18·5 grms. menthene, from solid Japanese camphor, on oxidation in a current of air at a temperature of 60°C., in the presence of 100 c.c. water, gave a solution in which the amount of peroxide of hydrogen was estimated by the iodide of potassium method after forty-four hours, and found to = 0·09114 grm. H_2O_2. A further amount was produced on continuing the oxidation. Meanwhile the oil grew yellow and thick, but was not examined on account of the small quantity. The aqueous solution contained also acetic and formic acids, which were identified by the usual test, and further an oily body which was deposited on concentration. This last body on oxidation with strong nitric acid (1 : 1) gave a yellow solution which was neutralized by soda, and this solution was found to give a barium salt insoluble in water, and also a precipitate with nitrate of silver. This silver salt on heating deflagrated, and was found to contain more than 64·45 per cent. silver (a little was perhaps lost). A small quantity of menthene derived from *liquid* Japan camphor by the action of zinc chloride gave similar results to those above ascribed to menthene from *solid* Japan camphor.

This limited inquiry exhausted my supply of menthene, nevertheless it supports the conclusion I stated in the third part of these researches (*Chemical News*, vol. 32, p. 138), to the effect that all bodies having cymene as a proximate nucleus give peroxide of hydrogen on oxidation by air. For Dr. C. R. A. Wright has (*Journ. Chem. Soc.*, series 2, vol. xiv p. 2) by the action of bromine upon menthene, succeeded in obtaining a terpene from it in the *first* place, and on further bromination, cymene. I have also demonstrated that clove terpene $C_{15}H_{24}$, by the fact that it fails to give peroxide of hydrogen on oxidation, *does not* contain cymene as a proximate nucleus. And more recently Wright has supported this statement, by showing that clove terpene gives no cymene by the action of bromine. Regarding cymene (paramethylpropyl benzene) (C_6H_4 (CH_3) (C_3H_7) as a hydrocarbon constituted of proximate nuclei, I was led by a study of the subject to consider the possibility of obtaining peroxide of hydrogen by the atmospheric oxidation of suitable compounds containing methyl, propyl, etc. And for the obvious reason that the ethers may in a sense be considered as oxides of the hydrocarbon radicles of the marsh gas series, I fixed upon them for my first experiments.

Ordinary ethylic ether has for long been credited with the power of producing ozone, but beyond this, the subject was at the time I commenced my investigation in a similar state of mystery as that which surrounded the so-called formation of ozone by the oxidation of essential oils. That is to say nothing was known about it, beyond that there had been recognized under these conditions a principle which was mistaken for ozone, and of whose production there was no reasonable theory.

I do not propose to relate in detail, my experiments, which are necessarily incomplete, but shall only state that ethylic ether gives apparently, by atmospheric oxidation, acetic ether and certainly peroxide of hydrogen. This latter I have obtained in estimable amount, but this subject presents great difficulty in working, on account of the volatile nature of the ether, and most of its compounds and derivatives.

The following equations may possibly represent what occurs when ethylic ether is oxidized in the presence of water in the way I have described.

$$(1.)\ \left.\begin{matrix} C_2H_5 \\ C_2H_5 \end{matrix}\right\} O + O_2 = \left.\begin{matrix} C_2H_3O \\ C_2H_5 \end{matrix}\right\} O + H_2O$$

$$(2.)\ \left.\begin{matrix} C_2H_3O \\ C_2H_5 \end{matrix}\right\} O + O_3 = \left.\begin{matrix} C_2H_3O \\ C_2H_3O \end{matrix}\right\} O_2 + H_2O$$

$$(3.)\ \left.\begin{matrix} C_2H_3O \\ C_2H_3O \end{matrix}\right\} O_2 + 2H_2O = \left.\begin{matrix} C_2H_3O \\ H \end{matrix}\right\} O + \left.\begin{matrix} C_2H_3O \\ H \end{matrix}\right\} O + H_2O_2$$

or (3.)

$$\left.\begin{matrix} CH_3CO\ O \\ CH_3CO\ O \end{matrix}\right\}\begin{matrix} H\ HO \\ H\ HO \end{matrix} = \left.\begin{matrix} CH_3CO\,OH \\ CH_3CO\,OH \end{matrix}\right\} + \left.\begin{matrix} HO \\ HO \end{matrix}\right\}$$

These equations may be explained as representing—

(1) The oxidation of ether into acetic ether and water.

(2) The oxidation of ether into the anhydride, and that into the peroxide.

(3) The decomposition of the latter with water, simultaneously with its formation.

I believe that we must assume the formation of acetic peroxide, a body which as yet has only been prepared by Brodie by acting on acetic anhydride with barium peroxide.

In my experiments it would appear that ordinary atmospheric oxygen plays the same part as the oxygen of the barium peroxide in Brodie's method.

If this be so, the mode by which the peroxide of hydrogen is assumed to be formed would give strength to my theory regarding its production from turpentine, which may be represented first as its oxidation into camphor (corresponding to ether); secondly, the oxidation of this body into camphoric anhydride, and the anhydride finally into the peroxide which is slowly decomposed by water.

I have observed these properties and isolated the products of its change by water, but have not succeeded further.

My method of experiment I hope at no distant period to apply to all the ethers available. Meanwhile the preliminary results I have obtained in this new direction already foreshadow a system of classification of the terpene derivatives.

Finally, I submit that the production of peroxide of hydrogen from camphoric peroxide (in the case of turpentine), and acetic peroxide (in the case of ether), amounts to a demonstration of the existence of the radicle hydroxyl in compounds.

