

This was unanimously agreed to.

The PRESIDENT said he had received a letter from Dr. Frankland, President of the new Association, stating that the Committee had carefully considered the objections made by the Council and being anxious to meet the views of the Pharmaceutical Society recommended that the name be changed to that of the "Institute of Chemistry," and that the clause with regard to granting certificates to which objection had been taken should be struck out. He added that no interference with the rights and privileges of the Pharmaceutical Society was contemplated, and under these circumstances he hoped that all objection would now be withdrawn. He thought this letter was very satisfactory, and the Council would simply have to write to the Privy Council and to Dr. Frankland withdrawing all opposition.

Mr. ATKINS said it was very satisfactory to find that the careful consideration that had been given to this matter had been so well received by the promoters of the new Association. The Pharmaceutical Society was by no means opposed to the advancement of the higher practice of chemistry, but quite the reverse.

Mr. SANDFORD remarked that he believed it was the solicitor employed to draw up the rules who had inserted the objectionable clauses. He would move that these clauses having been removed no further objection be raised by the Society to the registration of the rules of the new association.

Mr. Betty thought it would be well to carefully examine the rules as amended before withdrawing all opposition. He suggested that they should again be submitted to the Society's Solicitor.

After some further conversation, it was resolved that the President, Mr. Sandford, and the Solicitor be requested to examine the amended rules, and if they proved unobjectionable, to write to the Privy Council and to Dr. Frankland accordingly.

THE MEDICAL ACT AMENDMENT BILL.

Mr. Sandford said as he had been one of those deputed to wait on Dr. Lush, he might mention what had happened, especially as some misapprenhension seemed to have been entertained about it, and some idea that the Council had neglected its duty. He might perhaps take some blame to himself for not having published a note he had received from Mr. Atkins, under the circumstances he would explain. On the day following the annual meeting, May 17th, the President, Mr. Hills, Mr. Atkins, and himself, went down to the House of Commons to see Sir Trevor Lawrence and Dr. Lush. Mr. Hills and he went up-stairs to the Committee room while Mr. Atkins and the President remained below. They saw Sir Trevor Lawrence just at 12 o'clock, who told them if they did not see Dr. Lush then, they would not be able to do so at all, and, therefore, without going down again to their colleagues, they had an interview with Dr. Lush. He said the Bill was not intended to affect chemists at all, and suggested that they should see Mr. Pridham, solicitor to the Medical Defence Association, who had drawn the Bill. They then pointed out to Dr. Lush how the wording of the clause would affect them, and that the Society thought it would be a good opportunity for inserting a clause which should define and protect the rights of chemists. Dr. Lush was willing to do anything in reason which they desired. It was also agreed that Dr. Lush should see Mr. Atkins at Salisbury on the following Saturday. The President and himself called on Mr. Pridham on the Thursday, but did not see him; an appointment was made, however, for the following morning at half-past 10 o'clock; Mr. Pridham not arriving until 11, the President had to leave in order to attend the adjourned meeting of the Society, and he, Mr. Sandford, was left alone to see Mr. Pridham. That gentleman at once admitted that the Bill as drawn would affect chemists. They had a long discussion over it, and he told Mr. Pridham distinctly they should oppose the Bill unless some clause were inserted which would protect them. He also drew his attention to certain clauses in the Apothecaries Act and Medical Act, 1858, saving the rights of chemists and druggists, and asked him whether, as this new Bill was to be read as part of the Medical Act of 1858, those clauses would still be operative. Mr. Pridham thought they would, but did not seem very certain about it. Mr. Flux was afterwards directed to put himself in communication with Mr. Pridham, but he did not know if anything had come of it. On the Monday following, when he was in the country, a letter reached him from Mr. Atkins, dated on the preceding Saturday, when he had seen Dr. Lush, who had informed him that, after conferring with Dr. Carpenter, he had resolved to cut out the words objected to: "or who shall practise medicine or surgery for gain." From some further expressions in the letter he regarded it as a private communication, and therefore did not publish it. Matters went on for some time until it appeared, in some of the daily papers that the Plymouth Association had communicated with Dr. Lush, and that in compliance with their suggestion he had withdrawn those words. Dr. Lush saw that in the paper and immediately wrote to Mr. Balkwill, saying that he had withdrawn the clause a fortnight before hearing from the Plymouth Society, and that he had done so in consequence of the representation of Mr. Sandford and Mr. Hills, who came to him as a deputation from the Pharmaceutical Society. He might also say that in another letter there was a very complimentary allusion to the Pharmaceutical Society by Dr. Lush, for he said he had no idea until he looked into the matter that the Pharmaceutical Society had such a capital examination, and that in fact the Board of Examiners more perfectly secured the practice of pharmacy than the practice of medicine was secured by the Medical Acts. Mr. Balkwill had also sent to Mr. Sandford a rough sketch of a clause protecting the rights of chemists and druggists, in case it was deemed necessary to insert it. However, when he went down to the House of Commons on the Friday, when the Bill was to be read a second time, he found three notices of motion that it be read that day six months, and Dr. Lush informed him that he had just obtained leave to withdraw it and reintroduce it in an amended form. This was the Bill which had been printed that morning, and as it now appeared unobjectionable he thought it would be a pity to oppose it.

Mr. Atkins said Mr. Sandford had given a very correct account of the matter, but he wished to repeat what he had already said on a former occasion, that he was sure Dr. Lush understood their position, and that they might expect from him fair and honourable treatment. At the annual meeting there appeared to be a little incredulity on that point in some quarters, and he regretted to hear that some gentlemen had thought fit to cherish their suspicions, and to exercise their independence in a way that he thought was objectionable, Dr, Lush had been charged with trades-unionism, and with being the catspaw of the profession. It was a great pity that men could not give one another credit for honour and uprightness. Dr. Lush had assured him in the most frank manner that he had not the least idea of interfering with chemists and druggists, and after conferring with Dr. Carpenter he withdrew the obnoxious words. He should be sorry to deprive the gentlemen at Plymouth, whom they would probably know better after next August, of any credit in respect to their action, but when the Council was charged more or less distinctly with inaction and neglect of duty, it was only right that the truth should be known, and he regretted that the public would be misled by the particulars which had appeared in the papers, some of which were very indiscreetly worded.

Mr. Hampson was gratified to find that there was no longer any need for opposition to the Bill for the Amendment of the Medical Act, the promoters having found it unadvisable to press it in its original form. He had only one remark to make with reference to Mr. Atkins's statement, and that was, that although those who knew Dr. Lush personally might feel assured of his honourable intentions, others who were not so favoured were obliged to be guided by the actual words of the Bill, and therefore he was convinced that the policy of opposition was the right one, especially as it had come to their knowledge that one of the objects of the real promoters of the Bill was to interfere with counter practice. This was a very large question, and inasmuch as it could not be known all over England what was being done by the Council, he rejoiced that general action had been taken, petitions sent up, and notices of opposition given by Members of Parliament. It was very important that the House of Commons should know that the chemists and druggists formed an organized body, alive to their own interests and prepared to defend them if needful.

Mr. Atkins could not agree with Mr. Hampson that the Bill was intended to put down counter practice. It was really directed against quite another class of persons.

Mr Hampson said he did not wish to make any unfair charge against the promoters of the Bill, but they knew from what source it emanated, and had been informed that what he had stated was one of the objects in view.

The PRESIDENT remarked that he did not see that any objection could be taken to the Bill in its present form.

Mr. CHURCHILL said that it was a great pity that Dr. Lush's communication to Mr. Atkins was not made public earlier.

Mr. ATKINS said he must take some blame to himself in the matter. Dr. Lush's main communication was not in any way private, but in writing to Mr. Sandford he had added some other points which might have led that gentleman to think it unwise to publish the letter.

Mr. BETTY thought they might all feel very gratified that all source of irritation was now over, and drew attention to an article in that day's *Standard*, which distinctly stated that counter practice, if somewhat irregular, was indispensable to the public.*

FINANCE.

Messrs. Cracknell, Greenish, and Robbins having acted *ad interim* as a Finance Committee presented certain accounts which they had examined and recommended for payment.

Their report and recommendations were adopted.

BENEVOLENT FUND.

It was resolved unanimously that six annuitants be elected in October next.

Mr. OWEN said he was not certain whether the election for the British Orphan Asylum, at Slough, would not take place before the Committee met again, and asked if he would be authorized to expend in connection with it the sum of twenty guineas, which had been placed in his hands on a former occasion for the purpose of getting a child into that institution, but which he had returned to the Secretary, not seeing his way to apply it successfully. He wished the sum could be increased to £50.

Mr. GREENISH thought the Committee ought to consider the matter before any additional sum were granted, but that there could be no objection to the sum formerly granted being used.

The SECRETARY then presented several applications which had been made for relief, and the following grants were made:—

£10 to the widow of a member, who had received a similar grant in 1875.

£10 to a registered chemist and druggist, a female, aged 51, now out of business, and in very reduced circumstances.

£15 to the widow of a member.

£10 to another widow of a member.

The SECRETARY reported that the amount of ordinary annual subscriptions received up to the present time was about £150 less than at the same date last year, which was equal to the sum required for five annuities.

THE INAUGURAL SESSIONAL ADDRESS.

It was resolved that Mr. William Southall be invited to deliver the address to the students in October next.

THE EXAMINATIONS.

The SECRETARY reported that he had received the following letter from the Privy Council enclosing the report of Dr. Maclagan on the Society's examinations, and an extract from that of Dr. Greenhow.

"[Copy.]

"Privy Council Office,
"4th June, 1877.

"Sir,—I am directed by the Lords of the Council to inform you that their lordships have received reports from Dr. Greenhow and Dr. Maclagan with reference to the examinations, during the year 1876, of candidates for admission into the pharmaceutical profession.

"Their lordships direct me to transmit to you, to be laid before the Pharmaceutical Society, an extract from Dr. Greenhow's report, and a copy of that by Dr. Maclagan.

"I am, sir,
"Your obedient servant,
"(Signed) C. L. Peel."

"The Secretary and Registrar,
"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, W.C."

"[Copy.]

"Extract from Report on the Examinations of the Pharmaceutical Society, conducted in London during the year 1876.

"It only, further, remains for me to add that from personal observation during my attendances at the examinations of the Pharmaceutical Society, held in London in the year 1876, I am satisfied that they were conducted in such a manner as to constitute an ample guarantee to the public of the practical competency of persons admitted to register as chemists and druggists under the Pharmacy Act of 1868.

"(Signed) E. Headlam Greenhow, M.D."

"[Copy.]

"Dr. Maclagan's Report on Examinations by the North British Branch of the Pharmaceutical Society of Great Britain.

"Edinburgh, 23rd May, 1877.

"Since the date of my last report I have been present at these examinations on the following occasions:

"11th, 12th, and 13th July, 1876;
"24th and 25th October, 1876;
"19th and 21st December, 1876;
"and 22nd February, 1877.

"There were examinations also on 11th April and 20th December, 1876, at which I could not be present:

"The total number of candidates who presented themselves for examination during this period was 99, viz.:

"Majors	2	of whom passed	1	failed	1
"Minors	84	"	47	"	37
"Modified	13	"	5	"	8
	99		53		46

"Compared with the experience of the preceding year these numbers show that the proportion of rejections is pretty nearly the same, at all events as regards the Minors, who constitute the most numerous, and in a general sense most important, category of candidates. The Majors especially in this last year are too few, and the "Modified" who are undergoing a process of gradual extinction too uncertain, to afford reliable data.

"The percentage of failures in all classes of candidates in the two years was:—

	1875-76	1876-77
"Majors	28	50
"Minors	41	44
"Modified	75	68

"These results certainly show that there is no marked improvement in the qualifications of the bulk of the candidates who present themselves, but if there is no satisfaction to be derived from the contemplation of this fact, there can at all events be seen in it evidence of what I am sure is the fact, that the examiners continue rigidly and impartially to discharge their duty in remitting candidates who are not up to the mark.

"I should be very sorry, however, that it should be thought that by these remarks I mean that the continuance of a strict system of examination has had no good effect on the candidates for admission into the pharmaceutical profession. To judge of this we must look at the successful as well as unsuccessful candidates,

* See p. 1000.

and I have no hesitation in saying that in those who do pass I observe a distinct beginning of that improvement to which we must look for the elevation of the pharmaceutical profession in Britain. I see the evidence of this not only in the greater correctness of answer to question but in the more scientific style of answer in the really good candidates. There is thus, I think, the strongest ground of encouragement to the Pharmaceutical Society for maintaining a high standard of examination, especially in the scientific branches, and in gradually increasing their demands for still higher knowledge in those who seek their diploma.

"As regards the special subjects in which candidates proved unsuccessful by having failed to obtain four-tenths of the available marks, I have to note the following facts, confining myself for reasons stated above to the Minors :—

"Failed in prescription reading		4
"	" practical dispensing	4
"	" Materia medica	4
"	" Pharmacy	12
"	" Chemistry	13
"	" Botany	17

Of these it must be remembered that some came short of the four-tenths of the marks in two departments, and that in addition to the above there were eight candidates who, though they got the four-tenths in each branch did not attain the total number of marks which entitles to a pass. In my last report, I observed that the present system of marks was too recent to enable me to form an opinion as to its real value. I do not think that one more year's experience entitles me to express any decided opinion on this, and I am in the meantime content with noting its effects on individual cases, in order to form an estimate of its working.

"Upon these various subjects of examination, I have to offer a few remarks.

"*Prescription reading.*—This is an important test of the qualification of candidates alike in showing their being accustomed to decipher the writing of physicians, which it must be owned is not always of the best, and to observe errors in prescriptions which may lead to the dispensing of dangerous doses of potent drugs, but as a further test of the candidate's latinity. I have observed that generally the deciphering of contracted or indistinctly written words, and the detection of mistakes as to doses, are well done, but I must say that much is yet to be desired in the way of improvement in the latinity of candidates. It is painful to observe in many of them, who otherwise show good knowledge, their uncertainty or ignorance as to the declinable Latin numerals which occur in every prescription. One would suppose that *unus, duo, tres* did not constitute a grammatical mechanism of such complexity as to make it difficult for candidates to understand its working; and yet a large proportion of them hesitate or make actual mistakes in connecting them with the *uncia, drachma,* or *granum* with which they are associated in prescriptions. This is, however, a matter for the consideration of those who conduct the Preliminary rather than of those who conduct the professional examinations.

Pharmacy.—It is not pleasant to observe the large proportion of candidates who failed in pharmacy. This involves the recognition of official preparations by their colour, smell, and taste, and the knowledge of how these are prepared according to the Pharmacopœia. It has appeared to me that it was in the latter respect that candidates most frequently failed in this department. To attempt to learn the British Pharmacopœia by committing it to memory is a hopeless and useless task, and I can account for the deficiencies I have observed only on the supposition that a number of young men do not avail themselves sufficiently of the opportunities which they do or ought to enjoy during their apprenticeship period of carefully observing and studying the preparation of such compounds as tinctures, compound powders, etc.

"*Chemistry and Botany.*—As usual the largest proportion of failures is in these strictly scientific departments. I have on former occasions adverted to these and have only to repeat my conviction that the decided aim of the examiners ought to continue to be as it is to insist on thorough knowledge of these branches as a means of raising the scientific character of the pharmaceutical profession. I have still to observe that in practical testing too little attention is paid to the physical properties of the specimens given for analysis. I saw a recent example of this in a candidate who had so simple an article as borax given him for analysis, and who proceeded to attack it by chemical tests without ever trying its reaction with test paper or its taste. As a matter of display of chemical skill such a method of working may elicit approbation, but as a question of practical operating it is better that pharmacists should learn to use all the means of diagnosis of a chemical compound which they can command.

"I have only to add that it gives me pleasure to report my conviction that the various examiners, including those who have been added to the Board since my last report, discharge their duties with a judicious combination of strictness, impartiality, and consideration for candidates.

"(Signed) Douglas Maclagan."

Mr. Greenish said the report by Dr. Maclagan was very valuable, as it showed the weak points of the candidates.

Mr. Shaw thought it should be matter for consideration, whether some suggestions could not be made to teachers to strengthen the weak points of their instruction.

Chemists' Assistants' Association.

The Secretary read a second application on behalf of chemists and druggists' assistants asking for the use of the Lecture Theatre for the purpose of a preliminary meeting for considering the advisability of forming such an association, and the best method for rendering the same useful to both assistants and employers, at any date which might be convenient.

Mr. Hampson moved that the application be acceded to, which was unanimously agreed to.

The Secretary read letters from the Hull and Plymouth Chemists' Associations with reference to the Medical Act Amendment Bill.

Election of Annuitants—Canvassing Cards.

Mr. Bottle said he should be glad to know what was the general opinion in regard to members of Council allowing their names to be used on canvassing cards. It would be desirable that some uniformity of action should be adopted; and though he saw no objection himself to the practice, if it were the general wish that it should not be done he should in deference to that feeling not allow his name to be used.

Mr. Greenish said he had on former occasions strongly objected to the names of members of Council, and particularly of members of the Benevolent Fund Committee, appearing on the canvassing cards.

Mr. Shaw agreed with Mr. Greenish.

Mr. Sandford said he should have been glad if the question had been discussed earlier, as several gentlemen had left, and if anything were agreed to now it would not bind those who were absent.

Mr. Hampson had conversed with a great many persons outside on this question, and found a unanimous opinion that it was undesirable for the names of members of the Council to appear on the cards.

The Vice-President felt with Mr. Bottle that there was no reason why a member of Council should not have the same liberty as any other gentleman to support any case in which he might take an interest. Still he thought whatever was done should be done generally.

After some further conversation,

Mr. Betty moved,

"That it is undesirable for any member of Council to place his name on the canvassing card of any candidate."

Mr. Hills seconded the motion which was carried.

DINNER IN AID OF THE

BENEVOLENT FUND.

The following donation was inadvertently omitted from the list published May 26th :—

Langton, Edden, Hicks, and Clark, 232, Upper Thames Street, E.C. (Amount received in an arbitration case decided in favour of the donors) 16 13 4

The following amounts have also been received since the publication of the list :—

	Donations.	Annual Subscriptions.
Cheverton, George, The Broadway, Tunbridge Wells	1 1 0	..
Crispe, James, 4, Cheapside, E.C.	2 2 0	..
Fitch, R. O., 200, Wells Street, South Hackney, E.	5 5 0	..
Henderson, Henry James, Chester Street, Newcastle-on-Tyne	..	0 5 0
Hodges, Wm., Eastgate Row, Chester	..	1 1 0
Odling, Professor, F.R.S., Oxford	1 1 0	..
Roscoe, Professor, F.R.S., The Owens College, Manchester	5 5 0	..
White, Thomas, Church Street, Launceston	0 10 6	..

BENEVOLENT FUND.

Subscriptions Received During February, March, April, and May, 1877.

Provincial Transactions.

HULL CHEMISTS' ASSOCIATION.

A special meeting of the chemists of Hull and district, convened by the above Association, was held at the Cross Keys Hotel, on Wednesday evening May 30. Mr. C. B. Bell was elected chairman, and the following resolutions were unanimously agreed to.

Resolved:—"That this meeting pledges its strongest opposition to the latter part of clause I. of the Bill intituled 'A Bill to amend the Medical Act of 1858,' which if it became law would render every chemist who supplied the most simple medicine on his own recommendation, or performed the most trivial surgical operation and charged for it, liable, upon summary conviction, to a penalty of £20."

Resolved:—"That this meeting desires to express its hearty thanks to the Executive Committee of the Chemists and Druggists' Trade Association for the active opposition they have displayed against the objectionable part of the Bill, and hopes that their efforts will be crowned with success."

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

An Extraordinary General Meeting was held on May 31st; Dr. Gladstone, F.R.S., President, in the chair. More than 100 Fellows were present.

The President, after reading the letter in accordance with which the meeting was convened, said there were four subjects to be considered: the first was, "The status and functions of the Publication Committee, and the present condition of the Journal of the Society." He would be glad to hear any remarks on this question.

Mr. Kingzett rose to propose the following resolution:—"That in the opinion of this meeting the Publication Committee should be dissolved and be reconstituted." Up till 1871 the Committee had consisted of four members; the number then was increased to twenty-two; by bye-law fourteen, the only censorship was vested in the Council, and in his opinion the Committee should be more directly responsible to the general body of Fellows than at present. He proposed that any censorship henceforth should be exercised before the papers were read, and he would also suggest that a permanent committee of five be appointed. As to the Journal, he, after saying how much the Society was indebted to their indefatigable editor, Mr. Watts, would venture to point out that original papers read before the Society ought not to wait five to six months, whilst the space of the Journal was taken up by abstracts of doubtful value. In conclusion, he would call attention to the delay in the publication and distribution of the Journal. Last year, for instance, the average interval between the nominal date of publication and that of reception was forty days.

Prof. Odling rose to second Mr. Kingzett's resolution. In his opinion the complaints as to the delay in publication were well founded. He would mention, however, that the Council had already appointed a committee to promote a speedy and uniform appearance of the Journal. He did not think it would be advisable to exercise a censorship on papers before they were read; such a course must cause delay in publication.

Mr. Neison thought that if a paper were worth reading it was worth publishing. As to the delay, societies in which the plan of censorship before reading was adopted, published their papers more speedily than the Chemical Society.

Mr. Pearsall suggested that each author should send in an abstract with his paper, as was the custom in France.

After a few remarks from Mr. Howard and Mr. Friswell, the President put Mr. Kingzett's motion, which was carried by a large majority.

The second subject considered was "The proper steps to be taken to place the election of Fellows and Associates of the Society on such a footing as will remove the existing dissatisfaction, and especially with reference to the means of securing proper qualifications in the candidates."

Dr. Paul rose to propose the following resolution:—"That in the opinion of this meeting the principles on which the election of Fellows has hitherto been proceeded are unsatisfactory and necessitate revision." It was a matter of regret that during the past few months there had been a growing dissatisfaction as to the election of Fellows. He was not wedded to the idea that the title F.C.S. should give any idea as to the chemical ability of its owner, but there was the fact, that on the one hand, they had an executive body wanting the sinews of war wherewith to carry on the business of of the Society, and whose wishes, therefore, tended to a large accession of Fellows; while, on the other, many of the present Fellows were dissatisfied, and complained that admission into the Society had become too easy; as a result of this feeling several candidates had recently been blackballed. In his opinion the grade of Associate, if properly developed, would meet the requirements of the case. It gave access to the meetings, to the library, and option to purchase the Journal at an almost nominal price, and for his part he should like to see all future Fellows elected from those who had been Associates a certain time.

Mr. Friswell had much pleasure in seconding Dr. Paul's resolution. There could be no doubt that to the public the title F.C.S. did convey a certain amount of chemical competence. Taking this into consideration, he thought that admission to the Fellowship had been too indiscriminate, and that persons had obtained admission into the Society merely to use the letters F.C.S. for trade purposes in connection with the advertisement of spirits, building materials, etc., a practice which, though it might seem to some perfectly proper, was, in his opinion, not a desirable method of using the Fellowship of a learned society.

Mr. Tribe moved an amendment to the effect: "That this Society is of opinion that the present system of election to its Fellowship does not promote its interests or sustain its dignity, and that in place of this system, the Council of the Society should recommend to the Fellows annually not more than twenty of the more meritorious candidates for election to its Fellowship." Mr. Tribe concluded by proposing that the future Associates should take the place of the present Fellows, paying the same subscription, having the Journal, etc.

This was seconded by Mr. Herbert, who called attention to the fact that a somewhat similar plan had been proposed by a former committee in 1862.

Mr. Hartley thought that there was much looseness in the signing of certificates, but objected most strongly to limiting the number of Fellows.

Mr. De La Rue thought the plan of electing candidates as Associates and then passing them up was not feasible. He was afraid that it was impossible to prevent an improper use of the title F.C.S. He would therefore propose a second amendment: "That in the opinion of this meeting the election of Fellows should only take place on certain dates, to be fixed by the Council beforehand."

Dr. Roscoe seconded the amendment, and asserted the claims of science teachers as such to be considered worthy of being admitted to the Fellowship of the Society.

Dr. Williamson thought that a great deal of dissatisfaction had arisen from Fellows signing certificates too much out of their knowledge. From his point of view, personal knowledge should mean personal acquaintance and intercourse.

Mr. Kingzett suggested that Mr. De La Rue's proposal would be attended with practical difficulties as to time if fifty to sixty candidates had to be balloted for on one night.

Professor Odling objected to a spirit of exclusiveness, and thought that the charter was granted to the Society to advance chemical knowledge and not to found a caste of chemists. He did not at all agree with Mr. Tribe's resolution. Associates would, according to Mr. Tribe's proposition, have the privilege of riding in a second-class carriage paying first-class fare. Rather would he invite any one interested in chemistry to become a Fellow and take in the Journal; if there was any extra advantage in the letters F.C.S. let him have it and welcome.

Dr. Paul briefly replied.

Mr. De La Rue's amendment was then put, and carried by a large majority. It was then put as an original motion, and carried.

Dr. Thudichum rose to propose the following resolution: "That this meeting recommends to the Council that all contributions to the Research Fund which are not mortmained be applied directly in furtherance of original research."

The Treasurer (Dr. Russell) wished to make a short statement: The fund amounted to nearly £4000. One half was invested, in accordance with the wishes of the donors, the other was quite free, and the Council was ready to vote the whole of it at once should occasion arise.

Dr. Thudichum thanked Dr. Russell for his explanation and begged to withdraw the resolution.

The fourth subject was, the present condition of the Society in reference to its Executive and the Bye-Laws.

Mr. Kingzett proposed: "That in the opinion of this meeting it is desirable that henceforth the Council shall nominate twelve candidates to fill the annual vacancies in the Council." He thought that the Fellows should have some choice of names to fill up the six vacancies instead of having the exact number nominated by the Council.

Professor Odling explained at some length the way in which the Council proceeded to select the names, and concluded by stating his firm conviction that the names were selected after a minute inquiry and with every endeavour to obtain a fairly representative body.

Mr. Neison seconded Mr. Kingzett's motion.

Mr. Spratling proposed, as an amendment: "That this meeting thanks the Council for the frank explanations given on the points that have been discussed, and begs to express its confidence in the action of the Council."

Mr. Neison rose to protest against Mr. Spratling's amendment, as not being a true amendment to the original motion.

At the request of the President the amendment was withdrawn.

Mr. Kingzett's original motion was then put and lost.

Mr. Friswell proposed the adjournment of the meeting. The proposition was however lost.

Mr. Spratling's amendment was then put as an original motion, being seconded by Mr. Neison, and carried unanimously.

The meeting terminated with a hearty vote of thanks to Dr. Gladstone for presiding.

In the course of the meeting it was stated that the Council had under their consideration various proposed alterations in the Journal, election of Fellows, etc., and intended shortly to call a general meeting to consider them.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held at 17, Bloomsbury Square, on Thursday, May 17th, Mr. Harold Senier in the chair.

A paper on "Dispensing," by Mr. C. Shapley, was read. The author, after some introductory remarks, said that dispensing, taken by itself as a branch of pharmacy, might be stated to depend for its correct performance upon three points: (1) a correct reading of the prescription; (2) the detection of unusual doses when they occur; and (3) the accurate putting together of the ingredients ordered. In regard to the first condition, the author referred to the practice adopted by some prescribers of covering the names of drugs, and instanced the use of "vegetable calomel" and "resin. pelt." for podophyllin," "blue pill," and "pil. rubri" for "pil. hyd" subchlor. co." "podoph. min." for "calomel," "pil. cærulei" for The detection of unusual doses was then referred to, and the difficulty sometimes arising when large doses are intentionally prescribed. Under the last head the author remarked :—

"One great fault, which deserves the most severe reprimand, and which is sometimes carried to a most absurd extent, is the indiscriminate measuring of drugs into a bottle without any vehicle first added wherewith to mix them. Sometimes very peculiar results are seen. For instance, if a prescription containing mag. sulph., ℥j ; tr. ferri mur., ʒij. ; æth. chlor., ʒss., be dispensed, by first placing the necessary quantity of mag. sulph. solution in the bottle, and then adding the æth. chlor. and tr. ferri mur, a singular reaction takes place ; crystals first appear on the sides of the bottle where the liquids have been poured, and these extend, and with a kind of fibrous growth traverse the whole body of the liquid, till it becomes so solid as to allow of complete reversion of the bottle without loss ; on the addition of water, however, and some little shaking, the mixture becomes clear. Another fault which is sometimes adopted for the sake of expediency, but which should not be committed, is the measuring of tinctures, syrups, etc., into a bottle, on to a powder undissolved, and finishing with the water. In dispensing gallic or tannic acids, salicin, morphia for hypodermic use, boracic acid and other like drugs, hot water is often if not generally resorted to. The result at the time may be satisfactory and elegant, but it is preferable to use cold water to avoid the risk of having such solutions returned with the ingredients recrystallized. With gallic acid, so long as the quantity does not exceed ʒss. to ℥viij., hot water if used to the *full quantity* will produce a fairly permanent result, but if a certain quantity of hot be used and the remainder be made up with cold, it is likely to recrystallize again. The same remarks apply to salicin and the other bodies mentioned. Boracic acid is more easily managed, for being generally used as an external application it is enough to have the use of a cold saturated solution and to be used with agitation. The only difficulty in the dispensing of powders occurs in the weighing out of deliquescent substances, which is best provided for by finely pulverizing in a hot mortar, and then enclosing in tinfoil. Ointment and pills often require very careful and patient manipulation to produce good results. No question has raised so much discussion as that what is the best pill excipient. The author repudiated the idea of a general excipient, for one reason that it does not seem to be a desideratum. It is possible for the dispenser to help the prescriber in this work to a very great extent. In some cases the substance to be made into a pill indicates its own excipient. Thus, dec. aloes co., for p. ext. coloc. co. would be found to be a very good one. Secale cornute might be well rubbed with just a speck of mag. carb. levis. A prescription received some time since was written, ext. cannab. ind. gr. v. ft. pil. i. ter die. Mitte xij. The medical man was called upon but said it was quite usual for him to prescribe it and wished the pills made by adding 2½ parts p. sacchar. alb. for 1 of the ext., making into two pills and labelling accordingly ; the excipient answered well."

A meeting of the Association was held on May 24th, when a paper was read by Mr. J. F. Savory, on the "Different Methods of Flower Fertilization." We hope to have an opportunity of publishing this paper in a future number.

Parliamentary and Law Proceedings.

Important Prosecution under the Sale of Food and Drugs Act for Refusal to Sell.

On Thursday, May 30, at the Belfast Police Court, John Ussher, druggist, Castle Street, Belfast, was summoned at the instance of the sanitary officer, for refusing to sell to the officer sulphate of quinine the same being on sale by retail on his premises.

Mr. M'Lean said that the prosecution was brought under the 17th section of the Sale of Food and Drugs Act, 38 and 39 Victoria, which cited that "if any officer, inspector, or constable as described by the Act, shall apply to purchase any article of food or any drug exposed to sale, or on sale by retail, on any premises, or in any shop or stores, and shall tender the price for the quantity which he shall require for the purpose of analysis, not being more than shall be reasonably requisite, and the person exposing the same for sale shall refuse to sell the same to such officer, inspector, or constable, such person shall be liable to a penalty not exceeding £10." Anderson, the inspector, went into the defendant's shop, and asked for a drachm of sulphate of quinine ; and when the quinine was handed to him, he told the defendant that it was for the purpose of analysis. The defendant then snatched the quinine out of his hand, and threw the money—the amount that he had paid for it—back to him.

Wm. John Anderson deposed, that on the day in question he went into the defendant's shop and asked him for a drachm of sulphate of quinine. The sulphate was exposed for sale on the premises. In payment of the sulphate he gave a half-sovereign, but the defendant had no change, and witness went out to get it, and when he returned he gave the defendant 2*s.* 6*d.* for the drachm. When the defendant was handing the sulphate to him, witness informed him that it was for analysis. The defendant then snatched the quinine back, and told him to take the 2*s.* 6*d.*, and added, "You are done now." Witness replied that he was not, and that it was his duty now to inform him that he was liable to be summoned for refusing to sell him the article.

In reply to Mr. Sheals for the defence, the witness said he had the letters "S.S.O.," which were for sub-sanitary officer, on the collar of his coat, which the defendant could have seen.

Mr. Sheals said that there was no proof of a refusal on the part of the defendant to supply the complainant with the quinine as required by him. He contended that the officer did not intimate when he first went into the shop or establishment of the defendant that he was a sanitary inspector, or a person authorized or empowered to get from the defendant the quinine for the purposes of analysis. He maintained that when a person went into a druggist's house or shop in order to obtain articles for analysis, and, if necessary, afterwards to establish proceedings, he should announce his calling. He had asked the inspector how Mr. Ussher could recognize him as a sanitary inspector, or recognize him as a person authorized to get the drug, and the only answer he gave was that he had certain letters impressed or printed on the collar of his coat. Under all the circumstances he did not think that there was an absolute refusal. Mr. Ussher would tell the court that when this young men presented himself in the shop he took him as an ordinary individual ; but when the quinine was made up, and Anderson had informed him that he was about to have it analysed, he was suspicious, because he had not intimated to him that he was about to divide it into three parts.

The defendant was examined, and stated when the complainant came into his shop his collar was turned up, and the letters on it were not discernible. He asked witness for a drachm of quinine. Witness weighed it, and the complainant handed him half a sovereign in payment. He had to go out and get change. Up till the time he went out for the change he never intimated that he was a sanitary inspector authorized to get drugs for the purpose of analysis. When he put down the half-crown on the counter, and when witness was reaching the quinine over to him, the complainant make a remark that it was for analysis. Witness told him that he would not have it. Witness was under the impression that complainant was not a person authorized to get a drug for analysis. He was afraid that if he had got the quinine out of the shop the complainant might have tampered with it. If he had come in the proper way, and told witness that it was for analysis, he would not have hesitated to give it.

The defendant said, in reply to Mr. Sheals, that he bought his drugs from the best house he could find in Liverpool.

Mr. O'Donnell said the quality of the drugs was not before the court.

In giving the judgment of the court,

Mr. O'Donnell said that the observations of Mr. Shales in his defence were based entirely upon a wrong assumption. There was no necessity for the officer to announce himself as such, or to go in uniform, when he purchased the drug. It was the duty of the officer when he purchased a drug, to tell the vendor what it was for, and to divide it into three parts according to law. The officer, in his opinion, went in the proper discharge of his duty to buy a drug, and there was a distinct refusal to sell it. Having regard to the preceding section—section 14 of the same act—under it the mixer of a drug was dealt with very severely because if the drug was sold, and the quality or potency of it was injuriously affected, the party so adulterating it was liable to a penalty of £50. But as far as in this case, there was no evidence that the drug was adulterated. He thought the sale of adulterated drugs was about the worst offence any man could commit, although this was the first case brought under the act into this court. He would inflict the full penalty of £10 for refusal to sell.

Prosecution for Sale of Vermin Killer without Entry in Poison Book.

At Guisborough Petty Sessions on Tuesday, May 29, Mr. Peter Bamlett Ayton, a chemist and druggist, in business at Lingdale, was summoned for having neglected to enter in a certain book, as required by Act of Parliament for the purpose, the sale of a packet of poison.* The defendant pleaded that he was in London at the time, and that the mistake was made by his assistant.—It was stated by Superintendent Prest that the poison—a packet of Battle's Vermin Killer—was sold to a young woman named Mary Ann Lawrence, who, whilst in a low way, swallowed a considerable dose of it and poisoned herself.—The defendant said there was no evidence that the young woman poisoned herself, but Admiral Chaloner remarked that even if that were the case it did not alter the fact that the poison was sold and no entry had been of the sale. It was a serious offence, and the Bench felt it their duty to inflict the full penalty of £5 and costs.—*Northern Echo.*

Notes and Queries.

PREPARATION OF THIN PENCILS OF SILVER NITRATE.—Very thin pencils of caustic, such as are sometimes required for intra-uterine applications, may be prepared, according to A. Huber, in the following manner: Silver nitrate is fused in a capsule, and the liquid drawn up, by slow and cautious suction, into a glass tube, the calibre of which is a trifle larger than the required diameter of the pencil. Especial care is to be taken that no cavities filled with air-bubbles are produced in the contents of the tube. When entirely cold, the glass tube is warmed by turning over a spirit-lamp, until the outer surface of the stick has become soft, when it may be easily pushed out by means of a knitting-needle. With a little practice, very handsome pencils, of considerable length, may be obtained in this manner.—*New Remedies*, from *Schweiz. Woch. f. Pharm.*

* The fact that no such name appears on the Register of Chemists and Druggists for 1877 seems to indicate that a double offence against the Pharmacy Act has been committed by the defendant.—Ed. *Ph. J.*

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Cooperative Stores.

Sir,—In *Pharmaceutical Journal*, No. 362, 3rd series, I see correspondence applying to myself in which one of the correspondents allows himself to *wade* through the mire of two misrepresentations; in the first place he alludes to my being considered "a champion to fight underselling chemists." I deny that at the annual meeting I spoke of the rate of sale, well knowing that the Pharmaceutical Society is not a trade union for the purpose of regulating prices. In the second, he says, "accompanied by the handbills was a statement that all drugs are sold at equally low prices." That is absolutely untrue! and I am greatly surprised that any gentleman of common sense should be led away by a communication that is unattested by the writer's name; you, sir, and other journalists publish nothing unauthenticated, and not always that which is.

One gentleman on the Council had the honour and manliness to remit a similar communication to myself; I recognized the writing and found it emanated from an A.P.S. who resides not one hundred miles from my own dwelling. This part I conclude as I go in for principle and not personality.

The explanation your correspondents, Messrs. Walker and Wade, imply they require I now give.

The trading in medicines by unregistered cooperative store proprietors must be divided into two heads, viz., the lawful and the unlawful; the unlawful, viz., the dispensing, compounding, and retailing of poisons, is a matter for redress at the hands of the chemists, and for that purpose I addressed them at the annual meeting—this your correspondents seem to object to. The lawful (thanks to the Government having a share in the profit), I meet by competition at such a price that if they trade in them they shall have no profit. Why do not my brother chemists imitate myself so as to render the amount of business done by stores *nil*, and at the same time close all accounts with the wholesale patent medicine vendors that supply the stores.

My experience of the trade is that as a rule they have looked at their grains and scruples until their ideas are as small, and if they continue in this track we shall have large demands in future upon the grants of the Benevolent Fund, so I enclose by same post to Secretary a cheque for five guineas as a donation to that truly catholic charity that makes no distinction between the subscribers and the non-subscribers.

My apology is due to you, Mr. Editor, for having overlooked your acknowledgment to my letter of December, 1876, under the title M.P.S.G.B.

Robert Owen Fitch.

June 6, 1877.

The Benevolent Fund.

Sir,—Why should not some kind of arrangement be made in connection with the Benevolent Fund which would enable subscribers to claim immediate relief in times of sickness or distress?

Would not a chemists' benefit society meet the case of those among us who are anxious to make some slight provision against the day of adversity?

I am of opinion that the Pharmaceutical Society possesses unusual facilities for organizing an assurance fund for the relief of the more needy members of the trade, a fund which I venture to think would be of great benefit to the class of chemists who would subscribe to it. Many a chemist in a small business, and many a "Perpetual Chemists' Assistant," would feel his load of anxiety lightened if he could demand relief (when incapacitated by sickness or accident from attending to his business duties) from a fund to which he had subscribed when in health. I have made inquiries recently respecting a variety of benefit societies (most of them trade societies), but I can find none which exactly meet the requirements of members of our calling.

If gentlemen in the trade who understand financial matters would give their opinions as to the practicability of forming a chemists' benefit society they would confer a favour on

"ALBERTUS."

THE HISTORY OF PHARMACY.

Sir,—A reprint of the 'History of Pharmacy,' published in 1841, by the late Jacob Bell, and referred to at the annual meeting by Mr. Humpage, would at the present time possess special interest, and I have no doubt find a ready sale.

About four years ago the Council decided on having the work brought down to 1868, and I believe a sum of money was voted for the purpose. I am aware the work of compilation must necessarily be tedious. I hope, however, progress is being made and that we shall soon hear of the "copy" being in the printer's hands.

JAMES BAYNES.

Hull, June 5, 1877.

CHEMISTS' ASSISTANTS' ASSOCIATION.

Sir,—I notice the letter of "An Associate" in your impression of the 2nd instant, and I think with him, that there should be "something more sociable than the scientific meetings at the Square, to promote good fellowship among chemists' assistants," but in my opinion the want would be best supplied by a "Chemists' Assistants' Club," to be carried on without any reference to education or trade matters, merely for the social intercourse of chemists' assistants and their friends, provided that sufficient funds can be obtained, and the members have time to take advantage of the club. I certainly think that the association now being founded will make a fatal mistake in giving as your correspondent says it will, "the first and foremost place in the discussions to the subject of early closing," for I cannot see how employees can discuss such a subject without threatening coercion; and I hear a rumour that some of the bolder spirits, young and radical M.P.S.'s, not at present connected with the association, have stated it to be their intention, if they can obtain entrance into the committee of management, to keep a list of employers who refuse to close their establishments at an appointed hour, and prohibit any member, from giving his services to such persons. This spirit, as far as I can ascertain, is only possessed by a small minority, who seem to forget that it is more in the power of employers to declare a lock-out of all members of the association, than for the association to dictate terms. But fortunately chemists and their assistants are too far advanced to practise strikes and lock-outs.

Early closing is a subject which falls to principals to discuss and carry out. On the whole I am not at all surprised to hear that "An Associate," who is evidently a man of power among his fellows—observes "a tendency on the part of some members of the trade to throw cold water on the scheme, and to regard it in the light of a trade union;" for the language of the letters which I understand were sent to you, and very wisely refused insertion, in reference to the decision of the Council denying the loan of the Lecture Theatre, for the use of the embryo association, and the proposed attempt at coercion in early closing, would be quite sufficient, if true, to give it the character of a trades union. I am, however, pleased to learn that the majority of members who form the committee of management are actuated by right principles, and that M.P.S., and Ph.C., will not be the only qualification for office. No one wishes the association, if properly directed, success more sincerely than

"A PUBLIC SERVANT."

London, June, 4, 1877.

AVOIRDUPOIS WEIGHTS AND FLUID MEASURES.

Sir,—Your correspondent on p. 996 of this week's number takes exception to my mode of expressing formulæ in parts. It was adopted because, when the apothecaries' or troy weight was relinquished for the imperial or avoirdupois weight, I thought it safer to express the formulæ in parts, where practicable, and, after ten years' experience, I am of the same opinion. If dispensers, as your correspondent avers, weigh by the troy and measure by the imperial, that is not my fault. The weights of the British Pharmacopœia are, the pound, the ounce, and the grain. The ounce for solids and the fluid ounce weigh exactly the same, and if less division than the quarter of an ounce is required it must be expressed in grains. The grain is the same in all kinds of British weights.

P. SQUIRE.

277, Oxford Street, London,
June 4, 1877.

P.S.—If you have given his formula correctly (Ext. Opii 1; S.V.R. 16; Water 4) he has not copied my form correctly, my formula being Ext. Opii. 1; S.V.R. 4; Water 16.

Sir,—In reply to your correspondent who (under this heading in your last issue) comments upon the arrangement of formulæ in Squire's 'Companion,' I would direct attention to the fact that Squire, following the B. P., distinctly repudiates any division of the ounce other than in grains. I do not, therefore, think it fair to attribute to his misleading any tragical results contingent upon a retentive love of the drachm.

I think it equally unfair to Squire to misquote him as is done by your correspondent in the relative proportion of S. V. R. and water, and thus to exhibit him as a "companion" to be avoided by all pharmacists desirous of maintaining character for respectability.

ALEXANDER BOTTLE.

Dover, June 4, 1877.

CHLORAL HYDRATE.

Sir,—It may assist the Law and Parliamentary Committee of the English Pharmaceutical Society in arriving at a decision regarding "chloral hydrate" to know that last year it was added to part two of the schedule of the "Irish Poison Act."

Phosphorus and all preparations containing free phosphorus were also added to part two at the same time.

THE CULTIVATION OF MEDICINAL PLANTS AT BANBURY.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

The principal farmer of medicinal plants in the neighbourhood of Banbury is Mr. Usher, of Bodicote, a small village about two miles from the town. At present he has about sixty-five acres under cultivation, twenty of which are devoted to rhubarb, forty to henbane, and four or five only to the white poppy. He has also lately commenced the cultivation of *Rosa gallica*, L., on a small scale.

On a recent visit to Banbury much interesting information was kindly given me by Mr. Usher, and as it was the result of observations which had been made by that gentleman during the course of many years it seems very desirable that it should be placed upon record.

RHUBARB.

The history of the cultivation of this plant in this district has been briefly sketched by Hanbury in 'Pharmacographia.' In that work he attributes the plant cultivated at Banbury to *Rheum Rhaponticum*, L. It, however, more closely resembles *R. undulatum*, L., differing chiefly from the description of that plant, as given by Meisner, in the upper leaves being distinctly stalked. From *R. Rhaponticum* it differs in all the leaves being longer than broad and minutely ciliate at the margins, and in the petiole being distinctly channelled on its upper surface above the middle, although it becomes flat near the base.

The leaves have two or three somewhat triangular teeth near the point and the petioles and stem are slightly furrowed, and the ochreæ do not appear to be deciduous as in *R. undulatum*. It would thus appear to be a hybrid between the two, if indeed the two species are really distinct.

When in blossom the panicle is at first decidedly spreading, so much so as to present an appearance totally different to that it offers at a later stage, when its branches become quite erect. Indeed, had I not found the two stages proceeding from the same root, I could hardly have believed that there were not two species growing in the same field. On closer inspection, however, the character, leaves and leaf-stalks convinced me that only one species was present.

The soil on which the plant is chiefly cultivated is a rich red friable loam, which appears to suit it well, although in some spots where the soil is damp the root decays and the plants gradually disappear. Mr. Usher's experience with regard to this plant is as follows:—Up to three or four years of age the plants flower rather freely, but after that time they rarely produce inflorescence. Singularly enough, for many years past no fruit has been ripened, the little that is formed falling off soon after "setting," so that it would seem as if the plant had already acquired a tendency to become a root-producing rather than a fruit-yielding form.

The rhubarb plant does not appear to be much attacked by insects or by fungi. After about eight or nine years the soil becomes exhausted, and rotation of crops becomes necessary. The exhaustion of the soil is, however, in some degree counterbalanced by the matter returned to it by the leaves, which are allowed to decay on the ground, and even those which are taken up with the root are afterwards returned in the form of manure.

The young plants are not obtained from seed, but are always propagated from the lateral shoots of plants about four years old, at which period the shoots are more vigorous and produce finer plants than if obtained from older ones. The petioles are never gathered for food, because it has been found that so doing injures the size and quality of the root. The young plants are set at distances of three feet apart, and the root is not fit for collecting until the plants are about four years old. From that period up to nine or ten years of age the root improves in size and quality. Plants of different ages are of course cultivated in different fields so as to secure a succession of harvests each year. Plants of about four years old yield from one and a half to two tons of dried root per acre, but ten year old plants will yield about five tons per acre.