The PRESIDENT said the paper just read appeared to be one extremely well suited for a meeting of the Conference. In the first place the subject treated of had an important bearing on the interests of pharmacists. Mr. Kingzett had shown that the products of oxidation of these bodies possess, in a high degree, antiseptic properties. He considered, also, that this paper was valuable and very suitable as a communication, from the fact that it indicated the great importance of carrying out systematically and scientifically the complete investigation of what takes place in processes such as are referred to. For instance, as long as twenty years ago he had seen Faraday demonstrating in his way to the extent of the knowledge then possessed the presence and production of ozone, which was thought to occur during the oxidation of these bodies, and until comparatively recently it had been assumed that ozone was the body produced. But by further and more perfect investigation it was now demonstrated to us that not ozone, but peroxide of hydrogen was the body which exists in these products.

Dr. TILDEN asked if the author had ascertained whether any change had taken place in the atmospheric air used during the performance of these experiments.

Mr. GROVES asked whether the products of oxidation had a decolorizing action.

Mr. KINGZETT: Yes. He thanked the President for the remarks he had made upon the paper, for it was often said concerning such investigations, *cui bono?* The study of the question had led him to a satisfactory reply to that question. He and a scientific friend had patented this solution and intended to manufacture it so that those who were interested in the matter might have an opportunity of studying its value. With regard to the question of Dr. Tilden, he had proved in the first part of these researches that there was no ozone formed in these oxidations. As regards the many other applications to which this solution might be applied, Mr. Groves has pointed out one—decolorizing. A provisional protection had been obtained and he hoped to continue the study as regards the application in this way.

The Therapeutic Value of the Aloins.

BY WILLIAM A. TILDEN, D.SC., F.C.S.

At the last meeting of the Conference I brought forward the results of the analysis of barbaloin and socaloin and some of their derivatives. My experiments led me to the conclusion that these two bodies, although differing in chemical and some physical properties, have nevertheless the same composition, which is represented by the chemical formula $C_{16}H_{18}O_7$. They unite, however, with different proportions of water of crystallization. These results have since been confirmed by the observations of Dr. Ernst Schmidt of Halle. Nataloin differs altogether in properties and constitution from both barbaloin and socaloin, notwithstanding that it contains nearly the same proportions of carbon and hydrogen.

The fact that the crystalline constituents of the several varieties of aloes are different substances is now generally recognized. It therefore occurred to me that it would be desirable to ascertain if these substances were possessed of equal power as purgatives; especially as socotrine and Barbadoes aloes are constantly prescribed indiscriminately, and some difference of opinion had prevailed regarding the action of barbaloin.

I, therefore, begged Mr. Nelson C. Dobson, F.R.C.S., to undertake the administration of these crystalline principles in a sufficient number of cases to make conclusions based upon them tolerably secure. He has recorded his observations made in fifty cases in the Bristol General Hospital and his results have been published in the *Medical Times and Gazette* (Aug. 12, 1876), and in the *Pharmaceutical Journal* (Aug. 19, 1876).

It remains for me only to point out the conclusions at which Mr. Dobson has arrived. They are as follows:—

Barbaloin in doses under two grains frequently produces some slight laxative action. Two grains cause a decided effect, never, however, amounting to complete purgation.

Socaloin and nataloin seem to be less active than barbaloin, four grains having been frequently given without producing more than slight effect.

All three are decidedly uncertain and variable in their action, and seem to present no advantage over an equal dose of aloes, except perhaps that griping was rather less common than when aloes alone was given.

The superior activity of barbaloin seems to justify the apparently general preference for Barbadoes over the other varieties of aloes.

The President said no doubt it would be the pleasure of the Conference to return thanks to Dr. Tilden for the investigation he had been making into this practical subject. The observations which had been made with reference to the therapeutic value of the chemical compounds obtained from aloes had a considerable amount of interest to pharmacists as tending to show that at any rate there are some medical substances obtained from the vegetable kingdom that are perhaps as advantageously administered in the form in which they are got directly from their natural sources as after they have been submitted to chemical processes by which more definite chemical compounds were extracted from them. The investigation which had been made with reference to aloin separated from aloes was an important as well as an interesting investigation. Probably the investigation of some other substances, such as senna and rhubarb, would lead to very similar results. Whatever bodies of a chemical nature might be extracted, might not to any sensible extent be possessed of properties more advantageous than those found in the substance in its natural condition. Of course they were not to be discouraged on this account from making investigations in those directions, but rather might make a practical application of the result of the investigation pharmaceutically. There were many substances which might be included in the category with aloes, and while they investigated them as pharmacists, their practical object would be to ascertain what forms could be obtained which were most suitable for medicinal use. He knew some pharmacists had been using aloin with the view of obtaining more activity—getting a more decided action—than aloes themselves would afford. It did not appear however that the experiments which had been made were such as to fully justify that expectation.

Mr. Stoddart said he could confirm what Dr. Tilden had said. He had taken, with little effect, a dose of this aloin at the suggestion of a native of that part of the world who considered that aloin was better than aloes.

Mr. Proctor said he had prepared aloin from Barbadoes aloes, and had taken doses of the aloes and its separate constituents, that is the insoluble portion, the uncrystallizable extract and the aloin. He found they all acted almost equally as regards their purgative properties. He fancied the resinous matter was a little more griping, but he confessed he found the experiment rather unpleasant.

Mr. Groves said that the experiments of Dr. Dobson seemed to show that aloin and crude aloes did not differ much in their effects except that the latter was rather the more griping. In his own experience the extract of aloes had a very innocuous action in regard to hæmorrhoids, as compared with crude aloes. He had a client who was in the habit of taking pil. rhei co., and was perfectly able to distinguish by the effects when crude aloes was used and when the extract.

The next paper read was on—

The Solubility of Cinchona Principles in Glycerine.

BY F. ANDREWS.

A notice of the solvent powers of glycerine upon Peruvian bark having lately appeared in the *Pharmaceutical Journal* and the *Chemist and Druggist*, an account of a few observations made by myself, although very fragmentary and incomplete, may perhaps prove interesting.

Some months ago I had occasion frequently to mix tincture of bark with glycerine. As the mixture remained perfectly bright, it occurred to me that perhaps glycerine might prove as good a solvent of the cinchona principles as the spirit, and I therefore made the following experiment:—4 ozs. of yellow bark in coarse powder were mixed with 4 fl. ozs. of rectified spirit, and digested for several days; the mixture was transferred to a percolator, and spirit added until 4 fl. ozs. of a very strong tincture of bark had passed through. This was mixed with an equal quantity by measure of glycerine and the spirit evaporated. There remained 4 fl. ozs. of a thick syrupy liquid, dark brown in colour, and having the peculiar bitter and astringent taste of Peruvian bark in the highest degree; it was perfectly bright and entirely without deposit, showing that the glycerine had retained all that had been dissolved by the spirit. I then thought it would prove important to find whether there was anything further left in the bark that could be extracted by glycerine, and therefore poured water into the percolator until upwards of eight pints had passed through and the percolated liquid was colourless and tasteless. The apparently exhausted bark was then placed in an evaporating dish and 4 fl. ozs. of glycerine stirred in; the mixture was heated slightly and allowed to stand a day or two, again transferred to the percolator and water poured through until about a pint of turbid brownish liquid was obtained; this was evaporated to 4 fl. ozs., the result being a brown syrupy fluid, having the peculiar taste of glycerine, but with very slight bitterness or astringency.

Several experiments were then made by the direct action of glycerine upon powdered bark; percolation was tried but was so slow as to be practically useless, and finding upon trial that quinia and its sulphate were soluble in warm glycerine and were not precipitated from solution upon the addition of water, the following process was adopted as the best:—

Four ounces of coarsely powdered yellow bark were mixed with eight fluid ounces of glycerine, heated for a short time over a water-bath, and allowed to stand till cold; water was added in successive portions, and strained or pressed out until there appeared no extractive left; the whole was then evaporated to eight fluid ounces—the original bulk of the glycerine. This liquid, carefully made, appears to contain in each fluid ounce the whole extractive matter of half an ounce of Peruvian bark, and might, I think, be appropriately termed Glycerinum Cinchonæ.

The PRESIDENT said this was a useful and practical communication for which he was sure, as practical men able to appreciate it, they would be anxious to return thanks to the author.

Mr. CLEAVER asked whether the liquid obtained by the treatment precipitated on the addition of water.

Mr. MARTINDALE said that there was a similar preparation included in the United States' Pharmacopœia. He had kept it for three years and had had an opportunity of observing its keeping properties. It had this disadvantage, that on being kept for some time it became converted into a kind of jelly; it did not deposit, but got into a peculiar gelatinous condition. It mixed tolerably well with water. It took out more of the constituents of the bark, but whether in doing so it took more of the active alkaloid he did not know. It contained, however, more of the astringent matter than the B.P. fluid extract did.

Mr. EKIN said the gelatinous condition to which Mr. Martindale referred in the United States preparation was probably due to quinovic acid.

Mr. ANDREWS in reply said the preparation precipitated slightly but not so much as the ordinary tincture. With respect to the assay of the bark, that which he had used was fully up to the Pharmacopœia standard. He had intended to have made an assay of the bark after the extraction by glycerine, but had not yet been able to do so. There certainly was a trace of bitterness left, but it was very slight.

The next paper read was on—

ESSENTIAL OIL OF SAGE.

PART I.

BY M. M. PATTISON MUIR, F.R.S.E.,

Assistant Lecturer on Chemistry, The Owens College, Manchester.

Through the kindness of the Executive Committee of the Bell and Hills Research Fund, who placed a small grant at my disposal, I have been able to commence a research into the chemical nature of essential oil of sage. I have now the honour of submitting the first part of this investigation to the Conference, and can only express my regret that the time at my command has been too limited to allow me to do more than make a hasty survey of the field of investigation. From the results already obtained I am confident that future researches, which I hope to make and to communicate to the Conference, will be not altogether wanting in interest.

1. The only notices which I can find bearing upon the subject of the present paper are those enumerated in Gmelin's handbook. So long ago as 1811, Ilisch* appears to have made a few desultory experiments upon oil of sage, but without any very definite results. Herberger,† Rochleder,‡ and Zeller§ added but little to what was known; they seem to have contented themselves with qualitative experiments relating to the action of various reagents upon the oil, and to very partial fractionation and determination of the carbon and hydrogen in the various fractions.

2. The oil upon which I have worked was obtained from Messrs. Wright, Layman, and Umney, of Southwark Street, London: it was by them believed to be a genuine sample. The oil is obtained by distilling sag (I believe *Salvia officinalis*) with water. I was unfortunately unable to ascertain the age of the sample.

The oil was of a yellow-brown colour without any shade of green. According to some of the authors quoted above, sage oil, especially when prepared from young plants, has a green colour changing to brown. The smell can only be described by saying that it was intensely sage-like; the taste was hot and burning; the reaction was neutral.

3. A quantity of the oil was allowed to remain in a loosely covered vessel for several months; it did not deposit any solid matter, neither did it become resinous; the reaction remained neutral.

4. The oil readily absorbs oxygen from the air; a quantity of oil, about 80 c.c. was allowed to stand in an inverted tube containing air, and placed in sunshine. After two days the level of the oil in the tube showed that the oxygen (about 4 c.c.) contained in the confined air had been entirely removed. On testing the oil with paper soaked in starch paste and potassium iodide solution a blue coloration was produced, but only after some time.

5. Concentrated nitric acid acts most energetically upon sage oil with the production of a red semi-resinous body; this action is explosive in its violence if the oil and acid be shaken together.