The drying is by no means an easy task. The roots are dug up in hot weather, at any time between July and October, and for the first fortnight are exposed to a current of air on wicker baskets in a covered shed. They are then removed to the drying-room, where they are dried gradually but thoroughly for about six weeks, by means of a current of heated air. This part of the process requires great care, lest the outer portion should be dried too rapidly, while the interior is still moist. The large central portion, or tap root, furnishes the pieces known in trade as "fine large flats" and "fine large rounds." The "small rounds" and the cuttings commonly known as English "stick" rhubarb are obtained from the side branches of the root. Some of the flat pieces, except for their shrunken exterior, are not unlike the East India rhubarb of commerce, and being more thoroughly dried right through and harder in the centre seem to meet with a greater demand than the rounds. The raspings obtained in trimming the pieces are ground into powder. The average yield of the dried root every year is from eight to ten tons.

Of the *Rheum officinale*, Mr. Usher has now under cultivation in his garden about forty large plants between two and three years old, as well as about 200 seedlings. These plants are truly magnificent, each plant occupying a space from eight to twelve feet square, and standing four or five feet high. Some of the leaves are nearly three feet broad, and longer than they are broad. It is just suitable as an ornamental plant for lawns, where it would have plenty of room to grow. Indeed it is already used in this way in some of the public gardens in Paris.

The root of only one plant has as yet been dried, and was obtained from a plant barely two years old. A piece of this root has been presented to the museum of the Pharmaceutical Society, the remainder having been almost all sent to the Philadelphia Exhibition, where it obtained a medal, and was purchased.

In colour, the dried root is paler, although the veins are darker, than in the East Indian rhubarb. Mr. Usher informs me that it nevertheless yields a bright yellow powder. The external markings do not exactly correspond with those of the East India rhubarb, the peculiar reticulated appearance characteristic of that sort not being visible on the two pieces that I have seen. This may, however, be due to the age of the root, which was less than two years old. It yet remains to be seen whether the root differs when older, or whether some portions present a different aspect to others. These points I hope to have an opportunity of investigating a little later on, when Mr. Usher will dig up some larger roots. Towards the close of the year he will probably have sufficient of the dried root of this species to be available for therapeutic purposes, and it will then only remain to ascertain whether its purgative properties are equal to those of the foreign rhubarb, which after all will be the test of its acceptance with the medical profession. A chemist at Banbury has prepared some simple tincture from the trimmings of the root, in the proportion of two ounces to the pint of proof spirit, and has found it an effectual purgative in ounce doses.

Henbane.

Doubtless many of the readers of this Journal have often wondered at the high price of biennial henbane. The information which Mr. Usher has kindly furnished will probably throw considerable light upon this point.

The biennial plant is the only one cultivated at Banbury, it being found that the presence of the annual plant tends to deteriorate the biennial variety. With regard to the difference between the two plants, Hanbury says there is scarcely any distinctive character, except that the one is annual and the other perennial. There is, however, something very distinctive in habit. The biennial plant grows to the height of two or three feet, and is abundantly branched, and the stem is often nearly an inch thick at the base. At a distance, a field of biennial henbane looks like a field full of thistles, so much so, that Mr. Usher has occasionally heard the remark from farmers passing by, "That is bad farming, look at those thistles." This curious appearance is owing to the leaves being deeply cut, in fact almost pinnatifid. The chief difference in the leaves of the two varieties is, that in the biennial plant the leaves are about twice as long as in the annual one, and deeply cut, and the terminal lobe of the leaf is long and rather narrow.

The leaves of the upper branches, however, resemble when young those of the annual variety, being shorter and having the top of the leaf much broader, and more triangular, not lanceolate as in the stem leaves.

The seed of the biennial plant is sown in May or June, and either appears in a few days or not for several years. Mr. Usher informed me that in one field sown with henbane none of the seed came up and the field was again sown with other crops, and it was not until nine years afterwards, during which period the field had been several times ploughed, that it yielded a good crop of henbane quite unexpectedly, and without any more henbane seed having been sown. This uncertainty seems to depend upon the weather being dry soon after the seed is sown. If the weather is damp immediately after sowing the seed, it usually comes up at once.

The cultivation of the plant is beset with difficulties. In the first place, it grows very slowly when young, and is soon hidden by weeds of more luxuriant growth, so that it has been found necessary to mix some rapidly growing plant, such as mustard, with it in order to indicate where it is sown. It also requires shelter when young, This difficulty Mr. Usher has obviated by sowing it in rows between beans so that it may be protected in its early stage. As soon as the young leaves are fully formed the turnip fly attacks them; when the autumn leaves of the first year have decayed a white slug eats away the central bud; and if it still manages to live a wire worm attacks the root during the winter. It will be easily understood, therefore, why the fields of henbane often present very large bare patches, and why the price of the drug is so high. The plants are collected for drying about the third week in June. The upper leaves are deprived of the midrib, and these as well as the flowering tops are dried, and form the best biennial henbane of commerce. The lower leaves and stems are used for preparing extract, for which purpose they are crushed under an edge runner, and the juice squeezed out by hydraulic pressure and then evaporated down to a proper consistence. It is obvious that an extract prepared in this way on the spot by the grower is likely to be better than when prepared from the herb sent to a distance by rail, for these plants become heated in twenty-four hours when packed closely. The leaves and flowering tops are dried in malt kilns, of which seven are in use at once. The leaves are spread thinly at first and are turned over about three times a day, and as they become somewhat dry are collected closer together into rows or heaps on the kiln floor. As one lot becomes partially dried it is removed to another kiln until quite dry, which usually happens in about three days, and a fresh lot takes its place.

There are one or two points with regard to the flower which are rather interesting. The flowers are proterogynous, the stigma becoming mature and viscid before the anthers open, and the stigma and nearly half the style are protruded beyond the unopened flower bud. The corolla is more deeply divided in its lower half than elsewhere, and the stamens and pistil are depressed towards this portion, so that insects visiting the flower for nectar must pitch upon the stamens and receive the pollen upon their legs or abdomens, and must thus almost of necessity convey it to the protruded stigma of the unopened flower. When the corolla is fully grown it exceeds the stigma, so that the style does not appear to grow in proportion to the corolla. The anthers are furnished with a curious connective of a narrowly triangular form into which the filament tapers. As soon as the anther bursts it becomes bent backwards away from the stigma and towards the ovary as if to prevent the pollen from falling on the stigma of the same flower. Mr. Usher informs me that the annual variety does not possess a long protruded style, but as he had no plants growing I was unable to verify this observation. It would be interesting to ascertain if the henbane is dimorphic, and if the annual plant is the second form. Another interesting point of inquiry is whether the plant possesses the power of digesting the multitude of minute insects which late in the season are caught by the clammy glandular hairs. The frequent occurrence of henbane on manure heaps or places in which insects are abundant seems almost to point to such a property.

White Poppy.

The culture of this plant is attended with so much trouble and expense that it scarcely repays the labour expended on it. The seed has to be selected very carefully, for singularly enough the poppy shows a constant tendency to "sport," and if left to itself, the flowers of the white poppy become coloured in a few generations; the size of the capsule decreases, and the colour of the seeds and of the flowers becomes darker in proportion, until at length the flowers become purplish black, and the seeds quite black. Mr. Usher accounts for this fact by supposing that insects carry the pollen from the wild red poppy (*Papaver Rhœas*, L.) to the white one.

In order to get large capsules, only the very whitest seeds are retained and sown. Those poppies which have dark flowers, he states, produce darker coloured somewhat oblong capsules. The German poppy seed produces a large capsule much flattened at the top and bottom, and with the carpels strongly convex and prominent so as to have much the appearance of a peeled orange, or of the capsule of *Papaver hybridum*, L. This variety is not, however, readily accepted in commerce.

The seeds of the white poppy are sown in rows about 20 inches apart. When young the plants require constant weeding. The capsule, when the flower has fallen, is about the size of a walnut, and is stated by Mr. Usher to grow to the size of an orange in the short space of ten days, although it takes nearly five weeks to ripen. Each plant bears about two or three capsules. The harvest is collected during the last week in August or the first in September. A waggon load of the capsules is placed on the floor of each of the kilns and forms a layer about a yard deep, the whole of which becomes dry in about twelve hours, and is then ready for sale.

THE CONSTITUENTS OF COTO BARK.*

BY JULIUS JOBST AND O. HESSE.

This bark has been further examined by the authors† and the results have been communicated to the Berlin Chemical Society. The powdered bark extracted with ether yielded a yellow brown solution which left, after evaporation of the ether, a brown resinous residue that showed after a time an abundant crystallization. The crystalline mass consisted principally of three bodies, to which the authors have given the names "paracotoin," "oxyleucotin," and "leucotin;" these were separated by fractional crystallization from hot alcohol.

Paracotoin ($C_{19}H_{12}O_6$) forms yellow scales, easily soluble in chloroform, ether and boiling alcohol; less soluble in cold alcohol, benzin, petroleum spirit and boiling water. From the solution in boiling water it is obtained on cooling in almost colourless scales. In alcoholic solution it has no reaction on litmus paper and is tasteless. In ammonia it is insoluble, and from hot ammoniacal alcoholic solution it crystallizes unaltered. In dilute potash or soda it dissolves with a yellow colour, but only in small proportion. In strong sulphuric acid it forms a yellow solution becoming darker when heated; in strong nitric acid also it forms a yellow solution, but this upon heating becomes lighter. Perchloride of iron presents no reaction with it. Paracotoin melts at 152° (uncorrected) to a yellow liquid which upon cooling takes a radiating crystallization. At a higher crystallization it sublimes in yellow shining scales.

By the action of baryta water paracotoin is converted into paracotoic acid, according to the equation—

$$C_{19}H_{12}O_6+H_2O=C_{19}H_{14}O_7$$

This acid forms a chrome yellow amorphous powder, readily soluble in ether and alcohol, but almost insoluble in hot benzine. The alcoholic solution has a decided acid reaction and upon evaporation leaves the acid amorphous. The same acid is formed when paracotoin is boiled with dilute potash solution or only heated to 80° C.; but then there is also formed a smaller quantity of another product which has been named "paracumarhydrin." When the solution is boiled it escapes with the steam. Paracumarhydrin, $C_9H_8O_3$, forms delicate white scales, melting at 85° C. (uncorrected), readily soluble in alcohol and ether, less so in hot water, from which upon cooling it is again deposited in scales. Its formation from paracotoin may probably be represented as follows:—

$$C_{19}H_{12}O_6+2H_2O=CO_2+2C_9H_8O_3.$$

Paracumarhydrin has a smell recalling that of cumarin; and when it is rapidly heated the odours of oil of wintergreen and oil of bitter almonds are noticeable. Upon attempting to redistil it with water vapour only a small portion passes over, the greater part remaining dissolved in the water in the retort. Upon shaking this aqueous solution with ether and evaporating the latter white crystalline scales are obtained, having an extremely pleasant taste, and melting at 81° to 82° C. The same substance results upon treating paracumarhydrin with zinc chloride. Apparently in both cases it loses water and forms the paracumarin corresponding to paraoxybenzoic acid.

Comparison of this substance with cumarin shows that it resembles it only in smell. Whilst cumarin is deposited from dilute alcohol in four-sided prisms, the supposed paracumarin forms shining scales. The fusing points also differ. Zwenger and Bodenbender found that for cumarin prepared from *Melilotus officinalis* it was 67°, and Perkins for that from aceto-salicyl aldehyd between 67° and 67·5° C. By treatment of paracotoin with caustic potash an acid was obtained crystallizing in small needles, and melting at 200°, or nearly the temperature given by Tiemann and Mendelsohn for paracumaric acid. The crystals however were yellow, and gave on combustion only 60·91 per cent. of carbon and 4·05 of hydrogen, paracumaric acid requiring 65·88 per cent. of carbon and 4·87 per cent. of hydrogen. When fused with potassium hydrate paracotoin gave off a faint smell of paracumarhydrin, but an acid was formed, with evolution of hydrogen, corresponding with protocatechuic acid in its behaviour towards ferric chloride, though differing in other respects. A volatile acid (apparently formic acid) was also formed and a brown resinic acid.

Oxyleucotin ($C_{21}H_{20}O_7$) can be separated from leucotin by crystallization from alcohol, in which the latter is very soluble. It forms thick heavy white rectangular obliquely truncated prisms, melting at 133°, and solidifying amorphous on cooling. It dissolves freely in hot alcohol, ether and chloroform, less so in cold alcohol, and is nearly insoluble in cold water and alkalies. It is tasteless, and neutral, and in chloroform solution does not affect polarized light. Strong sulphuric acid colours it dark yellow. Strong nitric acid dissolves it upon warming with a blue green colour, leaving a bluish-black resin that forms a blue green solution in alcohol. When fused with potassium hydrate oxyleucotin yields a crystallizable acid, giving a green colour with salts of iron, and also differing from pyrocatechuic acid.

Leucotin ($C_{21}H_{20}O_6$) resembles oxyleucotin in its behaviour to sulphuric and nitric acids, dissolves very freely in alcohol, benzin and ether, forms very slender white prisms, and melting at 97°. In chloroform solution it has no action on polarized light. It occurred in considerable quantity in the bark examined.

Hydrocotoin ($C_{22}H_{20}O_6$) remained dissolved in the mother liquor from which the foregoing substances were obtained. This liquor being evaporated left a brown resin, which was exhausted with very dilute caustic alkali, excess of hydrochloric acid added to the solution, and the resulting reddish yellow flocculent precipitate dissolved in a little hot alcohol, from which the hydrocotoin crystallized on cooling in shining pale yellow prisms; from boiling water slender white needles were obtained. Hydrocotoin is neutral, tasteless, and in chloroform solution without effect on polarized light. It dissolves in alkalies with a yellow colour, and is again precipitated by acids, even carbonic; strong sulphuric acid forms with it a yellow, and hot nitric acid a purple red solution,

* *Berichte d. deutschen chemischen Gesellschaft*, vol. x., p. 249.

† See before, vol. vi., p. 764, vol. vii., p. 495.

from which upon dilution with water a purple red precipitate soluble in cold alcohol separates. When heated with manganese and sulphuric acid, or upon combustion of one of its lead salts, hydrocotoin gives off an odour resembling hyacinthin.

Cotoin, the substance obtained from the coto bark first examined,* the authors now represent by the formula $C_{22}H_{18}O_6$, so that paracotoin would appear to be a homologue differing by C_3H_6. Hydrocotoin appears to differ from cotoin in containing two atoms more of hydrogen in the molecule.

The authors state that Dr. Burkart, of Stuttgart, is making experiments with paracotoin, oxyleucotoin and leucotoin, the results of which will be reported in a medical periodical. Meanwhile, paracotoin, notwithstanding its high price, which is probably temporary, is finding a daily increasing use as a remedy against all kinds of diarrhœa.

TIMBO, ITS PROPERTIES AND COMPOSITION.†

In 1846 M. Stanislas Martin first described, in the *Bulletin Général de Thérapeutique*, a substance called guarana, much used in Brazil, where it was obtained from a plant belonging to the family of *Sapindaceæ*. In 1817 Cadet de Gassicourt, and in 1822, Mérat mentioned this substance without indicating its origin. At the present time the *Guarana*, or *Paullinia sorbilis* of Linnæus, occupies a place in our materia medica owing to its richness in caffeine.

Plants belonging to the *Sapindaceæ* are very common in Brazil, and comprise both trees and climbing shrubs. Some have such poisonous properties that the natives use their juices as arrow-poisons, while others are innocuous or simply narcotic. The Timbo (*Paullinia pinnata*, Lin.) belongs to the latter class. The Timbo is a tree found in Brazil, Mexico, the Antilles, and in Guiana. The leaves are composed of five leaflets, oval, lanceolate and crenellated. The flowers are polygamous, diœcious, and have five, or rarely four parts; an imbricate calyx; four unequal petals furnished with scaly appendices; eight stamens situated around a disc with notched edges; ovary with three cells, surmounted with three styles, and containing three seeds, and commonly one which has aborted, which is provided with an arillus and contains under its envelope an embryo without albumen. The bark of the timbo root is the only part used in Brazil; it is of a yellowish-grey colour, and variable in length and thickness. In transverse section there is observed from outside inwards, 1st. An exterior layer of periderm, composed of numerous masses of corky or woody tissue. 2nd. On reaching the central parenchyma there are seen here and there small masses of hardened cells (that is to say, having early incrustations); this element is frequent in the bark and in this situation. 3rd. A very thick layer of cortical parenchyma, in which the cells are distended with starch. 4th. In the midst of this parenchyma cells containing a resinous material. 5th. Bundles of liber arranged in interrupted lines and mixed with rays of the medulla. This bark is with difficulty reduced to powder. Five grams of it will absorb, cold, fifteen grams of distilled water.

The bark of timbo root has an agreeable aromatic odour, slightly resembling musk. In Brazil it is only employed externally. Poultices are made from it with boiling water, which are applied to the side in affections of the liver. It often causes intense eruptions, in which case the application is discontinued.

M. Martin has isolated from the root-bark, starch, resin, an essential oil, chlorophyll, tannin, an organic acid, traces of glucose, and an alkaloid to which he gives the name of "timbonine."

By first treating the finely powdered bark by carbon disulphide, the extraction of the alkaloid and other principles is facilitated. The sulphate of timbonine crystallizes in white needles.

SOME METHODS OF ESTIMATING TANNINS.*

BY H. R. PROCTOR, F.C.S.

There are few substances of equal importance to the tannins, of which the chemistry is in so unsettled a state. This is, no doubt, primarily due to their complexity and unstable character, which makes their investigation one of great difficulty; and, secondarily, to the indifference and ignorance of chemistry of those to whom the knowledge is of commercial importance. But tanners may be well excused for some distrust of chemical analyses when we consider the discordant results which are yielded by most of the processes in use. With a view to exhibit the relative merits of these processes, I have ventured to give the results of comparative experiments undertaken to test their accuracy, and to point out, if possible, those which merit confidence.

The process which has been brought most prominently before the public of late is that of Muntz and Ramspacher, which consists in forcing a tannin infusion through a piece of raw hide, taking the sp. gr. before and after, and calculating the tannin from the loss. In a paper which I communicated to this Society some little time since (Proceedings, III, 213), I pointed out that the raw hide not only absorbed the tannin, but also a large proportion of the free acids in the infusion, thus, in some cases, causing a notable error. To this I may now add that it is extremely difficult to absorb the whole of the tannin, that the first portion of liquor which passes is invariably lighter than succeeding portions, and that the sources of error are so large in proportion to the quantities to be measured, that the results are of little practical value. In proof of this, I may mention that a series of nine analyses of the same sumach, well mixed, and kept in a tightly-corked bottle, gave results varying from 18 to 28 per cent., and a mean error for each single experiment of 3·15 per cent. or upwards of 13 per cent. of the total tannin, while the mean value—23·9 per cent.—was probably itself too high. In these analyses the utmost care was taken and in each case the absence of tannin in the filtrate was proved by gelatin. If we assume that tannin is worth 20*s*. per ton per cent., which is not far from the truth, the chemical valuation of this sumach would vary from £18 to £28 per ton, with an average error of £3 3*s*., and obviously is far more erroneous than the merest guess. If any further proof of the inaccuracy of the method is needed, I may quote the results of a series of twelve analyses of a valonia by Mr. W. N. Evans, who, perhaps, has had more practice with the tan-tester than any other man in England. The average error exceeds 10 per cent. of the whole quantity of tannin, and the money values vary from, say, £17 5*s*. to £28 10*s*. per ton.

The older method of Hammer, in which absorption by hide raspings takes the place of the raw hide-filter, is in my experience still more inaccurate; and I cannot say that the slight modifications proposed by Nickerson are any improvement.

Another method which has long been in use is precipitation by volumetric solution of gelatin and alum. With a solution of 5 grms. of gelatin per litre I found it impossible to say whether tannin or gelatin was in excess, with less differences than about 4 per cent. of the total quantity employed, and then the reactions were somewhat doubtful. These experiments were made with pure tannin; with catechu or gambier the uncertainty would be far wider, and with used tan-liquors it would be worse still. Under favourable circumstances and with great patience it is possible to obtain rough estimates by this method; but this is all I can say.

Concerning Sir H. Davy's still older method of precipitating with gelatin, filtering, drying, and weighing, and reckoning four-tenths of the whole as pure tannin, Dr. J. Watts says (*Phar. Jour.* viii., 517) it has "been shown to be both tedious and incorrect, as the solution

* From the *Transactions of the Newcastle-upon-Tyne Chemical Society*, 1874–1877.

refuses to filter, and the first portions precipitated contain a far larger proportion of tannin than do those which fall towards the end." Other chemists make the same statements, so that I had not thought it necessary to repeat their experiments. Very recently, however, I have learnt that Mr. Stoddart, of Bristol, and Mr. Dearden, of Bury, are again employing the plan, using sufficient alum to make the precipitate coagulate, and washing by decantation with boiling water. Mr. Stoddart informs me that the results agree fairly with a modification of Allen's lead method, which he employs. I therefore purpose trying it at a future time; but the results can scarcely be very accurate, and it is improbable that all tannins combine with gelatin in the same proportions. This last objection is technically of less importance, however, since the power of precipitating gelatin is probably somewhat proportionate to that of making leather.

Some years ago Fleck announced a method depending on the fact that while tannin, gallic acid, and colouring matter are all precipitated by cupric acetate solution, the two latter are redissolved by ammonic carbonate. He proposed, therefore, to employ a standard copper solution, and to estimate the excess by potassic cyanide. Dr. Watts showed that this was impracticable (owing to the fact, as I found, that cupric ammonio-gallate is not blue but brown), but that gravimetrically some tannins might be estimated with considerable accuracy, while other gave precipitates more or less soluble in the ammonic carbonate. The precipitate is complicated and contains ammonia. Schiff gives its formula in the case of digallic acid, as $C_{14}H_4Cu_2 (NH_4)_2 O_9 + OH_2$ (*Ann. Ch.* and *Ph.* clxxvi. 171), which would give 1 gram of tannin (digallic acid) = 1·54 gram precipitate, and ·494 gram Cu O Watts, employing the number 1·489 (deduced from the assumption, now shown to be incorrect, that the salt was a simple cupric tannate), obtained analytical results fairly agreeing with those by gelatin for valonia, sumach, divi, oak bark, galls, and myrabolans; and also for mimosa, by employing the number ·2959 instead of ·489. All tannins giving green precipitates with iron gave copper precipitates more or less soluble in ammonia.

No doubt this method, reckoning the tannin as two-thirds the weight of precipitate, or twice that of cupric oxide left on ignition, would give fair technical results; but it is unlikely that all the various tannins actually combine with copper in the same proportions. In fact, as we shall see later on, the different tannins differ notably in their properties and reactions, only agreeing in their power of precipitating gelatin, and I fear tanners will have to give up all hope of measuring them by one common standard. Indeed, to a chemist, to do so seems about as reasonable as to compare the values of nitric and sulphuric acids by a standard solution of hydrochloric acid. Probably the differences between gallotannic, quercitannic, and catechutannic acids are quite as great as those of the mineral acids I have named. Chemists may fairly undertake to compare sumach with sumach, or bark with bark, but the relative values of the tannins of bark and sumach are commercial matters which no analysis can decide, though it doubtless might be done by carefully-conducted technical experiments.

The disadvantages of the copper method are that it is slow, troublesome, and difficult, and that the washing and drying must be rapidly and carefully done, as the precipitate is easily decomposed. This difficulty might be overcome by igniting, and weighing the Cu O, but this can only be done easily in oxygen, as otherwise the copper is so much reduced that it is apt to deflagrate with nitric acid or ammonic nitrate. I think the best way is to filter on a vacuum filter, and dry in an air-bath (with a thermostat) at 100°.

The mean error of such result in a series of eight analyses of commercially "*pure*" tannin, containing apparently about 85 per cent. digallic acid by the total employed, was only ± 4·2 per cent., a much better approximation than any of the foregoing. It is not likely that the results with tanning materials would be quite so good. Analyses of bark showed considerable divergence, and combustion of the precipitate proved that it was somewhat inconstant in composition, the Cu varying from 21·6 to 25·4 per cent. I fancy, too, that for oak bark tannin two-thirds of the weight of precipitate is decidedly too high an estimate. It must also be borne in mind that if lime be present, as is often the case with tanyard liquors, it will be precipitated as carbonate. This might be prevented by filtering off the precipitate before washing with ammonic carbonate; but the method is troublesome enough without this, besides being of rather questionable accuracy.

Another process which has been much recommended is Mr. A. H. Allen's volumetric one, with a standard solution of acetate of lead, using as an indicator a mixture of ammonia and potassic ferricyanide. This is described in the last edition of Sutton, but in its original form is quite inadmissible, since lead precipitates gallic acid as well as tannin, and both react equally on the indicator. In combination with some of the differential processes in which the tannin is removed by gelatin or hide raspings, it may no doubt give useful results, and as the lead compounds of the different tannins are better known than most others possibly factors might be calculated to give percentage results. I cannot insist too strongly that any calculation of percentages by comparison with "pure" tannin is utterly fallacious, both because the various tannins are of totally different constitution, and because really pure tannin is quite unattainable. That met with in commerce only contains 80 to 90 per cent., of really pure tannin, and is very variable.

Mr. Stoddart uses Mr. Allen's process in conjunction with absorption of tannin with hide raspings, when of course the loss is *proportional* to the tannin. He also employs Nelson's gelatin swollen in cold water as an absorbent in the same manner. Time and patience are necessary for the absorption of tannin thus, and it is seldom so complete that the results are not altered by prolonged digestion. In my experience the end-reaction of Allen's method is not very distinct, and it is necessary carefully to filter the drops tested, as the indicator is affected by the precipitate. This makes the process somewhat tedious.

The remaining methods which I shall describe are all based on the oxidation of tannin by various agents, and all involve double analyses after absorption of the tannin, as tannin and gallic acid are almost identical in their behaviour with oxidizers.

Mittenzwey, and afterwards Terreil, proposed to estimate it by the direct absorption of atmospheric oxygen in alkaline solution—a difficult and tedious proceeding, though doubtless capable of some accuracy in skilful hands.

Monnier proposed to determine with permanganate direct, but this proved quite impracticable, since the oxidation is rapid at first, and then slow and with *no* definite termination.

To Dr. Löwenthal is due the capital improvement, which, with his recent additions, constitutes to my mind the most practical method of tannin analysis yet discovered. He adds to the *very* dilute tannin infusion a considerable quantity of indigo, not only to act as an indicator, but to control the oxidation of the tannin. This reaction is both rapid and accurate, and, combined with his process of precipitation by gelatin, will give results strictly comparative for any single tanning material. As it is likely to be of great practical importance, I venture to give working details, referring for further particulars to Löwenthal's paper in the *Zeitschrift für Analytischen Chemie* (1877, p. 33), and to an excellent paper by Neubauer abstracted in the *C. S. Journal* (ix., 595).

Of solutions the following are required:—

1.—4 grams pure permanganate of potash in 3 litres of distilled water (or ½ decinormal answers well and saves calculation).

2.—5 grams of *pure* "precipitated indigo" in 1 litre of water (Woodroof Brothers, of Crutched Friars, supply a satisfactory article).

3.—Dilute sulphuric acid (1 to 3 of water).

4.—25 grams of good transparent glue well swollen in cold water, and then dissolved by the aid of heat. The solution is made up to a litre, and saturated with pure salt (table salt).

5.—A saturated solution of pure salt, containing 25 c.c. of sulphuric, or 50 c.c. of hydrochloric acid per litre.

To make an analysis, 10 grams of sumach or valonia, or 20–25 of bark, are exhausted by repeated boiling with portions of water, and the infusion, when cold, made up to 1 litre.

Of this infusion, 10 c.c. are mixed with, say three-quarter litre of good drinking water, 25 c.c. of the indigo solution, and 10 c.c. of the dilute sulphuric acid are added, and then the permanganate solution is run in drop by drop from the burette, with constant stirring, till the deep blue of the indigo changes to a clear yellow, and the moment this takes place we note the quantity of permanganate used. We will call this quantity A.

Next we repeat exactly the same process with the indigo and sulphuric acid alone, and will call the quantity B. Then, subtracting B from A, we obtain the amount of permanganate consumed by the total astringents of 10 c.c. of our tannin infusion. The permanganate acts, of course, as an oxidizing agent, oxidizing and consuming both the tannin and the indigo; but as the tannin is the most readily oxidized of the two, it is consumed first, and when the indigo is all bleached we may be sure that the tannin is destroyed also. In order, however, to obtain this satisfactorily, the proportion of indigo should be such as to require about twice the quantity of permanganate which would be consumed by the tannin alone. Thus, if the indigo alone requires 10 c.c. of permanganate to decolorize it, the indigo and tannin infusion together must not take more than about 15 c.c., and if it does so, the tannin infusion must be diluted accordingly, or a less quantity employed.

The next step is to ascertain the proportion of gallic acid and impurities in our sample. To this end we mix 100 c.c. with 50 c.c. of our salted gelatin solution, and then, after well stirring, add 100 c.c. of the salt and acid solution, and leave the mixture standing for some hours or all night, and then filter it through paper. The filtrate should be completely clear.

If we now test, say 50 c.c. of this filtrate with permanganate and indigo as before, we shall obtain the amount of permanganate required for the gallic acid and impurities alone, since the tannin has been entirely precipitated, and the gelatin has so trifling an action on the permanganate that it may be safely neglected. To make the working clearer, we will take an example from Dr. Löwenthal's paper:—

10 grams of sumach were boiled in three-quarter litre of water, and after cooling were made up to 1 litre.

(1) 10 c.c. sumach infusion 25 c.c. indigo solution	consumed	16·6 c.c. permanganate.
Ditto repeated		16·5 „
		33·1 „
50 c.c. indigo alone		13·2 „
Total permanganate for 20 c.c. sumach		19·9 „

(2) 50 c.c. filtrate from the gelatine 25 c.c. indigo solution	consumed	11·2 c.c. permang.
Ditto repeated		11·1 „
		22·3 „
50 c.c. indigo alone		13·2 „
Gallic acid and impurities		9·1 c.c.

Now deducting 9·1 c.c. from 19·9 c.c. we have 10·8 c.c. as the permanganate equivalent to the tannin of 20 c.c. of sumach infusion or 0·2 gram of dry sumach. If it be desired to compare two sumachs, these proportional numbers are all that is necessary, and indeed it will be quite safe to use them for comparing sumach with galls or pure tannin. In the same way bark may be compared with bark, and valonia with valonia, but it will not be safe to attempt by this means to compare bark with sumach or with valonia, because the different species of tannin consume different proportions of permanganate. Oser states that $1\frac{1}{2}$ gram of oak-bark tannin consumes only the same quantity as 1 gram of gall-nut tannin.

I may remark that where many analyses have to be performed, the constant stirring becomes very tedious, and a stream of air-bubbles forced through the liquid by an aspirator may be substituted with great advantage.

Neubauer reckons one litre of decinormal permanganate as equal to 4·157 grams of gallotannic acid, and consequently (according to Oser) to 6·235 of oak-bark tannin. Further research, however, is needed before percentages can be calculated with certainty, and chemists, in giving results, would do well to state the equivalent in permanganate, or to say that they use Neubauer's or Oser's equivalent. The first is applicable to sumach, galls, and myrabolans, the second probably to oak bark, valonia, and chestnut extract, at least approximately. It is a singular fact that gallic acid consumes not only a larger proportion of permanganate, weight for weight, than tannin, but even a larger proportion than the tannin from which it is derived, as I proved by digesting a solution of tannin with dilute sulphuric acid, when its reducing power was notably increased. Hence commercial tannin, which is largely contaminated with gallic acid, consumes more permanganate than the above-mentioned quantity.

As to accuracy, single tests should never differ by more than 0·1 c.c., or say $2\frac{1}{2}$ per cent. of the total quantity, but of course, in so rapid a process, no one would rely on single tests, and by repeating and taking the mean, any required accuracy may be attained. Separate portions of liquor precipitated by gelatin give identical results, at least within the limits named.

I should perhaps mention that Mr. Estcourt proposed some time since to precipitate with gelatin in conjunction with the permanganate method (*Chemical News*, xxiii, 110), but as he heated the solution, and tannate of gelatin is soluble in hot gelatin solution, the results were not satisfactory. Still he undoubtedly deserves the credit of the idea, while Löwenthal's cold gelatin solution, with the addition of salt and acid, completely overcomes the difficulty.

Several other oxidizing methods have been proposed. Carpeni precipitates the tannin with ammonio-acetate of zinc, redissolves and estimates with permanganate. M. Jean oxidizes with iodine in solution of sodic carbonate, and M. Pouchet with concentrated permanganate in a caustic potash solution. None of these methods seem to have any advantage over Löwenthal's, while the two latter are in my experience decidedly inferior. The end-reactions are much less distinct, and it is quite impossible to work them by artificial light, which is almost preferable with the indigo process, and is often a great convenience.

In speaking of the results I have obtained as a test of the accuracy of methods, I do not mean to convey that they are the best attainable, but simply such as would be likely to be obtained by a chemist of average skill and experience.

AN EASTER HOLIDAY IN LIGURIA.*

BY PROFESSOR FLUCKIGER.

(*Concluded from p.* 984.)

The gardens of this country also contain many noteworthy plants which have no claims to the citizenship of the Riviera. In this respect the public pleasure grounds and botanical gardens of Pisa, Genoa and Nice are worth notice. The garden at Pisa, one of the [illegible] university gardens, probably laid out about 1547 by Luca Ghini, *lector simplicium* in the university there, who also first founded a herbarium, is at the present time in exemplary condition and does credit to its director, Carnel, a distinguished Italian botanist. The camphor tree and the *Gingko biloba* of the garden will hardly be equalled again in Europe. The garden at Genoa is remarkable on account of its originally picturesque situation and its degeneracy, but it has still some old trees to speak of better times. The newer public gardens of Genoa, Monaco (Monte Carlo) and Nice show what considerable effects can be there obtained by the intelligent grouping of exotic plant forms, for which the climate is suited, with selected indigenous ones. The *aqua sola* grows with the elegant *Acacia Julibrissin*, Willd. (*Albizzia*, Boir.), which is well suited to give an idea of the great beauty of the tropical tamarind tree. In the grounds at Nice palms grow most charmingly with the oleander, eucalyptus, agave and araucaria, and similarly at Monte Carlo, Monaco.

Still further west, at Antibes, a prominent French botanist, Thuret, and a no less distinguished cultivator, Bornet, laid out a true botanic garden, which has been kept in unsurpassed cultivation until the present time, and now presents an incomparable collection of living trees and shrubs. Here stands, as before mentioned, the oldest eucalyptus in Europe, surrounded by a group of magnificent conifers, in the midst of green turf glistening with coloured anemones.

The gardens of the Marchese Pallavicini, in Pegli, is known in a much wider circle; a visit to it from Genoa is an obligation of the regular tourist, and usually yields considerable pleasure, notwithstanding that in it a taste for natural beauty reigns less supreme than showy magnificence and lavish expenditure, and of scientific judgment there is none. The charm of the landscape is, however, not injured thereby. The pines spread their crowns over the dark green cherry-laurel bushes. *Cinnamomum Camphora*, a magnificent specimen of which is met with here, is not remarkable, considering the by no means tropical climate of its native land; the Isola bella, in the Lago Maggiore, has in its gardens quite as handsome an example, and others are to be found in the gardens round Naples, as at Capodimonte. Evidently the camphor tree must have been introduced into Italy as early as the commencement of the present century, if not before. It succeeds everywhere very well, and has a much better appearance than many of the nearly allied Lauraceæ, its less rigid leaves being really mobile. When rubbed they give off a decided smell of camphor.

From the Ventimiglia road, planted with eucalyptus, the streets rise to the picturesquely and defiantly situated little town, and then fall again towards the sea; but not far from the village of Mortolo it reaches the highest point between San Remo and Monaco. Parallel with this modern road, in the lower ground not far from the coast, runs the old Roman road. Between the old and the modern highways, or rather intersected by both, extends the garden of the Palazzo Orengo, from the cliffs of Cape Orengo to the foot of the first hills. This beautifully situated estate, which will soon take its place in Murray and Bädeker, repays the visitor with an abundance of the most remarkable plants brought together with the finest judgment from the most diverse districts. The abundant warmth afforded by the Riviera sun fits the heavy marly and stony soil of these grounds for South African and Australian forms of vegetation, of which a good number thrive excellently, and together with indigenous or long naturalized plants present an extremely interesting picture of vegetation. In contrast to the other last mentioned garden, the far superior principle holds sway in the Palazzo Orengo of understanding, favouring, and assisting nature, instead of bringing her under the shears, and limiting her force with line and circle.

This garden presents an Australian character in a vigorously grown thicket of *Eucalyptus* and *Acacia*, several species of both being represented. Some of the eucalypti have already reached the pyramidal tops of the century-old cypresses, just now laden with fruit. In a few years that wonderful light shadeless wood, the Australian "bush," will be seen here in all its originality. Already the not very great diversity of the eucalyptus species has brought about some change, but much more has been wrought by the elegant acacias, many of which are now in full blossom. These trees and bushes, covered with a prodigal abundance of golden catkins of flowers, present an exceedingly exotic aspect. There is associated with some of the acacias—though not Australian species—as the *Acacia Cavenia*, Bertolani, from Chili, and the *A. Farnesiana*, Willd., from the West Indies, an extremely pleasant perfume, the flowers of the latter, under the name of "fleurs de cassie," being used in considerable quantity in Grasse and Cannes for perfumery purposes. Why should not these blossoms bear the name of cassia as well as many other extremely heterogeneous things? Both of these species have long been naturalized in South France and Italy, the *A. Farnesiana* first, it would appear, in the Farnesian Garden at Rome. The Australian *Acacia lophantha*, Willd., so far agrees with *A. Cavenia* and *A. Farnesiana* in a chemical aspect, that in all three of them there is evidently present some oil belonging to the oil of mustard or nitrile class. The seeds of these acacias, and probably their root-bark, when chewed, taste and smell execrably of garlic. According to some experiments carried out on a small scale, the quantity of oil appears not to be large, but certainly the preparation of some of it would be rewarded by the discovery of a noteworthy body, belonging to the class that includes the oils of mustard, horse-radish, tropæolum, nasturtium and lepidium.

In this respect it might be wished that a chemist would establish his residence here in the South, where he could carry out exact and important observations upon the ethereal oils. What a wonderful diversity of perfumes, for instance, are evolved by the numerous species of *Pelargonium*, the greater part of which are probably dependent upon ethers of pelargonic acid. And noteworthy is the closely allied *Pelargonium pulchellum*, with its large, thick, perfectly odourless leaves. An extremely disagreeable and very strong smell is given off by the leaves of three Cape Zygophyllaceous species—*Melianthus Trimenii*, *M. major*, L., and *M. minor*, L.; this will probably some day be referred to an ether or an aldehyd of cimicic acid, as the odorous matter of the tree-bug (*Rhaphigaster punctipennis*) already has been. To return to the acacias, the "*dornboom*," or scented thorn of the river banks of the Cape, rightly named *Acacia horrida* by Willdenow, may yet become prominent. The numberless bony thorns that stand out from the two examples here would probably in South Africa be much more menacing and attain several centimetres more of length. This thorn tree is there very common, and yields a considerable quantity of a serviceable gum. Probably the acacias from which gum acacia itself is derived would succeed in the neighbourhood of the Palazzo Orengo, for no doubt *A. horrida* may fairly represent the gum trees of the Nile and Senegambia districts. The appearance of the two very handsome bushes of this acacia that occur here testifies that the climate of the Riviera would be suitable to it and other acacias.

But this appears to be less the case with the Pernambuco tree, *Cæsalpinia echinata*, Lamck, which, however, is very intelligible, as the moist warm woods of middle and northern Brazil, in which this plant grows, are quite a different habitat to the dry Mediterrean coast with its glaring sunlight. Nevertheless, a couple of young trees, a metre high, already give sufficient evidence of the thorns to which this species owes its name.

Another notable African tree in these grounds, of which the success seems to be assured, but as yet represented only by two small specimens, is *Myrsine africana*, indigenous at the Cape and in Abyssinia. Under the name of "*tatse*" or "*zatse*," the spherical fruit, some millimetres in diameter, has for the last twenty years had a place in pharmaceutical literature as one of the numerous Abyssinian anthelmintics.

Equally insignificant for the time are the specimens of the Morocco oil tree, *Argania Sideroxylon*, Röm. et Schultes, of the Sapotaceous order, which replaces the olive tree in South Morocco, in the neighbourhood of the ocean, and also on the slopes of the Atlas mountains in the interior. The seeds contain an oil that appears to be very similar to olive oil, which can be obtained in large quantities, though not yet worked industrially. This evergreen thorny tree does not attain any considerable height, but the trunk is surprisingly thick; the wood is very hard. In the year 1220, the *Argania* attracted the attention of Ibn Beithar, the celebrated Arab writer on natural history.

The small-leaved, and, at any rate in young examples, not very striking-looking *Myrsine* and *Argania* will consequently only be numbered among the more remarkable plants of the Palazzo Orengo in the future, when multiplied and full grown. The contrary holds good in a high degree of the large leafless euphorbias and species of *Aloe*, which are now flourishing there quite successfully, and form so prominent a constituent in the flora of southern and eastern Africa. The candelabra-like euphorbias of the *E. antiquorum* and *E. canariensis* division stand out, 3 to 4 metres high, in full bloom from the prickly wood of the smaller cactuses and the herbage of mesembryanthemums. All abound equally in a very acrid milky juice, and the stems are 3, 4, or 5 angular, or cylindrical. It would be interesting to compare this milky juice and ascertain whether euphorbion, which is an important constituent of the official euphorbium, is always present in it. The mother plant of euphorbium (*E. resinifera*, Berg.) is also found in the Palazzo Orengo, though not yet quite sufficiently developed to allow of its characters being authentically determined, and which Berg, who only knew this species through the fragments occurring in commercial euphorbium, was not in a position to do. It appears probable that it will scarcely attain the magnitude of the species mentioned, or nearly that of the vigorous *Euphorbia abyssinica*, which here flowers upon a branching trunk as thick as a man's arm. It is interesting to contrast it with the delicate *Euphorbia dendroides*, and to note how the flowers and fruits of these perfectly dissimilar looking plants correspond.

Besides these cactus-like euphorbias there are not wanting cactuses of all forms, and equally plentifully represented are the South African species of *Aloe*, including *A. socrotina*, Lam., most of them being in blossom. Neither of those from which the official aloes is derived is absent. Succulent as the leaves are, however, they do not yield upon simple incision nearly so much juice as must be the case in their native country, or even in Barbadoes, where the official aloes exudes in sufficient quantity from the incised leaves without further trouble. In the time of the Salerno School of Medicine, in the twelfth century, the preparation of aloes was carried on in Apulia, but in the present day it is no longer carried on anywhere in Europe, although in the neighbourhood of Valencia and Granada *Aloe vulgaris*, Lk., and *A. purpurascens*, Han., and at Gibraltar *A. arborescens*, Mill., grow perfectly wild, as well as at the Palazzo Orengo.

Besides the great leafless euphorbias, the mesembryanthemums, and the species of aloe, there are three somewhat allied forms that appear prominently in the foreground. The first is the tree-like composite, *Kleinia neriifolia*, which, according to the testimony of an eye-witness, flourishes as luxuriantly at the Palazzo Orengo as upon the trachyte of its native habitat on the Pico de Teide at Tenerife. The second is the Indian fig, *Opuntia Ficus-Indica*, Haworth (*Cactus Opuntia*, L.), the stout stems of which, quite woody at the base, cling to the sunny rocks throughout the whole district; its fruit here appears to have no particular value. The third is the *Agave americana*, which flourishes surprisingly. Like the *Opuntia* it is a citizen of the New World, but together with the above-mentioned thick leaved or succulent-stemmed South African plants it forms a highly exotic looking but perfectly harmonious link in the flora of this district. Such a group, overshadowed by stately date palms, and especially the steep precipices in the neighbourhood of Monaco, might well transport the observer into quite another plant province. The agave presents the most charming aspect in September, when the flowering stalks, several metres high, make their appearance, like some at Sestra and Lavagna, in the Riviera di Levante, where the railway runs for a considerable distance between hedges of agave.

In its native country the *Agave americana* is one of the most important economic plants. The earliest information respecting it is referred to Petrus Martyr, of Anghiera, Lago Maggiore, who described it as "maguey," in 1516. By the middle of the same century it was introduced into Spain and Italy. The vigilant Nuremberger, Joachim Camerarius, who was probably the first possessor of a "botanic" garden in Germany, saw the agave in 1561 in Pavia, and figured it in flower in his 'Hortus Medicus et Philosophicus.' In Italy, the first flowering stalks appear to have been raised at Pisa, and to have excited surprise because the strong plants perished immediately after flowering.

Immediately before the development of the flower stem, the agave contains a saccharine juice which by fermentation yields an enormous quantity of the Mexican national drink, "pulque." In Italy this fact appears not to have attracted any attention, although it may be assumed that pulque could be obtained here also. The large older leaves certainly contain but little juice, and the loose spongy parenchyma is tasteless; but the plant would have to be treated as it is in Mexico, where, according to the most recent observers, as Humboldt and Boussingault, it takes a prominent place among the economic plants. From the account of the latter especially,* it appears that if the flower bud of the maguey, as the *Agave americana* is called in Mexico, be cut off, an abundant formation of sugar takes place after the expiration of some months. The right time for this mutilation is indicated by the appearance of the gigantic outspreading leaves; these, which previously appear so stiff and immovable that no organ could influence them, now bend upwards towards one another as if to protect the flower bud upon which the flower scape, 5 or 6 metres, is to be borne. The increased chemical activity of the plant, when once set up for the preparation of the necessary material for the flowering stem, is probably not increased by the removal of the flower bud, which has a diameter of 50 to 55 centimetres, but diverted into another direction. After the cicatrization of the wound from eight to twelve months are allowed to elapse, and then an excavation, 15 to 20 centimetres wide, is made with a large spoon in the inside of the maguey, where the flower bud was situated. In this the saccharine juice, "*agnamiel*," collects so plentifully that for six months an agave will yield 1 to 10 litres daily. The wound is kept continually open and the juice is exhausted by means of a calabash provided with a pipette. When fermented the juice is called "pulque," and it contains about as much alcohol as good cider. Boussingault found in a litre of it 74 c.c. = 58·1 grams of absolute alcohol, and 308 c.c. of carbonic acid, besides 1·90 gram of nitrogenous substances; the sugar was completely fermented. He calculated that in Mexico a hectare planted with agaves, which would contain about 4000 plants, would yield 25 to 56 hectolitres of absolute alcohol in the form of pulque, and this would place the plant in the first rank among those cultivated for alcohol. So much carbohydrate on the same surface

* *Annales de Chimie et de Physique*, vii. (1866), p. 429.

of soil is not produced by corn, the potato, the sugar cane, the beet, or the vine, as by the maguey. This enormous produce is of course in reality much diminished by the fact that the plant only forms sugar in such quantity immediately before the flowering, and that this does not take place until its fifth to its eighteenth year, after which the plant perishes. But the propagation of the agave by shoots from the root is easy both in Mexico and Italy. The later the plant is in flowering the more imposing dimensions does it attain, so that even in Italy agaves with leaves 1½ metres long are not unfrequent.