6. Strong sulphuric acid causes the production of a brownish-red, semi-viscid mass; by this action much heat is developed and sulphur dioxide is evolved. If the semi-solid mass be allowed to remain at rest for twenty-four hours and water be then added, and the liquid submitted to distillation in a current of steam, a distillate is obtained, the oily portion of which when separated from the aqueous part, and dried, boils for the most part between 215° and 225°; this distillate appears as a heavy yellow-coloured oil; it is most probably a polymeride produced by the action of the sulphuric acid upon the hydrocarbons present in the original oil.

The greater portion of the product of strong sulphuric acid upon the oil remains behind after distillation in steam, in the form of a very thick black resin, which becomes almost solid after standing in the air for some time.

7. On passing dry hydrochloric acid gas into a portion of the oil, it darkened in colour, becoming finally reddish-brown; heat was evolved, and considerable quantities of the gas were absorbed. On submitting the product to distillation, after washing with dilute caustic soda, and repeatedly with water, the greater portion boiled between 195° and 200° and presented the appearance of a light-yellow liquid with a peculiar, somewhat ethereal odour; this liquid darkened slightly after standing in diffuse sunlight. Portions of the oil saturated with hydrochloric acid were allowed to remain at rest for some days, both alone and also mixed with water, but in no case was any solid matter deposited.

Another portion of the oil was surrounded with a freezing mixture, whereby the temperature was maintained at—10° to—15°, and was then saturated with hydrochloric acid gas. As in the former experiment the oil darkened in colour, until it had become reddish-brown. No solid substance was formed, nor did any separate out on standing. After washing as before and distillation, two liquids were obtained, one boiling from 195° to 200°, and the other from 205° to 210°. Whether these actually represent two separate chlorhydrates, I am not as yet prepared to say. These liquids were light-yellow in colour, their reaction was neutral, they were lighter than water and were not decomposed by shaking with water whether hot or cold. Only after prolonged agitation and washing with water the reaction of the liquids became very slightly acid. Ribaw* proposes to adopt the behaviour of the various isomerides of the formula $C_{10}H_{16}HCl$ with water as a means of distinguishing them from one another. Some of these chlorhydrates are decomposed

* *A. Tr.*, 20, 2, 7.

§ Stud. über äther, oele. Landau, 1850.

* *Bull. Soc. Chim.* [2], xiv., 241

by mere contact with moist air, others by contact with water, etc. The chlorhydrates derived from sage oil appear to possess a great degree of stability in this respect.

8. The specific gravity of the oil determined at 14° C. was found to be 0·9339.

9. A portion of the oil, when mixed with about half its volume of water, the same quantity of strong nitric acid, and one volume of alcohol, became dark-red in colour, and after some days separated into an under light-yellow and an upper dark-red layer. No solid matter was, however, deposited after two months' standing, and at the expiry of that time the two layers had re-united.

Proximate Constituents of the Oil.

10. On submitting the oil to distillation, a small quantity of water came over; after the removal of this, distillation began at about 170°; four-fifths of the whole quantity of oil distilled between this point and 215°, the greater portion boiling between 175° and 195°. That portion which boiled below 190° was treated with sodium, which caused the formation of considerable quantities of red resinous matter, and again distilled: about four-fifths of the whole again passed over below 190°, leaving a semi-solid red gelatinous mass which dissolved in ether to form a brown coloured liquid with a slight green fluorescence.

11. The fraction boiling at about 190° deposited a small quantity of solid matter after standing for some time; it was therefore exposed to the cold of several successive days and night during a rather severe frost, whereby a larger quantity of solid matter was separated. This solid substance was separated from the liquid, pressed between paper, and set aside for further examination.

12. That fraction obtained in the first distillation of the oil which boiled above 190° was now submitted to fractionation without being treated with sodium; the greater portion came over below 210°. After repeated fractionation and removal of the solid matter which separated out on standing, the main portion of this liquid boiled between 198° and 203°.

After each fractionation, however, a considerable quantity of resinous matter remained in the flask, and it was only when this had been repeatedly removed that it was found possible to distil the liquid entirely below 208°. It would thus appear that the liquid contains compounds which become polymerized by the action of heat alone: in this respect it agrees with the behaviour noticed in the case of many other essential oils.

13. After repeated distillation over sodium, the fraction which on the second distillation boiled below 190° was entirely split up for the most part into two portions, a smaller, boiling from 156° to 158° and a larger, boiling from 166° to 168°. During the fractionation a very considerable quantity of yellow-red resin was formed, chiefly it seemed by the action of the sodium upon the oil. This resin was decomposed with water, the oil was separated, dried, and again fractionated; from the portion of higher boiling point a large quantity of the solid matter already noticed separated on standing at the ordinary temperature.

14. In the first distillation of the oil, boiling was discontinued when the temperature reached 215°; that which remained was a thick very dark coloured liquid. This liquid was now submitted to distillation: about one-half distilled below 250° leaving a semi-solid nearly black mass in the retort. On fractionating the distillate solid matter was deposited from those fractions which boiled below 220°, but not from the higher fractions: after the removal of all matter volatile below 240° a dark brown liquid with distinct green fluorescence remained in the flask.

15. The oil was thus separated into four, or perhaps into five main portions.

(1) A liquid boiling at 156°–158°.
(2) A liquid boiling at 166°—168°.
(3) A liquid boiling at 198°—203°.
(4) A solid deposited chiefly from those fractions of the oil boiling from 190°—220° and perhaps,
(5) A heavy fluorescent liquid boiling about 240°.

The resinous matter which remained behind was very probably produced, or at any rate partly produced, by the polymerizing action of heat upon the original constituents of the oil.

16. I shall now describe the results of the examinations of these different constituents of the oil so far as they have yet extended.