The pulque is turbid, and possesses an after-odour, not agreeable to everybody, which appears to have its origin in butyric and valerianic acids; the beverage resembles kumiss. It is, therefore, scarcely to be expected that this liquor would be relished by the Italian population in the presence of their capital wines. Nevertheless the experiment might be worth making, whether in Italy, where the agave grows so luxuriantly, it could be worked industrially for the production of sugar, alcohol, or vinegar. The agave stores up so readily the moisture it requires in its leaves, where it is exquisitely protected from evaporation, that the plant is fitted to flourish vigorously in the driest spots in the Riviera, as at Monaco, or even in the mountain regions of this district. In Mexico it sustains an elevation of 2500 metres above the sea. It may therefore be questioned whether this plant, which requires hardly any attention, could not here be made to yield a remunerative revenue. However, the frugal Ligurian population possesses in its olives and *agrumi*, its vines and potatoes, all that it requires, and does not take readily to novelties, not even to the eucalyptus, the value of which is so palpable.

Between the clumps of the maguey there remains a considerable space, which the Mexican utilizes in the cultivation of many of the smaller economic plants, such as corn and all kinds of vegetables. Many such spots in the Palazzo Orengo are covered with large-flowered species of *Mesembryanthemum*, the beautiful colours contrasting exquisitely with the succulent green of the close turf. There are also other species of agave besides the *Agave americana*.

Plants covered with an impermeable epidermis are suited in a high degree to this hot climate; but less so the succulent herbaceous forms, such as the bananas, one of which (*Musa Enseta*) shows by its mutilated leaves that it has suffered from occasional storms, though just now the gigantic blossoms bend towards the northern observer who has already made acquaintance with this Paradise or Adam's fig in the greenhouses. When at some future time a complete thicket of eucalyptus shall afford its shelter, and the wind shall break upon the closely planted stems of different species of *Bambusa*, already several metres high, the time for the full prosperity of these herbaceous plants will have arrived, provided that there is not too great a dearth of moisture.

Whilst plants from the most diverse districts and families have been transported into this garden, the careful efforts of the proprietor being to spread out over these sunny slopes and cliffs a truly vigorous vegetation, some shrubs and trees have found refuge here that did not receive attention elsewhere. As an instance, may be mentioned *Buxus balearica*, L., the stately broad leaved box-tree, which until 1852 formed extensive woods in the island of Majorca, and yielded as important an economic wood as the more slender *Buxus sempervirens*. The melancholy end which in 1852 the unreasonableness of the Balearic landowner brought upon this irreplacable tree by axe and by fire is exposed by Willkomm in the latest book of travels in these islands. At the present time a few isolated bushes of *Buxus balearica* occur in inaccessible places in the island, and possibly on the Spanish mainland, near Granada, but there are no trees. The specimens in the neighbourhood of the Palazzo Orengo, now 1 to 2 metres high, are meanwhile prospering very well, and notwithstanding the misfortune the plant met with in its native home it may yet attain considerable value.

There are still to be mentioned many economic plants in this garden to which pharmaceutical interest attaches. There is the *Ricinus communis*, L., which in four years has grown to a handsome young tree, with a woody stem 5 metres high and 4 centimetres in diameter, bearing flowers and fruit plentifully. In this plant also the southern producing power of the Riviera is confirmed, since even at Athens the *Ricinus* does not hold out with certainty. The leaves of the trees growing here are far less in circumference than in the summer plant of our gardens, which run so rankly into an herbaceous form, and scarcely find time and strength to ripen seed, though, in very favourable summers this take place in Christiana. As an ornamental plant, therefore, the annual form stands higher than the *Ricinus tree*, as seen here; though probably in the tropics, as a tree 10 metres high, this plant, or at least some of its numerous varieties, has a much more vigorous appearance. Here and there in Italy the *Ricinus* is cultivated for the sake of its oil, as at Naples, in Apulia, and at Florence, but not in the Riviera.

What success *Quercus Suber*, *Fraxinus Ornus*, *Callitris quadrivalvis* (the sandarac tree), *Persea* (*Laurus*) *indica*, and *Saccharum Maddeni*, will have here cannot be judged with certainty from the specimens of these plants cultivated in the grounds of the Palazzo Orengo. There are besides numerous beautifully luxuriant specimens of another little known Chinese shrub, *Gardenia florida*, L., belonging to the Rubiaceæ, the fruit of which, with that of *G. grandiflora*, under the name of "yellow shot" (Chinese, *wongschi*), is used in China as a pigment. The fleshy part of the fruit contains a beautiful reddish yellow colouring stuff, which corresponds with that from saffron; the smell and taste of the Chinese "yellow shot" also resemble those of saffron. This aromatic fruit appears to have been noticed by Marco Polo, the celebrated Asiatic traveller of the middle ages. In Panthier's edition, 'Le Livre de Marco Polo II.' (1865), p. 522, occurs the following passage, "Une manière de fruit qui semble saffran qui vaut autant en viandes comme saffran." Unfortunately the *Gardenia florida* is just now unprovided with either flowers or fruit.

Another well-known Chinese shrub, *Olea fragrans*, L. (*Osmanthus fragrans*, Loureiro) is on the point of unfolding its delicate white blossoms, which, on account of their fine perfume, are said to be used in China to aromatize tea. Although this may have been done formerly, at present, according to careful inquiries of well-known English tea merchants on the spot, it is no longer the case.

For the tea-plant itself there would be a deficiency of water in the grounds of the Palazzo Orengo; but the Arab-Abyssinian tea-plant, *Catha edulis*, Forskol, of the order Celastrineæ, is here in flower. Its leaves are used in Arabia like tea. The active principle of *Catha* has not yet been ascertained, so that the expectation that caffeine (theine) would be met with in it has not been justified.

In Thuret's gardens of Antibes, and also in those of the Palazzo Orengo, are respectable, but not properly tree-like specimens of the *Quillaja Saponaria*, a Chilian Rosaceous plant, the bast of which, as soap bark, or Panama wood, has been brought into prominent use in France and England for some years past. This bark is rich in saponin, which can be obtained from it purer and more plentiful than from any other material. It is to this substance that the bark owes its use in the washing of fine coloured stuffs. In its anatomical aspect the quillaja bark is extremely noteworthy through the plentiful delicate crystals of calcium oxalate, which in the sunlight can be detected by the naked eye. Further, this bark presents a very good instance of the *vasa cribrosa* generally diffused through the bast tissue. In Antibes the tree bears ripe fruit, the woody carpels of which do not recall the *Rosaceæ*. The plant seems to be one of very slow growth.

Thus these young grounds of the Palazzo Orengo show already a large number of extremely interesting plants, quite apart from the much larger number which do not present so much practical interest as remarkable forms that are full of instruction to the botanist. Still larger is the list of plants of which the cultivation is attempted, and which frequently afford most curious experience. Only in a very general way can it be anticipated which plants have a prospect of permanent success in this soil and climate, and frequently bitter disappointment is experienced. For a final result, however, as the names mentioned indicate, a very remarkable flora will have been gathered together on this beautiful spot in the Riviera.

MUSHROOM CULTURE IN JAPAN.*

The best of the edible species of mushrooms are known as "matsutaké" and "shu-take." The difficulties attendant on preserving the former kind almost exclude them from the market for export; for not only do they decompose very rapidly, but even when they are successfully dried they are nearly tasteless, and thus useless in cookery. The shu-take species, however, have this peculiar excellence, that though they are all but tasteless in their raw state, when they are dried they have an extremely fine flavour. The quantity that grows naturally on the decayed roots or on the stumps of the shu tree is not sufficient to meet the demand for them, consequently much skill has been brought to bear on their cultivation, notably by cutting off the trunks of the shu and other trees, and forcing the growth of the mushroom on them. The localities in which they are thus cultivated are Yamato, Isè, Mikawa, Yotonu, Suruga, Kai, Iclzu, Hitachi, Mutsu, and Dewa Serano and Hida, Ku and Sinvo. These provinces produce the largest quantities; indeed, the quantity produced elsewhere is insignificant. Small parcels are produced in Zezo. There seems to be no great difference between the wild and cultivated varieties of the shu-take mushroom, both being in taste and appearance very much the same, with this exception, that in the wild variety the upper surface is of a purplish brown colour, while the under surface and stalk are white; in the cultivated variety the shape is uneven and irregular.

Different varieties of oak appear to be the trees most in favour with the Japanese for the cultivation of mushrooms, the tree known to natives as "shu" giving the best results. This tree grows abundantly in warm places having a south-easterly aspect; it attains to a height of about eighteen or nineteen feet. It has a long, narrow, leaf, thin and stiff, the front surface of a deep green colour, the back of a brownish tint and glazed. The tree is an evergreen, the fruit (acorn) small, with a rough capsule. The acorns are steamed and eaten. The wood of the tree is used in the making of boats' oars; also for fuel and charcoal. Another oak, the kashinda, from which mushrooms are obtained, is also plentiful in warm localities, and attains to a height of thirty or forty feet. The leaves are used in cookery, and the wood is in great demand for divining sticks, for which it is considered the best. The donguri, another species, is to be found all over the country; it grows to about eighteen or nineteen feet, has very thick branches, and dense foliage; the leaf is slightly oval and slightly wrinkled. The fruit (acorn), after being pounded and steeped in water, is made into dumplings, and eaten in this form. The wood is much used in boat-making and also for carts.

Mushrooms are obtained from any of the above in the following manner:—About the beginning of autumn the trunk, about five or six inches in diameter, of any one of these trees, is selected and cut up into lengths of four or five feet, each piece is then split down lengthwise into four, and on the outer bark slight incisions are either made at once with a hatchet, or the cut logs are left till the following spring, and then deep wounds seven or eight inches long are incised on them. Assuming the first course to have been pursued, the logs, after having received several slight incisions, are placed in a wood or grove where they can get the full benefit of the air and heat. In about three years they will be tolerably rotten in parts. After the more rotten parts are removed, they are placed against a rack in a slanting position, and about the middle of the ensuing spring the mushrooms will come forth in abundance. They are then gathered. The logs are, however, still kept, and are submitted to the following process:—Every morning they are put in water, where they remain till afternoon, when they are taken out, laid lengthwise in the ground, and beaten with a mallet. They are then ranged on end in the same slanting position as before, and in two or three days mushrooms will again make their appearance. In Yueshin the custom is to beat the log so heavily that the wood swells, and this induces mushrooms of a more than ordinary large growth. If the logs are beaten gently, a great number of small-sized mushrooms grow up in succession. In places where there is a scarcity of water, rain-water should be kept for steeping the logs in. There is yet another plan. The cut logs are at once buried in the earth, and in a year's time are dug out and beaten in the manner above described.

The mushrooms thus grown are stored in a barn, on shelves, ranged along three sides, with braziers lighted under. Afterwards they are placed in small boxes, the bottoms of which are lined either with straw or bamboo mats. These boxes are then ranged on the shelves, and all approaches carefully closed. An even degree of warmth is thus diffused. The boxes ranged on the upper or lower tiers are constantly changed, so that the contents of each are thoroughly dried. Another mode of drying is to string the mushrooms on thin strips of bamboo, which are piled together near the brazier; the heat is well kept in by inverting a closely woven basket over them. Dried mushrooms are much esteemed in China, and they are largely consumed by Japanese, either as a dish by themselves, or as a condiment with other dishes. Dried mushrooms retain their flavour for a great length of time, and thus bear transport to any distance very well. Of other edible mushrooms in Japan, besides the shu-take, there is the kikurage, which grows in spring, summer, and autumn, on the mulberry, the willow, and other trees. It is a small, thin, soft mushroom, very much curled at the edge, and of a brownish tinge; when dried in the sun, the upper surface gets quite black, and the under surface a brownish grey. The flavour is somewhat insipid. The iwatake, which grows on rocks in thick masses. The so-take, a very delicately flavoured mushroom, to be found in precipitous crags, and consequently scarce, owing to the difficulties attendant on getting them. The kwa-take, to be found in shady spots on moorland; a funnel-shaped mushroom, with a long hollow stalk.

Consul Robertson, in addition to the above description, states the export of mushrooms from Kanayawa, amounted, for the year 1875, to 1461 piculs, valued at 55,024 dollars; in 1874 the export was 1603 piculs, valued at 61,656 dollars; and in 1873, 1218 piculs, valued at 34,170 dollars.

* From the *Journal of the Society of Arts*.

Melon Sugar.—It is stated that a company has been formed in California with the object of cultivating melons for the manufacture of sugar. Sugar is said to be made from them with far less trouble than from beetroot, and requires much less purification. The residues also can be turned to good account.

The Pharmaceutical Journal.

SATURDAY, JUNE 16, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE RELATIVE IMPORTANCE OF IMPURITIES IN DIFFERENT CHEMICALS.

To talk of the relative importance of impurities at a time when absolute purity is demanded from pharmacists as a *sine quâ non* by certain public officials, may sound like mockery, but for all that there is common sense and truth in the phrase. The subject is broached in a paper contributed to the *Practitioner* by Dr. LIEBREICH, the well-known Professor of Therapeutics in the University of Berlin, and some of the instances referred to are of considerable interest.

From a therapeutic point of view the presence of a small quantity of papaverine in morphine, or of one of the allied cinchona alkaloids in quinine, is probably of very little importance; they might affect in a very slight degree the activity of the compounds, but they would not destroy or counteract the medicinal action of the morphine or quinine. Other instances might be given in which this would hold good in varying degree. But there are also some cases in which the reverse is true, and especially among those bodies whose composition has been affected by chemical manipulation. Thus the removal of a molecule of water from morphia by treatment with hydrochloric acid yields apomorphine, a body not a soporific but remarkable for its emetic properties. Now it has been asserted that hypnotic effects have been observed to follow the use of so-called "apomorphia," and these were probably indications of the presence of untransformed morphia, which would not only weaken the therapeutic effect sought, but might exercise a directly antagonistic action.

There are also certain relatively important impurities that occur in chemical compounds of complex manufacture, which are not readily avoided, and frequently are not easily recognized. Dr. LIEBREICH states that he has had a sample of chloroform submitted to him, which, although it responded satisfactorily to all the tests of the German Pharmacopœia, produced such unsatisfactory—perhaps even fatal—narcosis, as to induce closer examination. Upon redistillation of the chloroform, a small oily residue, having a very disagreeable odour, was left, the nature of which could not be ascertained, but the chloroform thus purified was afterwards used with satisfactory effect.

The principal topic discussed by Dr. LIEBREICH, and that which presents the *raison d'être* of the memoir, is the impurities that occur in chloral hydrate, and considering the enormous quantities of this compound now used in medicine, the importance of the subject can hardly be overrated. Dr. LIEBREICH is of opinion that a large proportion of the chloral, both solid and liquid, now consumed, is not trustworthy in respect to its purity and that its impurities are calculated to have a directly and indirectly mischievous effect. In the first place, they may directly interfere with the simply hypnotic and anæsthetic powers of chloral, and confer upon it irritating and exciting properties. In the second, they may act indirectly, by rendering the chloral in certain cases feebly hypnotic, and so give rise to uncertainty as to the proper dose and sometimes involve serious consequences. Indeed Dr. LIEBREICH does not hesitate to say that the accidents that in this country have attended the administration of chloral have been largely due to this cause, the comparative inertness of a first dose having led to its reduplication at too frequent intervals, until suddenly a fatal result has been produced.

Great obscurity at present surrounds the nature of some of these impurities. Thus, Dr. LIEBREICH points out that sometimes impure chloral hydrate may be observed to become more acid; the acidity is generally due to the decomposition of an impurity (chloro-carbonic acid) which sets free hydrochloric acid, and when this occurs in the stomach it gives rise to great irritation. But it would not be safe to assume therefore that the irritation is due to this more obvious impurity, for hydrochloric acid administered in conjunction with pure chloral hydrate does not produce a similar result. Hence it would appear possible that the decomposition of one impurity is rather an indication of the presence of another that is more injurious.

It is now generally admitted that only crystalline chloral hydrate should be used in medicine, and the British and German Pharmacopœias require that the crystals shall be colourless and non-deliquescent. But some of our text-books on materia medica have enlarged upon this without sufficient warrant. Thus one says, "In colourless crystals (needles or rhom-" boidal plates)." A second says, "A mass of white "crystals, much like those of Epsom salts." Now Dr. LIEBREICH expresses most emphatically an opinion, and no one is better entitled to do so, that "chloral " hydrate in needles is quite unworthy of the confid-" ence of the practitioner, as it may very well be, and " is very likely to be, another chlorated substance or " a very impure chloral hydrate." In fact, there can be little doubt that the purest form of chloral hydrate is aptly described in the report on new medicines recently adopted by the Paris Society of Pharmacy as forming crystals of a saccharoid aspect. Of course the difficulty of ascertaining the purity of chloral in solution is much greater.

THE METRIC SYSTEM IN NEW YORK.

In a Bill which has already passed one branch of the New York State Legislature it is proposed to make it compulsory for every pharmacist in the city to have (1) a balance capable of carrying at least ten grams in each pan, and sensible to three milligrams when thus loaded; (2) a balance capable of carrying five hundred grams in each pan, and sensible to two centimetres when thus loaded: and (3) a set of metric weights, from two hundred grams to one centigram, which shall not vary from accuracy more than one per cent. in all weights under five grams, nor more than half per cent. for weights between five or fifty grams. It also provides that the only weights to be employed in compounding and dispensing of drugs and medicines shall be troy weights and metric weights.

In order to secure the object of this Bill it is proposed to appoint an "inspector of druggists' weights," the method of paying whom smacks more of novelty than does the office itself. The inspector is to be authorized to "collect" (a decided euphuism) the sum of ten dollars from every druggist or drug firm unprovided with the above-mentioned balances and weights, and from the "collections" he is to receive twelve hundred dollars yearly, if they amount to so much; if not, *tant pis pour lui!* As the inspector is to be appointed by the Mayor, a New York contemporary presumes that if the Bill passes in this form the merits of the successful candidate for the post will be rather political than pharmaceutical, and appears to anticipate frequent visits from an ignorant rough, having a strong pecuniary incentive to levy black mail.

THE TARIFF ON QUININE IN THE UNITED STATES.

Last year we referred to an attempt that was then being made in the United States to abolish the tariff on imported quinine, but which was opposed by the home manufacturers and other interested parties and defeated. The fight appears to have been renewed this year in a Bill before Congress, and the abolition of the tax is being supported by the medical profession, on the ground that "principles of justice and "humanity alike demand free quinine and an open "market."

Mr. R. H. Davies, Senior Demonstrator in the Laboratories of the School of Pharmacy, Bloomsbury Square, has been appointed Public Analyst for the district of Fulham and Hammersmith.

According to the *Gardener's Chronicle* it is proposed to erect, at Ootacamund, in the Neilgherry Hills, a statue of the late Mr. McIvor, the successful cultivator of the cinchona at that station.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

An ordinary meeting of this Society was held on Thursday, June 7, Dr. Gladstone, F.R.S., President, in the chair. After the announcement of visitors the minutes of the last ordinary meeting and of the extraordinary general meeting were read and confirmed. The list of presents to the library was then announced and the certificates of the following candidates were read for the first time: W. H. Martin and C. B. Fox, M.D. The President then gave notice that at the next meeting of the Society a ballot for the election of candidates would take place.

The following papers were read:

(1). *On the Gases Enclosed in Lignite Coal and Mineral Resin from Bovey Heathfield, Devonshire.* By J. W. THOMAS.—Four samples were examined. No. 1 Lignite consisted of the leaves and stems of plants in a closely compressed condition, and is known locally as "leafy coal." No. 2 Lignite, dense, compact, of a distinctly woody character, and dark brown. No. 3 Lignite was very dense but earthy, and wet in appearance, the cleavages being much incrusted with hydrated oxide of iron; in colour it was nearly black. No. 4. Mineral resin. Retinasphaltum, soft brown, powdery, lighter than water.

No. 1. Leafy Coal from Bovey Heathfield.—100 grm. after heating to 50° for twelve days, gave 56·1 c.c. of gas containing CO_2 87·25, O 0·24, CO 3·59, OH_3 8·92 per cent.; after heating to 50° 100 grm. were heated to 100° for eighteen days, and yielded 59·9 c.c. of gas: CO_2 89·53, C_nH_{2n} gases 0·33, CO 5·11, N 5·03 per cent. On raising the temperature to 150° decomposition set in and the pellets of mercury in the Sprengel became blackened by the formation of sulphide of mercury, the gas given off had at first an aromatic odour but afterwards became exceedingly disagreeable from the presence of organo sulphur bodies, mercaptan, sulphide of allyl, etc. At 200° more than 18 c.c. of gas was collected, the last portions of which contained CO_2 82·06, H_2 2·82, CO 14·00, C_2H_4 0·49, C_3H_6 0·48, N 0·27 per cent. Above 250° it was impossible to collect any gas, the action of the sulphur compounds on the mercury being so energetic as to block the Sprengel.

No. 2. Lignite 100 grm. at 50° evolved 48·5 c.c. of gas, consisting of CO_2 96·23 per cent., O 0·11, CO 2·42, C_nH_{2n} gases a trace, nitrogen 1·24 (the first portion of gas which came off contained 16·23 per cent. N.). At 100° sulphur sublimed in small yellow crystals; the lignite began to decompose at 185°. At 200° the gas consisted of CO_2 86·30, CO 7·41, C_nH_{2n} gases 2·08, marsh gas 3·34, hydride of propyl 0·53, nitrogen 0·34 per cent.

No. 3. Lignite began to decompose at 180°; the gas evolved at 200° consisted of SH_2 0·41, CO_2 91·68, C_nH_{2n} 0·41, CO 7·12, H traces, NO 38 per cent.

No. 4, Mineral resin from Bovey Heathfield.—At 50° a very small quantity of gas was given off; at 100° 21·4 c.c. of gas from 100 grm. came over: CO_2 88·24, O 0·23, C_nH_{2n} 0·47, CO 7·90, N 3·16 per cent. At 110–120° it began to melt and decompose, the sulphur compounds coming off so rapidly as to block the pump. When the temperature was raised to 160° about 180 c.c. came over, consisting of SH_2 0·41, CO_2 78·88, C_nH_{2n} gases 2·67, CO 7·82, marsh gas 8·05, hydride of propyl 1·86, nitrogen 0·31. When compared with the coals of the carboniferous period, it is seen that as far as the occluded gas is concerned these lignites resemble most cannel coal, but contain C_nH_{2n} gases and oily matters of the aromatic series, instead of gases and compounds of the paraffin series. The lignites are far less stable in vacuo, decomposing below 200°, whilst the true coals usually resist a temperature of 300°. The existence in Nos. 1 and 3 of organo-sulphur compounds in the presence of hydrated oxide of iron suggests that the iron pyrites of true coal may have derived their sulphur from that existing in organic combination in the plants from which coal is produced, and not from the reduction of sulphates. The author concluded by pointing out the extremely hygroscopic nature of the Bovey lignites.

Mr. Thomas also exhibited two mechanical appliances, driven by water or steam, for shaking a beaker containing a precipitate so as to promote its settling or for hastening the solution of a substances. He mentioned that with the aid of the apparatus the magnesia precipitate came down from a dilute solution in fifteen to twenty minutes.

After the thanks of the meeting had been given to the author, the President called on Dr. FRANKLAND to read a paper—

On Apparatus for Gas Analysis.—After giving a short description of the original apparatus introduced by himself and the late Mr. Ward, the author proceeded to point out the various modifications the apparatus had met with at the hands of Mr. Duppa and Professor M'Leod, notwithstanding all improvements there were still some disadvantages connected with the apparatus. In the first place the bottom of the water cylinder was closed by an indiarubber cork through which the two tubes passed; this cork after a time was liable to stick, and so on removal a risk of breakage was incurred; moreover, it was not rigid, so that when the measuring tube was filled with mercury, the weight depressed the indiarubber cork to a slight extent. This defect the author proposes to remedy by substituting a cast-iron plate through which the glass tubes pass water-tight by means of suitable collars and are clamped by a strong wooden clamp screwed to the cast iron bottom; a stopcock is inserted into the cast iron base for the introduction of water instead of passing it down a glass tube. Another defect of the old apparatus was the use of steel caps to unite the laboratory tube with the measuring tube; they are liable to rust, are expensive, form a rigid joint, are always liable to break away from the cement and unless very carefully ground, are difficult to make absolutely tight. The author therefore proposes to do away with the steel caps by the following contrivance. The upper end of the measuring tube terminates in a small cup like a small funnel with a very acute angle. The tube from the laboratory tube is bent twice at right angles, and then drawn out at its end so as to fit into the neck of the above cup (without grinding). It is then covered with a piece of thin sheet unvulcanized indiarubber, the edges of which are cut off, warmed, and joined so that a conical stopper of indiarubber is formed; this, when moistened, pressed down into the cup by an indiarubber band, and covered with mercury, forms a perfectly air-tight joint which is nevertheless flexible.

Mr. Warrington said the joint had been most severely tried not only with regard to its tightness, but as regards the possibility of any air space being left between the capillary tube and the cup, but no perceptible error could be detected.

Dr. Frankland said there was another point which he had forgotten to mention. The rack and pinion of Regnault's apparatus was replaced by a long screw, the shelf for the mercury trough sliding on a V-shaped guide, and having a nut to fit the screw. In answer to Dr. Wright, who asked if the indiarubber cone was greased or not to secure the tightness of the joint, Dr. Frankland said that the joint was only moistened with water.

Dr. Russell bore testimony to the necessity of wetting indiarubber and glass joints to secure the tightness. With regard to the improvements brought forward by Dr. Frankland, he would say that only those who had worked with the old apparatus could properly appreciate them.

Mr. Greenaway pointed out the great ease with which the laboratory tube could be cleaned by reagents now that the steel caps had been got rid of.

Dr. WRIGHT then read a paper *On Narcotin, Cotarnin, and Hydrocotarnin*, Part V.—A large number of experiments made with a view of breaking up cotarnin into simpler bodies, and so to elucidate its structure, were as fruitless as were attempts made to synthesise narcotin from mixtures of hydrocotarnin and opianic acid. By acting on hydrocotarnin hydrobromide with bromine, the following actions take place.

1. $C_{12}H_{15}NO_3,HBr + Br_2 = \underbrace{HBr + C_{12}H_{14}BrNO_3,HBr}_{\text{Bromhydrocotarnin hydrobromide.}}$.

2. $C_{12}H_{14}BrNO_3,HBr_2 + Br_2 = \underbrace{2HBr + C_{12}H_{12}BrNO_3,HBr}_{\text{Bromocotarnin hydrobromide.}}$.

3. $C_{12}H_{12}BrNO_3,HBr + Br_2 = \underbrace{C_{12}H_{12}Br_3NO_3,HBr}_{\text{Tribromhydrocotarnin hydrobromide.}}$.

The formation of the first two bodies is preceded by the production of the unstable addition products

$$C_{12}H_{15}BrN_2O_3HBr \text{ and } C_{12}H_{14}Br_3NO_3HBr$$

respectively; the third addition product, tribromhydrocotarnin hydrobromide, is a well defined crystalline stable substance. Bromhydrocotarnin and bromocotarnin resemble in general properties hydrocotarnin and cotarnin respectively. The first crystallizes anhydrous, and melts at 76°. The second is $C_{12}H_{12}BrNO_3,H_2O$, and loses water at 100° with decomposition. Their hydrobromides crystallize well, that of the first being sparingly soluble in H_2O and anhydrous, while that of the second is easily soluble, and contains $C_{12}H_{12}BrNO_3HBrH_2O$. When heated to about 200°, bromocotarnin hydrobromide fuses, gives off HBr, and combustible vapours (apparently CH_3Br), and forms a small quantity of the hydrobromide of a new base, termed "tarconin" (anagram on cotarnin and narcotin), $C_{11}H_9NO_3$, and a larger amount of an indigo blue substance, the hydrobromide of a base $C_{20}H_{14}N_2O_6$; this base and its salts are all but insoluble in water, ether, alcohol, benzene, CS_2, petroleum, etc. Boiling anilin and glacial acetic acid dissolve a minute quantity, forming a deep blue fluid; strong H_2SO_4 dissolves it, forming a sulphate $(C_{20}H_{14}N_2O_6)_2H_2SO_4$. The solution has a tint rivalling magenta in beauty, and intense colouring power. Tribromhydrocotarnin hydrobromide fuses at 200°, and decomposes in accordance with the reaction,

$$C_{12}H_{12}Br_3NO_3,HBr = HBr + CH_3Br + C_{11}H_8BrNO_3HBr,$$

forming bromotarconin hydrobromide. Bromotarconin forms fine scarlet crystals, $C_{11}H_8BrNO_32H_2O$, which become crimson when dried at 100°; the crimson anhydrous mass, when dissolved in hot absolute alcohol, perfectly free from water, separates on cooling in crimson crystals; but if the least trace of moisture be present the scarlet hydrated crystals appear. The salts are pale yellow, well crystallized, and sparingly soluble in cold water; the hydrochloride and hydrobromide contain $2H_2O$. Cotarnin hydrobromide, $C_{12}H_{13}NO_3HBr_2H_2O$, is very soluble; with bromine it forms the addition compound dibromhydrocotarnin hydrobromide, $C_{12}H_{13}Br_2NO_3HBr$, which, by further action of Br produces tribromhydrocotarnin hydrobromine, identical with that from hydrocotarnin. By the action of water dibromhydrocotarnin hydrobromide splits up into HBr and bromocotarnin hydrobromide. By the action of zinc and hydrochloric acid, bromocotarnin takes up H_2, and forms bromhydrocotarnin, identical with that obtained by brominating hydrocotarnin. By acting on opianic acid with a large excess of HI almost the theoretical yield of CH_3I is obtained for the reaction $C_{10}H_{10}O_5 + 2HI = 2CH_3I + C_8H_6O_5$ (noropianic acid). The noropianic acid thus produced crystallizes with $2H_2O$, and is not identical with the body recently described by Tiemann as isonoropianic acid.

The next paper was *On Otto of Limes*. By C. H. PIESSE and Dr. WRIGHT.—The otto from the rind of the fruit of the *Citrus limetta* had a sp. gr. 0·90516 at 15·5° C., when distilled about two-thirds passed over below 186°. After purification by fractional distillation and finally over sodium this yielded a terpene body boiling at 176°. On treating with bromine an unstable dibromide was formed, unlike the dibromide of the hydrocarbon from orange peel (hesperidene), this yielded but little cymene by simple heating, the greater portion being transformed into resinous non-volatile bodies. The cymene thus produced boiled at 176°, and yielded terephthalic and acetic acids by oxidation with chromic acid; hence it would seem that the terpene of the lime is not identical with that of the orange, notwithstanding the nearness of their boiling points, but that it is more like the terpene of the lemon (boils about 173°), which, as Oppenheim has shown, yields a dibromide, from which but small quantities of cymene are formed by simple heating. The residue not volatile at 186° was further heated, and gave a few drops of distillate between 186 and 250°. The residue in the retort was a semi-solid resin; on standing two or three months a quantity of crystals formed in this soft mass; these were extracted by the pump filter, well washed with the terpene and with alcohol, and crystalized successively from strong and dilute alcohol. They formed white micaceous plates, scentless, neutral, not volatile without charring, giving numbers agreeing with the formula $C_{24}H_{28}O_5$, melting at 162°, not forming protocatechuic acid on fusing with potash, and therefore not identical or even allied to hesperidin.

Mr. Grosjean said that in Sicily the otto was collected by squeezing the rind of the lime against a clean sponge; he objected to the formation of new names for chemical substances by the anagrammatic method.

The Secretary, Mr. Perkin, then read a paper by Mr. C. F. Cross, *On Primary Normal Heptyl Alcohol and Some of its Derivatives.*—Pure œnanthol was prepared by a rapid dry distillation of castor oil and fractional distillation; its sp. gr. was 0·823 at 16° C.; at 748·6 mm. it boiled at 152°. Heptyl alcohol was prepared by acting on 15 grm. of œnanthol dissolved in 150 grm. of 65 per cent. acetic acid with 10 grm. of sodium in 1000 grm. of mercury for ten days, the alcohol was drawn off, washed, etc., and purified by fractional distillation. From 300 grm. of impure aldehyde 120 grm. of pure alcohol boiling at 170–187° were obtained. Some of the alcohol was specially purified by rectification over metallic sodium. It is colourless, has an agreeable pear-like odour, sp. gr. at 0 0·833, at 16° 0·830, at 27° 0·824; at 764·1 mm. it boiled 175·5. The following substances were also prepared.

Heptyl	chloride	sp. gr. at 16°	0·881	boils	754·0	mm. at	159·2°
,,	bromide	,, ,,	1·133	,,	750·6	,,	178·5
,,	iodide	,, ,,	1·346	,,	754·8	,,	201·0
,,	acetate	,, ,,	0·874	,,	758·5	,,	191·5
,,	œnanthylate	,, ,,	0·870	,,	760	,,	270-272
,,	ethyl ether	,, ,,	0·790	,,	748·8	,,	165

In conclusion the author drew attention to the coincidence of the boiling points of the above compounds with those calculated by Schorlemmer, viz., chloride 158, bromide 179, iodide 202, acetate 191·5.

A short note was then read by the Secretary, from Messrs. Dale and Schorlemmer *On the Transformation of Aurin into Rosanilin.*—Since their last communication to the Society (May 24th) on this subject the authors have compared the spectra of the hydrochlorides of their base and of rosanilin and find them quite identical. They have transformed their base into Hofmann's violet, anilin blue, and anilin green, obtaining at the same time with the latter the violet. If aurin be treated with alcoholic ammonia for several days to 150° the rosanilin first formed is converted into leucanilin; a similar action does not take place in the formation of rosanilin from aurin because rosanilin is readily formed by heating aurin with aqueous ammonia to 120°, for 20 hours, if the temperature be raised to 180–200° other colourless bodies are formed.

The Society then adjourned to June 21st, when the following papers will be read:—1. "On Diamyl," by H. Grimshaw. 2. "On Dinaphthyls," by Watson Smith. 3. "On Certain Reactions between the Oxalates and Carbonates of the Alkalies and Alkaline Earths," by Watson Smith. 4. "Note on Thallious Platinocyanide," by R. J. Friswell and A. J. Greenaway. 5. "On Crystallized Barium Silicate," by E. W. Prevost. 6. "Note on Anethol and its Homologues," by W. H. Perkin.

Parliamentary and Law Proceedings.

A Child Poisoned by Misadventure at Leeds.

An inquiry into the circumstances attending the death of Frederick Stansfield, aged nearly three years, the son of a foreman furnaceman, has been held at the Potter's Inn, Hunslet.

Eliza Stansfield, the mother of the deceased, said that one of her boys was suffering from sore eyes, for which she had procured a bottle of "drops" from Mr. Taylor, surgeon. She knew the liquid was for outward application only, and, believing it to be poison, placed it upon a cupboard out of the reach of her children. On Monday evening she placed the bottle on the table, and went to fetch the ailing boy from his play in the street. Returning in about two minutes she found the bottle had been emptied. She asked the deceased, who had been left with the baby in the house, whether he had drunk any of what was in the bottle, and he said he had not. She noticed that his pinafore was wet, and thought he must have spilled the drops upon it. The deceased ate bread and meat, seemed all right, and went to bed soon afterwards. When his father returned at ten o'clock he screamed, and showed symptoms of poisoning, and Mr. Taylor was called in.

Mr. George S. Taylor, surgeon, Meadow Lane, said that on Monday morning he supplied the mother of the deceased with a small bottle of sulphate of atropia—probably about one and a half drachm—for applying to the eyes of the deceased's brother. He found the deceased suffering from what appeared to be atropine poisoning at eleven o'clock on Monday night, and death followed on Tuesday morning at nine o'clock. Had he been fetched immediately the child had taken the poison, an antidote might have been successful.

A Juryman: Is it customary to send out liquids that are poisonous without a label "poison" upon them?

Witness: It is customary for medical men. I have inquired. There is a label on the bottle (produced) which states that the contents consist of drops to be applied externally.

The Coroner: Druggists are compelled to label bottles "poison" in these cases, but not medical men.

Verdict of "Death by misadventure."

Poisoning by Strychnine.

On Tuesday the coroner for Christchurch resumed an inquest on Quartermaster-sergeant Hammerton, of the Royal Horse Artillery, who was found on Monday, June 4, in a cellar at Christchurch Barracks, apparently suffering from some irritant poison. Emetics were administered, but deceased died soon afterwards without accounting for his symptoms. Medical evidence attributed death to strychnine, and it was proved that deceased last April bought some vermin killer containing such poison. Major Ruck Keene said deceased's battery was ordered to India, which preyed on deceased's mind. The jury found, "That deceased died from strychnine, but how administered there was not sufficient evidence."

Attempted Poisoning by Arsenic.

Mr. J. J. Farquharson, county magistrate of Dorset, has remanded to Dorchester Gaol for a week Lucy Tizzard, the wife of a shepherd, charged with attempting to poison by arsenic her two daughters. Fortunately she had given them an overdose, and the result was that retching occurred, and a doctor being at once sent for, he succeeded, by applying the stomach-pump, in removing the poison, and they are progressing favourably. The woman, who is said to be very fond of her children, gives as the reason for her conduct, that she believes she is going blind, and as she feared she would not be able to see her children she thought it would be better for them to be in heaven. The husband had secreted the arsenic in a place where he had thought no one would find it, and had not used it for his sheep for the last two years.

Review.

TEXT-BOOK OF STRUCTURAL AND PHYSIOLOGICAL BOTANY. By OTTO W. THOMÉ. Translated and Edited by ALFRED W. BENNETT, M.A., B.Sc., etc. London: Longmans, Green and Co. 1877.

This volume forms one of a series of text-books of science, and consists mainly of a translation of a work which is largely used in the technical schools in Germany. The editor, whose labours in connection with the translation of Sachs' classical work on botany are so well known, has translated the present volume with his usual ability. The object of its publication at the present time has been to supply a work which, while of a size and price to bring it within the means of every student, shall embrace the whole range of elementary botany, and include the most recent additions to our knowledge of the subject. Special pains have been taken to render it useful to candidates preparing for science examinations in connection with the Educational Department at South Kensington, as well as for the different examinations at the London University, and it is believed by the translator, who is well qualified to judge, that it will furnish all the information necessary for any examination which does not exceed in severity that of the Second Bachelor of Science Pass.

Although professedly only a translation, it is really considerably more. Numerous explanatory notes added by the translator render the morphological part much clearer to the tyro than they would otherwise be. These are distinguished from the original text by being inserted between brackets, Many footnotes testify that the editor has been careful to notice any facts that have been brought to light since the last edition of the German work was published. The whole of the chapter on classification has been rewritten so as to bring it into accord with the system of Bentham and Hooker, which is the one followed by most of the leading botanists of this country. The usual plan of treatment of the subject is adopted. The individual cell is first treated of, then tissues or groups of cells, and then general morphology. The life of the plant is, however, treated of before classification, and special morphology is combined with systematic botany, which is perhaps the best way of treating it. The chapters at the end, on fossil botany, and on the distribution of plants throughout the globe, give a general outline of those subjects, the latter of which is made more useful by the addition of a coloured map. The book has illustrations on almost every page, and although some of them relating to microscopical structure will be recognized by those familiar with the use of the microscope as not representing the objects very naturally, yet they are sufficiently good to be useful as a guide to the practical study of the objects which they represent. Indeed, the use of the microscope and a knowledge obtained by work with the dissecting needle and section cutter can scarcely be dispensed with by those who wish to do do well in the science examinations of the present day.

Those who find Sachs' magnificent work to contain rather more than they require, but who wish to be abreast of the information of the present day will find just what they require in this little book. The index is good, and refers not only to the subject-matter, but also to the figures which illustrate the terms used. The type is clear, and the definitions are brief and to the point. We can confidently recommend it to all who have already obtained a bird's-eye view of elementary botany from some of the shilling treatises on the subject, and who wish to dip more thoroughly into the study of botany.

COUNTER PRACTICE.

Sir,—"The committees appointed by the Medical Council also suggested that endeavours to strengthen the Medical Acts in their penal relation to medical imposture would probably be best postponed until those Acts shall have received all essential amendments in relation to the profession itself."—*Pharmaceutical Journal*, June 2, page 985.

This "suggestion," sir, will I am sure be heartily applauded by every chemist in the kingdom, and it will be quite time when the medical profession has set its own house in order to begin to interfere with the internal arrangement of the chemist's. I for one have no fear of any restriction being placed upon counter practice, granted by the Act of 1815, through the desire of any local or central council. Firstly, because I believe that the general body of practitioners, as well as the higher faculty, would, for the sake of greed only, scorn to covet the work now carried on by the chemist "over the counter." I am sure they look upon the chemist as an important factor in medicating for the poor and middle class, and would regret to see the good faith now existing between the majority of us disturbed; for who is there of us can declare that, as a rule, a proper understanding and good feeling does not exist between the practitioners and the chemists? My experience leads me to opine that, as a rule, the apothecaries have the respect and cooperation of the chemists, and that this feeling is reciprocated. The surgeon is aware that many of the public who, either from being in debt to their medical attendant or from some other cause, prefer to ask the chemist for advice to increasing their indebtedness, well knowing that if there was cause the chemist would direct the applicants to consult a higher authority. More especially is this so when the practitioner does not supply his own medicines, but the chemist is sure of a prescription in return. Even if this were not the case, supposing "the doctors" were determined to use their combined strength to put a stop to counter prescribing they would have to apply to a legislature which, in these days of free trading, would never permit the public to be restricted in their choice of an adviser, unless they could show some grievous injury was likely to arise therefrom.

They would not listen to the injury inflicted upon the medical pocket, but would ask, "Where for the public good is the necessity for this restriction? Where the mal-practice they complain of?" The people are not deluded, so long as a chemist professes to be nothing more than a dispensing chemist, and then the public take upon themselves the responsibility in seeking such advice, instead of applying to a qualified practitioner. Any chemist who, either through ignorance or inadvertence, injures his customer, has to confront the law; as also would a medical man, with this difference, the chemist would have no protection. No injury has resulted to the public from counter practice, but the contrary, and the "greatest good to the greatest number" will in this case, as in all others of national importance, sway the legislature where medical monopoly is attempted.

Although, sir, I have no fear, especially when I know we have such energetic and combative sentinels in our Parliamentary Committee and on the Trade Society's executive, I am not blind to the good that might be effected by an alteration in the dispensing of medicine, and the treatment of disease. But the change should be brought about by combined effort, in an amicable manner, and not as antagonists. A chemist is certainly not by his tuition made competent to prescribe or to perform acts of surgery; but he is prepared for, and expects by the expense of his education, to have the medicines ordered by doctors to dispense; and a surgeon, with the responsibilities of life and death in his hand, is less qualified to prepare his medicines than the dispenser who has received a pharmaceutical education. If a change could be brought about, whereby the public could have advice from the surgeon, and their medicine from the pharmacist, at the same cost, a great boon would be allotted to the community, and all cause for jealousies and dissension among us removed. As in many places abroad, so it might be arranged here, for the pharmacies to be the places where patients might consult their medical advisers.

Then might the chemist permit free trade to the grocer and huckster, in the sale of common drugs and drysaltery; and to me it has always appeared illogical that whilst we assert the right of acting as semi-medical men over our counters, we should deny to others the right to retail common drugs and sundries; but if the arrangement I have suggested could be established, it would be for the general good. We should no longer suffer with stores upon the brain, and the doctors would be spared the anguish of seeing the public suffering from our illegal counter practice. If we take it for granted that the medical intentions are solely to protect the public from incompetent advisers, let us not be behind in showing that if the chemist is unfit to perform such service, so also are the majority of assistants in the employ of practitioners. And, I would suggest, a short Act to regulate the dispensing of medicine, and to amend the Apothecaries Act of 1815:—

"Whereas it is expedient for the safety of the public that all practitioners of medicine should employ only assistants who are qualified under the Medical Act, and that no one shall prescribe, visit, or perform any act of surgery for gain, for any medical practitioner, who has not himself become qualified to act as a medical practitioner; and whereas an Act was passed in the 31st and 32nd years of the reign of her present Majesty, entitled 'An Act to regulate the Sale of Poison and alter and amend the Pharmacy Act of 1852," compelling all who were not in business as chemists and druggists to pass an examination as to their practical knowledge of dispensing and other branches of pharmacy; and whereas it is expedient for the safety of the public that a record should be kept of all medicines prescribed by authorized medical practitioners, and dispensed by legally qualified chemists. Be it enacted, etc.,—as follows:

"From and after the 31st day of December, 1877, it shall be unlawful for any medical practitioner in any part of Great Britain to employ as his assistant, to prescribe, visit, or perform any act of surgery, either in his absence, or under his direction, any person who shall not have become qualified to act as a surgeon or an apothecary within the meaning of the act of 1815, and any person failing to comply with this regulation shall pay a penalty, etc., etc.

"2nd. From the aforesaid date it shall be unlawful for any medical practitioner, or his assistant, to dispense any medicine for any person that he may have prescribed for, in any city, or town, or village where there is situated any druggist and chemist, duly registered under the Pharmacy Act of 1868, and any practitioner dispensing or supplying medicine shall for every such offence pay, etc., etc.

"Nothing hereinbefore mentioned shall prevent medical practitioners in such parts where there is not a registered chemist situated within half a mile of his patients, or his own residence, supplying medicines or dispensing such drugs from his own surgery. Provided always in such cases, the said practitioner or his qualified assistant shall dispense the same; but it shall be unlawful for him to employ any unregistered person under either the Medical or Pharmacy Acts, and failing to observe the provisions of the law for each offence he shall pay, etc.

"3rd. And for the convenience and better safety of the public, be it further enacted that it be unlawful for any medical practitioner to write prescriptions in cipher, or secret symbols, unintelligible to the registered chemists and druggists of Great Britain under a penalty, etc.

"4th. And be it also enacted that every prescription dispensed by a legally qualified chemist shall be carefully copied in a book kept for that purpose, or the original prescription retained, and it shall be unlawful for any chemist to repeat the same prescription, either with or without alteration, unless under the sanction and by the express authority of the writer of the same; every chemist so offending shall pay a penalty, etc.

"5th. And whereas there are certain institutions and private dispensaries established by one or several medical men, where people are tempted to seek advice or purchase medicines, be it enacted that by this same Act, none but legally registered chemists shall be allowed to dispense, or vend poisons, either for medicine or other purposes, or failing to comply with this provision of the Act, every person or persons shall be liable, etc., etc."

I think with such an arrangement as this the medical men would have no reason to complain. The public would be protected, which is their chief object; and the chemist would have his legitimate duties assigned to him. There would be no need for Trade Protection Societies, no monopoly by pharmaceutical chemists; the two guinea entrance fee for membership could be abolished; every chemist would join the Society; one third of the Council would be returned from among the non-pharmaceutical chemists.

Every one would subscribe to the Benevolent Fund and all would feel a pride in elevating their business, and take a place in society befitting their education. I have not thought it necessary to insert any clause making it penal for chemists to prescribe, as there would not be any occasion for them to do so.

JOHN WADE.

174, *Warwick Street, Pimlico.*
June 4, 1877.

CHEMISTS' ASSISTANTS' ASSOCIATION.

Sir,—In the issues of the 2nd and 9th inst., I find letters on the subject of the proposed Chemists' Assistants' Association, and trust you will afford me space to say a few words to your correspondents and assistants and employers generally. Being closely connected with the movement, I am able to say something of what the committee, who have hitherto done all the work, purpose.

The Chemists' Assistants' Association is not intended to be in any way antagonistic to the Pharmaceutical Society, for pharmacy must ever look to Bloomsbury Square as its head quarters; neither is it intended to admit the "spirit of coercive trade unionism," which some members of the Council perceived in the petition submitted to them a few weeks ago.