That portion of the distillate which boiled from 156° to 158° was fractionated until the greater portion boiled constantly at 157° to 157·5° (thermometer surrounded with vapour, and barometer at 760 mm.). The liquid so obtained was perfectly colourless; it had an exceedingly slight odour of sage, its specific gravity was 0·8635 at 15 C

Action of Bromine upon the Terpene of lower boiling point.

17. Twelve grams of this liquid, placed in a flask, surrounded with snow and ice, were subjected to the action of bromine, added drop by drop, through a capillary tube. The bromine was very rapidly absorbed, a hissing noise being produced on the addition of each drop. When no further absorption appeared to take place, it was found that the liquid weighed 25 grams. In order to convert 12 grams of $C_{10}H_{16}$ into $C_{10}H_{16}Br_2$, 14 grams of bromine (in round numbers) are required: 13 grams were used in the foregoing experiment. The liquid thus obtained was a heavy colourless oil. On submitting it to distillation torrents of hydrobromic acid were evolved, and a nearly colourless liquid came over, which, however, quickly darkened, until of a reddish-brown colour. On attempting to distil this liquid, it was again decomposed, yielding hydrobromic acid, a distillate boiling from 175° to 180°, another and heavier portion boiling from 220° to 240°, and a considerable quantity of black resin. This process was repeated several times with the same result, nevertheless the greater portion of the liquid eventually distilled between 220° and 240°. That fraction which boiled between 175° and 180° gave all the qualitative reactions for cymene.

I have not yet performed a combustion of that portion of the distillate from sage oil boiling at 157°, but from its reactions I have no doubt that the liquid is a terpene of the formula $C_{10}H_{16}$. Like the other terpenes of this formula, the lower boiling terpene from sage oil appears to be readily converted into a dibromide, which is decomposed by the action of heat with the formation of cymene. This decomposition does not, however, take place with so great facility as has been noticed in the case of other terpenes of higher boiling points.*

Does the Terpene of lower boiling point contain Cymene?

18. About 20 grams of the liquid boiling at 157° was surrounded with a freezing mixture, and concentrated sulphuric acid was added drop by drop, the liquid not being allowed to become warm. A very small quantity of sulphur dioxide was evolved, and a deep-red semi-solid mass was formed. After twenty-four hours this was distilled in a current of steam, the distillate was dried and fractionated, the greater portion boiled between 175° and 178° and gave the reactions of cymene. In this way about 7 per cent. of cymene was obtained.

Oxidation of the 157° Terpene.

19. About 25 c.c. of the liquid was subjected to the action of 2 litres of boiling chromic liquor, containing 10 per cent. of potassium dichromate, and sulphuric acid sufficient to saturate the bases present. After thirty-seven hours, the boiling was stopped and the small quantity of solid matter which floated on the surface of the liquid was collected, washed with hot water, dissolved in boiling ammonia and reprecipitated by means of hydrochloric acid. It gave the reactions of terephthalic acid. The liquid when distilled showed the reactions for acetic acid.

* See Wright 'On Isomeric Terpenes.' *Chem. Soc. J.* [2], xi., 694.

Reactions of the Terpene of higher boiling point.

20. That portion of the original distillate which boiled from 166° to 168° was fractionated until the greater part boiled constantly from 167° to 168° (thermometer surrounded with vapour; barometer 760 mm.). The liquid so obtained had a somewhat more pronounced odour of sage than the fraction which boiled at 157°. The specific gravity was 0·8866 at 15° C. A portion treated with bromine reacted in a manner very similar to that already described in the case of the terpene of lower boiling point. Only, on distilling the brominated liquid it was very readily and almost entirely split up into hydrobromic acid and what appeared, from its reactions, to be cymene. Treatment with sulphuric acid, the liquid being carefully kept cold, resulted in the formation of a semi-solid mass from which about 8 per cent. of cymene was obtained by distillation in steam and fractionation of the distillate.

This terpene, for such it doubtless is, yielded on oxidation (which was carried out exactly as in the case of the terpene of lower boiling point) a considerably larger quantity of terephthalic acid than was obtained from the 157° terpene.

Oxidized Constituents (?) of the Oil.

21. I have as yet separated so small a quantity of that fraction of the oil which boils from 198° to 203° that I am not in a position to describe its properties. It is a nearly colourless heavy liquid, with a very strong odour of sage; it does not become sensibly darker on exposure to air. I have little doubt that this substance represents the liquid oxidized constituents of the oil. I propose for it the name of *salviol*.

22. The solid which separated from the higher fraction of the oil was dried by pressure between blotting paper. As thus purified it closely resembles ordinary camphor, both in appearance, smell and taste; it has, however, a peculiar sage-like odour, which ordinary camphor has not. This sage-camphor is soluble to a very slight extent in water; it swims upon the surface of water and exhibits the peculiar rotatory movements of camphor. It is soluble in alcohol—from which solution water precipitates it in the form of white flakes—in chloroform and in ether. Nitric acid dissolves sage-camphor with the evolution of small quantities of lower oxides of nitrogen; from this solution water throws down a white precipitate. Sulphuric acid dissolves it with difficulty, and hydrochloric acid only after continued boiling.

If sage-camphor be dissolved in chloroform, and bromine be then added, and the liquid be placed over strong sulphuric acid, light cream-coloured crystals are deposited having a bromine-like odour, and melting at 132°—133°C.

By sublimation sage-camphor is obtained in exceedingly beautiful crystals. The mean of several determinations of the melting-point of these crystals was 187° C., and of the point of resolidification 177° C.

23. I hope to continue this investigation, and to present a report of work done to the next annual meeting of the Conference. I shall endeavour more particularly to study the physical properties of the constituents of sage oil with a view to throwing some light on the questions of isomerism.