Your correspondent, "An Associate," suggests that the foremost place in discussion should be given to the subject of "early closing;" in this, I think, he errs somewhat, for assistants are certainly not at present, and I think never will be, in a position to dictate to employers at what hour their shops should be opened and closed. Furthermore, the interests of employers and employees are so nearly identical that this subject may safely be left in the hands of our masters, who, I doubt not, will endeavour to shorten, as much as is consistent with the trade in their respective districts, the hours of labour.

The rooms of this association will be open to members every evening, and will be supplied with books and periodicals for their instruction and amusement. Meetings will be held at stated intervals for the reading and discussion of papers.

I, for one, think that, if properly conducted, this association will prove a boon to the trade, and be productive of good to both employers and employees.

AN ASSISTANT.

June 12, 1877.

A. P. Luff.—Our available information is insufficient to justify our entering upon any discussion of the subject at present, but we may refer our correspondent to the discussion reported in our last number at page 1004.

"*Specimen*" (Bangor).—No. 1 is a Californian plant, *Bœria platycarpa*, Gray. The Curator would be glad of two or three well-preserved specimens and a few notes as to locality, etc., in which it grew. (2) *Arrhenatherum elatius.* (3) *Festuca sciuroides.*

"*Vincere.*"—(1) *Euphorbia amygdaloides*; (2) *Sisymbrium officinale*; (3) *Alliaria officinalis*; (4) *Ranunculus parviflora*; (5) *Polygala vulgaris*; (6) *Valerianella olitorea*; (7) *Vicia hirsuta*; (8) *Stellaria uliginosa.*

F. Gall.—*Fumaria officinalis.*

G. Taylor.—Probably you would get what you require from an ordinary nurseryman.

"*Olim.*"—We have no other means of estimating the present population of London than such as are afforded in the returns of the last census.

"*Ignoramus.*"—The indenture of apprenticeship is not accepted, but a form of application, which may be had on application, must be filled up. A second would not be required in the event of a failure to pass.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Kitchen, Mr. Yeats, Mr. Luff, Mr. Reynolds, Mr. Grey, Equality, Young Dispenser, H. L.

NOTES ON SOME OF THE PHARMACEUTICAL PRODUCTS EXHIBITED IN THE PHILADELPHIA EXHIBITION OF 1876.

BY JOHN R. JACKSON.

(*Concluded from page* 998.)

LEGUMINOSÆ.

Dalea citriodora, Willd. "Limoncillo." Valley of Mexico. The whole plant is antispasmodic.

Tamarindus occidentalis, DC. "Tamarinds." Warm damp regions of Mexico. Fruit laxative.

Eysenhardtia amorphoides, DC. "Palo dulce." Central table land; decoction of wood diuretic.

Myroxylon Pereiræ, Klotzsch. "Balsamo," State of Morelos and other warm and damp places. This is the well-known balsam of Peru. The balsam is employed as a stimulant and from the fruit and bark a dye is prepared.

Cæsalpinia Cacalaco, H. B. K. "Cascalote." Warm and damp regions. Fruits very rich in tannin and gallic acid, used as an astringent, and for tanning purposes.

Prosopis dulcis, Kth. "Mezquite." Central table land and other places. The gum produced by it is very similar to gums Senegal or Arabic, and it is used for the same purposes. The name mezquit seems to be a name generally applied to several species of *Prosopis*, and mezquit gum, probably from *Prosopis pubescens* (*P. juliflora*), has of late years attracted some attention in Texas both for medicinal and technical purposes. The plants have been proposed for extensive cultivation in warm countries as fodder plants for cattle, the pods together with the enclosed seeds being very nutritious and containing much saccharine matter. These pods ripen at different seasons of the year, and many bushels it is said can be obtained from each tree.

Acacia albicans. "Huisache." Table land. Fruits used as an astringent.

ROSACEÆ.

Cerasus Capollin, Zucc. "Capulin." Cultivated in orchards. Bark antiperiodic; used in dysentery; the leaves contain prussic acid and are used instead of those of the cherry laurel.

Cratægus mexicana. "Tejocote." Cultivated in orchards; decoction of the fruits as a pectoral; that of the roots as diuretic.

RHIZOPHORACEÆ.

Rhizophora Mangle, L. "Mangle." On the coast of the Mexican Gulf. Gum used a pectoral.

MYRTACEÆ.

Myrtus Arayan, Kth. "Arrayan." Temperate regions. Leaves used both as a tonic and an astringent.

LYTHRARIEÆ.

Cuphea lanceolata, H. B. K. "Atlanchana." Valley of Mexico. The whole plant is used as a corroborant after childbirth.

Heimia salicifolia, Link. "Hanchinol." State of Mexico. It is diuretic, diaphoretic, and antisyphillitic.

PASSIFLOREÆ.

Passiflora Dictamo, Sesse. "Dictamo real." Warm regions. A decoction of the plant is commonly used for diseases of the respiratory organs.

CACTACEÆ.

Opuntia Nopallilo, Kar. "Nopalillo." Temperate regions. A decoction of the root is commonly used in dysentery, diarrhœa, etc.

CAPRIFOLIACEÆ.

Sambucus mexicana, Priestl. "Sanco." Temperate regions. Flowers used as a stimulant and diaphoretic.

VALERIANACEÆ.

Valeriana mexicana, DC. "Yerba del gato." Valley of Mexico; roots used as an antispasmodic. Valerianic acid is obtained from them, also resins, starch, etc.

COMPOSITÆ.

Solidago montana. "Calancapatle." Valley of Mexico. Leaves used as a vulnerary.

Gnaphalium canescens, DC. "Gordolobo." Abundant in the Mexican plateau. Flowers used as an astringent.

Artemisia mexicana, DC. "Estafiate." Valley of Mexico. Leaves have tonic, stimulant, emmenagogue and anthelmintic properties.

Aplopappus discoideus, DC. "Damiana." Valley of Mexico. The whole plant used in baths against rheumatism. This plant is now well known in this country, and a full account of its uses has appeared in this Journal.

Sanvitalia procumbens, DC. "Ojo de Gallo." Abundant in the central plateau. "The decoction of the whole plant is used as a peptic."

Montagnea tomentosa, DC. "Zoapatle." Valley of Mexico. The juice and a decoction of the plant is used to "provoke the contraction of the womb."

Eupatorium collinum, DC. "Yerba del Angel." Guadalupe range, north of the capital. A decoction of the leaves used in atonic diarrhœa.

Erigeron affine, DC. "Peritre." Valley of Mexico. Roots used as a sialogogue.

Echinacea heterophylla, Don. "Raiz del Manso." Valley of Mexico. The plant is commonly used for healing wounds, the decoction in dysentery and the juice in fractures.

Senecio canicida. "Yerba de la Puebla." State of Puebla. Used as an antiperiodic and diaphoretic. A volatile acid has been extracted from the plant which has been used in tetanus. We do not know what species is here referred to as we find no trace of such a name in any book to which we have access.

Athanasia amara, Cerv. "Prodigiosa." Temperate regions. Leaves have tonic and vermifuge properties.

ERICACEÆ.

Arctostaphylos pungens, Kunth. "Pingüica." Temperate regions. Fruits and leaves used as a diuretic.

SAPOTACEÆ.

Sapota achras, Mill. "Chicozapote." Abundant in the warm and damp regions of the Republic. Bark used as an antiperiodic. The seeds deprived of their hard shell are used as a diuretic, from six to twelve seeds being considered a dose; in larger quantities they are said to have a poisonous effect. A gummy resinous substance somewhat resembling caoutchouc is found around the seed and is known as "chicle." It is of a whitish colour and like caoutchouc becomes plastic on the application of heat, on this account it is used for modelling and likewise as a masticatory, being imported into New York for this purpose. We recently drew attention to this substance at p. 409 of the present volume, in which from the similarity of the common names, and from this alone, it was conjectured that it might be identical with the plant yielding monesia resin. This latter, however, is a product of Brazil while the chicle gum is known to be derived only from Mexico.

Lucuma salicifolia, Kunth. "Zapote borracho." Warm regions. Bark used as an antiperiodic. The pericarp is edible, and it is said to "exercise a wonderful action on the brain."

APOCYNACEÆ.

Thevetia iccotli, DC. "Yoyote or Joyote." Very abundant on the western side of the great Mexican Cordillera. The plant contains an active principle which has been called *Tevetosin*. The seeds contain 40 per cent. of oil which with sulphuric acid takes a yellow colour becoming afterwards rosy and finally orange red. This plant and its properties have been recently fully described at p. 854 of the present volume of the *Pharmaceutical Journal*.

ASCLEPIADACEÆ.

Asclepias setosa, Bth. "Contrayerba de Julimes." Temperate regions; used as a tonic and diaphoretic, antiperiodic properties are also attributed to it.

A. linearis, L. "Romerillo." Very abundant in the central plateau. The milky juice and the leaves are used as a powerful emetico-cathartic. The pappus or down which crowns the seeds is used for the same purpose as eider down.

LOGANIACEÆ.

Buddleia verticillata, H. B. K. "Mispatle." Temperate regions. Leaves said to be used as a vulnerary.

Buddleia globosa, Lam. "Salvia real de Mexico." Temperate regions. Used as a general stimulant.

GENTIANACEÆ.

Erythrea stricta, Scheide. "Canchalagua." Warm regions. Used as a bitter tonic.

POLEMONIACEÆ.

Hoitzia coccinea, Gav. "Espinosilla." Temperate regions. An infusion of the plant is used as a diaphoretic, and in large doses as an emetic and cathartic.

BORAGINACEÆ.

Tournefortia mexicana, Cerv. "Tlachichinoa." Warm regions. Employed in cases of itch and ulcers of the mouth.

CONVOLVULACEÆ.

Ipomœa murucoides, R. S. "Palo del muerto." Warm regions. A decoction of the wood is used as a bath for paralytical patients.

Exogonium purga, Bth. "Jalapa." This, the well known jalap grows on the eastern side of the Mexican Cordillera. It is used as a cathartic.

SOLANACEÆ.

Nicotiana glauca, Grah. "Tabaquillo." Abundant in the temperate regions. Properties same as ordinary tobacco.

BIGNONIACEÆ.

Crescentia alata, H. B. K. "Cuautecomate." Warm and damp regions. Fruits are considered eminently pectoral, they contain a large quantity of sugar, gum, tannin, cellulose, and salts.

ACANTHACEÆ.

Sericographis mohintli, Nees. "Muitle." Grows in Xalapa and similar regions. The leaves contain an amorphous, dark blue colouring matter.

VERBENACEÆ.

Lippia graveolens, H. B. K. "Yerba dulce." Orizaba, Cordoba, and similar places of the great Mexicana Cordillera. The infusion of the plant is used as a pectoral and emmenagogue. It is said to contain a peculiar saccharine principle and a volatile oil.

L. citriodora, Kurst. "Cedron." Cultivated in gardens. An infusion of the leaves antispasmodic.

L. callicarpæfolia, H. B. K. "Salvia real de Puebla." Grows in Puebla. Inflorescence and leaves used as stimulants.

LABIATEÆ.

Cedronella mexicana, Bth. "Toroujil." Temperate regions. Flowers stimulant and antispasmodic.

PLUMBAGINACEÆ.

Plumbago scandens, L. "Tlachichinolli." Warm and damp regions. The leaves for external application are used as caustics and internally as emetics.

CHENOPODIACEÆ.

Chenopodium ambrosioides, L. "Epazote." Cultivated in orchards. Used as a spice, and in medicine as an anthelmintic and emmenagogue.

LAURACEÆ.

Persea gratissima, Gærtn. "Aguacates." This is the well known Avocado pear, and is largely cultivated in orchards for the sake of the fruit, which is edible. Both the leaves and fruits are used as emmenagogues; the latter is said to have the power of increasing the spermatic secretion and the suppuration of wounds. The fruit is also considered anthelmintic.

THYMELACEÆ.

Daphnopsis salicifolia, Meis. "Hojas de San Pedro." Grows in Cuernavaca in a region 3,000 ft. above the sea level. The leaves are the part used in medicine.

ARISTOLOCHIACEÆ.

Aristolochia grandiflora, Sw. "Guaco." Warm and damp regions. The roots are the only part used, and contain volatile oil, resin, tannin, gum, starch, etc. They are used as an antidote against the poison of serpents and other venomous animals, and also as a diaphoretic and emmenagogue.

A. fœtida, H. B. "Yerba del Indio." Grows in Ario. A decoction of the leaves is used to consolidate wounds, and the root as a stimulant.

A. mexicana. "Tla-copatle." State of Guerrero and other warm places. The root is said to possess antispasmodic properties.

EUPHORBIACEÆ.

Hura crepitans, L. "Quautlatlatzin." The common Sand box tree. Warm and damp regions. Seeds are commonly called *Habillas de San Ignacio*, and are used as a drastic. They contain 50 per cent. of fixed oil.

Euphorbia maculata, L. "Yerba de la golondrina." Temperate regions. The juice is employed to take out stains of the cornea, and the decoction in scabies and other skin diseases.

E. pulcherrima, L. Flor de noche Buena." Warm and damp regions; cultivated in gardens. Bracts used to increase the secretion of milk.

Acalypha prunifolia, H. B. K. "Yerba del pastor." Temperate regions. Used as a vulnerary.

Croton dioicum, Cav. "Yerba del zorillo." Abundant in the valley of Mexico and similar regions. An emulsion made with twenty or thirty seeds acts as a drastic. The powdered root also has a similar effect.

CANNABINACEÆ.

Cannabis indica, L. "Mariguana," Temperate regions. The narcotic properties of the hemp are well known.

URTICACEÆ.

Urtica mexicana. "Yesgos." Temperate regions. Roots used as a diaphoretic.

CONIFERÆ.

Taxodium mucronatum, Parlatore. "Ahuehuete." Valley of Mexico and similar places of the country. Bark used as emmenagogue and diuretic. Leaves act topically against the itch and as a resolutive. From the wood a liquid pitch is prepared which is used in the treatment of skin diseases.

Pinus teocote, Schiede. "Ocote." Abundant in the mountains that surround the valley of Mexico, and in some other localities in the country. The turpentine produced by this tree resembles that of Bordeaux. It produces 17 per cent. of essential oil.

Pinus religiosa, H. B. K. "Oyametl." Produces a turpentine of similar properties to Venice turpentine.

DIOSCOREACEÆ.

Rajania subsamarata? "Cuanchalala." Warm regions. Bark used as astringent.

COMMELYNACEÆ.

Commelyna tuberosa, H. B. K., "Yerba del pollo." Abundant in the temperate regions. The pharmaceutical properties of this plant have been studied by several eminent chemists in Mexico, who have confirmed its hæmostatic properties. Its fleshy rhizomes contain a large quantity of starch and mucilage, so that when cooked they are edible.

MELANTHACEÆ.

Veratrum frigidum, Schlech. "Cebadilla." Xochimilco mountains. Both the fruit and bulb contain veratrum, and are used to kill insects.

ORCHIDACEÆ.

Bletia campanulata, Llave. "Chaucle." Temperate regions. A decoction of the pseudo bulbs is used in dysentery.

CYPERACEÆ.

Cyperus rotundus, L. "Peonia del pais." Temperate regions. Stomachic properties are attributed to this plant.

GRAMINACEÆ.

Andropogon citratus, DC. "Te limon." Warm places in the Republic. Used as an antispasmodic and also as a tea.

LYCOPODIACEÆ.

Lycopodium nidiformis. "Doradilla." Mountains surrounding the valley of Mexico and in other parts of the country having a similar climate. The whole plant is used in inflammatory affections of the liver.

FILICES.

Polypodium lanceolatum, L. "Lengua de ciervo." Abundant in the same localities as the above. Twigs and leaves used as pectorals and for wounds.

P. Calaguala, Schaf. "Calaguala." Found in large quantities in "El Pedregæ de San Angel" and other places in the valley of Mexico. The rhizome is used as a diaphoretic and pectoral.

P. pseudo-filix-mas, Schaf. "Palmitas." Mountains surrounding the valley of Mexico and other parts of the country with similar climate. It is used against tænia.

From this list it will be seen that the medicinal plants of Mexico were very fairly represented at Philadelphia, and that many of them are not without real interest, though we must own to a difficulty in the identification of several of the species.

From Jamaica was exhibited a collection of medicinal products numbering only twenty-three specimens in all. Small as this collection was it was the most valuable from any British Colony. Besides Jalap, Bitter wood, Gum Guaiacum, Cassia pods, Pomegranate bark, Baobab fruits and Kola nuts, were shown some very fine samples of Cinchona barks; indeed the Jamaica barks are described as the best samples exhibited by any British dependency. The best samples, however, of any country exhibiting were those from Java, which also made a fine display of the different cinchona alkaloids. As a proof that the climate of Jamaica is suited to the growth of the cinchonas, it may be mentioned that a stem seven years old measured 22 feet in length.

FORMULÆ FOR NEW MEDICAMENTS ADOPTED BY THE PARIS PHARMACEUTICAL SOCIETY.

Ten years having elapsed since the publication of the last edition of the Codex, a large number of new substances and preparations have been introduced into French therapeutics during that time, for which there were no authoritative formulæ. The inconvenience resulting from want of uniformity was such that the Paris Société de Pharmacie was induced to refer the subject to a commission consisting of Messrs. Baudrimont, Gobley, Marais, Schaeuffèle and Petit. The Commission drew up a number of formulæ, which were embodied in a Report, M. Petit being the reporter, and after discussion at several meetings of the Society the Report was adopted and ordered to be printed. As these formulæ will probably be generally adopted as the standard for French prescriptions, and moreover as some of the substances and preparations are not included either in the British Pharmacopœia or the Additions, their reproduction in this Journal will be of interest to some readers.

CARBOLIC ACID (*Acide phénique*; *Phénol*) $C_6H_6O_2$.

Carbolized Water (Eau phéniquée à 1 p. 100).—Carbolic Acid, 1 gram; Distilled Water, 99.

Solution of Carbolate of Soda (solution de phénate de soude or phénol sodique).—Carbolic Acid, 70 grams; Caustic Soda, 30 grams; Water to complete a litre.

SALICYLIC ACID (*Acide salicylique*) $C_7H_6O_3$.

In a solution of commercial caustic soda dissolve a quantity of crystallized carbolic acid exactly equivalent to the soda employed, and evaporate the liquid in an iron capsule until by means of a pestle it can be obtained in a pulverulent form. The product is carbolate of soda; it is very hygrometric and should be kept in well-closed bottles.

To prepare salicylic acid, heat the carbolate of soda gently in a tubulated glass retort placed in an oil-bath. Pass in a current of dry carbonic gas and then raise the temperature to 100° C. The temperature should now be allowed to rise gradually during three or four hours until it reaches 180°. After a time carbolic acid commences to distil over, and soon becomes more abundant. Finally the temperature is raised to 220° and then to 250°. The operation is terminated when the current of carbonic acid gas no longer carries over with it any phenol vapour. Nothing then remains in the retort but anhydrous salicylic acid of a brown colour.

In order to obtain the salicylic acid crystalline and colourless the basic salicylate is dissolved in water and pure hydrochloric acid added in slight excess. The precipitated salicylic acid is drained on a filter and purified by one or two recrystallizations from water. It can be obtained very pure by sublimation. It melts at 200° and sublimes in slender shining needles.

Salicylic acid is only slightly soluble in ordinary water (1 in 300 at the ordinary temperature); it is very soluble in alcohol and in ether, the spontaneous evaporation of which yields crystals in the form of large and very regular prisms.

The aqueous solution of this acid gives with ferric salts a very intense violet colour. Theoretically 1000 grams of carbolic acid should give 734 grams of salicylic acid.

Solution (Solution d'acide salicylique à 1 p. 100).—Salicylic Acid, 1 gram; Alcohol (95°) 33 grams; Water, 66 grams. Dissolve the acid in the alcohol, add the water, and filter.

THYMOL (*Acide thymique or Thymol*) $C_{10}H_{14}O$.

Treat essential oil of thyme with an equal volume of an aqueous solution of potash or soda (1 in 5), and shake several times to facilitate combination. The thymol dissolves, forming a soluble compound, whilst the thymene, a carbide of hydrogen that accompanies it in the essence, does not combine with the alkali and separates. Filter the solution obtained and treat with an acid, hydrochloric acid for example, which sets free the thymol. The product should be purified by washing, dried and distilled.

Thymol thus prepared is liquid; it can be obtained crystallized by submitting essential oil of thyme to a low temperature for a time. Its odour is feeble, resembling that of thyme. It is slightly soluble in water and very soluble in alcohol.

Thymol is a powerful caustic.

Solution (Solution d'acide thymique au millième).—Thymol, 1 gram; Alcohol (90°) 4 grams. Dissolve and add Distilled Water, 995 grams. Mix.

This solution is employed for lotions, injections, inhalations, etc.

CRYSTALLIZED ACONITE (*Aconitine cristallisée*) $C_{27}H_{40}NO_{10}$.

Exhaust the root of wild aconite, carefully picked and powdered, with very strong alcohol, to which 1 per cent. of tartaric acid has been added. Distil at a gentle heat, and sheltered from the air, to recover the alcohol. Treat the extract with water to separate all the fatty and resinous matters. The solution, which contains the aconitine in the state of acid tartrate, is first shaken with ether to remove colouring matters, and then the alkaloid is set free by the addition of alkaline bicarbonate until the cessation of effervescence. A fresh treatment with ether of this alkaline solution removes the alkaloid, which crystallizes upon the concentration of the ethereal liquid, with an addition of petroleum spirit. The crystals are colourless tables, rhombic or hexagonal according to the modifications produced principally in the acute angles.

Crystallized aconitine is soluble in alcohol, ether, benzine and chloroform; insoluble in petroleum oils and glycerine.

Each granule prepared according to the Codex should contain ¼ of a milligram of crystallized aconitine.

Crystallized Nitrate of Aconitine (Nitrate d'Aconitine cristalisée).—Crystallized aconitine, q. s.; Nitric Acid, sp. gr. 1·422, q. s. Saturate the nitric acid with the aconitine and evaporate. Voluminous crystals are easily obtained.

AMMONIUM BROMIDE (*Bromhydrate d'Ammoniaque*). NH_4Br.

Add bromine very slowly to solution of ammonia, with continual stirring, until the liquid remains faintly and persistently coloured by a slight excess of bromine. Add a few drops more ammonia to decolourize the solution and evaporate to crystallization.

Ammonium bromide crystallizes in long colourless prisms, volatile without fusion or decomposition, and very soluble in water. In solution it ought not to be coloured by the addition of a few drops of concentrated hydrochloric acid. No blue or violet colour should be produced upon adding to the solution some drops of starch paste and of slightly nitrous nitric acid. 1 gram of pure dry ammonium bromide is entirely precipitated by 1·75 gram of silver nitrate.

AMMONIUM IODIDE (*Iodhydrate d'Ammoniaque*). NH_4I.

Add ammonium carbonate gradually to a solution of iodide of iron (1 in 5) until the iodide of iron is entirely decomposed, filter and wash the precipitate; evaporate to crystallization, taking care to maintain continually a slight excess of ammonia to prevent decomposition of the salt.

Ammonium iodide is white when pure; it crystallizes in anhydrous deliquescent cubes, very soluble in water and in alcohol, and sublimes without decomposition if sheltered from the air. Exposed to the air it decomposes, a portion of the iodine being disengaged. 1 gram of pure dry ammonium iodide is entirely precipitated by 1·17 gram of silver nitrate.

APOMORPHINE. $C_{17}H_{17}NO_2$.

Introduce into a strong glass tube, closed at one end, 1 part of pure morphia and 20 parts of pure hydrochloric acid; these should not occupy more than one fifteenth of the tube. Seal the open end and place the glass tube in another of cast iron, closed with a screw, and heat the whole in an oil bath at a temperature between 140° and 150° during three hours. After cooling, the morphine has been converted into apomorphine which can be purified as follows:—

The tube may be opened without fear of any disengagement of gas. The liquid it contains is diluted with water and neutralized by sodium bicarbonate; then an excess of this salt is added which precipitates the apomorphine with any morphine that may remain. The liquid is decanted and the precipitate is exhausted with ether or chloroform, which dissolves the apomorphine without acting on the morphine. To the ethereal or chloroformic liquor are afterwards added a few drops of hydrochloric acid to saturate the base. Crystallized hydrochlorate of apomorphine then separates spontaneously and is deposited on the sides of the vessel. These crystals are washed rapidly with cold water and purified by crystallization from boiling water. The apomorphine can be obtained by precipitating a concentrated solution of this hydrochlorate by sodium bicarbonate; the precipitate is white, but oxidizes and turns green rapidly in the air. It should be washed with a little cold water and dried promptly to avoid this alteration.

Apomorphine is an amorphous greyish powder, rather soluble in water, where it turns green rapidly by contact with air. Its solution in sugar syrup, kept in well-closed bottles does not undergo this modification. Apomorphine is distinguished from morphine by its complete solubility in ether, chloroform and benzine. Like morphine, apomorphine is reddened by nitric acid and coloured brown by iodic acid; but ferric chloride produces with it a rose colour, whilst it colours morphine blue.

CADMIUM IODIDE (*Iodure de Cadmium*). CdI.

Place in a flask 1 part of cadmium granules and 10 parts of water; add 2 parts of iodine in successive portions and apply heat to terminate the reaction.

The salt is pearly white, very lustrous, permanent in the air, and very soluble in water and in alcohol. 1 gram of pure dry cadmium iodide is entirely precipitated by 0·929 of silver nitrate.

CAFEINE or THEINE. $C_8H_{10}N_4O_2, H_2O$.

Pour upon green or black tea of good quality, reduced to a coarse powder, twice its weight of boiling water, and allow it to macerate for a few moments at the heat of a water-bath. Introduce the moist powder into a displacement apparatus and exhaust with chloroform. Treat the residue from the distillation of the chloroform with boiling water, filter, add a small quantity of animal charcoal, filter and crystallize.

Cafeine can be prepared from Guarana in the same manner.

Upon treating cafeine with concentrated nitric acid, and evaporating, a red brown residue is obtained, the colour of which is changed to a red violet upon the addition of ammonia.

BIBASIC CALCIUM PHOSPHATE (*Phosphate bibasique de chaux.*)

Dissolve 608 grams of crystallized calcium chloride in 1000 grams of distilled water and add gradually to this solution 1000 grams of sodium phosphate dissolved in 10,000 grams of water. Allow the precipitate to deposit, and wash it five or six times with 10 litres of water each time; drain the precipitate upon a moistened cloth. As soon as its consistence permits detach from it irregular pieces and place them to dry in the open air upon filtering paper; the spontaneous desiccation is sufficiently rapid.

The product obtained is very white, very light, and very fine, and corresponds to the formula $Ca_2H_2P_2O_8+3H_2O$, containing 20 per cent. of water.

CHLORHYDROPHOSPHATE OF LIME (*Solution chlorhydrique de phosphate de chaux* or *Chlorhydrophosphate de chaux*).

This product ought only to be prepared in the form of a solution in water, syrup, or wine, as the pasty or solid form cannot have a definite composition.

Syrup (Sirop de chlorhydrophosphate de chaux).—Bibasic calcium phosphate, 12·5 grams; Hydrochloric Acid, as little as possible, about 8 grams; Distilled Water, 340 grams; White Sugar, 630 grams; Alcoholate of Lemon, 10 grams. Suspend the calcium phosphate carefully in the water; add hydrochloric acid in quantity sufficient to dissolve this salt, but without excess. When the solution is complete add the sugar, coarsely powdered, and dissolve it cold or with a very gentle heat. Filter and add the alcoholate to the cooled syrup.

20 grams of this syrup represent 0·25 gram of bibasic calcium phosphate.

Solution (Solution de chlorhydrophosphate de chaux).—Bibasic calcium phosphate, 17 grams; Hydrochloric Acid, as little as possible, about 10 grams; Distilled Water, 973 grams. Suspend the calcium phosphate carefully in the distilled water, add the hydrochloric acid, allow the solution to go on for some minutes and filter.

15 grams of this solution will represent 0·25 gram of bicalcic phosphate.

GLYCERATE OF SUCRATE OF LIME.

Quick Lime, 80 grams; Powdered Sugar, 160 grams; Glycerine, 160 grams Water to complete a litre. Mix the lime and the sugar, adding in small quantities 700 grams of water. After remaining in contact for twenty-four hours, filter, add the glycerine and sufficient water to make a litre.

Saccharo-Calcic Liniment (Liniment saccharo-calcaire).—Olive Oil, 200 grams; Glycerate of Sucrate of Lime, 100 grams.

CALCIUM HYPOPHOSPHITE (Hypophosphite de chaux). $CaP_2H_4O_4$.

Mix milk of lime (1 in 5) in a porcelain capsule placed in a sand-bath with half its weight of phosphorus in small pieces and heat it to ebullition, operating in the open air or under a chimney with a good draught. Spontaneously inflammable phosphoretted hydrogen is given off, the vapour of which should be avoided. Add from time to time a little warm water, to replace that which has evaporated. Discontinue the heat when the phosphorus has disappeared, that is when inflammable bubbles cease to be produced. If the phosphorus remain in excess add more milk of lime and continue the heat until the complete disappearance of the metalloid. Allow the liquor to cool and then filter; then saturate it with a current of carbonic acid gas to eliminate any excess of lime remaining uncombined. Filter again and concentrate the liquor in a water-bath to dryness, keeping the temperature below 100° to avoid detonations. Preserve the salt from the air in well-closed bottles.

Calcium hypophosphite is solid, white, pulverulent, or in small shining crystals. It is deliquescent, freely and entirely soluble in water and soluble in boiling alcohol. It reduces salts of silver, and is precipitated by ammonium oxalate. Heated dry in a test tube it gives off spontaneously inflammable phosphoretted hydrogen.

Syrup (Sirop d'hypophosphite de chaux).—Calcium Hypophosphite, 5 grams; Simple Syrup, 445 grams; Syrup of Orange Flower, 50 grams: make a syrup by simple solution. It will contain in 20 grams 0·20 gram of calcium hypophosphite.

CALCIUM LACTOPHOSPHATE (*Lactophosphate de chaux*).

This product ought not to be employed except in the state of solution in water or in syrup. In the pasty or solid state its solubility varies and it is always an indefinite compound.

Solution (Solution de lactophosphate de chaux).—Bibasic Phosphate of Lime, 17 grams; Concentrated Lactic Acid as little as possible, about 19 grams; Distilled Water, 964 grams. Suspend the phosphate carefully in the distilled water, add the lactic acid, allow solution to go on for some minutes and filter.

15 grams represent 0·25 of bicalcic phosphate.

Syrup (Sirop de Lactophosphate de Chaux).—Bibasic Calcium Phosphate, 12·5 grams; Concentrated Lactic Acid, as little as possible, about 14 grams; Distilled Water, 335 grams; White Sugar, 630 grams; Alcoholate of Lemon, 10 grams. Suspend the calcium phosphate carefully in distilled water; add lactic acid sufficient to dissolve the salt, but no excess. When solution is complete, add the sugar coarsely powdered, and let it dissolve in the cold or with a very gentle heat. Filter and add the alcoholate to the cooled syrup.

20 grams of this syrup represent 0·25 gram of bibasic calcium phosphate. (*To be continued.*)

HISTORICAL NOTES ON OPIUM.*

Confidence in the doctrines of Galenus had already been undermined to such a degree among the successors of Paracelsus, that they began to reckon opium among the *calida* (warming remedies), instead of placing it among the *frigida* (cooling remedies), with Galen. This

* From *New Remedies*, May, 1877. Second portion of an abstract from a paper by Dr. Otto Billinger, of Munich; the first portion will be found in the *Pharmaceutical Journal*, before p. 452. The notes are by the Editor of *New Remedies*.

was done by Felix Plater,* Bauhinius,† Libavius,‡ Quercetanus,§ and others. Plater placed such a reliance upon opium, that he pretended to be able to retain or restore the life even of those who had been broken upon the wheel. His trochees, composed of opium, sugar, cinnamon, musk, tragacanth, and wine, were very famous in his time as a remedy against cough and hæmoptysis. According to Quercetanus, who was himself one of the most zealous chemists and followers of Paracelsus, the "sulphurous and oily constituents of opium produce its narcotic effects; the sulphur is dissolved in the body, its vapours mingle with the blood and are carried to the brain, where they fill up the ventricles and thereby produce narcosis." Similar views were entertained by the philosopher Cartesius;|| according to him the soporific effect is produced by the accumulation in the pores of the brain of the vapours of opium itself. Helmont,¶ on the other hand, denies the correctness of this explanation, because "the sulphur is in combination and not free." According to him, opium contains a bitter oil having soporific properties, and a sharp-tasting salt possessing sudorific effects. Between the contradictory statements of the old and new schools, respecting the heat or cold producing effects of opium, he seeks to make a compromise by acknowledging it to be a *calidum*, having, however, *occasionally* the qualities of a *frigidum*, since it is capable of overpowering or entirely driving away the *archeus*.** His principal antidote for poisoning by opium is caustic lye. "Opium should not be administered without corrigents. Happy the patient whose physician knows how to remove the deadly principles from the poppy, and to retain the salubrious ones; else the noxious ingredients are taken with the useful ones, and the effect of the latter is neutralized." His favourite solvent for opium was quince-juice, which he considered equal to alkahest, the imaginary universal solvent.

Helmont's contemporary, De le Boë Sylvius,†† the founder of the chemiatric school, proposed a new theory to explain the effects of opium. He considered the "spirit of life to resemble spirits of wine, and to circulate in the nerve-tubes. The former are coagulated by opium in the same manner as the latter by volatile alkali." Among his followers opium became very fashionable. One of these, Cornelius von Bontekoë,* appears to have used it very indiscriminately, for he recommends as the surest way to prolong life, "incessant smoking of tobacco, constant drinking of tea, and frequent doses of opium." A similar curious recipe for prolonging life had previously been given by Bacon of Verulam,† who maintained that life is prolonged by moderation in mental or corporeal work, moderate use of opium, nitrum, and the aurum potabile (drinkable gold), whenever it should be discovered.

Werner Rolfink,‡ the celebrated chemist and anatomist, gave important directions on the use of opium in phthisis; he says: "It is indicated in all cases where an acrid mucus flows down into the chest; but it is fatal in ulcerous conditions of the lungs, as it interferes with expectoration, and thereby causes suffocation."

The surgeons of the sixteenth century appear to have made considerable use of opium in the external treatment of wounds; but this practice was severely censured by the more observant members of the profession, as for instance, by Felix Würtz, of Basle, who particularly condemns its employment in gunshot wounds. Opium was likewise used, as in our times chloroform, to deaden the pain during operations; this was also disapproved by many, who contended that no sleep short of death itself could cause total insensibility to the pain of an operation.

Fallopia§ relates a case of poisoning by opium, such as occurred not unfrequently at that time. He received a condemned criminal, whom he was permitted to kill in any way he pleased, and to retain for dissection. For this purpose he gave him two drachms of opium, the effect of which was neutralized by an attack of quartan fever. The dose was repeated on a day during the intervals, and the patient died.

THE FIXED OIL OF STAVESACRE.||

BY BALMANNO SQUIRE, M.B.

Surgeon to the British Hospital for Diseases of the Skin.

In the prosecution of an investigation as to the pathology of prurigo senilis, some years since I had occasion to employ an ointment of stavesacre-seeds, as a means of therapeutically testing the accuracy of my conclusions as to the pathology of that disease. This remedy, as is well known, is a parasiticide, in the sense that it is fatal to all of those animal parasites, properly so called, with which the human skin is wont to be infested in this country; that is to say, the pediculus capitis, the pediculus corporis, the pediculus pubis, and the acarus scabiei. However, I have found that an ointment of stavesacre-seeds is a very coarse and unsightly preparation. On inquiring of those wholesale firms who undertake the business of "drug-grinding" for the general body of pharmacists, I ascer-

* Born in 1537, died 1614. Author of an anatomical work entitled '*De partium corporis humani structura et usu.*' Basle, 1583.

† Johann Bauhin, 1541-1613, born at Basle, died at Mümpelgard. His work entitled '*Plantarum historia universalis nova et absolutissima*,' the fruit of nearly fifty years' study, was published after his death. His younger brother, Kaspar Bauhin (1560-1624), was professor of botany at Basle, and author of the celebrated botanical work: Πίναξ *Theatri botanica*, being an index to all previous botanical works, with synonyms.

‡ Andreas Libau or Libavius, 1540-1616, born at Halle, died at Coburg. He was the first to banish from his writings the mysterious language of the alchemists, and to describe the processes in an intelligible manner. His '*Alchemia*' may be termed the first real treatise on chemistry.

§ Joseph Duchesne, surnamed Quercetanus, Lord of La Violette and physician to Henry IV. of France; born at Armagnac, in Gascogne, in 1521, died at Paris, 1609. Wrote: '*L'Antidotaire spagyrique, pour préparer et conserver les médicaments*,' '*Pharmacopœa dogmaticorum restituta*,' '*Recueil des plus rares secrets touchant la médecine métallique et minérale*;' and many others.

|| Réné Descartes, or Renatus Cartesius, born 1596, at La Haye, in Touraine, died 1650, at Stockholm. Founder of a new system of philosophy and of analytical geometry.

¶ Johannes Baptista van Helmont, born 1577, at Brussels, died 1644. He was the first to recognize the properties of gases, which word he invented for the purpose, according to his own statement, in imitation of the Greek word chaos. His works were published by his son, under the title of *Ortus medicinæ*.

** This is, according to Paracelsus and Helmont's theory, the all-pervading primum mobile, or fundamental principle of life, which penetrates all parts of the living body, and on the condition of which depends sickness or health—on its presence life, on its absence death. The word is formed in imitation of the term ἀρχαλη φῦσις, "fundamental principle of nature," used by Hippocrates.

†† Franz De le Boë Sylvius, 1614-1672, born at Hanau, died at Leyden. His efforts to explain the processes of life and the action of remedies upon the body, by means of chemical theories, were made abortive by the insufficient progress of chemistry at this time. He was very fond of using preparations of antimony.

* His real name was Dekker, and he was surnamed Bontekoe from the tavern-sign of his father, representing a piebald cow (Bunte Kuh). Born at Alkmaer in 1647, died 1685 at Frankfort. See Sprengel's *Gesch. d. Med.*, xiii., 6.

† Francis, Viscount of St. Albans and Lord of Verulam, born 1561 at London, died 1626.

‡ Born at Hamburg, 1599, died at Jena, 1673. Introduced at Jena the dissection of human bodies, which was nicknamed "rolfinking." He established also a botanical garden and a chemical laboratory.

§ Gabriel Fallopia, born 1523, at Modena, died 1562. Celebrated anatomist, author of many anatomical treatises, and of a pharmaceutical work entitled '*De compositione medicamentorum*.'

|| From the *British Medical Journal*, for June 1, 187J.

tained that it was impossible to grind the seeds to any finer condition than that of a coarse meal, on account of their excessively oily nature. It then occurred to me that I could obtain a much more finely pulverized condition of the seeds by first removing their oil from them. This, for the purpose of my experiment, was accomplished by percolating the bruised seeds with ether—a process which completely abstracted the oil. The seeds could then, as I found, be readily ground to a very fine powder, and a very smooth and excellent looking ointment was thus obtained; but, on making trial of it, I found that my ointment thus prepared had lost all its virtue as a parasiticide. It therefore became probable that the virtue of stavesacre seeds was contained in their fixed oil. On making trial of ointment made with this oil, I found that such indeed was the case. Now this oil may be obtained much more cheaply than by the method I employed; namely, by simply expressing it from the seeds in the same manner that linseed oil is commonly obtained from linseed. The fixed oil of stavesacre is quite colourless. It is also odourless, and so is a very unexceptionable remedy. Ointment of stavesacre-seeds has been obtained by digesting the bruised seeds in hot lard, and then straining the admixture; but this produces a strongly coloured brown ointment, whereas an ointment prepared with the fixed oil is perfectly colourless. The absence of smell and colour in an ointment so prepared gives it considerable advantages over sulphur-ointment in the treatment of scabies, if only its efficacy be the same; and I find it to be quite equally efficacious, but it possesses also another considerable advantage. It is well known that in the treatment of scabies by sulphur it is necessary to beware of the remedy as much as of the disease. The strongly stimulating action of sulphur-ointment sets up in many persons a persistent dermatitis of a very irritating kind, which is remarkably slow to subside, and which constitutes a condition rendering it very difficult for many practitioners to determine how far the persistent itching is due to the natural disease and how much to the artificial one. Now an ointment of the fixed oil of stavesacre, besides being colourless and odourless, is also non-irritant. By this I do not mean that it will not serve as an irritant to exceptionally sensitive skins, but that its irritating effects are vastly less in degree than those of sulphur-ointment, and that in the majority of cases it does not irritate in the least.

THE "LANCET" ON THE DISSOCIATION OF PRESCRIBING AND DISPENSING.

The *Lancet* of the 16th inst. contains the following editorial upon the above subject:—

"There are many cogent reasons why prescribing and dispensing must be considered as distinct and in practice generally dissociated. The division of labour dates from the earliest ages, when the search for simples and the concoction of compounds occupied more time than the professor of medicine could spare from his abstruse speculations. In this way the apothecary sprang into existence, and took rank as "the physician's cook." The practical man progressed steadily, and more rapidly than the philosopher, who was too much engrossed with his alchemy and star-gazing to press forward in the path of discovery by rational experiment. Meanwhile, having distanced his master, the collector and compounder of drugs began to perceive their uses, and a new development of the remedial art arose out of this contingency. The apothecary became a practitioner on his own account, appropriating the knowledge acquired by the healer of wounds and the investigator of morbid actions and causes. During a long epoch the prescribing druggist continued to be the general practitioner, and under the fostering care of a London city company, which honourably and usefully discharged an important public duty, the apothecary became a skilled and technically educated exerciser of the art and mystery of medicine. The obligation which this service, rendered to the community by the Company of Apothecaries, has created cannot be overstated. It not only bridged over a fault in the history of scientific medicine, but contributed not a little to the consolidation of a profession which at the outset gave scant promise of rising above the level of a school of philosophy. The enterprise of a commercial corporation supplied the energy needed to rescue medicine from this peril, stimulated research as to the nature and uses of the drugs in which it traded, and in a large and practical way contributed to the supply of that information on medical subjects which the legitimate professors of medicine so tardily accumulated. The Company of Barber Surgeons did a like service for surgery. Nevertheless, it is to this accidental association of scientific pursuits with what is in fact a branch of trade, we owe much of the difficulty that besets the task of defining the practical boundaries of medicine and pharmacy. It would be better for both departments of industry and enterprise if the limits of each could be sharply laid down. Viewing the problem in the light of history, it must be obvious that it can never be solved, except in the separation, by mutual agreement, of interests that have grown up together, and to which the profession of medicine at least, owes a lasting obligation.

"The formation of a Pharmaceutical Society, with the view of reconstituting the craft of the druggist on a solid basis, was a necessity. The Company of Apothecaries, carried away by the success of its enterprise, aspired to the permanent position of a medical corporation, and neglected its proper duties as the protective guild of a trade. Shops for the sale of drugs were kept with impunity by persons having no qualification for the business, while the civic company was engaged in the fruitless struggle to impose the obligation of apprenticeship to the pestle and mortar upon medical practitioners. The company was misled, and, proud of the service it had rendered the cause of science, had not the wit to retire within its own province as soon as the profession of medicine began to assume its proper functions. If the Apothecaries' Company had been well-advised in this particular, the progress of medicine would have been accelerated, and its professors spared many perplexities, and saved from a position seemingly ungracious. Having usurped the authority of a medical corporation, and most worthily discharged exceptional functions during a period of pressing need, this trading company should have resumed its legitimate responsibilities as soon as the emergency was past. The opportunity was lost. The Pharmaceutical Society was called into existence, and has efficiently occupied the sphere deserted by the Apothecaries' Company. It is too late to retrieve the mistake. The company may be again successful as a purely commercial speculation, but its *raison d'être* as a body granting medical licences is extinct; and the time cannot be far distant when, like the fossil which fixes the relative position of some deposit in the earth's crust, the posthumous interest of this honourable company will be embodied in a conjoint scheme, and Macaulay's New Zealander will cudgel his brains to discern how, in the chequered course of progress, an old civic guild came to possess the strange privilege of nominating a certain number of representatives on a board of medical examiners!

"The argument for a sound basis of agreement as to the boundary lines of medicine and pharmacy must be addressed to the Pharmaceutical Society. The practical question at issue takes a shape which may be briefly indicated as follows: It is admitted on all hands that the two departments of work are distinct, and would be better kept wholly apart. In large cities, where druggists' shops are numerous, a little concession on both sides would render the separation practicable. On the part of the druggists there must be a revision of tariff, so as to place the supply of medicines within the reach of the class who cannot pay a fair fee for prescription and then defray the charge for dispensing as at present formulated. This is one of the most serious obstacles to the abandonment of medical dispensing. Again, if practitioners are asked not to provide their patients with drugs, it must be guaranteed that their prescriptions shall be uniformly and accurately dispensed. This is far from being an unnecessary stipulation. The most dissimilar results are produced by sending the same prescription to different establishments, even at the West End of London and among the *élite* of the trade. The effect of discrepancies observed is to weaken the confidence of patients and prescribers. Next, and by no means of minor importance, is the question of convenience. The delay caused in urgent cases by the difficulty of getting a prescription made up and delivered at the residence of a patient out of what are called "business hours" induces not a few practitioners to cling to the custom of dispensing their own medicines, a mode of procedure they would be only too glad to relinquish if it were possible to do so without imposing additional cost on their patients and involving them in great inconvenience. Such are a few of the surface obstacles to the total surrender of this undoubtedly trade industry to the druggists. There are, however, even more formidable difficulties behind. The medical practitioner starts with the presumption that he has a right to fair recompense for his professional skill, acquired at the cost of much time, pains and pecuniary outlay. The dispenser of drugs has the power of preventing this requital, and unless the retail trade in medicines can be conducted with due regard to the interests of the allied profession, it will remain impossible for general practitioners among the lower middle and necessitous classes to discontinue dispensing. The consideration we are about to urge applies only in a limited degree to physicians' prescriptions; but even in regard to these it has a substantial application. The written directions for a remedy are given with the intent that it shall be used only for the case under treatment and at the time specified. It would be convenient if these formulæ could be dealt with as drafts on a banker, and cancelled when their immediate purpose has been fulfilled. In the case of prescriptions written by general practitioners engaged among the classes which cannot adequately remunerate their professional adviser, the principle ought to be recognized. Under no circumstance is the druggist justified in using the advice given by the practitioner for his own purposes. As the trade in drugs is at present conducted in many populous districts, it is impossible for medical men engaged in general practice to abandon dispensing. In fact, apart from the injury inflicted on the profession by counter practice and the assumption of obviously medical functions by druggists, there is a continuous war of interests waged against the general practitioner, which the vigilance of a body such as the Pharmaceutical Society, supposing that authority willing to assume the control of the trade, alone can bring to an end. If the druggists are sincere in their expression of a desire to co-operate with the profession in the adjustment of difficult and delicate points of variance and conflict, the matters to which we have now directed attention deserve a consideration they have not yet received.

"A timely solution of these difficulties may pave the way for measures of reciprocity with regard to the final separation of branches of industry which ought never to have been confounded. It will probably not be possible to put an end to medical dispensing in districts exclusively rural, and where druggists, able and willing to conduct the trade in medicines efficiently and fairly, do not exist. The question in such localities is simply one of supply and demand, and it must be determined by the force of circumstances to the end of the chapter. In the meantime and everywhere, the profession has a right to enforce the rational and legal requirement that those whose business it is to trade in drugs will not overstep the obvious boundary and prescribe. They have no moral or scientific competence to exercise medical functions; and their interest lies in a strict adherence to the limits laid down by common sense and political expediency. The practice of medical dispensing is, we think, undesirable, and should be abandoned where its avoidance is possible; but there can be no objection to the procedure on the score of competency. Medical training includes the acquisition of a sufficient knowledge of drugs and pharmacy, and the practitioner is fully capable of performing the duty from which he seeks to relieve himself. This is not the case with regard to the information a druggist may obtain as to the uses of drugs, which it is his sole business to prepare under medical direction. The maker of a surgical instrument may, in the course of his trade, pick up many scraps of knowledge as to the mode of applying the implement he has produced, but it would be madness or audacity on his part, in the face of an entire ignorance of anatomy and the nature of morbid growths, to undertake the performance of surgical operations. The druggist who prescribes is equally culpable. He presumes, in spite of his non-acquaintance with the science of therapeutics, physiology, and disease, to introduce an agent into the system over which he has no control, and of whose working he has no knowledge. The experiment is not less reckless or perilous because he *intends* to operate only in minor cases. It is out of his power to determine whether the malady for which he prescribes is really trivial, or the insidious commencement of serious disease. It is necessary, in the interests of the public, to put an end to "counter practice" and the unqualified performance of medical functions by druggists. To what extent further legislation on the subject may be necessary must, in great measure, depend upon the action taken by the Pharmaceutical Society. The Apothecaries' Company at the present moment enjoys the right of interdicting the practice of unqualified persons, and it has done good service by putting the law in force against offenders. We confess, however, it would be more satisfactory to find the matter taken up by the Pharmaceutical Society, which might assert its authority in this matter with great propriety, and in a manner equally advantageous to the public, the profession, and the trade."

NOTTING HILL AND BAYSWATER CHEMISTS' EARLY CLOSING ASSOCIATION.

At a Committee Meeting, held at the Mall Hall, The Mall, Notting Hill, on the 24th April, 1877, a resolution was passed to canvass the district to ascertain the feeling of the chemists in regard to the second and third resolutions passed at the General Meeting at Bloomsbury Square. The following agreed to adopt them:—

Foster D. Downs.	J. Horncastle.
Edward Butterfield.	Abeland Co.
James Barrett.	S. Lynn.
Alfred Baker.	C. S. Williams.
William Hickman.	Arthur Tangstre.
G. W. Passingham.	J. Maitland.
J. J. Rees.	W. C. Jones.
C. H. Russell.	W. J. Hudson.
J. Westrup.	Henry Long.
H. Taylor.	G. W. Sargeant.
Robert A. Johnson.	F. Wright.
J. G. Shirley.	C. Harvey.
S. J. Weston.	G. Godolphin.
D. Gunn.	Harsley Thomas Wood.
J. Skidmore.	Squire Thomas.
J. H. Mathews.	Robert Samuel Bathe.
P. Stoneham.	E. B. Starkey.
A. W. Hitchcock.	Walter Snape.
Robert Hogg.	George Richardson.
Al. Trotman.	W. Shirtliff.
F. Anderson.	H. C. Edwards.
J. Beattie.	Charles Butler.
W. Halknet.	Sydney Drury.
George Cawdell.	C. Grosvenor and Co.
Miss Isabella S. Clarke.	W. Smith.
Frederick Andrews.	

The Pharmaceutical Journal.

SATURDAY, JUNE 23, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE DISSOCIATION OF PRESCRIBING AND DISPENSING.

ONE of the principal aspirants to the leadership of medical opinion, *The Lancet*, commences an article in the number for Saturday last, which is reproduced on p. 1043, by stating that "There are many "cogent reasons why prescribing and dispensing must "be considered distinct and in practice generally dis-"sociated." But notwithstanding the alleged necessity, it is difficult at present to consider prescribing and dispensing as being "in practice dissociated," and probably the writer hardly intended to say they were. Still there was in what appeared to be the spirit of the statement sufficient indication of accord with a desire frequently expressed in these columns, to induce a closer examination of this the latest contribution to the literature of the subject. We regret to say, however, that a perusal of the rather fatuous paper has left the impression that however correctly it may recount the history of the past it fails to grapple with the difficulties of the present.

Our contemporary appears to consider the Apothecaries' Company to have been a prime agent in producing the present confusion between medicine and pharmacy, and to look towards the Pharmaceutical Society as the *Deus ex machinâ* by which it is to be dispelled. "The Company of Apothecaries, carried "away by the success of its enterprise, aspired to the "permanent position of a medical corporation, and "neglected its proper duties as the protective guild "of a trade. . . The opportunity was lost. The Phar-"maceutical Society was called into existence, and "has efficiently occupied the sphere deserted by the "Apothecaries' Company. It is too late to retrieve "the mistake. . . The argument for a sound basis of "agreement as to the boundary lines of medicine "and pharmacy must be addressed to the Pharma-"ceutical Society."

This may appear to some rather curt behaviour towards a Company upon whose Act the Medical Defence Association depends as a means of coercion; but it is not a subject for more than passing comment here. It will be more pertinent to examine the "sound basis of agreement."

In the first place there is to be a revision of tariff —on the part of the *druggists*—so as to place the supply of medicine within the reach of those who cannot afford to pay a fair fee for a prescription as well as defray the cost of dispensing it at the present rates. With respect to this we may remark that we see no way to the artificial creation of a low tariff, or reason to doubt that the ordinary influence of competition will be inoperative in this case, when the eventuality contemplated arises.

Secondly, our contemporary thinks the uniform and accurate dispensing of prescriptions must be guaranteed. We confess we thought that this was already done. If it be true that "medical training "includes the acquisition of a sufficient knowledge "of drugs and pharmacy" to render the practitioner "fully capable of performing the duty," although it would not help him much in passing the Minor, it may be safely asserted that the man who has passed the ordeal of the Pharmaceutical Society's examinations will acquit himself of the task satisfactorily. Moreover, at present the medical man's patients do not always reap the benefit even of the pharmacy involved in a medical training, and the employment of unqualified assistants by medical men is probably also a circumstance by no means unimportant in promoting counter prescribing. Another "surface "obstacle" to medical men abandoning dispensing is said to be the delay involved in urgent cases in getting prescriptions made up and delivered at times falling beyond what are called business hours. Probably a delay may happen now and then, but certainly there has been almost an over-anxiety to meet the difficulty and there has been no disposition on the part of pharmacists to shirk the responsibility. So far, therefore, as the pharmacist can contribute towards the attainment of the conditions requisite for a "sound basis of agreement" they appear to be already existent, though they are to a great extent ineffective in bringing about the separation of prescribing and dispensing.

But more formidable difficulties remain behind. A prescription once dispensed is to be considered cancelled; the meaning of this is obvious, but it is not very evident that even if pharmacists were to assist in attempting to educate the public into the view that the prescription paid for remains the property of the prescriber the public would take kindly to the teaching. This introduces into the consideration of the subject another factor which does not appear to have been much regarded by that section of the medical profession which holds extreme views respecting "counter practice."

Last, but not least, counter practice is to be put an end to; and this in a most thorough way; the intention to confine it to minor cases being denounced as reckless and perilous. Judging from probabilities it may be assumed that simultaneously with the accomplishment of that feat, or prior to it, there will be an arrival of the Greek Kalends, and, according to Dr. WOOD, the proper regulation of the medical profession. And then it is gravely announced that "a timely solution of these difficulties "*may pave the way* for measures of reciprocity with "regard to the final separation of branches of industry "which ought never to have been confounded!" If the last two stipulations are indispensable constituents of the "sound basis of agreement," we are afraid the argument addressed to the Pharmaceutical Society will not be followed by very startling results. We agree, however, with our contemporary that further legislation on the subject must depend on the action taken by the Pharmaceutical Society.

Perhaps if the "sound basis of agreement" were less one-sided and chimerical it might be worth while to inquire whether the *Lancet* is expressing more than its own opinion on the matter. We should like to know, too, where it got the idea that the Pharmaceutical Society could, if it were willing, assume the control not only of the trade but also of a large portion of the medical profession, and bring the war of interests to an end, apparently by giving up all that is asked for. However flattering it may be for the Society to be placed in such vivid contrast with a witless "commercial speculation" which presumes to nominate representatives on a board of medical examiners, it is useless to call on it to "exercise its authority" in interdicting the practice of persons without a medical qualification, for the simple reason that it has no such authority. No doubt, as an important section of the trade, the Society can and will exercise a considerable influence in the direction of a clearer distinction between medicine and pharmacy. But the Pharmaceutical Society has no more authority, even if it had the desire, to interfere with the supply of simple remedies across the druggist's counter than the Medical Council has to order a medical practitioner not to retail salts or senna.

The course consistently advocated in this Journal should exonerate us from suspicion of wishing to impede so desirable a movement as the separation of medicine and pharmacy. But the fact is, a numerous class of educated and trained dispensers is now in existence, created for the special purpose of relieving professional gentlemen of "this undoubt- "edly trade industry," and this they have not been allowed to do to the extent that might fairly be expected. Instead of facilitating this transfer, impossible stipulations, which nobody can enforce against the will of the public, are put forward as indispensable preliminaries. In our opinion this is a reversal of the proper order of procedure. The natural result is that the would-be dispenser, tired of waiting for absent prescriptions, and frequently having a medical competitor in the retail branch, sometimes finds himself compelled to cultivate a business, which although it may be strictly within his right, is less congenial to him and more disagreeable to some members of the medical profession.

DISPENSING MEMORANDA.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, commencing with the present number, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be considered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken occasionally of calling attention to the more important points brought out in the various discussions.

EARLIER CLOSING.

Three months have elapsed since the meeting to consider the subject of Earlier Closing was held in the Theatre at 17, Bloomsbury Square, and it is rather disappointing, after the unanimous agreement as to the desirability of local effort towards carrying out the resolutions then passed, that so little appears to have been done. The first and almost the only sign of movement that has reached us has come from Notting Hill, the district where that meeting had its origin. The Early Closing Association there met at once and decided to canvass the district in favour of the second and third resolutions. The favourable result is shown on p. 1044, where will be found the names of about fifty chemists and druggists, residing in Notting Hill and Bayswater, who have agreed to put up their window shutters at 8 p.m. and close entirely at 8·30 p.m. every evening except Saturday, and to keep their establishments closed throughout Sunday. In order to prevent inconvenience to their customers a small handbill has been circulated announcing their intention, and in order to facilitate uniformity in the movement we reproduce it here.

NOTICE TO THE PUBLIC.

Earlier Closing of Chemists' Shops.

The Chemists and Druggists of this District respectfully inform the Public that on and after the 1st of August, 1877, their SHOPS will be

CLOSED AT 8·30 EVERY NIGHT,

EXCEPT SATURDAYS, and they earnestly appeal to the Public to assist them to shorten the present excessively late hours of business, by applying for Medicines, whenever practicable, before Eight o'clock.

The Establishments will be closed throughout the day on Sundays.

N.B.—In cases of emergency, Prescriptions and Medicines may be obtained at any hour.

We plead no excuse for referring to the subject again, our sole object being to rekindle, if we can, the enthusiasm which appears to have so soon become dormant. We need hardly say that we shall be glad to assist, with such publicity as we can give, any local efforts that may be put forth to extend this arrangement throughout London.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening next, June 28th, at eight o'clock, when a paper will be read by Mr. CHARLES H. HUTCHINSON, on "The Atomic Theory."

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

June 20th, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Southall, Taylor and Umney. Dr. Greenhow was also present, on behalf of the Privy Council.

MAJOR EXAMINATION.

Eight Candidates were examined. *Two* failed. The following *six* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Bullen, George William ....Newark.
Francis, Rawson Parke ....Diss.
Greenish, Henry George... .....London.
Gutheridge, George Frederick .Falmouth.
Parker, Robert Henry...........Barnstaple.
Radford, Charles ....Nottingham.

MINOR EXAMINATION.

Fifteen Candidates were examined. *Four* failed. The following *eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Baker, George ....London.
Brearey, Arthur William ......Douglas.
Goldstraw, Charles ....Bilston.
Hill, Arthur ....Cheltenham.
Lambert, Frederick Ernest......Hull.
Newth, Francis Henry ....Southampton.
Phillips, Evan ... .St. Clears.
Savory, Arthur Ledsam ....London.
Stubbs, Edwin ....Hull.
Williams, William ....St. Clears.
Wright, George ....Park, Sheffield.

June 21st, 1877.

Present:—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Southall, Taylor, and Umney. Dr. Greenhow was also present.

MINOR EXAMINATION.

Twenty Candidates were examined. *Fifteen* failed. The following *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Alcock, Joseph Pitman ....Worcester.
Bell, Henry ....Newcastle-on-Tyne.
Blunt, Thomas Porter ....Shrewsbury.
Lunn, Alfred.........................Spalding.
Troughton, Henry....... . ...Lancaster.

MODIFIED EXAMINATION.

Three Candidates were examined. *Two* failed. The undermentioned passed, and was declared qualified to be registered as a Chemist and Druggist:—

Davis, Joseph Burnard ....Tunbridge Wells.

PRELIMINARY EXAMINATION.

The under-mentioned certificates were received in lieu of the Society's Examination:—

Certificate of the College of Preceptors.

Roberts, William Rowe ....Manchester.

Certificates of the University of Cambridge.

Bunting, Frank Alexander......Witney.
Coslett, Thomas .... Bilston.
Gulliver, Walter Frederick......London.
Smart, William Pechey ....Thetford.
Waldron, John Henry...... .....Chertsey.

Proceedings of Scientific Societies.

ROYAL SOCIETY.

FURTHER RESEARCHES ON THE DEPORTMENT AND VITAL RESISTANCE OF PUTREFACTIVE AND INFECTIVE ORGANISMS, FROM A PHYSICAL POINT OF VIEW.*

BY JOHN TYNDALL, LL.D., F.R.S.,

Professor of Natural Philosophy in the Royal Institution.

The investigation embodied in the memoir now submitted to the Society was opened in the summer of 1876 by a series of tentative experiments on turnip-infusions, to which were added varying quantities of bruised or pounded cheese. I was soon, however, drawn away from them to other experiments on infusions of hay. With this substance no difficulty was encountered in my first inquiry. Boiled for five minutes, and exposed to air purified spontaneously or freed from its floating matter by calcination or filtration, hay infusion, though employed in multiplied experiments at various times, never showed the least competence to kindle into life. After months of transparency, I have, in a great number of cases, inoculated this infusion with the smallest specks of animal and vegetable liquids containing *Bacteria*, and observed twenty-four hours afterwards its colour lightened and its mass rendered opaque by the multiplication of these organisms.

But in the autumn of 1876, the substance with which I had experimented so easily and successfully a year previously appeared to have changed its nature. The infusions extracted from it bore in some cases not only five minutes' but fifteen minutes' boiling with impunity. But on changing the hay a different result was often obtained. Many of the infusions extracted from samples of hay purchased in the autumn of 1876, behaved exactly like those extracted from the hay of 1875, being completely sterilized by five minutes' boiling.

To solve these discrepancies, numerous and laborious experiments were executed with hay derived from different localities, and by this means in the earlier days of the inquiry, it was revealed that the infusions which manifested this previously unobserved resistance to sterilization were, one and all, extracted from old hay, while the readily sterilized infusions were extracted from new hay, the germs adhering to which had not been subjected to long-continued desiccation.

I then fell back upon infusions whose deportment had been previously familiar to me, and in the sterilization of which I had never experienced any difficulty. Fish, flesh, and vegetables were re-subjected to trial. Though the precautions taken to avoid contamination were far more stringent than those observed in my first inquiry, and though the interval of boiling was sometimes tripled in duration, these infusions, in almost every instance, broke down. Spontaneously purified air, filtered air, and calcined air,—calcined, I may add, with far greater severity than was found necessary a year previously,—failed, in almost all cases, to protect the infusions from putrefaction.

I had the most implicit confidence in the correctness of my earlier experiments; indeed, incorrectness would have led to consequences exactly opposite to those arrived at. Errors of manipulation would have filled my tubes and flasks with organisms instead of leaving them transparent and void of life. By the unsuccessful experiments above referred to a clear issue was therefore raised: Either the infusions of fish, flesh, and vegetable had become endowed in 1876 with an inherent generative energy which they did not possess in 1875, or some new contagium external to the infusions, and of a far more obstinate character than that of 1875, had been brought to bear upon them. The scientific mind will not halt in its decision between these two alternatives.

* Abstract. Reprinted from *Nature*, June 14, 1877.

For my own part the gradual but irresistible interaction of thought and experiment rendered it at first probable, and at last certain that the atmosphere in which I worked had become so virulently infective as to render utterly impotent precautions against contamination, and modes of sterilization, which had been found uniformly successful in a less contagious air. I therefore removed from the laboratory, first to the top, and afterwards to the basement of the Royal Institution, but found that even here, in a multitude of cases, failure was predominant, if not uniform. This hard discipline of defeat was needed to render me acquainted with all the possibilities of infection involved in the construction of my chambers and the treatment of my infusions.

I finally resolved to break away from the Royal Institution, and to seek at a distance from it a less infective atmosphere. In Kew Gardens, thanks to our President, the requisite conditions were found. I chose for exposure in the Jodrell laboratory the special infusions which had proved most intractable in the laboratory of the Royal Institution. The result was that liquids which in Albemarle Street resisted two hundred minutes boiling, becoming fruitful afterwards, were utterly sterilized by five minutes' boiling at Kew.

A second clear issue is thus placed before the Royal Society :—Either the infusions had lost in Kew Gardens an inherent generative energy which they possessed in our laboratory, or the remarkable instances of life development, after long-continued boiling, observed in the laboratory are to be referred to the contagium of its air.

With a view to making nearer home experiments similar to those executed at Kew, I had a shed erected on the roof of the Royal Institution. In this shed infusions were prepared and introduced into new chambers of burnished tin, which had never been permitted to enter our laboratory. After their introduction the liquids were boiled for five minutes in an oil-bath.

The first experiment in this shed resulted in complete failure, the air of the shed proving to be sensibly as infective as the air of the laboratory.

Either of two causes, or both of them combined, might, from my point of view, have produced this result. First, a flue from the laboratory was in free communication with the atmosphere not far from the shed; secondly, and this was the real cause of the infection, my assistants in preparing the infusions, had freely passed from the laboratory to the shed. They had thus carried the contagium by a mode of transfer known to every physician.

The infected shed was disinfected; the infusions were again prepared, and care was taken, by the use of proper clothes, to avoid the former causes of contamination. The result was similar to that obtained at Kew, viz., organic liquids which in the laboratory withstood two hundred minutes' boiling, were rendered permanently barren by five minutes' boiling in the shed.

A third clear issue is thus placed before us, which I should hardly think of formulating before the Royal Society, were it not for the incredible confusion which apparently besets this subject in the public mind. A rod thirty feet in length would stretch from the infusions in the shed to the same infusions in the laboratory. At one end of this rod the infusions were sterilized by five minutes' boiling, at the other end they withstood two hundred minutes' boiling. As before, the choice rests between two inferences :—Either we infer that at one end of the rod animal and vegetable infusions possess a generative power, which at the other end they do not possess; or we are driven to the conclusion that at the one end of the rod we have infected, and at the other end disinfected air.

The second inference is that which will be accepted by the scientific mind. To what, then, is the inferred difference at the two ends of the rod to be ascribed? In one obvious particular the laboratory this year differed from that in which my first experiments were made. On its floor were various bundles of old and desiccated hay, from which, when stirred, clouds of fine dust ascended into the atmosphere. This dust proved to be both fruitful and in the highest degree resistant. Prior to the introduction of the hay which produced the dust, no difficulty as regards sterilization had ever been experienced; subsequent to its introduction my difficulties and defeats began.

In these and numerous other experiments a method was followed which had been substantially employed by Spallanzani and Needham; and more recently by Wyman and Roberts, the method having been greatly refined by the philosopher last named. The flasks containing the infusions were only partially filled, the portions unoccupied by the liquids being taken up with ordinary unfiltered air. Now as regards the death-point of contagia, we know that in air it is higher than in water, the self-same temperature being fatal in the latter and sensibly harmless in the former. Hence my doubt whether, in my recent experiments, the resistance of the contagium did not arise from the fact that it was surrounded, not by water but by air.

I changed the method, and made a long series of experiments with filtered air. They were almost as unsuccessful as those made with ordinary air.

One source of discomfort clung persistently to my mind throughout these experiments. I was by no means certain that the observed development of life was not due to germs entangled in the film of liquid adherent to the necks and higher interior surfaces of the bulbs. This film might have dried, and its germs, surrounded by air and vapour, instead of by water, might on this account have been able to withstand an ordeal to which they would have succumbed if submerged.

A plan was, therefore, resorted to by which the infusions were driven by atmospheric pressure through lateral channels issuing from the centres of the bulbs. As before, each bulb was filled with one-third of an atmosphere of filtered air, and afterwards heated nearly to redness. When fully charged, the infusion rose higher than the central orifice, and no portion of the internal surface was wetted save that against which the liquid permanently rested. The lateral channel was then closed with a lamp without an instant's contact being permitted to occur between any part of the infusion and the external air. It was thus rendered absolutely certain that the contagia exposed subsequently to the action of heat were to be sought, neither in the superjacent air nor on the interior surfaces of the flasks, but in the body of the infusions themselves.

By this method I tested in the first place the substance which, at an early stage of the inquiry, had excited my suspicion—without reference to which the discrepancy between the behaviour of infusions examined in the winter of 1875-76 and those examined in the winter of 1876-77 is inexplicable, but by reference to which the explanation of the observed discrepancy is complete—I mean the old hay which cumbered our laboratory floor.

Four hours' continuous boiling failed to sterilize bulbs charged with infusions of this old hay. In special cases, moreover, germs were found so indurated and resistant, that five, six, and in one case even eight hours' boiling failed to deprive them of life. All the difficulties encountered in this long and laborious inquiry were traced to the germs which exhibited the extraordinary powers of resistance here described. They introduced a plague into our atmosphere—the other infusions, like a smitten population, becoming the victims of a contagium foreign to themselves.*

It is a question of obvious interest to the scientific surgeon whether those powerfully resistant germs are amenable to the ordinary processess of disinfection. It is perfectly certain that they resist to an extraordinary extent the action of heat. They have been proved competent to cause infusions, both animal and vegetable, to

* A hard and wiry hay from Guildford, which I have no reason to consider old, was found very difficult to sterilize.

putrefy. How would they behave in the wards of a hospital? There are, moreover, establishments devoted to the preserving of meats and vegetables. Do they ever experience inexplicable reverses? I think it certain that the mere shaking of a bunch of desiccated hay in the air of an establishment of this character might render the ordinary process of boiling for a few minutes utterly nugatory, thus possibly entailing serious loss. They have, as will subsequently appear, one great safeguard in the complete purgation of their sealed tins of air.

Keeping these germs and the phases through which they pass to reach the developed organism clearly in view, I have been able to sterilize the most obstinate infusions encountered in this inquiry by heating them for a minute fraction of the time above referred to as *insufficient* to sterilize them. The fully developed Bacterium is demonstrably killed by a temperature of 140° F. Fixing the mind's eye upon the germ during its passage from the hard and resistant to the plastic and sensitive state, it will appear in the highest degree probable that the plastic stage will be reached by different germs in different times. Some are more indurated than others and require a longer immersion to soften and germinate. For all known germs there exists a period of incubation during which they prepare themselves for emergence as the finished organisms which have been proved so sensitive to heat. If during this period, and well within it, the infusion be boiled for even the fraction of a minute, the softened germs which are then approaching their phase of final development will be destroyed. Repeating the process of heating every ten or twelve hours, and before the least *sensible* change has occurred in the infusions, each successive heating will destroy the germs then softened and ready for destruction, until after a sufficient number of heatings the last living germ will disappear.

Guided by the principle here laid down, and applying the heat discontinuously, infusions have been sterilized by an aggregate period of heating, which, fifty times multiplied, would fail to sterilize them if applied continuously. Four minutes in the one case can accomplish what four hours fail to accomplish in the other.

If properly followed out the method of sterilization here described is infallible. A temperature, moreover, far below the boiling point suffices for sterilization.

Another mode of sterilization equally certain, and perhaps still more remarkable, was forced upon me, so to speak, in the following way:—In a multitude of cases a thick and folded layer of fatty scum, made up of matted *Bacteria*, gathered upon the surfaces of the infusions, the liquid underneath becoming sometimes cloudy throughout, but frequently maintaining a transparency equal to that of distilled water. The living scum-layer, as Pasteur has shown in other cases, appeared to possess the power of completely intercepting the atmospheric oxygen, appropriating the gas and depriving the germs in the liquid underneath of an element necessary to their development. Above the scum, moreover, the interior surfaces of the bulbs used in my experiments were commonly moistened by the water of condensation. Into it the *Bacteria* sometimes rose, forming a kind of gauzy film to a height of an inch or more above the liquid. In fact, wherever air was to be found, the *Bacteria* followed it. It seemed a necessity of their existence. Hence the question, What will occur when the infusions are deprived of air?

I was by no means entitled to rest satisfied with an inference as an answer to this question; for Pasteur, in his masterly researches, has abundantly demonstrated that the process of alcoholic fermentation depends on the continuance of life without air—other organisms than *Torula* being also shown competent to live without oxygen. Experiment alone could determine the effect of exhaustion upon the particular organisms here under review. Air-pump vacua were first employed, and with a considerable measure of success. Life was demonstrably enfeebled in such vacua.

Sprengel pumps were afterwards used to remove more effectually both the air dissolved in the infusions and that diffused in the spaces above them. The periods of exhaustion varied from one to eight hours, and the results of the experiments may be thus summed up:—Could the air be completely removed from the infusions, there is every reason to believe that sterilization *without boiling* would in most, if not in all cases, be the result. But, passing from probabilities to certainties, it is a proved fact, that in numerous cases unboiled infusions deprived of air by five or six hours' action of the Sprengel pump are reduced to permanent barrenness. In a great number of cases, moreover, where the unboiled infusion would have become cloudy, exposure to the boiling temperature for a single minute sufficed completely to destroy the life already on the point of being extinguished through defect of air. With a single exception, I am not sure that any infusion escaped sterilization by five minutes' boiling after it had been deprived of air by the Sprengel pump. These five minutes accomplished what five hours often failed to accomplish in the presence of air.

The inertness of the germs in liquid deprived of air is not due to a mere *suspension* of their powers. They are *killed* by being deprived of oxygen. For when the air which has been removed by the Sprengel pump is, after some time, carefully restored to the infusion, unaccompanied by germs from without, there is no revival of life. By removing the air we stifle the life which the returning air is incompetent to restore.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The Different Methods of Flower Fertilization.*

BY J. F. SAVORY.

If a complete flower be examined it will be found that the pistil is normally surrounded by a row of stamens, and it would seem at first sight a very simple matter that the pollen of the latter should fall on the former. This in fact does happen in many instances, and flowers which thus fertilize themselves have evidently one great advantage,—few remain sterile for want of pollen.

In a flower which is capable of self-fertilization we find that at the proper time the anthers dehisce or burst open, and the pollen is discharged on to the stigma, which is at that time covered with a viscid secretion. This secretion, besides containing the pollen, acts on it in such a way, that, after a short time numerous small tubes are developed. These latter pierce the stigmatic tissue and convey the fovilla through the canal of the style (if present) to the ovule, which is then fertilized.

The emission of these tubes sometimes commences half a minute after the pollen has been applied to the stigma. In other cases, as in the *Mirabilis Jalapa* or spurious jalap, it does not take place until from twenty-four to thirty-six hours. Geleznoff says, that in the larch, these tubes do not emerge for thirty-five days.

Although these pollen tubes are frequently several inches long, they are also very minute, the diameter varying from $\frac{1}{7000}$ to $\frac{1}{7000}$ of an inch. Amici estimated the number of pollen tubes formed from the pollen masses of *Orchis Morio* to be no less than 120,000 in number.

Experiments have been made, however, which show that, under favourable circumstances, very few pollen grains suffice even for a many-ovuled ovary. Kölreuter found that when twenty-five pollen grains were placed on the stigma of *Hibiscus trionum*, from ten to sixteen ovules were developed; with fifty or sixty pollen grains, above thirty ovules, whilst one, two, or three at most sufficed the single ovules of *Mirabilis Jalapa*, and *M. Longiflora*.

Having made these few cursory remarks, let us now proceed. The cases of self-fertilization are much less frequent than might at first be supposed, and there are

* Read before the School of Pharmacy Students' Association, Thursday, May 24th, 1877.

three principal modes by which it is prevented. Firstly, in many species, the stamens and pistil are situated on different flowers; such species are called "diclinous"; when the male and female flowers are on the same plant, they are "monœcious"; when on different plants "diœcious."

Secondly, in other cases, as was first discovered by Sprengel, though the stamens and pistil are both situated on one flower, they are not mature at the same time, and the pollen, therefore, cannot fertilize the pistil. These plants are called "dichogamous." Sometimes, as in the arum, the pistil matures before the anther, and these plants are termed "proterogynous"; but much more frequently the anther matures before the pistil, and then the plant is said to be "proterandrous."

Thirdly, there are some plants in which, as was first discovered by Mr. Darwin, the same object is secured by the existence, within the limits of the same species, of two or more kinds of flowers, differing in the relative position of the stamens and pistil, which are so placed as to favour the transference by insects of the pollen from the anther of one form to the pistil of the other. These plants are termed "heteromorphous;" some of them have two kinds of flowers, and are called "dimorphous," while others have three forms, and are called "trimorphous."

But even in plants which belong to none of the categories, we find minor modifications which tend to prevent self-fertilization; and Mr. Darwin is probably right in his opinion that no plant invariably fertilizes itself. Thus in some species where the stamens surround the pistil, and which might therefore be supposed to be arranged in such a manner as to insure self-fertilization, the anthers do not open towards the pistil, but on the sides, and, by no means, therefore, in a favourable position with reference to the transference of the pollen.

In most, if not all the cruciferæ, the anthers in young flowers have the side which opens turned towards the pistil; but before the anthers come to maturity, they twist themselves round, so as to turn their backs to the stigma.

Again, in pendent flowers, where the pistil hangs below the anthers, the stigmatic surface is never the upper one which would catch any falling pollen, but on the contrary, the lower one which could hardly be touched by the pollen of the same flower, but which is so placed as to come in contact with any insect or other body approaching the flower from below.

It is also probable that many cases will be found to exist in which, though the pollen necessarily comes in contact with the pistil of the same plant, fertilization does not take place. This is said to be the case in *Verbascum nigrum*, *Lobelia fulgens*, and *Primula verticillata*.

Other cases are recorded in which plants are more or less insusceptible of fertilization by their own pollen. Moreover, even where plants *are* capable of self-fertilization, the pollen from another flower is often more effective than their own, whence it follows that if a supply of pollen from another plant be secured, it is comparatively unimportant to exclude the pollen of the plant itself; for in such cases the latter is neutralized by the more powerful effects of the former.

In some few cases the pistil ripens before the stamens, in which case the species is "proterogynous," as above stated. Thus Aristolochia has a flower which consists of a long tube with a narrow opening closed by stiff hairs which point backwards, so that it much resembles an ordinary eel trap. Small flies enter the tube in search of honey, which, from the direction of the hairs, they can easily do, though, on the other hand, it is impossible for them to return. Thus, they are imprisoned in the flower; gradually, however, the pistil passes maturity, and the stigma ceases to be capable of fertilization, while the stamens ripen, and shed their pollen, by which the flies get thoroughly dusted. Then the hairs of the tube shrivel up and release the prisoners, which carry the pollen to another flower, and thus fertilize it.

Again, in the common arum, we find a similar kind of fertilization. The well-known green leaf encloses a central pillar, which supports a number of stigmas near the base, and of anthers somewhat higher. Now, in this case, nothing would at first sight seem easier or more natural than that the pollen from the anthers should fall on and fertilize the pistil. This, however, is not what occurs. The stigmas mature before the anthers, and by the time the pollen is shed, have become incapable of fertilization. It is impossible, therefore, that the plant should fertilize itself. Nor can the pollen be carried by the wind. When it is shed, it drops to the bottom of the tube, where it is so effectually sheltered that nothing short of a hurricane could dislodge it, and although arum is common enough, still the chances against any of the pollen so dislodged being blown into the tube of another plant would be immense.

As, however, in Aristolochia, so also in Arum, small insects which, attracted by the showy central spadix, the prospects of shelter or honey, enter the tube while the stigmas are mature, find themselves imprisoned by a fringe of hairs, similar to those in the Aristolochia, which, while permitting their entrance, prevent them from returning.

After a while, however, the period of maturity of the stigmas is over, and each secretes a drop of honey, thus repaying the insects for their captivity. The anthers then ripen and shed their pollen, which falls on and adheres to the insects. Then the hairs gradually shrivel up and set the insects free, which carry the pollen with them, so that those which then visit another plant can hardly fail to deposit some of it on the stigmas. Sometimes more than one hundred small flies will be found in a single Arum. In these two cases, there is obviously a great advantage in the fact that the stigmas arrive at maturity before the anthers.

On the other hand "proterandrous" flowers are much more numerous. To this category belong some species of Thyme, Pinks, Epilobium, Geranium, Malva, Gentians, many of the Labiatæ, Umbelliferæ, most of the Compositæ, Lobeliaceæ and Campanulaceæ. In fact, the greater number of flowers which contain both stamens and pistil are more or less "proterandrous." Here we have a pink in the first or male condition. The stamens are mature, and project above the disk of the flower, while the pistil is still concealed within the tube. On the other hand, we have here another flower in a more advanced condition, viz., the second or female condition. The stamens have shrivelled up, while the pistil now occupies their place.

Here it is at once obvious that insects alighting on the younger or male flowers, would dust themselves with pollen, some of which, if they subsequently alighted on an older flower, they could not fail to deposit on the stigma. In some cases, flowers which are first male and then female, are male on the first day of opening, female on the second. In others the period is longer. Thus Nigella, according to Sprengel, is male for six days, after which the stigma comes to maturity, and lasts three or four.

I now pass to the third of the principal modes by which self-fertilization is prevented, viz., heteromorphous flowers; and in this class I will more especially draw your attention to the genus Primulaceæ. If a number of specimens of primroses or of cowslips be examined, we shall find that about half of them have the pistil at the top of the tube and the stamens half way down, while the other half, on the contrary, have the stamens at the top of the tube and the pistil half way down. In Lythrum, the existence of different forms had been observed by Vaucher in 1841, and in the genus Oxalis by Jacquin, who regarded them as indicative of different species; but it was reserved for the genius and perseverance of Mr. Darwin to explain the significance of this curious phenomenon and the important part it plays in the economy of a flower. Now that Mr. Darwin has pointed this out, it is sufficiently obvious. An insect thrusting its proboscis down a primrose of the long-styled form, would dust its proboscis at a part, which, when it visited a short-styled flower would come just opposite the head of the pistil, and could not fail to deposit some of the pollen on the stigma. Conversely, an insect visiting a short-styled plant would dust its proboscis at a part further from the tip, which, when the insect visited a long-styled flower would again come just opposite to the head of the pistil. Hence we see that by this beautiful arrangement insects must carry the pollen of the long-styled form to the short-styled, and *vice versâ*.

There are other points in which the two forms differ from one another: for instance, the stigma of the long-styled form is globular and rough, while that of the short-styled is smoother and somewhat depressed. The pollen of the two forms is also dissimilar, that of the long-styled being considerably smaller than the other,—$\frac{7}{7000}$ of an inch in diameter against $\frac{10 \cdot 1}{7000}$, or nearly in the proportion of three to two; a difference, the importance of which is probably due to the fact that each grain has to give rise to a tube which penetrates the whole length of the style, from the stigma to the base of the flower, and the tube which penetrates the long-styled pistil must therefore be nearly twice as long as in the other.

Another point of great interest is the spontaneous movement of the stamens and pistil in dichogamous plants, first observed by Kolreuter in *Ruta graveolens*. He, however, supposed that the object was to bring the stamens in contact with the pistil, whereas, the real advantage, as Sprengel pointed out, is that in consequence the stamens and pistil successively occupy the same spot in the flower and thus come in contact with the same part of the insect. For instance, in the *Geranium pratense*, when the flower first opens, the stamens lie on the petals, at right angles with the upright pistils. As, however, they come to maturity, they raise themselves parallel and close to the pistil, which, however, is not as yet capable of fertilization. After they have shed their pollen they return to their original position, and the stigmas unfurl themselves. More or less similar movements have been observed in various other flowers. Thus the anthers of *Digitalis purpurea*, which are at first transverse, become longitudinal as they ripen.

In aquatic plants the blossoms habitually come to the surface. In *Valisneria spiralis* the female flower has a long spiral stalk, which enables it to rise to the top of the water. The male flowers, which are small, very numerous, and attached lower down, separate themselves altogether from the plant, rise to the surface, and fertilize the female flowers among which they float. When this is effected, the spiral stalk of the female flower again contracts, and draws it down below the surface.

The pollen is transferred from the stamens to the pistil in different ways. In some species, it is carried by the action of the wind, in a few cases by birds, but in the majority of instances this important object is secured by the visits of insects, and the whole organization of such flowers is adapted to this purpose.

Sprengel, Darwin and Müller have shown that the form and colours of wild flowers are mainly owing to the unconscious selection exercised by insects, although, no doubt, the existence of a certain amount of colouring matter is, as we see in autumn tints in various fungi, and seaweeds, due to other causes.

As I have mentioned above, the transference of the pollen from one flower to another is principally effected either by the wind or by insects. In the former case, the flower is anemophilous, in the latter entomophilous.

In anemophilous plants the flower is rarely conspicuous and to use the words of Mr. Darwin, he finds that "it is an invariable rule that when a flower is fertilized by the wind it never has a gaily coloured corolla." Conifers, grasses, birches, poplars etc., belong to this category.

In such plants, a much larger quantity of pollen is required than where fertilization is effected by insects. You have all observed the showers of yellow pollen produced by the Scotch fir. Here it is an advantage that the tree should flower before the leaves are out, because the latter would greatly interfere with the access of the pollen to the female flower. Hence as a rule, such plants flower early in the spring.

Again, in such flowers, the filaments of the stamens are usually long, and the pollen less adherent, so that it can easily be detached by the wind, which would manifestly be a disadvantage in the case of those flowers which are fertilized by insects. On the other hand it is an advantage to most seeds to be somewhat tightly attached, because they are then only removed by a high wind, which is capable of removing them to some distance. The above does not apply to such seeds as the dandelion, which are specially adapted to be carried by the wind.

According to Sprengel, the pollen of wind-fertilized flowers is dried, and therefore more easily carried by the wind, than that of most insect-fertilized flowers. Mr. Bennett also states that the pollen of wind-fertilized flowers is generally spherical; while that of insect fertilized flowers is usually furrowed, the furrows running along the longer axis of the grain.

Wind-fertilized flowers, moreover, generally have the stigma more or less branched or hairy, which evidently tends to increase its chance of catching the pollen. Take for example, the stigmas of the alder, hop, and wheat, all of which are anemophilous, and compare them with those of the willow, flax and nuphar, which are entomophilous.

Mr. Darwin has pointed out that irregular flowers appear to be always fertilized by insects. The Orchidaceæ may be taken as the most characteristic order of entomophilous plants.

There are some plants, of which we have a few in this country, whose normal time of flowering is almost the depth of winter, such as the hazel nut, butcher's brown, and the gorse.

There is also a more numerous class, which flowers and fructifies all through the year, almost regardless of season and temperature, among which may be mentioned the white and purple dead-nettle, daisy, dandelion, groundsel, common spurge, shepherd's purse, and some others.

During the winter of 1868-9, numerous observations were made on this class by Mr. Bennett, and he found, that as a general rule, fertilization or, at all events, the discharge of the pollen by the anthers, takes place in the bud, before the flower is opened, thus insuring self-fertilization under the most favourable circumstances, with complete protection from the weather, assisted, no doubt, by that rise of temperature which is known to take place in certain plants at their time of flowering. The dissection of a flower of the white dead-nettle, gathered the last week in December, showed the stamens completely curved down, and brought almost in contact with the bifid stigma, the pollen being at that time freely discharged from the anthers. A more complete contrivance for self-fertilivation than is here presented would be impossible.

The same phenomena were observed in *Veronica buxbaumi*, where the anthers are almost in contact with the stigma, before the opening of the flower (a circumstance which occurs but seldom). In *Veronica agrestis* and polita, the larger periwinkle, gorse, dandelion, groundsel, daisy, and shepherd's purse. In the latter case, the four longer stamens appear to discharge their pollen in the bud, the two longer not until a later period. Also in the purple dead-nettle, *Cardamine hirsuta*, and chickweed, in which the flowers open only under the influence of bright sunshine.

In contrast with these, a large number of wild plants, which had been tempted by the mild January to put forth a few wretched flowers at a very abnormal season, were also examined. Among these were the charlock, wild thyme, and fumitory, in all of which instances was there not only no pollen discharged before the opening of the flower, but also no seed was observed to be formed. An untimely specimen of the common garden bean, presented altogether different phenomena from its relative the gorse, the anthers not discharging their pollen till after the opening of the flower: and the same was observed in the *Lamium galeobdolon*, or yellow archangel gathered in April, notwithstanding its consanguinuity to the dead-nettle.

The description detailed above cannot of course apply to those winter flowering plants in which the male and female organs are produced on different plants; but here we commonly find another provision for insuring fertilization. In the case of the hazel nut, the female flowers number from two to eight or ten in a bunch, each flower containing only one ovule destined to ripen. To each bunch of female flowers, belongs at least one catkin (often two or three) of male flowers, consisting of from 90 to 120 flowers, and each flower containing from three to eight anthers. The pollen is not discharged till the stigmas are fully developed, and the number of pollen grains must be many thousand times in excess of what would be required were each grain to take effect. The arrangement in catkins also favours the scattering of the pollen by the least breath of wind, the reason probably why so many timber trees in temperate climes, many of them flowering very early in the season, have their male inflorescence in this form.

The euphorbias or spurges have flowers structurally unisexual, but which for physiological purposes may be regarded as bisexual, a single female flower being enclosed along with a number of male flowers in a common envelope of involucral glands. Two species are commonly found flowering in the winter, and producing abundance of capsules, viz., *Euphorbia Peplus*, and *E. Helioscopia*. In both the species, the pistil makes its appearance above the involucral glands, considerably earlier than the bulk of the stamens. A single one, however, of these latter, was observed to protrude beyond the involucral glands, simultaneously, or nearly so, with the pistil, and to discharge its pollen freely on the stigma, thus illustrating a kind of quasi-self-fertilization. The remaining stamens do not discharge their pollen until a considerably later period after the capsule belonging to the same set has acquired a considerable size.

In *Euphorbia Helioscopia* the capsules are almost entirely included within the cup-shaped bracts, and the stigmas are turned up at the extremity so as to freely receive the pollen from their own stamens.

We now come to a case of complete cross-fertilization without the aid of insects. Take the *Euphorbia Amygdaloides*, which does not flower before April. In this plant, the heads of the flowers which first open are entirely male, containing no female flower; in the hermaphrodite heads which open subsequently, the stigmas are completely exposed beyond the involucral glands, long before any stamens protude from the same glands. The pollen from the first opened male flowers no doubt fertilizing the stigma of the next opened hermaphrodite heads and so on. In this species, the bracts are not cup-shaped, but nearly flat; the stamens hang out very much farther than in *Euphorbia Helioscopia*, and the styles are perfectly flat.

As a rule, we find that in different species of the same genus, the more conspicuous flowers are adapted to cross-fertilization, and the less conspicuous ones to self-fertilization.

The *Malva sylvestris* and *Malva rotundifolia* are very good examples of this class. In both the species, whenever insects visit these flowers, cross-fertilization is largely effected, owing to the structure of the plant, whereas self-fertilization can scarcely take place, neither spontaneously, nor by means of insects, nearly all the pollen grains having been removed before the unfolding of the stigmatic branches. Since, however, both these plants grow for the most part in the same locality, and flower during several months at the same time, insects flying about and seeking for honey are much more likely to find out and visit the highly conspicuous flowers of *Malva sylvestris*, than the far less ones of *Malva rotundifolia*; the former, when fully opened, presenting bright rose-coloured bells of from 40 to 50 mm. in diameter, the latter, on the contrary, light coloured bells, of only 20 to 25 mm.

Direct observation, indeed, fully confirms this supposition; the flowers of *M. sylvestris* being always found in sunny weather, visited by a variety of insects, whereas those of *M. rotundifolia*, especially when growing intermixed with *M. sylvestris*, are commonly overlooked by them all. It is evident from these facts that wherever our two species of *Malva* grow together in the same locality, *Malva rotundifolia* would be rapidly extinguished unless it were able to produce seed by self-fertilization; *M. sylvestris*, on the other hand, is so commonly visited and cross-fertilized by insects that self-fertilization, if it were possible, would never be effected, or only exceptionally. Thus, in the flowers of *M. sylvestris* when precluded from the visits of insects by covering them with a gauze net, the anthers remain filled with pollen, and never, or only exceptionally, come spontaneously into contact with the stigmatic branches, the free ends of their filaments at a later period bending downwards, and the branches of the styles remaining considerably above them. Conversely in the flowers of *M. rotundifolia*, when the visits of insects are prevented, the anthers filled with pollen grains remain in so high a position and the stigmatic branches bend so far downwards as to come abundantly into contact with the pollen grains, self-fertilization being thus inevitable.

(*To be continued*).

Parliamentary and Law Proceedings.

Death from Chloral.

Mr. W. S. Donaldson, deputy coroner for East Middlesex, held an inquest, at the Talbot Arms, Kingsland, respecting the death of Mr. John Tuer Hepworth, aged 27 years, a solicitor, carrying on business at Regent Circus, and residing at Kingsland.—Marian Hepworth stated that deceased was her husband. He had latterly been unwell, but able to attend to business. On Saturday last he returned home, and shortly afterwards went upstairs to lie down. On her retiring to bed, at 11·30, she found him lying dead on the bed. She knew that he was in the habit of taking chloral to procure sleep. Dr. Horton, on making a *post-mortem* examination, found the heart and other organs diseased. On the table was an empty bottle, which had contained chloral, and a glass. The cause of death was due to an overdose of chloral, acting on a diseased constitution.—A surgeon, of Leeds, a brother of the deceased, stated that he had often cautioned him against taking chloral. The jury returned a verdict in accordance with the medical evidence.

Death from an Overdose of Paregoric in Newcastle.