The PRESIDENT said this must be taken as the commencement of the investigation. As Mr. Muir had stated, the investigation had to be carried much further. They would of course be glad to have a determination of the composition of some of these products, and something more than a mere inference or opinion that they possess the properties and characters which Mr. Muir assigned to them. All this would probably come in subsequent communications.

Mr. KINGZETT suggested that in the portion boiling at 167°, there was cymene existing in a free state.

Dr. TILDEN asked what proportion of terpenes was obtained from the oil, and whether they existed in considerable quantity. He did not hear whether they formed the main constituents of the oil or whether the oxides constituted the main part.

Mr. MUIR, in answer to Mr. Kingzett, said the portion of higher boiling point almost certainly contained cymene, as was shown by the action of strong sulphuric acid upon the carefully cooled liquid, and subsequent distillation in steam. In answer to Dr. Tilden, he said the greater portion of the oil consisted of the oxidized constituents, liquid and solid, of the terpenes; that boiling at 167° was present in larger quantity than that of lower boiling point.

(To be continued.)

Parliamentary and Law Proceedings.

POISONING BY LAUDANUM.

On Monday last an inquest was held at the Davenport Hotel, Middlesborough, before Mr. J. T. Belk (Borough Coroner), on the body of Mr. John Baker Walker, who poisoned himself by taking laudanum on the previous Saturday. Deceased had been much depressed in mind owing to the failure and bankruptcy of the firm with which he was connected. After the medical evidence, from which it appeared probable that the deceased had swallowed two separate half-ounces of laudanum, Mr. James Crosby Robson, chemist, 37, Linthorpe Road, Middlesborough, said he knew deceased, and last saw him at about half-past five on Saturday night. He went into his shop and asked for half-an-ounce of laudanum for his daughter, who, he said, had a swollen face. He was then in his usual state, and nothing was particularly noticeable in his manner. He said his daughter had a decayed tooth, and he wanted the laudanum. The bottle was labelled "Laudanum—poison," and witness cautioned him as to its use. He would not have sold it to him had he not known him to be a man of education and likely to know of the power of the drug. It was only necessary, in accordance with the Act, to label the bottle "laudanum—poison," with the name of the seller added.

The jury returned a verdict that the deceased "Died from the effects of an overdose of laudanum, administered by himself during a period of temporary insanity."—*Middlesborough Daily Exchange.*

Notes and Queries.

[525]. BLEACHING OF TALLOW.—Can any reader of the Journal tell me the best and quickest way to bleach tallow?—H. B.

---

[518]. COCKROACHES.—At page 108 of the current volume of the Journal (July 29), Chas. M. Foottit asks how to keep cockroaches away. Is this a pharmaceutical subject? However, the insect is a disagreeable one, alhough not so destructive as its fellows in tropical climates—say the Barata of Brazil. The insect can be poisoned; but a more salutary plan is to buy a beetle-trap, and use it; also to go with a candle every night, and destroy them; a ready way to kill them, on the walls, is the sole of a slipper, held by the heel. The winter helps to destroy them; except where a constant fire is kept.—JOSEPH LEAY.

[**** It cannot be pretended that the subject of cockroaches is very closely allied to pharmacy and the above answer suggests but a very mechanical remedy. Nevertheless our correspondent should bear in mind that many questions equally foreign to their calling are daily brought before chemists and druggists. We consider this fact a sufficient justification for the appearance of this and similar questions in the Notes and Queries column.—ED. PH. J.]

PHARMACEUTICAL POLITICS.

Sir,—I am sorry my conviction compels me to oppose the formation of a Trade Protection Society, for pedlars are doubtless a boon in out-lying districts. We have a Pharmaceutical Society which undoubtedly represents the trade more effectively, and should render a protective association quite unnecessary. Surely the Conference of chemists in 1841 were quite as much in earnest in defence of their rights and privileges as the Conference of chemists in Birmingham in 1876. It is impossible to educate a great body of independent workers into a phalanx for self protection and promotion of general weal in a few years, especially among a class who cannot claim a superior stock of commercial knowledge or very sound common sense, judging by the way many of us open expensive shops where much more lucrative trades could not exist, and living by the combination of extraordinary and incompatible trade,—dispensers of medicine, purveyors of ice-cream, soda, Gilbey's agency, grocery, etc., etc., take umbrage at Epsom salts and patent medicines being sold at an oil-shop.

There are too many chemists, and a man when he finds a young family growing around him, is bound to make the best income he can by honourable trade; but this is a misfortune for pharmacy. The chemist exercises his legitimate calling only occasionally for the families by whom he is surrounded, while his neighbours exercise theirs daily; hence he is the first to encroach, first on the one side then on the other.

It is a slow process, but as men become better educated they will recognize their position better, and many of the hopeless essays will never change hands. Close confinement at £100 or £150 a year will not tempt Mr. Parnassus who has done the Square. He will for years at least prefer more freedom in a larger establishment. No change can be effected, alas, without much individual suffering, and the hopeful ground for concerted action lies in our Benevolent Fund. The thousands of chemists who do not belong to us now will gradually join us, more especially if we could out of their guinea a year set aside 20 or 25 per cent. to the account of the Benevolent Fund, to raise the scanty pittance or increase the number of annuitants. £1 1s a year in the heyday of life is not missed, and in the dark evening £40 or £50 a year is not to be despised, and none of us can say we are sure not to want it.

These smaller organizations embracing each minute subsections of a trade, and each in their turn having to bear the rebuke of non-supporters "What are you doing for us?" "What has the Pharmaceutical Society done for us?" is a well-known cry. Apathetic or half educated men expect to reap where they have not sown, and curse the earth because they are starving.