On Thursday, June, 14, an inquest was held by Mr. J. T. Hoyle, coroner, at the Durham Ox Inn, Cattle Market, on the body of David Pearson, eighteen months old, son of David Maxwell Pearson, 121, Elswick East Terrace, lamp maker. On Tuesday night the deceased boy was not very well, and his mother bought some paregoric at a hosier's shop in Elswick East Terrace, and gave him a portion of it in a tea cup. She then put him to bed, and he slept soundly. The next morning she observed that there was something wrong with him, and she went for Dr. Ellis, of Rye Hill, who came and found the deceased suffering from the effects of a narcotic poison, and in a dying state. He applied the usual remedies, and, having told the mother what to do, he left. About half an hour afterwards the father of the deceased came and told him the child was dead. The doctor produced a bottle containing about two and a half spoonfuls, or three drachms, of paregoric, and the mother said she had given the deceased about the quantity left in the bottle. The verdict of the jury was, that "The deceased died from an overdose of paregoric administered to him by his mother, and that his mother was wrong in administering it without medical advice."—*Newcastle Daily Chronicle.*

Alleged Attempt to Poison.

At Winterborne (Dorsetshire) Divisional Petty Sessions, Lucy Tizzard, wife of a farm servant, has been examined on the charge of administering poison to her two daughters, one a married woman, and the other a domestic. On Monday week prisoner invited her daughters to visit her, and after drinking some cocoa they became ill. It transpired that the prisoner had mixed a quantity of arsenic with the drink, but the poison was brought away by the stomach pump. Since the prisoner has been in goal she has behaved strangely, and has stated that she also intended poisoning her husband, her son, and afterwards herself, as she wished them all to be together in heaven. The magistrates had decided to commit the prisoner for trial, but ultimately a warrant was issued for her removal to an asylum.

Attempted Poisoning by Laudanum.

At Marlborough Street Police Court, on Friday, June 15, Henry Hall, bootmaker, was finally examined before Mr. Newton on a charge of having administered laudanum to Jane Hall, aged 8, Frank Hall, aged 6, Anne Hall, aged 4, and Louisa Hall, aged 2, his four children, with intent to murder them. Mr. H. Kisch, barrister, defended the prisoner. The evidence was to the effect that the mother, finding the children lying on the bed ill, took first one and then another to Dr. Clarke, who, perceiving they were labouring under the effects of narcotic poison, applied remedies, and kept them at the surgery until they were sufficiently recovered to be removed—two to the hospital and the others home. Inspector Turpin said that he found two bottles which had contained laudanum, one marked to that effect, in an open box containing shoemaking tools, placed by the side of a bench in the prisoner's room. Dr. Clarke produced two other bottles, which he received from a Mrs. Tice, who said she saw the prisoner's wife pick them up from a corner of the room occupied by the prisoner. Both bottles had contained laudanum.

Mr. Arrowsmith, of Bonner Road, chemist, stated that the prisoner purchased two pennyworth of laudanum at the shop of Dr. Cooper, Moor Street, where he was employed as assistant, on Wednesday week. The prisoner, on being told that the drug was poison, replied it was either for faceache or toothache. Witness supplied the drug, and labelled the bottle "Laudanum; poison," with the name of the vendor He had sold laudanum since to several persons, but was certain the prisoner was the purchaser of the laudanum on the day in question.

Mr. Frederick Paine, clerk to the executors of Mr. Hartnell, chemist, 9, Tichborne Street, stated that on Wednesday or Thursday week a man—he believed the prisoner—brought a small phial and asked for two pennyworth of laudanum. Asked him if it was for the toothache, he either said "Yes" or nodded. The bottle produced bore the label of the house.

Mr. Newton inquired if an entry was made at the time.

Witness said a poison book was kept and everything necessary to be entered was entered in it, but he did not think an entry was made of the sale in question.

Mr. Steedman, resident medical officer of the Charing Cross Hospital, stated that on the evening of the 8th inst., two children were brought to him. The girl had suffered more than the other child. Both children had contracted pupils, vomiting, and were suffering from sleepiness. He had them put into a ward and kept them there until Thursday. After he examined them he came to the conclusion that they were suffering from narcotic poisoning. Laudanum would cause the effects he perceived in the children Replying to Mr. Kisch, witness said he did not give the children the medicine until he had first examined them. One child fell asleep while standing. The child could not be affected in that way by merely smelling the laudanum in the bottle. The children were not all of them out of danger.

Jane Hall, an intelligent child about eight years of age, said she lived with her father and mother, and had a brother and two sisters. That day week her father gave her some stuff out of the bottle produced telling her she was to drink it. Her father then gave some to her brother and sisters, but not all out of the same bottle. Her father did not say why they were to take it. Her mother was out at the time at work. After taking the stuff she felt ill. Witness also saw her father give some of the stuff to the other children, but could not say whether he gave any to the baby Anne.

Mr. Newton fully committed the prisoner for trial to the Old Bailey.

"Condy's Fluid."

In the High Court of Justice, Chancery Division, on June 15, before Vice-Chancellor Sir James Bacon, a suit was brought by Mr. H. B. Condy, the inventor and patentee of "Condy's Fluid," to restrain the defendants from selling Condy's Fluid, and, by adopting the name or style of "Condy's Fluid Company," inducing the public to believe that what they sold as Condy's Fluid was actually manufactured by the plaintiff. The plaintiff and the defendant, Dr. Mitchell, had been in partnership from March, 1870, to October, 1873, and it was not disputed that upon the dissolution of the partnership the defendant had a right to manufacture and sell "Condy's Fluid," but the plaintiff complained that the name was not used honestly, but that the style of "Condy's Fluid Company" was adopted by the defendant for no other purpose than to induce the public to believe that Mr. Condy, the plaintiff, was the manufacturer of what the defendants sold. It was also suggested that the defendants sold as Condy's Fluid an inferior article. But the Vice-Chancellor said that there was no jurisdiction for the Court to restrain persons who had a right to sell their articles under the name of Condy's Fluid, from selling any compound they liked to sell under that name.

Vice-Chancellor Bacon said that no case of fraud had been made out. The defendants had done nothing to mislead the public. They did not pretend that they were selling articles actually made by Mr. Condy; they were only exercising their right, which could not be denied, of selling an article called "Condy's Fluid." The plaintiff's bill must be dismissed with costs.

Dispensing Memoranda.

(*See the Note respecting this Column on p.* 1046).

[1]. DISPENSING QUERY.—The following prescription was sent me to dispense:—

℞	Tr. Ferri Mur.	℥iss.
	Liq. Ammon. Acet.	℥iss.
	Tr. Guaiaci	℥vj.
	Aquæ . . . . ad	℥viij.

I sent it out with the usual appearance of a guaiacum mixture, when it was brought back as made up wrongly. The customer has since had it made up in a West-end establishment, when it was sent out perfectly clear. Could you inform how it is to be done?— Radix.

[2]. DISPENSING QUERY.—Is it possible to make an attractive mixture with the following recipe, and if so in what order should the ingredients be mixed:—

℞ Vin. Ipecac. . . . . ʒss.
Tr. Tolu. Bals. . . . . ʒj.
Chlorodyne . . . . ʒj.
Tr. Opii Am. . . . . ʒiij.
Glycerini . . . . ʒij.

J. KITCHEN, *Glasgow.*

---

[3]. EXPLOSIVE MIXTURE.—As a contribution to the literature of "pharmaceutical torpedoes," I enclose a copy of a prescription dispensed by me with a result equally alarming to the patient and annoying to the dispenser.

(Copy).

℞ Bismuthi Subnit. . . . . ʒiiss.
Sodæ Bicarb. . . . . ʒiss.
Aq. Menth. Pip. ad . . . . . ℥viij.
Coch. mag. ii. omne mane.

This mixture was made up as ordered, and sent home. Within an hour of its delivery the bottle burst. Another was prepared, but the precaution was taken to allow the mixture to stand before being finished off. Shortly after it had been made the cork was blown out with great violence, the mixture presenting the appearance of a freshly opened bottle of soda-water. Had the mixture been sent home as soon as prepared it would most certainly have gone the way of its predecessor. On testing the bismuth subnit. it was found to be slightly acid; this may account for the whole phenomena. But the real cause is possibly a decomposition which takes place between the two salts. I have not been able to find an explanation in any work on chemistry. Probably the following equation would represent the decomposition which takes place.

$$4\,BiONO_3 + 4\,NaHCO_3 = 2\,Bi_2O_2CO_3 + 4\,NaNO_3 + 2\,H_2O + 2\,CO_2.$$

Perhaps some of your readers will acquaint me if they have had occasion to dispense the prescription. The medical man possibly meant the subcarbonate, but in these times of strictly pharmaceutical relations between physician and dispenser, I submit that there is no alternative but to follow to the letter these chemical incompatibilities as ordered, even at the risk of converting the harmless-looking, neatly wrapped up bottle of medicine into an aggressive torpedo, which may damage or possibly kill instead of curing the patient. JOHN W. YEATS.

Review.

BUTTER, ITS ANALYSIS AND ADULTERATIONS, specially treating on the Detection and Determinations of Foreign Fats. By OTTO HEHNER, F.C.S., and ARTHUR ANGELL, F.R.M.S. Second edition. J. and A. Churchill. London. 1877.

This small book of eighty-six pages calls for notice chiefly by virtue of its doubtful value, a matter which becomes the more serious when we read that the treatise has been entirely re-written, improved, and augmented. It is impossible to read this book and to avoid the impression that not only is it pretentious beyond reason, and very badly written, but worse than all it is full of lamentable errors—errors of a kind that a national school boy would be ashamed to commit. That our judgment is neither of unmerited severity nor partakes of prejudice we hope to substantiate by pointing out some of the gross blunders to which we have above referred.

Speaking of what they call their process of butter analysis, but to which they have no virtual claim, the authors write as follows in their preface: "Butter analysis has, in fact, now been placed upon as sound a basis as any branch of food analysis, and the most difficult of problems is considered to be solved by every one who has a voice in the matter."

Let us now inquire upon what grounds this conclusion, so laudatory of themselves, is based.

In the first edition of their book the authors claimed to have demonstrated on the data therein contained, that butter fat yields from 85 to 86 per cent. of fixed insoluble fatty acids, or about 9·5 per cent. less than any other fat. On repeating the calculations based upon their own mathematical data, it is seen, however, that they have blundered at all points in their arithmetic (see pp. 46–49, first edition), and hence, instead of obtaining the above figures representing the insoluble fatty acids in butter fat we obtain figures varying from 85·5 per cent. to 93 per cent.

The following instances which we quote from the first edition of the book in question will serve to illustrate our criticism, and the authors' errors.

"Experiment II.—3·159 grams of genuine farm butter-fat yielded 2·922 grams, or 86·16 per cent. of fixed acids."

Now the quantity of solid fatty acids obtained really indicates 92·49 per cent. Again,

"Experiment VI.—3·302 grams of fat from best Normandy butter yielded 3·076 grams, or 85·40 per cent."

The true percentage = 93·15.

We forbear mention of further arithmetical blunders, but it is desirable to point out once more that it is upon these results and similar ones that the authors base their conclusions.

Remarking upon their results they write on p. 48, of the first edition of their book: "It is remarkable to notice that the composition of butter fat is exactly as constant as the amount of 'solids not fat' in milk, upon which Mr. Wanklyn has based his method for the analysis of that article." After what we have shown we can only hope this is not true.

Since the publication of the first edition of the book we are examining, Dr. Muter and others have pointed out that Messrs. Hehner and Angell's standard of fixed fatty acids in butter fat (85–86 per cent.) is too low, judging by their personal experience. In the present edition the authors admit the truth of this criticism, and curiously enough throw the error upon the faulty methods of manipulation, as in fact being occasioned by a loss experienced by spirting during the act of saponification of the butter! After this ingenuous confession Messrs. Hehner and Angell proceed to describe a modification they have introduced into the proceeding, due to the suggestion of Dr. Turner, which consists in the use of an alcoholic solution of potash. These new determinations lead the authors to fix the percentage of solid fatty acids in butter fat at 86–88 instead of at 85–86 as originally. All butters, therefore, containing more than 88 per cent. insoluble fatty acids in the butter fat are viewed and condemned by the authors of this work as adulterated with foreign fat.

These facts will suffice to demonstrate the utter worthlessness of their results and the value of that method which they regard as scientific, accurate, and accepted. We leave our readers to judge of the truth of their assertion, which is as follows: "Practically, it is impossible to evade detection of adulteration!"

Let us, however, pass from this matter to consider a few other points presented by this remarkable book. Even if we for the moment accept their standard of 88 per cent. solid fatty acids in butter fat, then, according to their own confession, 12 per cent. of foreign fat may be added to certain low class butters before the extreme of 88 per cent. is reached.

It is almost a difficulty to decide upon the points best illustrative of the imperfect and loose analytical method described in this book; they are so numerous and faulty. The use of an alcoholic solution of potash for saponification of butter fat is now extended, among public analysts at least, and no care seems taken of the danger to be expected from this source, viz., the formation of ethers. It is true that Messrs. Hehner and Angell have observed the smell of butyric ether (whatever that may be worth), but it seems never to have occurred to them or others that other ethers may be similarly produced from the higher fatty acids obtained from butter. No chemist of any repute at all, can read the book before us and not receive a moral shock at the loud boast made in it, and the amount of loose work therein described.

Notwithstanding the attempts that have been made by Dr. Dupré, Mr. Bell, and Dr. Muter, to improve known methods of butter analysis, it cannot be said that this is a subject at all well understood by chemists, and, in fact, much more remains to be done than has yet been accomplished. In the meantime we may express our conviction that desirable results can only be reached by observing mathematical principles in chemical researches. Empirical results are often useful; but they are never absolute.

Obituary.

Notice has been received of the death of the following:—

On the 30th of May, 1877, Mr. John Hopper Pain, Chemist and Druggist, Hadleigh, Suffolk. Aged 45 years.

On the 2nd of June, 1877, Mr. James G. F. Alexander, Chemist and Druggist, Greenock. Aged 60 years.

On the 5th of June, 1877, Mr. Hamerton Peacock, Chemist and Druggist, High Street, Poplar. Aged 40 years.

On the 8th of June, 1877, Mr. Robert Sanderson, Chemist and Druggist, High Street, Watford. Aged 42 years. Mr. Sanderson had been a member of the Pharmaceutical Society since 1869.

On the 10th of June, 1877, Mr. Harry Grove, Chemist and Druggist, Park Street, Walsall. Aged 46 years.

Notes and Queries.

LIME JUICE AND GLYCERINE :—

Lime or Lemon Juice . . .	1 pint.
Rose Water	4 ounces.
Elder Flower Water . . .	4 ,,
Alcohol	4 ,,
Glycerine	5 ,,
Oil of Lemon	1 drachm.

Heat the lemon juice in a porcelain capsule to near the boiling point. To the liquid add gradually the rose water, the elder flower water and the alcohol. Mix well together, and, after twenty-four hours' repose, filter the liquor through paper and add to it the glycerine; and lastly, the oil of lemon dissolved in a small quantity of alcohol. The liquid should be somewhat milky, but free from sediment or coarse floating particles.

HUNTER'S TOOTH POWDER ;—

Powdered Cream of Tartar .	3 ounces.
Powdered Alum.	4½ drachms.
Powdered Cochineal . . .	4 ,,
Powdered Cinnamon . . .	½ drachm.
Powdered Sugar.	1 ounce.

Druggists' Circular.

The Estimation of Tannin.

Sir,—In your issue of 16th inst. you publish a paper, by Mr. H. A. Proctor, F.C.S., on "Some Methods of Estimating Tannins." The author is exceedingly liberal in his strictures upon the processes which have been proposed by other chemists for the estimation of the various vegetable astringent substances grouped, for convenience sake, under the generic name of "Tannin;" but beyond reproducing Dr. Löwenthal's method, I am unable to discover that he has contributed anything either positive or original to the history of the subject upon which he discourses.

Amongst other processes which come in for a share of his adverse criticism is a method which I proposed some three years since for the estimation of the astringent matter in tea, and which has since become known as the "lead-tannin process." If Mr. Proctor had taken the trouble to refer to Mr. Allen's papers in the *Chemical News*,* or had read with ordinary care the description of my process in the last edition of Sutton's 'Volumetric Analysis' (p. 236), he would have learnt that neither Mr. Allen nor myself ever proposed to extend this particular method to any substance other than tea. We were perfectly aware of the fact, which Mr. Proctor seems to think a discovery of his own, viz., that gallic acid (so called), is precipitated from its solutions by plumbic acetate as well as is "tannin," but in the examination of teas for adulteration it is quite needless to attempt a separation of the two (?) acids—a determination of the total astringency being all that is required.

How Mr. Proctor has been able to come to the conclusion that commercial tannic acid only contains eighty to ninety per cent. of "really pure tannin," when in the sentence immediately preceding he has informed us that "really pure tannin is quite unattainable," and *ergo* undeterminable, is a question which I leave more expert chemists to decide.

Fred. W. Fletcher, F.C.S.

North London Chemical Works, Holloway, N., June 19, 1877.

* Vol. xxix., pp. 169 and 189.

Sir,—In the last number of the *Pharmaceutical Journal* (page 1020), there is an interesting paper, by Mr. H. R. Proctor, on "Some Methods of Estimating Tannins." In the course of his remarks the author makes several references to my method of determining tannin in tea by acetate of lead, using ammoniacal ferricyanide as an indicator. Mr. Proctor says that the method "in its original form is quite inadmissible, since lead precipitates gallic acid as well as tannic, and both react equally on the indicator." Of course this is perfectly true, but so far from the process being inadmissible on that account, in my original paper I claimed it as one of the advantages of the method. It must be remembered that the process was originally applied to the estimation of the astringency of tea, and if chemists have since sought to use it for purposes for which it was manifestly unsuited, it is not the process which is to blame.

That I never regarded the method as adopted for the determination of actual tannin is evident from the following extract from my original article, in the *Chemical News*, of April 17, 1874:—

"It seems to me that the separate determination of the tannic and gallic acids is a needless trouble and a complication of the methods of detecting tea adulteration. It also seems probable that a portion of the tannic acid may be converted into gallic acid by the prolonged boiling in water necessary for the thorough exhaustion of the tea, and on this account a method which will estimate the total amount of astringent matter, without distinction of its nature, is preferable to a process that gives merely the amount of tannin while ignoring the gallic acid."

These remarks were followed by a description of the lead process with the use of ammoniacal ferricyanide as an indicator, the precipitator being referred to as "mixed tannate and gallate of lead."

I may take this opportunity of reminding your readers that the process referred to was really originated and worked out by Mr. F. W. Fletcher, who was at that time my assistant, and that I merely contributed the colour test which indicates the end of the reaction. As the process was first published in the article above referred to, it has got connected with my name, though in the original paper Mr. Fletcher's claims were fully recognized.

I can quite indorse all that Mr. Proctor says respecting the variable quality of commercial tannin, some of the samples I examined when interested in the subject containing 30 and 40 per cent. of inert matter as indicated by the lead process.

Sheffield. ALFRED H. ALLEN.

CHEMISTS' ASSISTANTS' ASSOCIATION.

Sir,—I have read with great interest the letters of three of your correspondents respecting the new Chemists' Assistants' Association, and beg you will allow me a small portion of your valuable space to express my views on the subject.

I must say that I agree with "An Associate" that the first and foremost place in the discussions ought to be given to early closing. In this, I think, sir, you will entirely agree with me, if I understand aright your excellent article on earlier closing in the Journal for November 14th, 1874.

It is argued by some that it is not a question in which assistants ought to interfere at all, but that they should wait until their employers choose to take action in the matter. Now my opinion is that action may, and ought to be, taken by those who are most interested. It would be as reasonable to say that masters must wait until their masters (the public) call upon them to close earlier. Early closing is not such a difficult question as many appear to think; it is for the younger members of our calling to decide whether the future pharmacists shall resemble the majority of those of the present day in knowing nothing of the world beyond the four walls of their shops, and the view of the street in front, and mixing in no society but that of their assistants and porters, or whether they shall by mixing with the outside world diffuse their scientific knowledge and take the position in society which their education entitles them to.

I am no advocate of "Coercive trades unionism" or "strikes" in this case, as the question, being of a less complex nature than the Eastern question, may be easily settled by a Conference without recourse to arms; in proof of which I will give you my experience. I have lived in two provincial towns in which assistants' associations existed and flourished. It was felt by the members in each town that the late hour of closing (in one case 8 p.m.) did not allow the assistants and apprentices sufficient time for study and outdoor recreation. Accordingly the employers were respectfully asked to take the matter into consideration and, if practicable, to close earlier. The result was a considerable curtailment of the hours of labour, and a better feeling, if possible, between employers and employees than before. Now what is there to prevent something of the kind being done in London, where assistants are more numerous and more unjustly treated than in any other place?

I think also that the new society should devote considerable attention to the advancement of education by encouraging young men to come forward and read papers on pharmaceutical subjects and the sciences on which the art of pharmacy is based.

If the hours of labour could be shortened, doubtless many valuable papers would be forthcoming, and the Pharmaceutical Society would have less cause to complain of lack of interest in the evening meetings.

A MEMBER OF THE PHARMACEUTICAL SOCIETY.

"NO DISSENTER NEED APPLY."

Sir,—I have been speculating upon the meaning of an advertisement in a recent number, offering a business for disposal with this condition annexed, that the "purchaser must be a pharmaceutical chemist and a Churchman." Some employers require that their assistants shall be of the same religious denomination as themselves, for which it is possible to conceive some little excuse, though not much. But why should any one impose such a condition upon his successor? Is he anxious to preserve the "healthy agricultural district" from an inundation of Nonconformist or Roman Catholic poison?

In Roumania certain trades are still forbidden to Jews; in the United States similar restrictions were formerly placed on the negro race; but surely it is rather late in the day to play this game in England.

EQUALITY.

GLYCERINE OF PEPSINE.

[*** At page 928 of the Journal we published a letter from Mr. Elliott of Gateshead, in which he stated that half a drachm of his liquid pepsine would dissolve 250 grains of hard boiled white of egg. We have since learned that this result was not obtained at the ordinary temperature, but at a temperature of 100° to 104° F. Mr. Elliott would appear not to have been cognizant of the fact that the difference between that result and the one with which it was compared is wholly due to the different conditions under which the several results were obtained.]

"*Syrupus*."—(1) *Ranunculus peltatus*; (2) *Linum catharticum*; (3) *Habenaria chlorantha*; (4) *Brachythecium rutabulum*; (5) *Eurhynchium prælongum*; (6) *Amblipleqium riparium*.

D. Jenkins.—*Parietaria diffusa*.

G. S.—(1) *Corydalis claviculata*; (2) *Trifolium minus*; (3) Probably *Veronica serpyllifolia*, no leaves sent; (4) *Arenaria serpyllifolia*; (5) *Lathyrus macrorrhizus*; (7) *Chærophyllum temulum*.

"*Nu*."— We have no qualification for giving legal opinions. Consult your solicitor.

"*Amateur*."—Lime juice is the expressed juice of limes. If you mean the preparation known as lime juice and glycerine, see p. 1055, and various recipes given in previous numbers.

"*Williams*."—We cannot understand our correspondent's object in sending leaves only for identification; it is impossible to name plants with certainty from the leaf alone. The following can only be guessed at:—(8, 12, 13.) *Heracleum sphondylium*; (11) *Nepeta glechoma*; (4) *Potentilla anserina*; (17) *Pteris aquilina*. We must refer our correspondent to our rule concerning the number to be sent in one week.

W. P.—*Phlomis fruticosa*, commonly called Jerusalem Sage.

J. Robinson.—The "Tic Powders" label would certainly require a stamp. The other had better be submitted to the Inland Revenue Authorities.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Dott, Professor Dymock, Mr. Vertue, Dr. Pavy, Mr. Greig, C. W. C., Acetum, Fair Custom, Cardamoms, Auld Reekie.

"THE MONTH."

The fine sunshiny weather of the last few weeks has brought forth such a profusion of flowers that our list this month will be an unusually long one.

In the country hedges the elder is now white with its handsome cymes of white flowers. The cymes are sometimes umbellate, but are often more or less corymbose. In the West of England the poor use these flowers largely in the form of tea for colds, etc., and prefer to have the flowers with the stalks. There is some difficulty in drying the flowers of a good colour. If the bunches are formed into small heaps they heat in a few hours and turn black in drying, so that it is necessary either to suspend them separately on lines of string or to scatter them loosely over network, in a current of dry air. Those who wish to separate the flowers from the stalks take advantage of the rapidity with which they become heated to allow the bunches to remain together just long enough to loosen the flowers, when the latter are shaken off through a cane sieve upon a drying apparatus heated by steam.

By the side of ditches and in marshy places the tall valerian, with its coarsely serrated pinnate leaves and pretty corymbose cymes of small pink flowers, may be found in abundance. The small corolla is somewhat funnel-shaped and has a minute projection at the base (gibbous); the stamens are three in number and are attached to the corolla. The style is furnished with three stigmas, which do not appear to expand until after the pollen has been shed. The tube of the calyx is united to the ovary, and instead of teeth there will be seen at the top of the ovary a projecting rim which afterwards unrolls in a most curious way, and is seen to consist of feathery pappus. Although valerian is cultivated in this country yet a considerable quantity of the root is also imported from France and Germany. This plant must not be confounded with American valerian, which is an orchidaceous plant (*Cypripedium pubescens*).

In cornfields, especially on a chalky soil, the white mustard may now be seen in blossom, and is often confounded with the charlock (*Sinapis arvensis*, L.), which frequently grows mixed with it. Both plants have hairy spreading fruits, but the siliqua of the white mustard ends in a long flat sword-shaped beak, while that of the charlock has a short narrow beak. The black mustard grows generally in waste spots near rivers or in damp places, and the fruits are erect and pressed to the stem, and have only a short cylindrical beak.

One of the handsomest of our wild flowers, the foxglove, is now beginning to adorn dry hedge banks, heathy places and woodlands with its lovely raceme of drooping flowers. Although a common plant in many districts, it is yet so rare in some parts of Lincolnshire as to be cultivated in gardens, an honour which it well deserves. Although it is not possible to mistake the plant when in flower for any other, yet several plants have leaves so similar in shape as to be easily mistaken for those of digitalis. The ploughman's spikenard, *Inula Conyza*, DC., is one of these, but by carefully observing the base of the leaf it may easily be distinguished. In the digitalis the smaller veins form a network running down the tapering base of the leaves, while in Inula there are no small veins running parallel with the stalk, the lowest passing direct to the midrib. It has been said that the leaves of *Verbascum Thapsus*, L., have been gathered for digitalis, but it can hardly be believed that the most ignorant herb gatherer could possibly mistake the thick woolly leaf of that plant for digitalis. The leaves of *Verbascum nigrum*, L., do indeed much resemble those of digitalis at first sight, but are easily distinguished by their cordate base.

Another common wild flower which often gives a bright colouring to the landscape is the red poppy, *Papaver Rhœas*, L. There are several species of red poppy having blossoms of a similar colour although differing in size; they are chiefly distinguished by the shape of the fruit, and by the presence or absence of bristles upon it. The flower is very difficult to preserve for the herbarium, and should be brought home in bud. The petals turn very dark in drying, owing apparently to the development of some alkaline body, since the colour may be in great measure restored by hydrochloric acid.

The woody nightshade (*Solanum Dulcamara*) now decks hedgebanks and woods with its pretty lilac blue blossoms. This plant is very commonly mistaken for the deadly nightshade (*Atropa Belladonna*), a much rarer plant. The leaves are very variable, although they are usually furnished with two lobes at the base (auriculate), there are sometimes three or more, or when growing in dry places there are sometimes no lobes at all, and the leaves then resemble those of the common nightshade (*Solanum nigrum*, L.), which may, however, be distinguished easily by its white flowers and black berries. The corolla of the Dulcamara is rotate and furnished with green spots at the base. The stamens are united into a tube around the style (syngenesious) and open by pores at the apex. The berries are red, but a curious variety is found in Jersey which has yellow berries. Although very common about London it is comparatively scarce in Scotland. *Belladonna*, or deadly nightshade, is nowhere very common, but may be found scattered here and there in woods on a chalky or limestone soil. It has an erect bushy habit, caused by the repeated forking of its succulent stems. The leaves are ovate and quite entire at the margin and are given off in pairs (geminate), one leaf in each pair being smaller than the other, a leaf bud occupying the axil of the larger leaf and a flower bud that of the smaller one, so that if the smaller leaf be regarded as a bract, the inflorescence, although apparently axillary, is really extra-axillary. Any one who has once seen its pendulous brown-purple lurid bell-shaped flowers could never confound Belladonna with the woody nightshade. The fruit is baccate and has the size and colour of a black cherry, presenting a very tempting appearance.

The *Matricaria Chamomilla*, L., sometimes called the German chamomile to distinguish it from the true or Roman chamomile (*Anthemis nobilis*, L.), is now in blossom everywhere about London, in waste places and on railway cuttings. The odour of the bruised leaves and flowers is similar to that of the true chamomile but fainter. The flowers may be readily distinguished from those of the true chamomile by the absence of chaffy bracts (paleæ) between the florets; in all species of *Matricaria* these are absent, while they are present in the genus *Anthemis*. Another difference lies in the fact that the true chamomile has a solid conical receptacle and the German chamomile a hollow one. But however much the flowers outwardly resemble one another, it is scarcely possible to confound the plants, since the true chamomile does not commence flowering until the end of July, when the other has usually withered away. *Matricaria Chamomilla* has also an erect branching habit without procumbent stems, while the true chamomile is a prostrate creeping plant, only the flowering stalk being erect. The true chamomile also grows in damp grassy places or commons, not on rubble heaps like the other.

The horseradish (*Cochlearia Armoracia*, L.) is a semiwild plant, which may often be met with in a botanical ramble. Like most of the Cruciferæ the flowers are without bracts, although there is a bract at each branch of the inflorescence. The petals are white, and twice as long as the calyx.* The fruit does not ripen in this country, indicating that the plant is not a native.

Rhamnus catharticus, L., and *R. Frangula*, L., have been in blossom since the end of May, and are now forming young fruit. In the former the flowers are diœcious, although there are rudimentary stamens in the pistillate flower, and a rudimentary pistil in the staminate flower. The calyx is four-cleft, and the corolla consists of four minute green petals, which, especially in the pistillate flower, are not readily seen without the aid of a lens. The thorns are not very conspicuous, but may be seen here and there terminating the branches. In the fruit there are four carpels, and although these are externally united to form a fruit of a baccate appearance, yet the endocarps are distinct, and form four little stones inside the fruit, each stone containing one seed. The structure of them is well shown in Part 2 of Bentley and Trimen's 'Medicinal Plants.' *Rhamnus catharticus* is found chiefly in chalky or oolite soil, and is rather local, being abundant in some districts and rarely seen in others.

Rhamnus Frangula, on the other hand, is much more widely distributed, and may be found in damp woods, especially in hilly districts, very frequently, although rare in Scotland. It is very easily distinguished from *R. catharticus* by the leaves, flowers, and fruit. In *Rhamnus Frangula* the leaves are quite entire at the margin, and the lateral veins are directed toward the sides of the leaf. In *Rhamnus catharticus* the leaves are minutely but distinctly serrated, and the lateral veins are directed towards the apex of the leaf. In *R. Frangula* the flowers have a *five*-parted calyx, and five petals and five stamens. Although the stones in the fruit are usually only two in number, or rarely three, their number will not serve to distinguish the fruit from that of *R. catharticus*, because in the latter some of the stones are often undeveloped. The shape of the stones will, however, readily distinguish between them, those of *R. catharticus* being somewhat triangular in section, the inner face having a sharp angle, and the outer face being convex, while those of *R. Frangula* are flat on one side, and slightly convex on the other, and are broader in proportion. They are also of yellow not brown colour, as in the other species.

The bark of *Rhamnus Frangula* may be easily known from all other official barks by presenting a deep red colour when the epidermis is scratched off with the nail. It is chiefly imported into this country from Holland. Under the name of Dogwood the wood is largely used for making gunpowder. It is not a little singular that emodin, a crystalline principle found in rhubarb, should also occur in this bark. The fact of its producing sickness when fresh, although only acting as a purgative after it has been kept about a year, is one the reason of which requires investigation.

The young fruit of the juniper is now in a capital state for examination, and the shrub may be looked for on chalky downs. *Linum catharticum*, L., or purging flax, which is still used, we believe, in some parts of Scotland as well as by herbalists in this country, may now be found abundantly in heathy places and among short grass in dry hilly fields. But for its small white flowers it would scarcely be noticed. It differs from all the other British species in having opposite leaves and very small flowers; indeed were it not for the fruit it might almost pass for a caryophyllaceous plant.

In the various botanical gardens a large number of interesting plants may now be seen in blossom, so many, indeed, that it will be necessary to reserve a description of some of them until another year. The aconite (*Aconitum Napellus*, L.), has a very singular flower. Immediately beneath the blossom are two minute bracts; the calyx is petaloid and consists of the hood or helmet (galea), (whence its name of Monkshood,) two large lateral sepals and two smaller ones at the base. When all these are pulled off it will be found that there are two hammer-shaped petals hidden under the hood, the rounded apex of each petal forming a nectary containing a honey-like liquid; besides the two singular petals there will be found five or six or sometimes more slender petals no larger than the filaments of the stamens, but readily distinguished from them by their blue colour. The stamens are numerous and the filaments are white and petaloid, the carpels are usually three in number and form follicles when ripe. The varieties of aconite are very numerous, no less than twenty-nine forms of *A. Napellus* being described by De Candolle, so that it is by no means easy to find a typical plant. It is, perhaps, most easily distinguished from other species by the semicircular shape of the helmet, the loosely divided appearance of the leaf, and the time at which it flowers, *A. Napellus* flowering earlier than almost all the other species cultivated in this country, most of which flower at the end of June or beginning of July, while it commences to blossom at the end of May. The tendency to form varieties seems to indicate that the plant might be improved by cultivation, and there cannot be much doubt that a better article than that at present in the market would command a better price and lead to more satisfactory results, both in the hands of the physician and of the manufacturing chemist.

The linseed plant (*Linum usitatissimum*, L.) is now in full blossom, and is conspicuous by reason of its large deep blue flowers. The petals are remarkably fugacious, and the stamens are united together at the base, and have the rudiments of another row of stamens alternating with each perfect one. The styles are five in number, and terminate in stigmas which look just like anthers, and would be mistaken for them by a careless observer.

The hemlock (*Conium maculatum*, L.) will be in perfection in a week or two, and is already being gathered for making extract. This plant is very similar in appearance to many other umbelliferæ, but is easily distinguished by certain characters. Although the smooth spotted stem is very characteristic, yet the spots are often present only on the

* Bentham in 'Genera Plantarum' states that this species has no petals.

lower portion of the stem. The plant which most closely resembles it in appearance is fool's parsley (*Æthusa Cynapium*, L.), which may be distinguished as follows:—Underneath each partial umbel there are three long pendent bracts, but there is no general involucre. The fruit has vittæ, two of which form very distinct lines on the flat surface of the half fruits, and the ridges on the fruit are not crenated. The leaves also have *brownish* points to every segment, and are minutely serrated below each point. The serrated character is easily seen with a lens.

In conium each partial umbel has three, or rarely four, short bracts, which do not surround the stalk, but are placed on the outer side of it. The fruit has no vittæ whatever, and the ridges of the fruit are minutely crenate, and the leaves have minute *white* points to every segment, which are quite entire below the points. The only fruit with which that of conium could be well confounded is the Russian aniseed, which is very similar in shape, size, and colour, but is seen by the aid of a lens to be covered with minute white hairs. Two other plants are known in this country under the name of water hemlock, which must not be confounded with the true hemlock. One of these, *Œnanthe crocata*, L., is not uncommon in ditches and damp places in woods. It may be recognized by the somewhat cylindrical fruit, which has two long erect styles, by the wedge-shaped segments of the leaves, and by the root consisting of five large fusiform tubercles. It is properly called hemlock water dropwort, but is often confounded with the true water hemlock, *Cicuta virosa*, L., a much rarer plant, found here and there in the midland counties, but rarely seen in the south of England. The leaves have narrowly lanceolate, serrate segments, and the fruit is spherical, like that of coriander, but rather smaller. Both plants are extremely poisonous, and fatal accidents have frequently happened through persons eating the root of *Œnanthe crocata*, which has a not unpleasant taste, death usually resulting in two hours after partaking of it, and sometimes even in so short a space as half-an-hour. Most cases of poisoning reported as owing to water hemlock are probably caused by the hemlock water dropwort, the *Cicuta virosa* having a simple root without tubercles, which is not very likely to be eaten, and being a comparatively rare plant.

At the Chelsea gardens several interesting plants may now be seen in blossom.

Masterwort (*Imperatoria Ostruthium*, L.), occasionally found wild in Scotland, and used as a tonic on the conntient, has large handsome leaves and is a very conspicuous plant; *Veratrum album*, L., has large ribbed leaves very closely resembling those of *Gentiana lutea*, L., in shape and general appearance, and dense panicles of green flowers with a disagreeable cheesy odour; Fenugreek (*Trigonella Fœnum-græcum*, L.), a small plant with white flowers about the size of melilot or clover; Lentil (*Ervum lens*, L.); one or two species of *Astragalus*; Wild Indigo (*Baptisia tinctoria*), a plant used in the United States as an antiseptic in ulcerated sore throat, etc.; Motherwort (*Leonurus Cardiaca*, L.), a labiate plant with curiously shaped trifid upper leaves, used by herbalists for diseases affecting the heart, but probably possessing only tonic properties; *Coriaria myrtifolia*, L., a small shrub with leaves having three veins arranged like those of the myrtle, and possessing poisonous properties. The leaves were at one time detected in senna leaves in France. The two lateral veins near the margin of the leaf at once distinguish them from senna leaves. Hedge hyssop (*Gratiola officinalis*, L.), a scrophulariaceous plant, possesses purgative and emetic, and, in large doses, poisonous properties. This must not be confounded with the common hyssop (*Hyssopus officinalis*, L.) a plant with much narrower leaves, belonging to the Labiatæ. The hyssop of Scripture is supposed by some to have been the caper plant (*Capparis spinosa*, L.).

Ferula Tingitana, L., the African ammoniacum plant, is now in full blossom both at Chelsea and at Kew and forms a conspicious feature in the garden. The leaves are finely cut and very handsome, and the tall flowerstalk, more than six feet high, with its numerous large umbels of yellow flowers, can be seen at a considerable distance. Although another species, *Ferula orientalis*, L., has been received by Dr. Leared as the source of African ammoniacum, Pereira is probably right in thinking that the former is more likely to be the plant yielding it, or at all events the chief proportion of it, since it agrees with the drug both in taste and smell, which *F. orientalis* does not.*

At Kew, in the economic house, there are only two or three plants at present in blossom. *Cissampelos Pareira*, Lam., a slender climbing plant with cordate hairy leaves and minute green flowers, might easily escape notice, and like most of the climbing plants must be looked for overhead, as it is allowed to climb over the sides of the hothouse. The Pharmacopœia is utterly wrong in attributing *Pareira brava* to this plant, since its stem and root have no concentric rings but only a single zone composed of wedge-shaped woody bundles. It is rather singular that most of the recent works on materia medica persist in perpetuating the error, although it has so clearly been pointed out by Hanbury.

Asclepias curassavica, L., the root of which possesses emetic properties and is used in the West Indies like ipecacuanha, occasionally finding its way to this country, is a very handsome plant, with umbels of bright orange coloured flowers, which have a very singular structure, an explanation of which we must defer to a future period. The citronelle grass (*Andropogon nardus*, L.) and the castor oil plant are also in blossom, and the cocoa tree, although only a diminutive plant about three feet high, is putting forth its small rose coloured flowers from various parts of the trunk and branches. The flowers occupy a very curious position, for instead of appearing in the axils of the leaves they arise from the bare trunk or branches. The structure of the flower is curious, and well explained in Bentley and Trimen's 'Medicinal Plants,' part 2, No. 38.

In the open ground the first plant to strike the eye is the *Sarracenia purpurea*, L., or side-saddle flower, which derives its name from the large umbrella-shaped disk into which the style is expanded, and which quite hides the stamens from view. The pendulous flower terminates a stalk more than a foot long, which arises directly from the ground. The calyx is externally of a purplish-red colour, and in shape and size resembles the yellow water lily. The five petals are oblong, of a deep red colour, and overlap the large disk-like style. The structure of this style is very remarkable. It has five projecting notched angles, and underneath the notch at each angle may be seen a small stigma not larger than a

* See *Pharm. Journ.* [3], vol. vi., p. 142.

pin's head. As the angles occupy the space between each petal, the only openings to the centre of the flower are between the petals and the angles of the style, so that it is almost impossible for insects visiting the flower to avoid touching the stigma. The leaves are hollow and usually contain a little water in their base, the interior of the leaves being lined with hairs pointing downwards, so that wingless insects entering the leaves in search of the water cannot return, and are therefore drowned. *Matricaria Parthenium*, L., may also be seen in flower. This species is easily distinguished from *M. Chamomilla*, L., by the flattened or slightly convex receptacle of the flower heads and by the disagreeable odour of the leaves. A variety of this plant with pale yellow foliage is now a favourite plant for edging borders, etc. Under the name of featherfoil or feverfew the plant is used in domestic medicine in the West of England. *Pyrethrum roseum*, Bbrst., one of the plants yielding Persian insect powder, may also be seen in full flower. Except for the pink tinge of the florets and the more divided leaves, it might almost be passed by for the ox-eye or moon-daisy. Most of the plants alluded to as occurring in the Chelsea Gardens may also be seen in blossom here. One plant, however, remarkable for its elegant appearance, we have only noticed at Kew. This is the *Gillenia trifoliata*, Moench, a North American plant, belonging to the Rosaceæ, the root of which is sometimes found accidentally mixed with that of senega, but with which it could not possibly be confounded since it is of a deep brown colour and much branched. The flowers are white with a faint rose tint, and are somewhat like those of cyclamen in shape and size, but grow in a light spreading panicle. The leaves are trifoliate and the leafy portion of the plant has the habit of the meadowsweet. It is an exceedingly pretty plant and well worth cultivating in gardens for ornamental purposes. Several species of aconite are now coming into blossom; indeed the coming month will be the best time for studying the intricacies of this genus.

At the Botanical Gardens at Regent's Park, there may be seen in blossom in the Economic House, the *Quassia amara*, L., with handsome racemes of tubular scarlet flowers, very like those of the socotrine aloe in shape and size; the leaves resemble those of the ash tree. The cinnamon plant is just beginning to open its panicled cymes of small white flowers. The foliage of this plant, always very handsome, is now remarkably beautiful; the young leaves being of a delicate reddish tint, which contrasts well with the green glossy appearance of the older ones. Each leaf has about three distinct veins running from base to apex of the leaf and this gives it a very distinguished appearance. The stamens have the curious four-celled anthers opening by four valves, and the glandular appendages at the base of the stamens, which are so often found in the Lauraceæ.

The ordeal plant of Madagascar (*Tanghinia venenifera*, Poir), belonging to the natural order Apocynaceæ, is now in bud both here and at Kew, and will probably be in blossom in a week or two. One of the pimento plants, *Pimenta acris*, is also in blossom. It is a tall plant, reaching nearly to the top of the greenhouse, and flowering only on the upper branches. The flowers are very similar to those of the myrtle, but smaller, and are arranged in panicled cymes. The plant cultivated both here and at Kew, although labelled *Pimenta officinalis*, appears to be *Pimenta acris*. It is distinguished from the *P. officinalis* by having shorter, oval, instead of oblong-lanceolate leaves, by the flower stalks being almost at right angles with the rachis, and by the calyx having five instead of four sepals. The flower stalks are jointed a short distance below the calyx, and soon fall off after being gathered.

The fruits of *Pimenta acris* may sometimes be found mixed with the allspice of commerce. They are very similar in taste, but may be distinguished by the five teeth of the calyx; and they are also rather larger than the fruits of *P. officinalis*. The leaves of *P. acris*, when distilled with rum, yield the Bay rum of the U. S. Pharmacopœia, in which work the plant is named *Myrcia acris*, Swartz. The stems are imported into this country for walking sticks and umbrella handles.

In the open ground may be seen *Ptelea trifoliata*, L., a small tree with leaves like the ash tree, and abundant corymbs of sweet scented rather small green flowers. This plant is called in America the wafer ash, from the curious fruit, which is furnished, like the fruit of the elm, with a membranous wing which gives it the shape of a wafer.

The sweet flag, *Acorus Calamus*, L., is also worth notice and may be seen growing by the margin of the pond mixed with the yellow iris (*I. Pseudacorus*), which it so closely resembles in habit that it can only be distinguished at a distance by its paler green colour and the wrinkled margins of the leaves. The delicious fragrance of the leaves when rubbed at once distinguishes them from those of the iris. The inflorescence consists of a fleshy tapering spike or spadix, which apparently arises from the side of the leaf, but is considered to be terminal, the flower-stalk being continued beyond the spadix in the form of a leaf-like bract. The ovaries, which are closely packed together, are surrounded by a minute perianth of six membraneous leaves, within which are six stamens furnished with two-celled anthers. The arrangement of the flowers is best seen by breaking the spadix transversely. Although a common plant in several of the Eastern countries it is rare in the West of England and in Scotland. Another singular looking plant is now in blossom, the birthwort (*Aristolochia clematitis*, L.). The yellowish-looking irregular flower consists of a calyx only, which is lined with hairs pointing inwards. The anthers are sessile on the sides of the radiate stigma and the ovary is inferior. The hairs lining the calyx tube permit the entrance of small insects but do not permit their egress until the pollen has been shed, when the hairs become flaccid and pressed against the calyx and thus allow the insects to escape. The angelica, lovage, alkanet (*Anchusa tinctoria*, L.), borage, white and black bryony, Spanish broom (*Spartium junceum*, L.), distinguished from common broom by its smooth cylindrical stem, and many other interesting plants are also now coming into blossom, but want of space forbids their description.

One flower, however, *Nigella damascena*, L., can scarcely be passed on account of its abnormal structure. It is sometimes called "love in a mist," or "the devil in a bush." The leaves are as finely divided as those of fennel, whence the plant is sometimes called fennel flower. The blossom consists of five coloured sepals surrounded by an involucre of leafy bracts, which are often mistaken for a calyx, while the true calyx is confounded with the corolla. The petals, however, are very small and are hidden under the stamens, each one being hollow and containing nectar, which is protected from the rain by a little lid covering the short tube of the petal. The ovary consists of several carpels, of which the portions containing the seed are united into a kind of capsule, the styles being free. The inner portion (endocarp) of the carpels is very loosely attached to the mesocarp and separates during the ripening of the fruit. In its capsular fruit it differs greatly from the rest of the Ranunculaceæ.

A closely allied species, *Nigella sativa*, yields a seed which is supposed to have been the fitches mentioned by Isaiah, xxviii., 25, 27. The seeds are used in the east for keeping away insects from clothes and as flavouring for cakes, in the same way that caraways are used in this country, and also as a carminative.

In the last number of 'Medicinal Plants' the following are figured: *Sambucus canadensis*, L., a plant very similar in appearance to the common elder, but with leaves somewhat bipinnate, and a less arborescent habit. This is the only figure of the plant extant, as it has not been previously figured. Boneset (*Eupatorium perfoliatum*, L.), a powerful sudorific, diaphoretic and diuretic, and acting also as an emetic in large doses. It is used in America for colds, influenza, etc., and is recommended by the authors for trial in the latter complaint in this country. *Hedeoma pulegioides*, Pers., from which the American oil of pennyroyal is made, somewhat resembles the true pennyroyal in appearance, but grows in dry places. *Monarda punctata*, L., the American horsemint, which yields an oil possessing powerful rubefacient properties and contains thymol. *Plantago Ispaghula*, Roxb., an Indian plant, also has not been previously figured. The seeds are small and curiously boat-shaped and are extremely mucilaginous. They are used in India in cases where mucilaginous or demulcent drinks are requisite. They possess the great advantage of being tasteless and yielding gradually twenty times their weight of gelatinous mucilage. They are well worthy of trial in this country. *Chenopodium anthelminticum*, L., yields the oil of wormseed of the U. S. Pharmacopœia, a most nauseous remedy, which is used for the round worm in children. The authors point out that *C. ambrosioides*, L., is often confounded with it. This is very true; in fact the latter is the plant usually grown under the name of *C. anthelminticum* in botanical gardens. The other two plants figured are the *Areca Catechu*, L., and the Sago Palm (*Arenga Saccharifera*, Lab.).

In the present number, therefore, there are described and figured five American and three Indian plants. The colouring is rather above the average, the bracts of *Monarda punctata*, and the areca nut being particularly true to nature.

In the drug market we have noticed during the past month, among other things, quantities of China galls; considering the frequency with which these appear, they must be of some value in trade. Large quantities of Kowrie gum have also met with a ready sale. We believe this resin forms an excellent varnish when treated with proper solvents. Carnauba wax, used in candle making, might probably be turned to other useful purposes. Japanese peppermint oil is another article which is frequently met with at the sales now, and probably finds its way into the inferior class of peppermint lozenges. Mangalore cardamoms have of late been several times offered; they do not appear to have been noticed in 'Pharmacographia.' In shape and size they resemble the Malabar cardamoms, but are rather warty outside; the flavour is equal to that of the best kinds. Persian insect powder and the flowers from which it is prepared begin also to appear on the market, intimating that the time for insecticides and fly papers is approaching. About 250 packages of "mother cloves" have been offered during the past month. It will be remembered that Hanbury has pointed out that the presence of these fruits may be detected in powdered cloves by the presence of starch granules. There is no reason, however, why they should not form an ingredient in mixed spice, which is their probable destination. Ceylon cardamoms, salep, purree, gum acroides, pistachio nuts, and Chinese insect wax have also lately been offered. The insect wax is a very beautiful substance resembling spermaceti in appearance, but much harder. Japanese aconite, coca leaves, and jaborandi, still put in an appearance, and even condurango is offered but is scarcely likely to find many purchasers. It is rather singular that Nepaul aconite, *Aconitum ferox*, Wal., so seldom appears at the drug sales, since if of good quality it would probably meet with a ready sale on account of the quantity of alkaloid it contains, an alkaloid which is probably more powerful than that obtained from *A. napellus*; and since the root, from its large size, is less likely to be mixed with other species, it would probably be more uniform in quality.

Timbo, the root of some species of *Paullinia*, probably of *P. pinnata*, L., a native of South America, and noticed at p. 1020 in the last issue, appears to have lately attracted attention in France and in the United States. It possesses poisonous properties, and if thoroughly investigated will very probably yield another powerful therapeutic agent for use by skilful hands. Tayuya seems to have made some stir in Italy and has been lauded as a specific in syphilis; the amount of subcutaneous injection recommended to be used appears, however, to be very large.

Chrysophanic acid in the form of ointment has lately been recommended as a cure for *acne rosacea*, and the fixed oil of stavesacre as a substitute for sulphur ointment in destroying animal parasites, by Mr. Balmanno Squire. Dr. E. Woakes has found hydrobromic acid successful in certain forms of *tinnitus aurium*. An inhalation of the fumes from camomile flowers has recently been recommended in the treatment of hay fever.

The drug known as Jaborandi, which excited so much attention some short time since, is now but rarely heard of in its medical aspects, although the alkaloid pilocarpine is manufactured in Germany and elsewhere. But the drug itself seems to have suddenly dropped into disuse. Nevertheless, Dr. Bruen, physician to the Philadelphia Hospital, advocates its employment in Bright's disease, and relates some good results he has obtained with it. One or two drachms of jaborandi are made into an infusion with two ounces of water, and the entire quantity taken in one or two hours. In this way profuse prespiration is induced; the dose causing it may be repeated daily or otherwise as required. Certainly some time ago, Dr. Laycock gave an account of the successful treatment of some cases of diabetes, in the *Edinburgh Medical Journal*, but we should be inclined to question the virtues of jabo-

* The *Philadelphia Medical Times*, April 14, 1877.

randi for diseases of such serious organic nature as diabetes and Bright's disease. At least, we are convinced its properties cannot be considered to be curative, but merely of an allaying nature through some nervous interference.

Writing to the *American Journal of Pharmacy*, for June, Mr. Theodore G. Davis describes his examination of "Giles's Liniment of Iodide of Ammonium," from which he concludes that a very similar preparation may be obtained as follows:

Take of	Iodide of Ammonium . . .	grs. ii
	Camphor	
	Oil of Lavender	āā ʒi
	Water of Ammonia	℥iv
	Alcohol sufficient to make . .	Oi

and mix well.

A prize of £100 has been awarded to M. Melsens, by the Paris Academy of Sciences, for his method of curing and preventing lead and mercurial poisoning. It is now thirty years since M. Melsens advocated the use of iodide of potassium for these purposes, and further experiments, conducted conjointly with Professor Guillot confirmed M. Melsens' original view. M. Melsens considers these saturnine and mercurial affections to be due to the presence of the metals in the organs of the body in a state of combination with albuminous principles, from which the potassic iodide removes them as soluble iodides that are then carried away in the urine.

These views have of late years received singular proof, for not only has the presence of the said metals in such cases of poisoning been incontestably proved, but it has quite lately been shown that they are in actual chemical combination with definite principles such as albumin, or the phosphorized substances entering into the constitution of the brain.

The curative and preventive properties of iodide of potassium, have been abundantly substantiated during the past thirty years, by the successful treatment of large numbers of cases arising in the working of lead and mercury ores, etc.

A. Poehl, in a recent contribution,* states that he has found 0·25 per cent. of cholesterine in the urine of an epileptic patient, to whom large quantities of potassic bromide had been administered. The cholesterine which was extracted by means of ether was accompanied by glycocholic acid. These results would undoubtedly indicate a disturbance in the biliary function, for both the substances named occur in bile, and, excepting the existence of cholesterine in the brain and nerves, are indeed confined to it in health.

The *Archiv der Pharmacie* for March contains a paper by F. A. Flückiger, on the rotatory power of the volatile oils, in which the author arrives at the following conclusions:

1. There are in volatile oils both rotating and non-rotating constituents.

2. The total rotatory power is the expression of the combined powers of the individual rotating constituents.

3. As the proportions in which these constituents are present are changeable, the same kind of oil does not invariably give the same rotating power.

4. Moreover, as oils of the formula, for instance, $C_{10}H_{16}$ undergo spontaneous changes on keeping, by absorbing oxygen, or assimilating water, the optical qualities are also thereby affected.

5. Bodies which may be present in the oils and which have no effect themselves on the plane of polarization, influence the rotation nevertheless both by their quantity and quality.

6. A similar disturbance is to be expected in mixtures containing several optically active substances.

7. The dangers pointed out in (4) prevent us from viewing the total rotating power as the result of different co-operating ones, unchangeable.

In short the author is of opinion that the rotation power of volatile oils is of no real practical value of the pharmacist.

In the course of two lectures delivered before the King and Queen's College of Physicians in Ireland during last January, Dr. J. Emerson Reynolds made some observations on the influence of chemical constitution on physiological activity. The substance of these remarks has been embodied in an article printed in the *Dublin Journal of Medical Science* for May and June, 1877, and an abstract of this paper will be reproduced in a future number of this Journal.

During the past month a great deal has been heard regarding the establishment of coffee taverns with the view of promoting habits of sobriety among the people. In the appeal which the promoters of this movement make to the public, the matter is put forward, wisely enough, not in any philanthropic manner, but in a commercial spirit. This is fortunate, for the people are not to be cajoled into sobriety by overtures of patronage; if, however, they can be persuaded or weaned from the use of one principle which exercises such an intoxicating influence, to that of another free from these objections, so much the better for them. Alcohol is a food, and a pleasant food, and one which every man is justified in partaking of, so long as he does this in moderation—so long as his imbibitions do not prevail upon him to outstep the boundary of his moral relations to the world. Certain members of the medical profession have of late years lectured and acted in favour of teetotalism; and Dr. B. W. Richardson has carried the matter to such an extent, that it might be wondered why his denunciation of the use of alcohol did not include that polyatomic and potent one—sugar. It must be remembered, however, that in spite of these facts, and the recent formation of a Medical Abstinence Association, nearly two thousand physicians and the British Medical Association have (on grounds best known to themselves) recommended the use of a sherry with qualities distinctly different from those of coffee.

In calling attention once more to the contamination of green articles of clothes and furniture with arsenic, Dr. Owen Rees, of Guy's Hospital, has but confirmed what has been exposed dozens of times. It is well known that arsenical pigments have a brightness of colour which is much esteemed, and unfortunately for the public it does not care to remember that this luxury can only be had at a price—often that of health. Dr. Debus has found in a piece of green muslin which he bought—for analysis—as much as sixty grains of Scheele's green in every square yard, just as Dr. A. W. Hofmann did years ago, and it has often been pointed out that the green of venetian blinds and of wall paper is also frequently and highly charged with arsenic. Whether it is a matter calling for Government interference or not, it is certainly one that should be made widely known, so that the public may be well acquainted

* *Phar. Zeitsche. f. Russl.* 1876, pp. 737–740.

with the danger to their health from the sources indicated.

In a review of Dr. Charles Murchison's book 'On Diseases of the Liver, etc.,' *The Lancet*, speaking of chemical pathology, says: "Now that physiological and chemical laboratories, in which students can obtain manipulative skill as well as a theoretical knowledge, are attached to most hospitals, observations in this department of medicine will become every year more extensive, more accurate, and above all more practical." This would be good news indeed, if it were true, but it is a delusion. In the first place, the chemical education of medical students is not of the nature to enable them to cope with questions in chemical physiology and pathology, and even were it so, there is scarcely a laboratory in Great Britain where such subjects are investigated. This is the more to be regretted, because there can be but little doubt that the future of medical science depends in no small measure upon advances in animal chemistry.

Some experiments conducted at the West India Docks a few days ago have scarcely attracted the attention they merit. The apparatus experimented with was Jablochkoff's electric light, which consists of an electro-magnetic machine worked by a small steam-engine. With it some insulated wires are connected, and these communicate with M. Jablochkoff's electric candles, consisting of two carbons placed side by side with an insulating slip between them. It is this insulating substance which burns away with the carbons exactly in the same way as the body of an ordinary candle is consumed with the wick. The light thus obtained appeared to be quite free from the glare of ordinary burners which so painfully affects the eyes, while at the same time it is said to be so powerful that it is possible to read small print at a considerable distance from the candles. All the experiments were eminently successful, and each candle is stated to have furnished an illumination equal to that given by 100 gas-lights; moreover, the light is said to be much less expensive than gas. If this be correct, a large use may be anticipated for the invention of M. Jablochkoff.

The proposal to establish "Home Hospitals" is one which merits special and earnest consideration, inasmuch as such institutions will, if properly carried out, meet a most serious public requirement. A meeting was held on the 27th inst., at the Mansion House, and presided over the Right Hon. the Lord Mayor, to consider the advisability of establishing an association for purposes which may be briefly set forth as follows:—

To provide hospital buildings fitted with all desirable accommodations and conveniences for receiving patients of all classes who can afford to pay for medical assistance and proper skilled nursing. In this way it will be seen that not only will patients have the advantage of being treated by their own doctor, and there can be no doubt that this is a great advantage, but such an institution would meet an ever increasing and growing demand. As ordinary hospitals are now conducted, they can scarcely be said to be palatable to persons whose social position admits of the enjoyment even in sickness of those comforts indissolubly connected with such homes and assistance as affluence can secure. At the same time, to fall ill in one's own home, and to remain there during treatment, often exposes the other inmates to serious danger; infection proceeds but too often, and that not rarely to a fatal extent. But if there existed home hospitals or institutions where it would be possible by virtue of the 'sinews of war' to experience all the comforts of a home and to be attended by one's own doctor, such places would be free from all objections, and would but meet a demand which people in health may fairly make of those friends who are sick. It is therefore to be hoped that the movement now on foot will meet with the greatest success and encouragement at the hands of the general and medical public.

The month of June has been singularly devoid of news so far as chemical science goes, and there remains but one subject on the list which is to form matter for comment. It is purposed, however, to consider more fully at a future opportunity the few observations which here follow. If there be one subject more than another which is uppermost in the minds of people during this hot weather, it is that of cooling drinks. But where are they to be had? On all sides it has been demonstrated that the ordinary supplies of water are not above suspicion, and so much has been heard regarding the impurity of water and the danger accruing to health from the consumption of contaminated water, that although there may be water everywhere, it appears there is not a drop to drink. And this in such thirsty weather leads us in despair to the effervescent and diuretic waters of Wildungen, and the acidulous alkaline waters of Carlsbad, the refreshing aerated water of the Taunus Brunnen, and the springs of Apollinaris. It is a question partly of palate to decide which to drink, and partly the determination must rest upon the chemical constituents. One natural water is said to be highly charged with lime salts, and warnings of diseases of the nature of stone are urged against its use; then turning to another, the presence of potash salts may conduce to heart disease, and worse than all, a recent writer* suggests, on the basis of some experiments he has conducted, that the natural sulphuretted waters derive their sulphurous properties from the reduction of sulphates by the agency of confervæ and vegetable detritus. Thirst increases, however, and men must drink, spite of objections raised against the various natural waters. But what a moral shock would be experienced should a suspicion cross the mind that certain waters, described in such a way that mentally they may be seen flowing and sparkling from the real springs, were after all—compounded! And where is the guarantee that many of them are not? For viewing the published analyses of mineral waters, it is so palpably easy to make them artificially, that for the moment, at least, the suspicion forces itself upon the mind.

Professor Hufeland exclaims, in speaking of the Wildungen natural mineral water: "Praise and thanks to the Almighty who gave us the delightful gift of the Wildungen springs;" and yet, from the published analyses of George Victor-Quelle and Helenen-Quelle, a chemist could well undertake to compound a water which should satisfy Professor Hufeland, and he would still thank the Almighty!

To be serious, solutions containing, in a concentrated form, the peculiar constituents of mineral waters, could easily be prepared, and upon the addition of a small quantity to ordinary water, charged with carbonic acid, such artificially mineralized waters would not be distinguishable from the most charming natural waters of Germany or other countries.

* E. Planchard (*Compt. Rend.*, lxxxix., 235-237).

FORMULÆ FOR NEW MEDICAMENTS ADOPTED BY THE PARIS PHARMACEUTICAL SOCIETY.

(*Continued from page* 1041.)

CALCIUM ACID PHOSPHATE (*Phosphate acide de Chaux*).

This product, which is prepared by treating bones calcined to whiteness with dilute sulphuric acid (see Codex) and evaporating the solution obtained after removal of calcium sulphate, occurs in the solid crystalline form, or, more frequently, as a paste. In consequence of the variable quantity of water it contains in the latter state, it is preferable to prepare solutions, syrups, etc., with the bibasic calcium phosphate (see before, p. 1041) and medicinal phosphoric acid, according to the following formulæ :—

Syrup (Sirop de phosphate acide de chaux).—Bibasic Calcium Phosphate, 12·5 grams; Phosphoric Acid, sp. gr. 1·45, as little as possible, about 18 grams; Distilled Water, 335 grams; White Sugar, 625 grams; Alcoholate of Lemons, 10 grams. Suspend the calcium phosphate carefully in the distilled water and add sufficient phosphoric acid to dissolve the salt. When solution is effected, add the sugar, coarsely powdered, and let it melt in the cold or with a very gentle heat. Filter and add the alcoholate to the cooled syrup.

20 grams of this syrup represent 0·25 gram of bibasic calcium phosphate, or, approximately, 0·40 gram of pure acid phosphate.

Solution (Solution de phosphate acide de chaux).—Bibasic Calcium Phosphate, 17 grams; Phosphoric Acid, sp. gr. 1·45, as little as possible, about 23·5 grams; Distilled Water, 959·5 grams. Suspend the phosphate carefully in the distilled water, allow the solution to go on during some minutes, and filter.

15 grams of this solution represent 0·25 gram of bibasic calcium phosphate, or, very approximately, 0·40 of pure acid phosphate.

MONOBROMATED CAMPHOR (*Camphre monobromé*) $C_{10}H_{15}O, Br$.

Coarsely powdered camphor is introduced into a flask of about ten times the capacity of the amount it is intended to prepare. A fine stream of bromine is then allowed to fall upon the powder, with continual agitation; the addition of bromine ceases when the camphor is liquefied. A large long abductor tube is then fitted to the flask and the other end plunged into an alkaline solution which will absorb the vapour that would otherwise incommode the operator. The flask is placed in a water-bath that is raised to ebullition, when the reaction soon commences. This is at first rather active, there being an abundant evolution of hydrobromic gas, and some vapour of bromine and undecomposed camphor. The liquid, which is at first dark brown colour, acquires an amber colour and the evolution of gas suddenly slackens. The operation should be carried out at a temperature between 80° and 90° C. The amber coloured liquid that remains in the flask solidifies upon cooling and appears then as a slightly citrine-coloured friable mass. It is purified by treating it several times with boiling 90° to 95° alcohol, filtering the liquor and leaving it to crystallize. The crystals obtained are dried in the air upon unsized paper.

Monobromated camphor consists of tufts of acicular crystals, which are prisms with a rectangular base, attaining an inch or more in length. The crystals are hard and crackle between the teeth; they have an odour of camphor and turpentine, less pungent than that of camphor, but also less fugacious. Their slightly bitter taste recalls that of camphor and Venice turpentine. Monobromated camphor is insoluble in water; soluble in alcohol, fixed and volatile oils, ether, carbon bisulphide, chloroform, etc.

CHLORAL. C_2HCl_3O.

This body is obtained by passing into absolute alcohol a current of dry chlorine until it is saturated. When the alcohol becomes coloured yellow the vessel is heated gently and the colour disappears. The heating of the alcohol is continued and a rapid current of chlorine is kept up, until the chlorine ceases to exercise any further action upon the nearly boiling liquid. Two layers are formed. The lower is hydrate of chloral, which is separated and agitated with a considerable quantity of sulphuric acid. The chloral is found in the upper layer, and it is purified by distilling over sulphuric acid, then over quicklime. It is rectified by distilling it at a temperature of 94° to 95°.

Chloral is a very thin, colourless liquid, greasy to the touch, with a pungent odour, irritant to the eyes; it is very soluble in water, alcohol, ether and chloroform.

CHLORAL HYDRATE (*Hydrate de Chloral*) C_2HCl_3O,H_2O.

Anhydrous chloral is mixed with one eighth its weight of distilled water. There is a considerable elevation of temperature and a formation of crystals having a saccharoid aspect. The product is purified by dissolving in boiling chloroform, from which the greater part is again deposited on cooling.

Chloral hydrate boils without decomposition at a temperature of 120° C. Its odour is sharp and purgent, and it is very disagreeable to the taste. It is soluble in alcohol, ether, benzine, chloroform, carbon bisulphide, and spirit of turpentine, and extremely so in water. In aqueous solution it should be without action on or scarcely redden blue litmus paper. It is not precipitated by silver nitrate. Treated with a concentrated solution of caustic potash it is decomposed into formic acid and chloroform. The odour of chloroform ought to be very clear and the liquid colourless.

Syrup (Sirop d'dydrate de chloral).—Syrup of Orange Flowers, 950 grams; Crystalized Chloral Hydrate, 50 rams. Dissolve the crystals in the syrup and filter. 20 grams of syrup contain 1 gram of chloral hydrate.

COCA. *Erythroxylon Cocà* (*Erytroxylées*).

Only the leaves of this shrub are employed in medicine, under the following forms:

Powder (Poudre).—Powdered s. a. almost without residue.

Infusion (Tisane).—Leaves, 10 grams; Boiling Water, 1000 grams. Infuse in a close vessel and filter.

Wine (Vin).—Bruised Coca Leaves, 30 grams; Alcohol (60°), 60 grams. Macerate for 24 hours and add Lunel wine, 940 grams. Leave in contact ten days, stirring frequently, and filter.

Elixir.—Bruised Coca Leaves, 100 grams; Alcohol (60°), 600 grams. Leave in contact during ten days; express strongly; mix the liquor with 100 grams of sugar syrup, and filter.

Extract (Extrait).—Coarsely powdered Coca Leaves, 1000 grams; Alcohol (60°), 6000 grams. Introduce the powder into a displacement apparatus, and pour upon it, moderately packed, sufficient alcohol to allow it to become uniformly saturated. Close the apparatus and allow the spirit to remain in contact twelve hours; then run the liquor off, and afterwards pass through the remainder of the alcohol. Distil off the alcohol and bring the residue to the consistence of a soft extract.

Syrup.—Coca Leaves, 100 grams; Boiling Water, 1000 grams. Infuse for 24 hours, express, and filter upon sugar in the proportion of 100 parts of infusion to 190 of sugar.

CALUMBA WINE (*Vin de Colombo*).

Lunel Wine, 940 grams; Alcohol, 60 grams; Calumba Root, 30 grams. Add the wine and alcohol to the coarsely crushed Calumba root, macerate for ten days with occasional stirring, and filter.

Calumba Wine may also be prepared with Malaga wine, but in that case wine must be substituted for the alcohol.

(*To be continued*).

The Pharmaceutical Journal.

SATURDAY, JUNE 30, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W.*

Envelopes indorsed "Pharm. Journ."

SWEET SPIRIT OF NITRE.

SWEET spirit of nitre has again become the subject of discussion in a court of law, under the circumstances detailed in the report we publish at page 1071, but fortunately the case to which we refer was not in this instance based upon the assumption that the British Pharmacopœia is the sole standard of quality and authority for the preparation of all the compounds that are sold to the chemist and druggist. Such an assumption would be in our opinion not only unreasonable but untenable. To object to sweet spirit of nitre, such as is very commonly met with, having a specific gravity of ·850, upon the ground that it does not agree with the description given in the British Pharmacopœia, and because it has probably not been prepared exactly according to the directions there given, and to institute a prosecution on that ground against a person selling it, would be straining the Sale of Food and Drugs Act beyond the intention even of those who hold strong views as to the magnitude of the evil of adulteration.

It is, however, a very different case when we find an article sold under the name of sweet spirit of nitre, which contains some 20 to 27 per cent. more water than it ought to contain, while at the same time it is entirely destitute of the particular substance which is considered to constitute the active medicinal ingredient of this preparation. Having regard only to the excess of water, amounting to from one-fifth to nearly one-third of the article as it was sold, the difference between such compound and that to which the title of sweet spirit of nitre can be properly applied, is evidently one that is not fully allowed for by the difference in price at which they are sold. The difference in price, upon which so much stress was laid by the defence, is moreover not a difference to the advantage of the consumer, and its character is partly indicated by the total absence of any nitrous ether in the samples.

The allegation that the preparation, for the sale of which the defendants were prosecuted, was used popularly in a manner distinct from the medicinal use of the legitimate sweet spirit of nitre is not entitled to very much respect. If, indeed, it be true that, as stated by the solicitor who conducted the defence, it is the popular practice to administer as much as half an ounce of the compound which he sought to represent as a proper article of trade, there is in this circumstance alone a reason for preventing its sale. We should be loth to see our druggists' shops become in any degree tippling shops or offering inducements to drunkards to seek intoxication under the guise of medication, after the manner which gave the United States Government a pretext for bringing the trade in that country under the operation of the Excise laws. But there is another use to which sweet nitre is frequently put, viz., as a simple remedy for slight febrile conditions in young children, and it does not require great power of imagination to conceive the effect produced upon children by giving them copious doses of an article three times as strong as common gin, and using it in the free manner MR. BERRY stated to be usual.

In conclusion, there is one point to which we would allude as worthy of note, and that is, that in not one case was the defendant a chemist and druggist. Of course it would be more gratifying to know that the sale of such preparations was not carried on by incompetent persons, like grocers and herbalists, but it is some consolation that the prosecution and publication of such cases will help to educate the public as to the folly of going for their medicines to persons to whom the label on the bottle or package is usually the sole character by which they can identify or judge of the quality of the articles they sell.

THE MEDICAL ACT AMENDMENT BILL.

THE curtailment which this Bill has met with at the hands of its nominal author does not appear to recommend itself to the judgment of the Nottingham Branch of the Medical Defence Association. On the 14th inst. a meeting was held by that body and several resolutions were passed, which have been communicated to the medical papers. The first urges upon DR. LUSH, and the other Members of Parliament associated with him in introducing the Bill, the great importance of adopting a clause whereby prescribing, as at present carried on by "many druggists and "other unqualified practitioners," should be considered an infringement of the Act, and render such persons liable to a penalty. Another lays down the proposition that no amendment of the Medical Act can be considered satisfactory which does not make the carrying out of prosecutions of offenders incumbent on the General Medical Council.

The Bill does not appear to make much progress in the House, the second reading having been again postponed until the 9th of next month.

COPPER IN PEAS.

AT the Borough Court of Bradford, on the 25th inst., several wholesale grocers were summoned for having sold preserved peas coloured with copper. MR. RIMMINGTON, the Borough Analyst, submitted his certificate which showed that the three samples of peas contained copper varying in amount from

2 to 2½ grains of sulphate of copper to the pound. In the course of the defence it was mentioned that in reply to a letter addressed to the parties who supplied the peas sold, a statement had been received to the effect that ten pint tins of the peas contained barely two grains of copper, and that this quantity was the minimum amount required to preserve the colour of the peas.

The opinion has more than once been stated in these columns that the copper undoubtedly present in preserved peas does not constitute an addition made with the view either of colouring them or of preserving their colour, and this opinion remains unaffected by the above statement. The copper is not unlikely introduced in an accidental manner. But what is more important to determine is the truth as to the oft-stated prejudicial influence of such peas as an article of food; this is a matter by no means definitely established, and we question whether it would bear investigation.

THE BRITISH ASSOCIATION.

SOME of the arrangements for the next meeting of the British Association for the Advancement of Science, which is to commence at Plymouth on Wednesday, August 5, under the presidency of Professor ALLEN THOMSON, M.D., LL.D., F.R.S., etc., have now been announced. The reception room will be opened for the issue of tickets, etc., at 1 P.M., on Monday, August 13, and on following days at 8 A.M.; no tickets will be issued after 6 P.M. The first General Meeting will be held on Wednesday, the 15th, when Professor THOMSON will assume the presidency and deliver an address. On Thursday, the 16th, and Tuesday, the 21st, *soirées* will be held. On Friday evening, August 17, at 8·30, there will be a discourse by Professor WARINGTON SMYTH, F.R.S., on the Physical Phenomena connected with the mines of Devon and Cornwall; and on Monday evening, the 20th, there is to be another discourse, the final arrangements for which have not yet been made. The concluding General Meeting will be held on Wednesday, August 22.

The local arrangements are not yet matured, but they will probably include an exhibition of paintings chiefly by artists of Devon and Cornwall. There will also be excursions to Torquay or Kent's Hole, and the Dart; up the Tamar or Cotehole; to the Moss Clayworks, over Dartmoor; to the Eddystone Breakwater and Government establishments; to the Caradoc Mines; and to Penzance, the Lizard, the Land's End, etc.,

In accordance with usual arrangements, the annual meetings of the British Pharmaceutical Conference will also be held in Plymouth, commencing on Tuesday, August 14, at 10 a.m. It may also be added that at the last meeting of the Council of the Pharmaceutical Society of Ireland a resolution was passed instructing the Secretary to write to the President of the British Pharmaceutical Conference, expressing a hope that the Conference will meet in Dublin in 1878, at the time of the visit of the British Association.

Transactions of the Pharmaceutical Society.

DINNER IN AID OF THE BENEVOLENT FUND.

The following donations have also been received since the last publication of the list:—

Cresse and Blackwell, 21, Soho Square, W.	10	10	0
Lockyer, George, Jun., 21, Mincing Lane, E.C.	1	1	0

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A Meeting of the Society was held on Thursday, June 21; Dr. Gladstone, President, F.R.S., in the chair. After the announcement of visitors, the minutes of the previous meeting were read and confirmed.

The President then announced the following grants from the Research Fund of the Society: Mr. Johnson, £50, for researches on potassium triiodide; Dr. Wright, £50, for researches on chemical dynamics; Mr. Neison, £25, for researches on octyl compounds; Mr. C. Williams, £25, for a research on hydrocarbons of the paraffin series; Mr. G. Harrow, £10, for a research on acetoacetic ether.

The list of presents to the library was then read by Dr. Armstrong. The following certificates were read for the first time: Dr. G. Kühnemann and J. Hadkinson; the following gentlemen were then balloted for and duly elected, the balloting occupying the Society till nine o'clock: F. H. T. Allan, H. S. Bell, C. T. V. Buck, J. Y. Buchanan, Dr. A. E. N. Franchimont, J. Gardner, W. Lapraik, G. A. Milne, J. Napier, C. G. Neison, J. L. Notters, J. H. Poland, I. Scarf, H. Senier, H. G. Stacey, S. G. Thomas, Beeby Thompson, F. W. Toms, A. Watt, W. Webster, jun., J. R. Young.

The Secretary then read a paper—

On Diamyl. By H. GRIMSHAW.—This substance was prepared from amyl bromide, boiling at 119°–123°; to 300 grm. of the bromide were gradually added 50 grm. of sodium, and the mixture finally raised to 140°–150° C. for about six hours. On distilling, diamyl was obtained, which was dried and purified by fractional distillation. When pure it boiled at 160° C. at 751 mm. By passing dry chlorine into the vapour of the boiling hydrocarbon, the chloride was obtained, boiling at 198°–213°. By heating the chloride in sealed tubes at 160°–170° for about forty-eight hours with lead acetate and acetic acid, an acetate was formed, boiling at 198°–215°, as a colourless mobile liquid of a fruity smell. On mixing this liquid with an excess of caustic potash and a little water, allowing to stand for twenty-four hours, and then boiling for six hours, an inverted condenser being attached, two alcohols were obtained, boiling at 202°–203° and 211–213° respectively; they were light, colourless liquids, having an agreeable orange-like odour. These two liquids were mixed and oxidized with bichromate of potash and sulphuric acid, and the acid distilled. The silver salt had the composition $C_2H_3O_2Ag$. Another acid, whose silver salt contained 63·66 per cent. Ag was obtained by the action of bichromate in the cold.

The next paper was read by the Secretary.

On the Action, at a high Temperature, of Certain Volatile Metallic Chlorides on Certain Hydrocarbons. By WATSON SMITH.—The author investigated the action of antimony trichloride and tin tetrachloride on naphthalin benzene and toluene, when these substances were severally passed in the state of vapour through red-hot tubes. Benzene was boiled and the vapours passed through a flask containing boiling antimony trichloride, the mixed vapours then passed through a heated combustion tube, loosely filled with fragments of pumice and porcelain; the products of the reaction were passed into a receiver connected with which was a Liebig's condenser. The contents of the receiver were returned to the benzene flask, a fresh quantity of trichloride added to the other flask, and the distillation repeated a second and third time. The reaction expected was

$$6C_6H_6+2SbCl_3=3\begin{matrix}C_6H_5\\C_6H_5\end{matrix}+6HCl$$

The diphenyl was extracted from the residues and purified: it melted at 70°, boiled at 243°, the yield of diphenyl by this process was much larger than that obtained by passing the vapour of benzene alone and through a red-hot tube (Proc. Lit. and Phil. Soc., Manchester, 1871), but was not quite satisfactory, so the action of tetrachloride of tin was tried: 62·4 grm. of benzene were distilled with 52 grm. of the tetrachloride. A very large yield of diphenyl was obtained in one distillation and very little benzene escaped decomposition. *Toluene and antimony trichloride:* oils were obtained, boiling 270°—320°, having very disagreeable odours resembling burnt cheese. *Naphthalin and Antimony Trichloride*—77 grm. of naphthalin were distilled with 46 grm. of trichloride, the mixed vapours being passed through a red-hot tube. The distillation was repeated three times, 15 to 16 grm. of trichloride being added. 37·4 grm. of a crude product were obtained by distillation; this yielded 24·2 grm. of yellow crystalline isodinaphthyl. *Naphthlalin and Tin Tetrachloride.*—Some difficulty was experienced from the blocking of the tubes by the separated carbon, and a special form of apparatus had to be devised. A large yield of isodinaphthyl was obtained, but the process is not so convenient as when antimony trichloride is used. A reddish oil boiling about 250°–300°, resembling "Red Anthcraene Oil," and some quantity of a citron yellow powder were formed.

II. *Isodinaphthyl Sulphoacids and Salts with certain other Derivatives.*—By treating 1 part of naphthalin with 5 parts of concentrated sulphuric acid for four hours to 140°–150°, treating with barium or lead carbonate, and evaporating, a large yield of the soluble barium or lead salt was obtained, the difficultly soluble β salts separating out during evaporation. By heating 4 parts of isodinaphthyl with 2 parts of concentrated sulphuric acid to 180°–190° for five hours, a large yield of the β acid was obtained with but little α acid. The α acid was prepared from the barium salt as minute transparent, yellowish, slightly fluorescent scales, easily soluble in water and ether, slightly in absolute alcohol, insoluble in benzol; the lead salt is easily soluble in water and weak alcohol. The β acid resembles the α acid, but is less soluble; its lead salt is difficultly soluble in water. An oxydinaphthyl or phenol, a nitro-substitution product, and a cyanogen derivative were prepared, and to some extent examined.

III. *A new Dinaphthyl.*—When napthalin is submitted to a high temperature, either alone or in the presence of a volatile easily decomposable chloride, a yellow substance, soluble in petroleum spirit, is formed together with isodinaphthyl. In the purification of the crude isodinaphthyl by petroleum spirit a fine red solution was obtained, which by spontaneous evaporation yielded several crops of warty crystals. These were distilled and gave a transparent bright resinous distillate. By fractional crystallization and the expenditure of much time and trouble, the author succeeded in separating three substances melting at 75°, 147° and 250°–255° respectively; the body melting at 250°–255° was present in very small quantities in brown transparent plates, and was soluble with a magnificent blue fluorescence in benzene or alcohol. The author believes it to be identical with Lossen and Otto's polymeric dinaphthyl (Ann. Chem. Pharm. lxviii. 89, and cxlvii. 170, 181). The body melting at 147° is an isomeric dinaphthyl, obtained also by Lossen by the action of manganese and sulphuric acid on naphthalin (Ann. Chem. Pharm. lxviii. 71); it boils at 300°. The body melting at 75° is a third dinaphthyl. So three isomeric dinaphths are obtained by passing naphthalin together with antimony trichloride through a red-hot tube; the one melting at 187° is formed in the largest quantity; next, the one melting at 75°, whilst only a small quantity of that melting at 147° is obtained. The three isomers are, then—

Dinaphthyl, No. 1.—Isodinaphthyl. β.β.

Melts at 187°

Crystallizes most readily in beautiful rhombic plates.

Soluble with difficulty in alcohol and ether, with moderate facility in boiling petroleum spirit and benzol.

Dinaphthyl, No. 2.—Lossen's. α.α.

Melts at 147° Smith.
154° Lossen.

Crystallizes readily; form variable, modified by impurities.

Soluble in alcohol and ether; easily in petroleum spirit and benzol.

Dinaphthyl, No. 3. α.β.

Melts at 75°

Crystallizes with much difficulty, requiring days or weeks.

Soluble. Very soluble in alcohol, ether, benzol and petroleum spirit.

In conclusion, the author points out the interesting results to be obtained by gentle oxidation, chlorination, etc., of the above bodies, a subject which he intends to take up on an early occasion.

The next paper was—

On the Action of Alkaline Oxalates on the Earthy Carbonates, and of Solutions of Alkaline Carbonates on the Earthly Oxalates. By WATSON SMITH.

The author having observed that when a solution of ammonium oxalate was brought into contact with chalk or powdered marble an ammoniacal odour at once became apparent set to work to measure the extent of this and similar reactions. Sodium oxalate in solution on calcium carbonate, if the reaction were complete, 5·3 grm. of sodium carbonate would have been formed; in the cold 1·05 grm. was obtained = 19·83 per cent.; boiling for three hours, produced 1·2135 grm. or 22·90 per cent. Sodium carbonate solution on calcium oxalate in the cold, 16·07 per cent.; boiled for thirty minutes 52·34 per cent. Sodium oxalate in excess on powdered marble in the cold, 20·97 per cent.; boiling, 26·00 per cent. Sodium carbonate in excess on calcium oxalate, cold, 13·09 per cent.; boiling, 78·35 per cent. By treating the same portion of calcium carbonate with successive quantities of sodium oxalate, 45·87 per cent. of sodium carbonate was obtained, the action gradually ceasing. By heating the same quantity of calcium oxalate with successive portions of sodium carbonate, 93·83 per cent. was decomposed. Sodium oxalate on strontium carbonate, cold, 7·63 per cent.; hot, 7·63 per cent. Sodium carbonate on strontium oxalate, cold, 57·24 per cent.; hot, 79·96 per cent. Sodium oxalate on barium carbonate, cold, 4·84 per cent.; hot, 4·97 per cent. Sodium carbonate on barium oxalate, cold, 73·20 per cent.; hot, 87·96 per cent. Ammonium oxalate on calcium carbonate, cold, 12·27 per cent.; with excess of oxalate, 13·53 per cent.; with excess of carbonate, 19·94 per cent. Sodium oxalate on lead carbonate, cold, 6·35 per cent.; hot, 13·08 per cent. Sodium carbonate on lead oxalate, cold, 81·54 per cent.; hot, 90·61 per cent.

The next paper was entitled

Note on Thallous Platinocyanide. By R. J. FRISWELL and A. J. GREENAWAY.—In 1871, one of the authors described a compound of thallous platinocyanide with thallous carbonate Tl_2PtCy_4,Co_3Tl_2, crystallizing in dark red crystals reflecting a green metallic light; by treatment with nitric acid colourless crystals were obtained, having the formula Tl_2PtCy_4. Carstanjen, however (Jour. Prac. Chem. 102, p. 144; Watts, Dic. Supp., I., 536), states that he obtained thallous platinocyanide in blood red needles having a metallic green lustre by reflected light. As this is not in accordance with the above statement, the authors have reinvestigated the subject with great care. Hydroplatinocyanic acid was prepared and neutralized with an equivalent quantity of thallous carbonate $Tl_2CO_3+H_2PtCy_4=Tl_2PtCy_4+CO_2+OH_2$, a colourless neutral acid was obtained. On adding to a fresh portion of the acid, twice the above amount of thallous carbonate, the dark red salt, already described, was obtained. Baric platinocyanide was also decomposed by thallous sulphate; the resulting crystals were quite colourless. The authors gave the following analysis of the colourless thallous platinocyanide: Pt 28·09 C 6·60 and 6·78 N 7·76 and 7·91. Theory requires Pt 27·82 C 6·76 N 7·89. These numbers show conclusively that the salt described by Carstanjen (especially as he gives no analysis) was really the double carbonate, and that thallous platinocyanide is a colourless compound.

The next paper was—

On Crystallized Barium Silicitate. By E. W. PREVOST. Pisani (*C. Rend.*, lxxxiii., 1056) states that he has found the above substance attached to the sides of bottles in which barium hydrate solution had remained for several years. The author has obtained crystals formed under the same conditions, and having the same measurements, but containing 0·78 per cent. silica: they consist of barium hydrate, and contain 45·4 per cent. water, and 72·5 per cent. barium. Theory requires 45·6 per cent. and 73·09 per cent.

The next paper was—

A Note on Anethol and its Homologues. By W. H. PERKIN. —The author mentioned that he had already (*Chem. Soc. Jour.*, 1877, 409-414) stated that methylparoxyphenylacrylic, methylparoxyphenylcrotonic, and methylparoxybenzylangelic acids, when heated, split up into carbonic acid and oily products; that from methylparoxyphenylcrotonic acid, being supposed to be anethol, and those from the other acids, homologues of that substance. Further experiments on this subject have since been made. On boiling *methyparoxyphenylacrylic acid* in a bulb-tube provided with a side delivery tube, the heat being so moderated that a thermometer placed in the upper part of the tube does not rise above 220°-240°, an oil gradually distils over, but after a time ceases, leaving a good deal of a dark coloured residue in the retort. The oil after purification gave numbers on analysis corresponding with the formula $C_9H_{10}O=C_6H_4\left\{\begin{matrix}OCH_3\\ CHCH_2\end{matrix}\right\}$ When cooled in a freezing mixture it solidifies to a crystalline mass, having an odour and taste like fennel. When heated in a retort it rapidly changes, and before much has distilled over the principal part of it thickens, and on cooling forms a transparent nearly solid product. When oxidized it yields apparently anisic acid. *Methylparoxyphenylcrotonic acid*, when distilled in the same manner as the above also yields an oil but leaves less residue in the retort. This oil does not change much on distillation, and when fractionated begins to boil at 220°, the principal quantity, however, comes over between 230°-240°, leaving a little high boiling residue in the retort. Both of these fractions when cooled in a freezing mixture solidify, but the higher fraction freezes most readily and becomes harder; on pressing these products between bibulous paper white crystals were obtained, which were purified by crystallization from alcohol. This substance has the composition, melting and boiling points as well as the taste, odour, and appearance of anethol. This indicates that the constitution of the C_3H_5 group in anethol has the constitution $CH=CH-CH_3$ as will be seen thus—

$$\underbrace{C_6H_4(OCH_3)CH,CH,CH_2,COOH}_{\text{Methylparoxyphenylcrotonic Acid.}}=\underbrace{C_6H_4\left\{\begin{matrix}(OCH_3)\\ (CHCHCH_3)\end{matrix}\right.}_{\text{Anethol.}}\begin{matrix}\\ \\ +CO_2\end{matrix}$$

The author proposes to examine this body more critically when a sufficient quantity has been prepared. Methylparoxylphenylangelic acid also, when carefully distilled, yields a crystalline anethol-like body as already mentioned in the paper previously referred to, but although there can be no doubt about its formula, it has not yet been obtained sufficiently pure for analysis.

Dr. Armstrong thought that it was not at all proved that the C_3H_5 group had the constitution $CH=CH-CH_3$, as isomeric changes might occur in the heating and from other considerations it seemed much more probable that its constitution was $CH_2=CH-CH_2$.

The next paper was entitled—

Note on Persulphocyanic Acid. By R. W. ATKINSON, Japan. The author commences by stating that the constitution of the above body is still uncertain, and points out the decompositions which must be indicated by its formula. The substance was prepared and purified by recrystallization from boiling water; its properties are described, also the precipitates produced by argentic nitrate, mercurous nitrate and solution of iodine. Numerous experiments were made by adding varying quantities of argentic nitrate to the acid dissolved in alcohol, and evidence of the existence of $Ag_2C_2N_2S_3$ and $AgHC_2N_2S_3$, was obtained. When the yellow argentic persulphocyanate is boiled with water it quickly decomposes with effervescence, a heavy black precipitate being produced. Attempts were made to determine the composition of this precipitate but the results obtained vary widely. The general nature of the reaction is probably—

$$Ag_2C_2N_2S_3+3\,AgNO_3=$$
$$2\,Ag_2S+AgCNS+CO_2+N_2O_4+N_2O_3.$$

The mercurous salt is not apparently decomposed by boiling. In conclusion the author points out the resemblance between the (probably correct) formula proposed by Glutz (*Deut. Chem. Ges.*, iii., 343), with that of parabanic acid.

The next paper was on—

The Oxidation Products of the Aloins. By W. A. TILDEN, D.Sc., Lond.—When nataloin is digested with 10 per cent. solution of bichromate of potassium, acidified with sulphuric acid, carbonic and acetic acids were alone obtained. If, however, barbaloin be similarly treated, only a small quantity of acetic acid is formed, but a brown precipitate is deposited; this on analysis gave C 63·3 per cent. H 3·2 per cent. The corresponding body from socaloin, and purified by a solution in acetic ether, etc., gave C 63·8 per cent. H 3·4 per cent. On treating in a rapid current of carbonic anhydride, a yellow pulverulent sublimate, containing a few orange needles, was obtained: this recrystallized from acetic ether, gave C 61·6 per cent. H 3·4 per cent. The substances from socaloin and barbaloin are identical, and the author proposes the name of aloxanthin. This substance forms an orange granular powder, melting imperfectly at 260°-265°, subliming slowly at the same temperature in orange scales and dust. It is slightly soluble in water, very slightly in bisulphide of carbon, chloroform, alcohol, and ether. Its best solvents are ethyl acetate and glacial acetic acid. In caustic soda it dissolves to a bright cherry red solution without absorption bands. Heated with zinc dust, a hydrocarbon having a greenish fluorescence is obtained, melting at 203°-205°: this consists principally of methylanthracene. Aloxanthin, fused with caustic potash, forms an indigo-blue mass. Aloxanthin does not combine with mordants. Its formula is probably $C_{15}H_{10}O_6$, being a methyltetroxyanthraquinone. Three analyses of the purest sample gave C 62·2 H 3·3. Theory requires C 62·9 H 3·3 per cent. An acetyl compound was formed. Aloxanthin treated with fuming nitric acid in the cold yields a yellow nitro-acid, having the properties of aloetic acid.

The Society then adjourned over the vacation to Thursday, November 1.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

THE DIFFERENT METHODS OF FLOWER FERTILIZATION.*

BY J. F. SAVORY.

(*Concluded from p.* 1052.)

Another striking instance occurs in *Epilobium angustifolium* and *E. parviflorum.* These two flowers again, differ most strikingly in a similar manner. The flowers of *Epilobium angustifolium* being of a larger size, brighter colour, grouped in splendid clusters, and exciting attention at a great distance are so largely visited by insects as never to have any need of self-fertilization. Indeed, this is impossible, the four stigmatic branches unfolding so long after the maturity of the eight anthers, and so far overtopping them as to be completely shut out from the pollen of the same flower. The flowers of *Epilobium parviflorum,* on the other hand, being of smaller size, lighter colour, and single, are so inconspicuous that insects but rarely visit them. Accordingly, its four upper anthers so closely surround the four-lobed stigma, which is mature at the same time, as to cover it largely with its pollen, whilst the pollen grains of the four lower anthers, lying on the way to the honey, cannot reach the stigma of the same or of another flower unless transferred by insects.

One more illustration. Among the many species of the genus Polygonum which grow in our country, there are two, *P. Fagopyrum* and *P. Bistorta,* most distinguished by their attractiveness for insects, which is due, not only to the size and colour of the single flowers and to their collection into handsome spikes, but also and even more perhaps, to the abundance of honey secreted by eight globular nectaries at the base of the filament. Thus by the frequent visits paid them by insects, they have been adapted to inevitable cross fertilization by these visitors, self fertilization having become difficult or even impossible.

The least attractiveness for insects, on the contrary, among all native species of Polygonum, is possessed by *P. aviculare,* its flowers being of small size and of a greenish and white or reddish colour, standing singly on procumbent plants and offering only a small quantity of pollen to insects, but no honey. No wonder then, that insects are induced in very rare cases only to visit and fertilize them and in compensation for the loss of cross fertilization, these little flowers regularly experience spontaneous self fertilization, the three inner anthers lying so close to the stigma, that their pollen grains inevitably come into contact with them.