The Pharmaceutical Society, if moulded aright,—and members and associates have the power to mould it, as much if not more than the people of this country mould their imperial and municipal government,—can accomplish more than any other; we have a Charter and two Acts of Parliament and a prestige to which no new organization can possibly aspire; we have an assured income, and funded property enough to render hostile attacks difficult,—and if we had the moral and substantial support of all the chemists in this country such attacks would be impossible. The thousands of chemists who do not belong to us must be the last to blame us for short-comings, and our Council or for want of energy or for whatever arises in the future to their hurt, by hostile attacks, or vexatious legislation, or too rapid a diminution of their numbers. Many of our members complain, perhaps justly, of the Society's action or inaction; they doubtless belong to a section of the trade so little represented in the Society that there are not enough representative men on the Council. The same thing would occur if the House of Commons represented one fifth of the ratepayers of this country, and that part only which took an interest in land and the mercantile marine.

It is possible for a thoroughly representative Council to meet in Bloomsbury Square, but nowhere else. The influence of the Society is the collective influence of its individual members. It is not a God nor a Spirit, it is not a mystic body, it is the sum of its units.

GEORGE MEE.

79, Grosvenor Road, Highbury New Park.

DISPENSING CHARGES.

Sir,—The fact that you can buy a bottle of physic at a lower price in one part of the town than in another, has frequently of late been held up to the chemist and druggist as a proof that the dealer in drugs is no better than a rogue, because of this well known circumstance. It is not perhaps surprising that persons who have no technical knowledge of the subject should fall into absurd errors in discussing such a question as the charges of chemists and druggists generally for dispensing medicines, but it is unfortunate that those who have better judgment should follow them in their errors. A gentleman, an old customer, recently complained to me that he could get a prescription dispensed at the east end of the town for one half of what he had to pay if he took his prescription to a west end druggist, forgetting that the expenses of a west end druggist to meet the requirements of a more wealthy and fastidious *clientèle* are on a very different scale from those of the small druggist in the back street. Even on the ground of ordinary trade-differences of price, depending on the differences between east and west, the poor and rich, a considerable difference in price is to be expected for articles much more delicately chosen, more carefully prepared and issued. A chemist who lives in a neighbourhood where the poor get all or nearly all their medicines from public hospitals and dispensaries, who is not called upon to keep the most costly drugs, nor those of the best quality, and where the resident doctors do their own dispensing, carries on a business very different in character, and requiring far less skill, than one whose whole time, as is the case with most of the leading chemists at the west end, is in great part occupied in acting as the physician's assistant, in the nicest possible operations with drugs, when life or death is but the matter of half-a-grain. To regard men who have such duties continually in hand as mere retailers of salts and rhubarb is as absurd as to complain because Sir W. Jenner charges 50 guineas for a visit when the parish doctor may be had for perhaps as many pence.

The skill of the chemist, and his professional self-respect and knowledge are appreciable elements in his value, and the value of his drugs, and should bring the award of higher social standing and higher remuneration, for better education, professional trustworthiness, the cultivation of nice skill, and a professional standard of decorum.

Llanberis Terrace, Lewisham. ALEX. COURTENAY.

"*Pharmacist, G.*"—We think the label would be held to recommend the preparation for the relief of disease, and, therefore, to require the stamp. The best way would be to ask the opinion of the Inland Revenue Authorities.

C. B.—We are not aware that the oil has been used for the purpose stated.

W. Wilson.—The dose was by no means an excessive one. In a paper published in *The Practitioner* for March last, Dr. Ewald, of Berlin, states that he has seen cases in which 15 or 20 grams of salicylic acid have been given during twenty-four hours without ill effect.

SOME CONSTITUENTS OF GELSEMIUM SEMPERVIRENS.

BY F. L. SONNENSCHEIN.

For several years past various preparations of the so-called Carolina jasmine (*Gelsemium sempervirens*, Pers.) have been used in medicine in North America, the two principal being the fluid extract and "gelsemin." The first of these is a concentrated alcoholic extract, the latter is a dried alcoholic ethereal extract, containing much resin. Notwithstanding that different chemists, and more recently Wormley, have been engaged in the investigation of this drug, hitherto no exact information has been given as to the composition and nature of the two principal constituents, namely, a non-nitrogenous body approaching to an acid, and a non-nitrogenous basic compound. In a paper lately read before the Berlin Chemical Society,* Professor Sonnenschein gives the following information, which is based upon a series of experiments carried out in his laboratory with a suitable supply of material, by Mr. C. Robbins, of New York.

The powdered root was extracted to exhaustion with a mixture of equal parts of alcohol and water; the extract was concentrated, and after separation of the resin thus thrown out of solution basic lead acetate was added as long as any precipitate was formed. This precipitate served especially for the preparation of the indifferent compound. A mixture of 1 part of ether and 3 parts of alcohol used instead of the aqueous alcohol for extraction gave a larger yield. The filtered liquid was used for the separation of the nitrogenous body.

The lead precipitate was suspended in water, decomposed by sulphuretted hydrogen, filtered, the filtrate concentrated by evaporation, and the liquid so obtained was shaken several times with ether. The ethereal solution, upon spontaneous evaporation, left behind some light acicular crystals, which had to be separated from adhering resinous matter by treatment with absolute alcohol. The same compound may be obtained direct by shaking the commercial fluid extract with ether, a method that was adopted by Wormley.

Thus purified, this substance is white, crystallizes readily in tufts, is without smell, and almost tasteless, and possesses feebly acid properties. The acicular crystals are best obtained after slow crystallization from an alcoholic-ethereal solution. If heated to about 160° C., this substance melts, and solidifies upon cooling to an amorphous mass. Upon heating it above the melting-point it is decomposed and turns brown, and upon raising the temperature still higher it is at last completely volatilized. If heated very carefully a portion can be sublimed. The compound is soluble with difficulty in cold, but much more readily in hot water; it is soluble in about 100 parts of cold alcohol, almost insoluble in pure ether, but easily soluble in ether containing alcohol.