There are many other genera containing species quite analogous to those just mentioned, such as the geranium, stellaria, cerastium, rubus, veronica, carduus, hieracium, etc.; and as a summary of the recorded facts, we may admit the following propositions: In many species, the flowers vary, and have always varied in size, colour, the quantity of secreted honey, and consequently in their attractiveness for insects. Whenever in such a varying species, the one variety possesses such a degree of attractiveness for insects as to receive sufficiently frequent visits from them, those variations which afford facility for cross-fertilization by insects have always been preserved and accumulated by natural selection, whereas the possibility of self-fertilization has, at the same time, frequently been lost. Hence we may infer that cross-fertilization is more advantageous to a plant than self-fertilization. Whenever, on the contrary, another variety presents so little attractiveness for insects as to remain commonly overlooked by them, only such individual peculiarities as induce self-fertilization have been preserved and accumulated by natural selection, whereas cross fertilization by insects has frequently become very difficult, although perhaps never quite impossible.

There is another curious point in regard to the facts stated above. We have seen that more or less attractive flowers, adapted to cross or self-fertilization, sometimes occur in slightly differing, sometimes in well marked species; sometimes in doubtful, sometimes in good and distinct varieties.

The two functions of crossed and self-fertilized flowers, which we have seen to occur in different forms of the same species or genus, are in most cases successively presented by the same form of flowers, and the modifications by which self fertilization is attained by different plants, where the visits of insects are wanting, are almost as various as the contrivances by which cross-fertilization by insects is secured. I will now give an illustration.

Myosurus minimus is as remarkable for the great variability in the size of its flowers and in the number of its parts, as for the enormous growth of the cone of pistils, which affords no other benefit to the plant but the self-fertilization of the greater part of the numerous stigmas by the small number of anthers, in case it is not visited by insects. When the flower opens it stretches forth its small petals, which serve as nectaries, and offers a small drop of honey, by which very minute insects (their size not exceeding 1½ mm. in length), are attracted in sunny weather. These little visitors, licking up the drops of honey and walking round the cone of ovaries, stop many seconds in a single flower before visiting another. The anthers lying close round the cone of ovaries open by two lateral slits and are soon afterwards covered with pollen on their whole outer surface. Consequently, insects walking round the ovaries may easily be charged with pollen, and flying to another flower effect cross-fertilization. But upon the whole the flowers, because of their being scentless, and very inconspicuous, are so scantily visited by insects, that I believe that even in sunny weather more than 90 per cent. remain without any visit.

This deficiency of secured cross-fertilization is supplied by regular self-fertilization in the following way:—The axis of the flower, extending gradually during the blooming time into a long cone, brings a great part of the stigmas into contact with the lateral pollen grain of the anthers, those which now are in contact with the anthers soon overgrowing them, and others below the anthers now reaching them. Thus a number of styles grazing the anthers during the growth of the long cone, are self-fertilized by about five or more pollen grains; besides, also, the lowest stigmas of the flower are fertilized by their own pollen, many pollen grains falling down from the anthers. Consequently, only those ovaries are never self-fertilized which are already situated above the anthers before the opening of the flower.

Whilst in *Myosurus minimus* self-fertilization is effected by a number of stigmas passing along each of the anthers, *Myosurus versicolor* attains the same effect in the contrary way, viz., all five anthers of the flower passing along the single stigma.

We now come to fertilization without insect aid. There are some attractive flowers which are as much adapted to secure self-fertilization, as other flowers are for cross-fertilization. For example, take the greenhouse annual, *Boswallia elata,* belonging to the Scrophulariaceæ, having an attractive blue flower. Not only does it produce abundance of perfect seeds without insect acid, but also, the entrance of an insect would ensure self fertilization. The style is nearly as long as the corolla tube, and the slightly longer stamens are arranged closely around it. Two of the anthers are inverted over the stigma, and their connective is densely bearded, appearing like petaloid processes completely closing the tube of the corolla. No insect can thrust it proboscis into the tube except through this mass, and if it has any foreign pollen adherent to it, it will be cleaned off by the beard. Furthermore, the very act of penetration will thrust the anthers forward on to the pistil, and aid in rupturing the pollen sacs, and securing self-fertilization.

Fertilization by birds.—In *Marcgravia Nepenthoides*, a native of America, there is a group of pitchers below the flowers, which attracts insects. Numerous insectivorous birds come to feed on these insects, and in doing so necessarily brush off the pollen and convey it to other flowers. In a species of *Erythrium*, having a sword-shaped flower, which will only admit very minute insects to the nectary, two species of long-billed humming birds, probe the flower in search after the insects, and in doing so get the pollen on their heads, and convey it to other flowers. In this case, the nectar is protected by a thick fleshy calyx, which effectually prevents bees and wasps from breaking in and stealing the attractive liquid.

I now pass to another remarkable peculiarity of plants, which I think may possibly have reference to their relation with insects, and that is the habit of "sleeping," which characterizes certain species.

Many flowers close their petals during rain, which is obviously an advantage, since it prevents the honey and pollen from being washed away or spoilt. Everyone however, has observed that even in fine weather, certain flowers close at particular hours. This habit of going to sleep is surely very curious. Why should flowers do it?

In animals we can understand it: they are tired and require rest. But why should flowers sleep? Why should some flowers do so and not others? Moreover, different flowers keep different hours. The daisy opens at sunrise, and closes at sunset, whence its name, "day's eye." The dandelion is said to open about seven and close about five. The white water lily from about seven to four. *Tragopogon pratensis* opens at four in the morning and closes just before twelve, whence its English name, "John, go to bed at noon." Farmers' boys, in some parts, are said to regulate their dinner time by it. Other flowers on the contrary, open in the evening. Now, it is obvious, that flowers which are fertilized by night flying insects, would derive no benefit from being open by day; and on the other hand, that those which are fertilized by bees and day insects, would gain nothing by being opened at night. Nay, it would be a distinct disadvantage, because it would render them liable to be robbed of their honey and pollen by insects which are not capable of fertilizing them. I would venture to suggest then, that the closing of flowers may have reference to the habits of insects, and it may be observed also in support of this, that wind fertilized flowers do not sleep; and that some of those flowers which attract insects by smell, emit their scent at particular hours: thus *Hesperis Matronalis* and *Lychnis vespertina*, smell in the evening, and *Orchis bifolia* is particularly sweet at night.

But this sleep of plants, or closing of the flower at nightfall, has also been found to have reference to self-fertilization in *Claytonia Virginica*, and some buttercups, which seed abundantly without being visited by insects.

In *Claytonia*, the stamens, on expanding, fall back on the petals expanded during daylight. At night, when the flower closes, the petals carry the anthers into closer contact with the stigmas, and actual fertilization only occurs in this way. In many cases, the stamens recurve so much as to be considerably doubled up by the nocturnal motion of the petals; thus the anthers are not brought into contact with the stigmas, and the flowers are barren.

In specimens of *Ranunculus bulbosus*, in the evening following the first days' expansion of the flower, the immature anthers and young stigmas were found to be covered with pollen. This would naturally be supposed to be the consequence of insect visits, but none had taken place in the cases examined. However, on carefully examining the flower, it was found that coincidently with its expansion, a single outer series of stamens shed their pollen into the petals, from which it easily fell on to the immature anthers and stigmas when the flower closed for the night.

Another equally remarkable instance of self-fertilization occurs in *Ranunculus abortivus*, whose petals do not close at night. It seeds profusely, yet is wholly neglected by insects, notwithstanding that it possesses large nectariferous glands. Instead of the flower closing, the slender pedicles droop at night, inverting the flowers and thus allowing the pollen to fall from the petals on which it is shed upon the stigmas.

In connection with this subject of fertilization, the production of "hybrids," or "mules," deserves attention. When the pollen of one species is applied to the stigma of another species, so as to effect fecundation, the seeds thus formed give rise to individuals which are intermediate in their characters between the two parents. The plants produced by this heterogeneous fertilization are called hybrids or mules.

A true hybrid is a cross between two species, but the term is often applied to crosses between mere varieties, races, or sub-species. The latter sort of crosses have been occasionally denominated "sub-hybrids" to avoid confusion. In hybridizing it is necessary to bring together species which are allied, as for instance, the species of the same genus, or those of allied genera. It is not easy, however, to determine the plants which can produce hybrids. Many plants which seem to be nearly allied do not inoculate each other. Sageret failed in his endeavours to fecundate an apple tree by a pear tree, and no one has succeeded in getting hybrids between the currant and gooseberry, nor between the strawberry and raspberry. It is not common to meet with hybrids in a wild state, because there is a much greater likelihood of the pistil being impregnated by the pollen of the anthers beside it, than by that from a distance, and if fecundation has taken place, then pollen applied from other sources has no effect.

It has been found that for successful hybridizing the pollen must be in perfection, and the stigma also must be fully developed. There appears always to be a preference for its own pollen on the part of the stigma. When strange pollen is applied, even in the case of species which hybridize, it does not act so effectually on the ovules as the pollen belonging to the flower.

When impregnation takes place between two pure species, the characters of the parents never remain pure and unaltered in the formation of the hybrid. In general every part of the new product is modified, so that it presents a decided difference from either of the parents, though resembling one more than the other. Sometimes the influence of the male predominates, sometimes that of the female. Hybrids occur in which the characters of the parents are intimately blended, so that it is impossible to say to which there is a greater resemblance. Sometimes the number of the organs is curiously intermediate, thus cucubalus has three stigmas, and lychnis five, and a hybrid between them has four. Again hybrids occurs in which one part or another approaches the paternal or maternal form, though the characters of the parent never pass altogether pure into the new organism. There is a third set of hybrids in which there is a resemblance to one of the parents, whether male or female, so decided, that the agreement is at once perceptible and beyond doubt.

Hybrids, although they may be fertile at first, rarely continue so for many generations. The cause of sterility in mules has not been fully ascertained. Henslow could not find in a hybrid digitalis any structural changes which could account for barrenness. Hybrids may be fertilized by pollen taken from one of the parents, and then the offspring approaches in character to that parent. Hybrids impregnated for a third or fourth time with the pollen of the original male plant approach more and more to the male type. Such is also the case when the impregnation is effected by pollen taken from the original female plant, but in this instance the change is usually slower. Gärtner gives a tabular view of the number of impregnations requisite to complete change of species by hybridization. He produced hybrids between two species, and then by using the pollen of the original male or female parent, he found that in process of time, the species were brought back to the male or female type.

Hybridizing is an important horticultural operation. By it the gardener endeavours to increase the size of flowers, to improve their colour, to approximate their form to some assumed standard of perfection, to enlarge the foliage, as in esculents, to render tender plants hardy, to heighten the flavour of fruits, and to exchange early for late varieties.

The changes produced by muling on the size and colour of the blossoms are very remarkable. By inoculating *Cereus speciosissimus* with *C. grandiflorus*, we find that the *immediate* result is a seedling, whose flowers are ten inches in diametre. The hues resulting, however, from the union are not necessarily intermediate. Blue and yellow do not produce green, as proved by a hybrid between *Verbascum phœniceum* and *V. Phlomoides*. In the cases of rhododendrons, gardeners have been able to secure the fine colour of the Indian *R. Arboreum*, with the hardiness of the American species. By inoculating the common heart's-ease with the large flowered pansy of the Altai Mountains, a degree of vigour has been infused into the former which we could not hope to obtain by ordinary means. The fine varities of pelargonium have been obtained by cultivation and hybridizing from the small-petaled pelargonium of the Cape.

Fruits and culinary vegetables are sometimes improved by hybridity. These hybrids cannot be continued from seeds, but must be propagated by offsets or cuttings. The effects of hybridizing or crossing is very marked in the case of certain cereal plants.

Parliamentary and Law Proceedings.

Adulteration of Sweet Spirit of Nitre.

At the Bradford Borough Court, on Monday, before Alderman Law and Mr. Wilson Sutcliffe, Messrs. Stephenson Brothers, grocers, etc., Thornton Road; Mr. George Batty, herbalist, Otley Road; and Mr. Joseph Robinson Lund, Barkerend Road, appeared to answer informations laid at the instance of the Town Clerk (Mr. W. T. McGowen), charging them with having, on the 19th March, sold sweet spirit of nitre which was not of the nature, substance, and quality demanded by the purchaser, contrary to the provisions of section 6 of the 38 and 39 Vict. cap. 63. The Town Clerk appeared in support of the informations; Mr. B. Terry was present on behalf of Messrs. Stephenson Brothers and of Mr. Batty and Mr. Lund was represented by Mr. J. Berry.

Mr. Booker, Inspector of Nuisances, stated that he went to the warehouse of Stephenson Brothers, and asked for a pound of sweet spirit of nitre. A liquid was given him for which he paid three shillings, and he subsequently placed it in the hands of Mr. F. M. Rimmington, the borough analyst. He purchased six ounces of what was called sweet spirit of nitre at the retail shop of Lund.

The Magistrates' Clerk (Mr. G. R. Mossman) read out the certificates of Mr. Rimmington's analyses as follows:

Lund's Sample.

	Per cent.
Sweet spirit of nitre	67
Water of composition	13
Water over and above that which ought to be present	20
Parts	100

Batty's Sample.

Sweet spirit of nitre	60
Water of composition	13
Water in excess	27
Parts	100

Stephenson's Sample.

Sweet spirit of nitre	61
Water of composition	13
Water in excess	26
Parts	100

Mr. Berry was about to ask witness whether two strengths of sweet spirit of nitre were not sold in many retail shops, when

The Town Clerk objected, saying he was there to make a specific complaint.

Dr. B. H. Paul (Consulting Chemist) was next called. He stated that in the course of his practice he had had his attention directed to the article, sweet spirit of nitre. Specimens of the sweet spirit of nitre under consideration had been laid before him, and he quite agreed with the results reported by Mr. Rimmington. He might state, however, that the standard specific gravity of ·845 was one very seldom adhered to, but the sweet spirit of nitre made by respectable houses had a specific gravity not below ·850. The specific gravity of one of the samples produced was ·915. The preparation having a specific gravity of ·850 was very much in favour with medical practitioners. In making up a physician's prescription the pure spirit of nitre should be used. The ether, which was the essential medicinal constituent of sweet spirit of nitre, would not be formed by using spirit so diluted as the sample referred to (specific gravity ·915).

Mr. Rimmington also stated that ·843 or ·845 was the proper specific gravity, but he should not reject sweet spirit of nitre having a gravity of ·850.

In order to demonstrate the difference between a good and proper spirit and one highly diluted, Dr. Paul poured a quantity of the genuine liquid into a test tube, and added small quantities of sulphate of iron and sulphuric acid; the effect was at once apparent, the liquid in the tube turning a deep black. Treating one of the diluted samples in the same way, no such reaction was observed. The difference, he said, consisted in this, that ether was present in the former, but absent in the latter specimen. At the request of Mr. Berry, Lund's sample was tested, and, although least diluted with water, it was found to be the worst sample with regard to the absence of ether.

Mr. Jno. Nettleton Terry, surgeon, Bradford, said he had tested the adulterated spirit of nitre by tasting it. The samples were of a very poor quality. They were almost tasteless; indeed, if he had not been told he would not have known that they were intended for spirit of nitre. The drug did not act properly when water was present in such excess.

Mr. Terry, in defence, said that the article before the court was sold at a certain price, and purchasers knew what they were getting it for; they took it at the price, and did not complain of being prejudiced by it. If a purchaser had asked for the pure spirit of nitre, the person supplying it would have known that he wanted a certain other thing under a different name. If the Bench could not see any course open to them but to convict, he would ask that the penalty should only be a nominal one.

Mr. Berry then addressed the magistrates on behalf of his client. He contended that manufacturing chemists throughout the country had on their lists sweet spirit of nitre of specific gravity ·900; but they also kept the Pharmacopœia strength if required, and when they got a physician's prescription, it was made up with spirit of ·850 specific gravity. If an ordinary customer asked for the best spirit he got the stronger nitre, so that there was not the slightest imposition. Then this dilution was, he argued, a matter of proper precaution. The usual practice of medical gentlemen might be to give sweet spirit of nitre in doses up to two teaspoonfuls, but where, as was often the case, it was administered in the family without calling in the doctor, as much as half an ounce would be given in gruel or in other ways. In these cases, if the stronger spirit were used, serious results might arise. Sweet spirit of nitre was a thing known in commerce; and this he held was of the same strength as the samples, and if the defendants had been selling it he thought they would hardly be liable. Besides, there was no other sweet spirit of nitre. The only compound answering to it in the Pharmacopœia was called by another name—*spiritus ætheris nitrosi*, and that could not be bought for 2½*d.* per ounce as this had been. The vendors did not profit by the addition of water, for it was sold to customers at a reduced price. He pointed to acetic acid, which he said was treated in a somewhat similar way. Mr. Berry in conclusion asked for a mitigation of the penalty, if one was to be inflicted.

The Bench imposed the nominal penalty on each defendant of £1, with costs £3 10*s.*, and said they had seldom heard evidence of a more conclusive kind than that given by Dr. Paul.

Poisoning by "Nurse's Drops."—Prosecution under the Pharmacy Act.

An inquest, opened some time since, at the Queen's Head, Acle, by R. T. Culley, Esq., Deputy Coroner for the county of Norfolk, upon the body of John Morse, aged seven weeks, and adjourned from time to time; first, that a *post-mortem* examination might be made, and next, that a mixture called "Nurse's Drops," and the stomach of the deceased infant might be subjected to analysis, was concluded on Wednesday, the 13th inst. The evidence adduced at the several sittings of the Coroner and jury may be briefly stated. The infant son of a labourer died on the 18th of May, after ailing for a few days. It had been healthy from its birth, except that it seemed to suffer pain, which made it cross. To remedy this, on the 16th of May, the mother ordered Edwin Braddock, an assistant to Mr. Charles William Clarke, grocer and draper, of Martham, to bring her when next he called some Nurse's Drops. Braddock accordingly poured an ounce of Nurse's Drops out of a large bottle which Mr. Clarke had amongst his stock of medicines, into a phial, which he enclosed in Mrs. Morse's parcel, and left it at her house. The bottle in Mr. Clarke's shop is labelled "Nurse's Drops—Poison;" but Braddock put no label upon the phial, and stated that he did not generally put labels on the bottles he sent out. It was subsequently elicited from Ezekiel Everson, another assistant of Mr. Clarke, and who had had four years' experience in a druggist's shop, that he was in the habit of writing labels, with directions for the use of the contents, upon the bottles he sent out from his employer's shop. The Nurse's Drops were obtained from Messrs. Smith and Sons, druggists, Norwich; and if a customer had asked him for the drops for a child seven weeks old, he should have said that a dose was not to exceed five drops. According to the statement of the mother, finding the bottle not labelled, and not knowing what quantity to give the child, she first of all tasted the mixture, and perceiving that it was hot, she administered only two drops in some water and sugar. An hour and a half later, the child, which had previously suffered from, was seized with, convulsions, which continued intermittently till half-past nine, when it died. Mr. Cufaude, surgeon, saw the child before it died. It was then in an insensible condition, suffering, in his opinion, from some narcotic. By direction of the Coroner, he made a *post-mortem* examination, when he found great congestion at the base of the brain, with effusion of serum; fluid blood and a small clot in the right side of the heart, and nothing in the left. He was of opinion, finding no traces of inflammation in any other organ, that death was caused by congestion of the brain and spinal cord. What caused this congestion he could not say, but he thought the symptoms pointed to poisoning by some narcotic substance. The phial and stomach of the child, both placed under seal, were submitted for analysis to Mr. F. Sutton, analyst for the county of Norfolk. Mr. Sutton found the phial to contain a composition known as Nurse's Drops, consisting of laudanum, oil of caraway seed, and spirit of wine. The proportion of morphia in the composition he estimated to be little more than one grain, which would represent one-third of the contents of the bottle, and be laudanum of full strength. He also found the presence of meconic acid, a constituent of opium. The stomach, which was in a state of partial decomposition, and contained no food, showed traces of meconic acid and oil of caraway seed. Considering the strength of the composition in the bottle, five or six drops would be sufficient to kill a child seven weeks old. The mixture, which was of the ordinary strength, was dangerous on account of its strength, and required great care and attention in the administration of it. He did not think two drops would be sufficient to cause death, though it might accelerate the death of a child seven weeks old. The mother was further questioned as to the dose she gave, and she said it was only two drops. The jury came to the following verdict: "That deceased died of having had a composition or mixture called Nurse's Drops administered to him, but whether the said composition or mixture caused the death, or in any way accelerated the death, there is no evidence to show. But they are of opinion that the sale and consumption of such a dangerous composition or mixture as aforesaid is most irregular and improper, and ought at once to be discontinued."

On Monday, the 25th of June, Mr. Charles William Clarke, the shopkeeper who sold the Nurse's Drops mentioned in the above case, was charged before the magistrates of the Blofield and Walsham Hundreds, with illegally selling a preparation containing opium, he not being on the Register of Chemists and Druggists.

Mr. Francis Sutton, the Local Secretary of the Pharmaceutical Society for Norwich district, attended with a copy of the Register, and was prepared to prove by his analysis the composition of the mixture.

The defendant, however, pleaded guilty, and the magistrates fined him the sum of £4, which, together with costs, £3 1*s.* 6*d.* were paid by him, the magistrates remarking that in case of a second offence they would inflict the fullest possible penalty, and the superintendent of police, at the instance of Mr. Sutton, expressed his determination to put the law in force wherever he could find any infringement of the Pharmacy Act.

Poisoning by Carbolic Acid.

Mr. Humphreys held an inquest at the Gladstone, Mare Street, Hackney, on Monday, relative to the death of Sarah Silver, aged 52 years, a widow. Deceased had been found on the floor in the kitchen, apparently the worse for drink, and on the table was a pint champagne bottle, labelled "Carbolic acid—Poison." A doctor was called, but she died in three hours from poisoning by carbolic acid. The Jury returned a verdict of "Death from misadventure."

An inquest was also held the same day by Mr. Bedford, at York Street Board Room, on the body of Frederick Cresswell, aged four years. A bottle of carbolic acid had been left on the washstand, inadvertently, in the room where three infants were playing, and on the mother's return she found the deceased insensible and another child very ill. Mr. S. K. Birch, a surgeon, stated that when he was called there was a strong smell of carbolic acid in the room. There was an unaccountable patch on the stomach of deceased and another on the head.—The inquest was adjourned for an analysis to be made.

Charge of Personation at the Preliminary Examination.

On Monday last, George Frederick Webb, a chemist's assistant, was charged before Mr. Vaughan, at Bow Street Police Court, with fraudulently procuring his registration under the Pharmacy Act, 31 and 32 Vic., 1868.

Mr. Douglas Straight prosecuted on behalf of the Pharmaceutical Society, and stated that the defendant presented himself for the Preliminary examination, and having failed, allowed one named Andrew Ritchie Hunter to pass the examination on another occasion in his (Webb's) name. A warrant was out against Hunter, but he was not yet apprehended. He had already been charged with the same offence on a previous occasion in conjunction with two men named Colegrove and Hinks, all of whom at their trial had pleaded guilty.

Evidence of handwriting, etc., was given by Mr. Elias Bremridge, the Registrar under the Act, who had sent the forms of application to the defendant; and Detective Sergeant Andrews, Scotland Yard, deposed that he arrested the defendant at his employer's place of business. The defendant then denied all knowledge of the case, but now expressed a wish to plead guilty to the charge.

Mr. Straight said he did not intend to proceed further with the case that day, and note having been taken of the defendant's plea, the case was adjourned.

Strange Accident.

The following paragraph appeared in the *Echo* on Tuesday:—"A correspondent sends the following: An extraordinary accident occurred yesterday at a small shop in Fleet Street, where American 'crullers' and iced drinks are sold. Some person, it is stated, had recommended to one of the young ladies employed in this shop the use of nitric acid and quicksilver for cleaning silver. The person thus advised purchased the prescription, telling the chemist, it is alleged, for what purpose she intended it. Whether this was so or not, negligence would seem to have been shown in giving to an inexperienced person two such dangerous agents without due warning of the consequence of their admixture. The poor girl proceeded to mix what she had obtained directly she returned to her place of occupation, with the result of a violent explosion, which, it is feared, has destroyed her sight. She now lies in a hospital."

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be considered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[3]. Explosive Mixture.—In reply to Mr. J. W. Yeats's query on No. 3, it may give him some consolation to know that he is not the only one who has been troubled by such mixtures. On one occasion after I had dispensed the mixture, the effect of the effervescence was such that it left on the ceiling a mark which was decidedly not ornamental. It is more than three years since I met with any bismuth subnit. which produced any chemical action with soda bicarb., although I am constantly dispensing it. I found then that the only way to dispense such mixtures, was either to keep them until such a time as the effervescence had subsided, or better still to use *warm water*, which rapidly effects the decomposition. J. J. Smith, *Pharmaceutical Chemist.*

[3]. Explosive Mixture.—In reference to Explosive Mixture, query 3, I beg to state a similar occurrence happened to me on two occasions when dispensing bismuth nitr. with potas. bicarb. On one occasion the cork was driven with violence out of the bottle, and in the other the bottle burst. There can be no question this result is owing to the liberation of carbonic acid.
Wm. Proctor.

[3]. Explosive Mixture.—About three and a half years ago we dispensed the following:—

2.	Bismuthi Trisnit.	ʒiv
	Sodæ Bicarb.	ʒiii
	Tinct. Nucis Vomiciæ	ʒi
	Aqua ad	℥vi

A tablespoonful three times a day. The resulting mixture exploded in the messenger's pocket. We again dispensed it, again it exploded. Finally we got over the difficulty by allowing the bottle to stand uncorked for some time before sending it out. On mentioning the matter to the prescriber, he informed me he never heard of such an occurrence before, and had ordered it often, but he at once saw that it arose from the decomposition of the two salts, and since then has ordered the subcarbonate in place of trisnitrate in similar mixtures. J. Hallaway.

[3]. Explosive Mixture.—The nitrate of bismuth of commerce is not unfrequently acid even to the taste, owing to the incomplete decomposition of the nitrate. In such cases it has been made by washing the crystals with water, a process which yields a much more variable product than that of pouring the solution into water. The best method for getting bismuth nitrate in the pure state is to dissolve the metal in nitric acid, being careful to leave a portion of the metal undissolved, and to throw the solution into a large quantity of water. The use of the small portion of bismuth left undissolved is to keep other metals, such as copper and silver, out of the solution. The acid nitrate of bismuth which remains in solution may be afterwards thrown down as carbonate or chloride, for use as pearl powder. Bismuth has the repute of turning the skin brown, when used as a cosmetic. It seems worthy of inquiry if the effect be not due to the action of nitric acid. E. H. Holmes.

[3]. Explosive Mixture.—In this query there is evidently an error, it should be eight ounces not eight drachms. I have made up many similar prescriptions of bism. subnit. and soda carb., and never met with the occurrences described by Mr. Yeats: No doubt it (the explosion) was owing to the acidity of the bismuth and being corked so quickly. An Assistant.

[4]. AMORPHOUS QUININE.—Can you give me any information as to the *dose* and *therapeutical action* of the sulphate of Amorphous Quinine (De Vrij)? I have read all I can find about it in the Journal, but all the information relates simply to its chemical and physical properties. J. J. Smith.

[5]. ANOTHER EXPLOSIVE MIXTURE.—I should like to ask a few questions relative to a prescription. When Ung. Sulph. Hypochlor. Crass. is prescribed, what proportion of Sulph. Hypochlor. is used? What chemical article is meant? (I know the description of Sulph. Hypochlor. in Bentley and Redwood's 'Materia Medica,' also the descriptions of the chlorides of sulphur given by standard chemical works.) I think the commercial hypo. is meant, but what are the tests for this article? Having recently required a fresh supply of it, I obtained ten ounces from a leading London house, it was sent to me in a strong stoppered bottle; I put away unopened in a cupboard; two days after I heard a sharp report, and directly after scented an odour of some compound of sulphur (it was neither H_2S nor SO_2). The bottle had burst and scattered the Sulph. Hypochlor. all over the cupboard, which also contained nearly a pound of sodium as well as some potassium and liquids. The reason why this latter fact is mentioned is to show that if the explosion had had more force it would only have been the fusee to a still greater one. Has any one known Sulph. Hypochlor. burst the bottle, and what is the cause? A question similar to one of the above is sent out by the British Pharmaceutical Conference. OCCIDENT.

[6]. CHLORIC ETHER.—Would it be correct to dispense Spt. Chloroformi or Æther. Chlor. when "Spt. Æther. Chlor." is ordered? T. N. LEIGH.

[7]. SYR. QUINIÆ DIKINATIS.—Will you kindly give me the formula for Syr. Quiniæ Dikinatis. I am informed it was published by Dr. Donovan in the *Pharmaceutical Journal* many years ago, but I cannot find it.

[*** The article in which this preparation was described appeared in the first series of this *Journal*, vol. iv., p. 155. The following abstract of it is taken from Beasley's 'Pocket Formulary,' where it appears as Syr. Cinchonæ Conc.:—Digest ℥viij of yellow bark in coarse powder in two successive pints of proof spirit, and press strongly; boil the residue for half an hour with a pint of water, strain, and press; repeat this a second and third time; evaporate the mixed decoctions to f℥viij; reduce also the mixed tinctures to f℥viij; mix the concentrated liquors, and boil them with a solution of 55 grains of oxalic acid and 284 grains of dry quinine; add ℥xxj of sugar and ℥iv of gum arabic, and water q. s. to make f℥xxxij of syrup, which strain, while hot, through flannel.

Obituary.

Notice has been received of the death of the following:—

On the 6th of June, 1877, Mr. Robert Appleford Watson, Chemist and Druggist, Wilton Place, Knightsbridge. Aged 69 years.

On the 17th of June, 1877, Mr. John Shaw, Chemist and Druggist, Broughton Furness. Aged 54 years.

On the 19th of June, 1877, Mr. Edwin John Huggins, Chemist and Druggist, Wainfleet. Aged 31 years.

On the 21st of June, 1877, Mr. Henry Lawrence, Pharmaceutical Chemist, Lower Phillimore Place, Kensington. Aged 43 years.

On the 25th of June, Mr. William Edward Chapman, formerly of Queen Street, Hull. Aged 83 years. For many years Mr. Chapman was a Member of the Pharmaceutical Society.

BOOKS, PAMPHLETS, ETC., RECEIVED.

ON THE SCIENCE OF WEIGHING AND MEASURING AND STANDARDS OF MEASURE AND WEIGHT. By H. W. CHISHOLM. Illustrated. London: Macmillan and Co. 1877. "Nature Series." From the Publishers.

COUNTER PRACTICE.

Sir,—I am sure many of your readers will coincide with the opinions expressed in the communication of Mr. Wade, in your last issue, especially with the tenor of the proposed Act which he has so pertinently framed. If such a bill once passed into law, it would prove an inestimable boon to our trade, for, at present, we appear to be harassed on all sides, and the majority of our *confrères* have a hard struggle to eke out a respectable and comfortable livelihood, notwithstanding the common belief of the public, who labour under the delusion that our profits are enormous, and with that idea instilled into their minds (ignoring altogether the limited demand for drugs), constantly rave about the chemists' business being so exceedingly lucrative.

It does seem preposterous to think that we could not from behind the counter recommend anything calculated to relieve sickness, nor yet express our approval of sundry remedies when appealed to; yet any person outside the fold of pharmacy can tell his neighbour what benefit he has derived from the judicious use of a certain medicament, and recommend a trial of the same. In the face of such a lawful custom who dare dispute our rights as individuals, apart from our avocation?

So long as we do not charge for the advice given, there could be no restriction of this sort in a free country; the people would be up in arms against any such measure, and with the cry of "*pro bono publico*" stamp out the excessive legislation which threatened to destroy or check their liberty.

I heartily agree with your correspondent about the insufficient equipment of medical men for the routine of dispensing, considering the little stress laid upon that point by the faculty; all the training in that department required in their curriculum being three months' experience either in a pharmacy or hospital, a period of tuition which is quite insignificant when compared with the five years' apprenticeship supposed to be necessary to fit one as a reliable dispenser amongst ourselves. Then why, seeing they cannot efficiently perform the responsible duties connected with "compounding," should they so largely monopolize our proper work? To look on the other side of the question, although not advocating counter prescribing, I maintain that chemists, by virtue of prolonged observation, have many opportunities of learning what substances are best adapted for the cure of specific complaints, as well as the best methods of administering them, and can mark the progress the patient makes towards recovery, when under the physician's treatment; so that, even when he cannot diagnose disease, he may effect a cure if the nature of the malady be told him. I am afraid difficulties would attend the establishment of a rule prohibiting us from repeating prescriptions at the invalid's request, still there is great need for alteration is this respect. Thousands of people, it is well known, continue to renew the physic ordered at a time when the condition of the body was vastly different; the consequence is that hundreds who follow this course, instead of enjoying the greatest of all earthly blessings—good health—are always ailing, and by inducing an abnormal state of the system, gradually, but surely, undermine their constitutions, which are thereby rendered more susceptible to the contraction of other illnesses, perhaps worse than the first. I have known instance of personal injury occurring in this way in spite of the remonstrances of the conscientious chemist (which too often prove futile). The result of declining is then a demand for a copy of the formula, which is immediately taken elsewhere to be made up. Probably numerous cases of opium and chloral eating might be traced to the above cause.

I take exception, however, to that part of Mr. W.'s letter wherein allusion is made to the selection of members of Council from simple "chemists and druggists." I certainly think that no candidate should be eligible for election in the capacity of examiner, nor take a seat in the Council, unless he bear the title of "Ph. C." Then every one can pass the "Major" if he wishes to share in the "monopoly" or rather the privileges accruing to pharmaceutists proper.

JAMES B. L. MACKAY.

Newcastle on-Tyne, June 19, 1877.

Sir,—Mr. Wade's letter in the Journal of to-day is simply absurd, and for the honour of the medical profession it should not be allowed to pass without protest. To begin, there was no need of such a letter, for the obnoxious clause of Dr. Lush's bill was withdrawn, and as the bill now stands it will operate only against pretenders; rightly so too! what more do we want? There should therefore be an end of the matter.

By the withdrawal of the clause counter-prescribing is indirectly acknowledged to be legal, and Mr. Wade states that it is "granted by the Act of 1815." This he confirms by stating, in the same paragraph, "to put a stop to counter-prescribing they would have to apply to a legislature which," etc. He means, I suppose, that a law would have to be passed to put a stop to counter-prescribing, in order to make it illegal. Right! Why then does he say, in the fifth paragraph of his long letter, "the doctors would be spared the anguish of seeing the public suffering from our illegal practice?" Illegal practice! What does he mean? Counter-practice has never been illegal, and as to its producing "public suffering," I think this would be universally denied. If Mr. Wade means the practice of pretenders, then Dr. Lush's bill meets their "illegal practice." I pity the conscience of chemists if they think they act illegally when they prescribe over the counter. They could not lay claim to the title of a "law-abiding community." But do they break the law? Certainly not! All noxious pretenders, however, should be banished from society.

The absurd part of Mr. Wade's letter is seen in reference to the medical profession. He draws up "a short Act to regulate the dispensing of medicine, and to amend the Apothecaries Act of 1815." "It shall be unlawful to employ as his assistant, to prescribe, visit or perform any act of surgery, either in his absence or under his direction, any person who shall not have become qualified." How about the medical student learning his profession, the nurse, the attendant on the sick, the chemist? Such a "suggestion" needs no comment.

Mr. Wade proceeds: "It shall be unlawful for any medical practitioner, or his assistant, to dispense any medicine for any person that he may have prescribed for, in any city, or town, or village," in case there should be "a chemist within half a mile of his patient's or his own house." Monstrous! You deny a medical man a privilege which every other person in the kingdom enjoys to the full. And at the end of his letter Mr. Wade says, "I think, with such an arrangement as this, the medical men would have no reason to complain;" and a host of other advantages are to follow, which I for one fail to see.

I think the draughtsman of such an Act should at the same time have informed us what he means by an "Act of surgery," "illegal practice," and the word "dispense," the latter term he uses in more senses than one. Let the medical men alone (except to recommend them patients), and they will let us alone. Our relations with them have been very ably and rightly settled by the Council of the Pharmaceutical Society, and they are secured by our own "Act," by the Act of 1815 and indirectly by Dr. Lush's bill. Why should we then stir up the mud? Let that come from without, and when it does, I have no doubt that the Pharmaceutical Society will be equal to the task of allaying the troubled waters as it has done hitherto.

GEO. P. POND.

June 16, 1877.

Sir,—I have read with much interest the draft of that which will, of course, speedily become law, and probably be known as Wade's Act, and if so, the name of Wade will remain an evergreen on the memory of all future generations of chemists and druggists.

The intention of his proposed Act is clear and distinctly defined. The last clause of the fourth section relative to repetitions will be specially applicable, and doubtless appreciated by those who live miles from a medical man who seldom sees some of his patients, and those who for years have been in the habit of having certain prescriptions repeated as often as necessary without let or hindrance.

But, sir, in spite of all its excellences, which will make it so acceptable to all dispensing chemists, it is far from being so perfect as I think it can be made with my assistance, and proud ought I to be to help in so noble a cause, and no feelings of a false modesty or unpardonable reticence shall prevent my immortalizing myself in such a high and noble undertaking!

While the proposed Act will doubtless meet the necessities of all dispensing chemists, my case, which is but a sample of many more, will be to a certain extent unblessed by such a measure unless it is extended, and therefore I crave a space in your columns to state my case and suggest a remedy.

My business is situate near the river side of a large commercial city, where wharves, yards, works, and warehouses abound; the dwelling-houses near are densely populated by the working classes and their numerous offspring (at the present time it is said there are one hundred and twenty cases of whooping cough among the latter), so you can easily imagine the kind of business I do—general retail, prescribing, tooth extraction, and dispensing. Sometimes I bind lint or adhesive plaster upon cuts, wounds, or bruises; sometimes I plaster broken heads. Some of these cases are honorary as regards payment; sometimes promises are made for future payment. Some of the latter still remain in the indefinite future.

But all this in compliance with "Wade's Act" must of course be put a stop to, and therefore I beg to suggest that such addition as the following be made if not too late.

"And be it further enacted that from and after the 31st of December, 1877, it shall be unlawful for any legally qualified chemist to discuss with any of his poorer customers the relative advantages of dill water over peppermint water for wind in infants, or the superiorities of rhubarb (either syrup or powder), over magnesia (fluid or powder), as an aperient for children, or the merits of rhubarb pills or other pills, commonly known as or styled antibilious pills as an aperient for themselves, over sulphate of magnesia, commonly styled Epsom salts; neither shall it be legal for him to answer any question whatever, however simple, or dire the necessity, or render assistance of any kind which ought to be obtained from a medical man; and failing to observe the provisions of the law for each offence he shall pay," etc.

"And be it further enacted, That no legally qualified chemist shall apply any remedy to allay toothache, or upon any pretence whatever extract a tooth; neither shall he apply any remedy to allay any pain whatever, no matter from what cause it proceeds; neither shall he apply lint, adhesive plaster, or in any other way render assistance in any cases of cuts, burns, or bruises that may be brought under his notice." [To make this section more binding it might be made punishable with fine or imprisonment]. "And be it also enacted that no legally qualified medical man shall under any pretence whatever keep drugs, lint, or plaster at hand, in case of emergency, but all shall be procured from the nearest legally qualified chemist, unless he resides more than five miles therefrom; in which case he shall be licensed to keep such remedies and in such quantities as shall hereafter be determined upon by special Act of Parliament; neither shall he be expected to prescribe in any case, or answer any question without a fee, which he shall be enabled to demand beforehand if he has any doubt in his mind as to whether his patient has it in his or her pocket ready at hand."

I have not thought it necessary to insert any clause making any of these things penal (except where it is specially mentioned), as there would not be any occasion for them so to do.

With these trifling additions I think the Act will be as near perfection as possible. Doubtless it will cause much anxiety, pain, loss of time, and even in some cases death. Still these will be trifles light as air (as medical man and chemist will, of course, be held legally free from all that may occur by the provisions of this Act being strictly carried out) in comparison with the greater blessings of our "taking pride in the elevation of our business and a place in society befiting our education."

YECAPNHOJ.

Bristol, June 26, 1877.

The Council Prizes.

Sir,—As the time is near at hand when the Council prizes annually offered for competition to those who have passed the Major examination during the preceding year will be competed for, permit me to express, through the medium of your columns, an opinion which is pretty generally held on this side of the Tweed, and certainly by all to whom I have spoken on the subject. Last year, a complaint was raised that out of all who were eligible to compete for these prizes, so few entered the lists. An examination of the papers then set will not, I think, tend to draw out more candidates. Surely the questions should have been intimately connected with the subjects of the Major, yet, in many cases they seem to be far separated from these. For instance, in materia medica we have, "What are the alkaloids yielded by the plants of the order Melanthaceæ, and how are they distinguished?" Now truly, many Major men might answer the first half of the question, at least with regard to the more important plants; but I venture to think that but very few (excepting those who have studied in a London school of pharmacy) would be competent to answer that second half. I know from experience that even a course under Professor Sir Robert Christison, for so many years the distinguished professor of materia medica in this city, would not assist in this matter, and how then is a country pharmacist to manage? Certainly "cram" is the only door open. Again,—"Describe the drugs imported as pareira, and state how they are distinguished."

This smelt strongly of the 'Pharmacographia,' but is not to be found in Scoresby Jackson, the common text-book in this unenlightened part of the country. While I uphold, as strongly as any, the advantages of making the "Major" and its connections as scientific as possible, I still think that catch questions and such as can only be answered after a special course, should be avoided and are unfair to provincial and Scotch candidates alike. Science, while it deals with minutiæ, has always first striven to establish the great general features, and so it should be with pharmacists. Surely in the wide field of materia medica there is ample scope for scientific searching questions, without being compelled, out of four, to give the two already mentioned, and another belonging more to chemistry than to materia medica, "How would you detect the adulteration of essential oil of almonds with nitro-benzol?"

With the other two papers, viz: Botany and Chemistry, little fault can be found, as although not easy, they are fair questions, if we except the following, "What is the average composition of coal gas?" If by this is meant merely, a very rough approximation, good and well, but if a percentage composition is required, many a scientific chemist would fail to give it. Why? Simply because it is a matter of no consequence to remember. One may as well ask for the atomic weights of all the rarer elements. I trust that, although not coming from a Major associate, these remarks may not fall amiss to those who frame the next set of questions, but that they will remember that they being entirely chosen from the London Board of Examiners, to the utter exclusion of the Scotch board, matters with which they and London students are perfectly conversant are not necessarily of importance, and therefore not so well known in other cities, and that if the examiners were all Scotch and did not give general but catch questions, the Englishmen might find themselves non-plussed.

Edinburgh, June 20, 1877. Auld Reekie.

Castor Oil Pills.

Sir,—The police of Hampshire are just now scouring the county for the purpose of capturing as many samples of "castor oil pills" as they can effect, in order that the county analyst may test if they are being sold "genuine" or "adulterated."

I am no advocate for misnomers, and wish no druggist would frame any; but surely no one outside an asylum for lunatics or idiots can imagine that a little globule about the size of a large pin's head can possibly be made of castor oil, the well-known ordinary dose of which is half a large wine-glassful! The Adulteration of Food and Drugs Acts were passed to prevent the public being defrauded or damnified by the admixture of a cheaper and inferior foreign article with the genuine one. But here no one is either damnified or defrauded. The pills, though called "castor oil pills," are simply intended as, and understood to be, a very mild and gentle laxative in pill form, the use of which may avoid the necessity of taking the nauseous purgative oil.

I recently ordered of my tailor a top coat, and pair of trousers, and chose from his pattern book what he told me was a "beaver" for the one, and a "doeskin" for the other. Both garments appear to be made of sheeps' wool. I have not examined them microscopically—certainly neither is made of the skin of the animal with whose name it is identified in the account rendered me. Were I to enter an action against the tailor, contending that he has consequently defrauded me, the ludicrousness of my act would be about on a par with this Hampshire raid on castor oil pills! The druggists of this unfortunate county must be prepared for harass of no ordinary kind. Probably the next step will be to prosecute them for professing to sell plasters spread on "moleskin," which, instead of being made of a mole's skin, is nothing but cotton!

Southampton. Robert Chipperfield.

"No Dissenter Need Apply."

Sir,—Your correspondent, "Equality," infers so much animus "in the meaning of an advertisement in a recent number," that I had the curiosity to refer to it, and I found it in the advertising sheet of the Journal, for June 2, 1877, p. xviii.

I know nothing whatever of the advertiser or of his business, but it appears as if he had some good customers, who are churchmen, and if he were succeeded by a stiff dissenter these customers might go over to some opponent.

It is evidently intended to appear as a tempting opportunity for a pharmacist who happens to be a churchman. This may, or may not, be true; and the pharmacist may safely rely on his knowledge of the business and on his honesty.

But "Birds of a feather, flock together," and I suppose baptists may go to baptists, Scotchmen to Scotchmen, churchmen to churchmen, etc., if they think proper so to do.

Fraternity.

G. Andrew.—If you are in possession of such information as to breaches of the Pharmacy Act as will secure a conviction, you are recommended to communicate at once with the Registrar, 17, Bloomsbury Square. We believe inquiries are already being made respecting the case referred to.

"*Herba.*"—(1) *Centaurea nigra*; (2) *Apargia hispida*; (3) *Chiococca racemosa*, not indigenous; (4) *Rhinanthus Christa-galli*; (5) *Bryonia dioica*; (6) *Torilis nodosa*.

C. T.—*Polemonium cœruleum*, *β album*.

J. W.—There is not at present any legal obstacle to such a course.

"*Spes.*"—'A Manual of Dental Mechanics,' by O. Coles (Churchills), price 7*s.* 6*d.*

Justicia.—By the 16th section of the Pharmacy Act, the "business of wholesale dealers in supplying poisons in the ordinary course of wholesale dealing" is exempted from the provisions of the previous sections.

S. G.—(1) You will find ample information in the "Students' Numbers" of the medical journals published just before the commencement of the session. (2) There is nothing to prevent such an arrangement being made.

H. L.—We entirely disagree with the opinions you express, and think that harm is rather done by pharmacists charging too low for the exercise of their skill in the most legitimate part of their trade, namely, dispensing. It is not so much to have medicines dispensed that people go to the stores, as to purchase articles for the sale of which no skill is required.

"*Stellaria.*"—(1) *Geranium dissectum*; (2) *Epilobium montanum*; (3) *Myrrhis odorata*; (4) *Veronica arvensis*; (5) *Stellaria graminea*.

J. Hope.—(1) *Chiococca racemosa*: (2) *Linum catharticum*; (3) *Stachys sylvatica*.

F. G. Walton.—*Habenaria viridis*.

E. F. Jarvis.—A formula for Syr. Calcis Lactophosphatis will be found on p. 1041.

W. Greig.—*Marking Ink.*—Try the following, from the 'Chemists and Druggists' Diary.'—Nitrate of Copper, 3 parts; Carbonate of Soda, 4 parts; Nitrate of Silver, 8 parts. Mix and dissolve in Liq. Ammon. 100 parts.

Communications, Letters, etc., have been received from Mr. Evans, Dr. Hesse, Messrs Mawson and Swan, Dr. Cooke, Mr. Baynes, Mr. Sindall, Mr. D. Howard, Mr. Baker, Mr. Hooper, Occidens, One Interested, An Assistant, Delta, J. A. C. B.