The aqueous solution is distinguished by its fluorescence, which can be observed even after very considerable dilution. In an alkaline solution this appearance becomes yet more manifest; the solution then appears yellow by transmitted light, and by reflected light blue.

* *Berichte d. deutschen chem. Gesselschaft*, jahr. ix. (Sept. 18), p. 1182.

Concentrated sulphuric acid dissolves this substance with a reddish-yellow colour; carefully heated, the solution becomes chocolate brown. Hydrochloric acid causes no particular change of colour. If the substance be shaken with a small quantity of nitric acid a yellow solution results, which upon the addition of ammonia takes a deep blood-red colour. This reaction is so delicate that 0·00002 gram can be detected by it.

The same results were obtained by Wormley, who named the compound "gelseminic acid;" principally because of its acid reaction, but also because, the compound with an alkali produces precipitates in the solutions of most of the heavy metals. These precipitates Wormley considered to be insoluble gelseminates. Careful experiments and examination under the microscope have, however, proved that with the exception of the lead compound they consisted of the hydrated oxides of the metals mixed with the supposed acid.

It was, therefore, thought probable that this substance instead of being a new acid would prove to be identical with æsculin (formerly called polychrom), obtained from the bark *Æsculus Hippocastanum*. An agreement was observed in its external characters as well as its chemical behaviour, especially in the blue fluorescence of the aqueous solution, the dichroism of an alkaline solution, the reaction with nitric acid and ammonia, and its behaviour at high temperatures. This agreement was established by parallel experiments with commercial æsculin. Also, by digestion of æsculin prepared from gelsemium with dilute sulphuric acid sugar was separated and detected by Fehling's test.

In order further to establish the identity of the two substances a combustion was made with some of the prepared substance that had been dried at 115° until it ceased to lose weight. There was found—

	I.	II.
C	52·04	51·82
H	5·18	4·98

According to Rochleder, æsculin has the formula $C_{30}H_{34}O_{19}$, which would give a percentage composiof C, 51·57; H, 4·87.

A further confirmation was found in the hydration. The air-dried substance obtained from gelsemium lost at 110° C. 4·73] per cent. of water. Æsculin = $C_{30}H_{34}O_{19}+2$ aq. lost by drying 4·90 per cent.

Professor Sonnenschein, therefore, thinks there can be no doubt that the acid reacting body prepared from gelsemium is perfectly identical with æsculin.

The solution from which the lead precipitate had been separated was freed from dissolved lead by sulphuretted hydrogen; then from the still acid liquid any yet remaining æsculin was removed by shaking with ether, the ether was chased off by heat, and potash added up to an alkaline reaction. A light flocculent precipitate was thus thrown down, which was collected on a filter, and after washing, which could not be continued long on account of it being slightly soluble, it was dissolved for purification in hydrochloric acid. The filtered solution was, after the addition of potash, several times shaken, with ether which was left to evaporate spontaneously, when a colourless, transparent, varnish-like coating was left on the sides of the vessel. It was found that the largest yield of this substance was obtained from the aqueous alcoholic extract.

When the dish was gently warmed the residue puffed up strongly whilst parting with entangled ether, and then appeared as an amorphous transparent brittle mass, which could be rubbed to an almost colourless, perfectly amorphous powder. Upon gently heating this it melted, under 100° C., to a colourless liquid; at a higher temperature it was partially decomposed. In water it was with difficulty soluble, more readily in alcohol, and very freely in ether and chloroform. Its reaction was strongly alkaline and its taste very bitter.

The behaviour of this body, which has all the characters of an alkaloid, and has been named gelsemine, was briefly as follows:—

It completely neutralized acids, but hitherto no crystallizable salts have been prepared. The combination with hydrochloric acid, upon evaporation over sulphuric acid, leaves an amorphous mass, which is white in the centre, red towards the periphery, and blue grey at the outer edge.

The residue readily formed a solution with water, which only when concentrated gave a white precipitate with tannin, but when diluted gave it first with ammonia. Gold chloride gave a yellow precipitate that was not altered by heating. Iodine in iodide of potassium gave a flocculent red brown turbidity, which became somewhat conglomerated by heating. Potassio-mercuric iodide gave a white flocculent precipitate, which dissolved upon heating and again separated on cooling. Phosphomolybdic acid gave a flocculent yellow precipitate. Platinic chloride gave an amorphous citron yellow precipitate, soluble in water, especially upon heating. It was also readily soluble in alcohol. An aqueous solution of the platinum salt left upon spontaneous evaporation transparent square octahedra, which upon the addition of water immediately took the amorphous form, with separation of platinum chloride.

The pure alkaloid dissolves in concentrated nitric acid with a yellow green colour. In concentrated sulphuric acid it gives at first the same colour, but this passes immediately to a reddish brown and upon heating to a dark dirty red colour.

If gelsemine be dissolved in concentrated sulphuric acid and potassium bichromate be added, it takes, especially at the line of contact, a cherry red colour, changing a little to violet, which soon forms a bluish green spot. This reaction cannot be confounded with that of strychnine, although it shows some similarity. If instead of potassium bichromate ceroso-ceric oxide be added to the sulphuric acid solution there is produced a bright light cherry red colour, especially at the point of contact, which by stirring is diffused through the mass. This reaction takes place so sharply with the smallest trace that it may be looked upon as the best test for the presence of gelsemine.

The amorphous platinum precipitate left upon incineration 16·25 and 16·85 per cent of metallic platinum. The hydrochloric acid compound contained 8·73 per cent. of chlorine. Upon incineration with soda lime the nitrogen in two experiments was found to equal 7·26 and 7·23 per cent. The carbon found in two experiments was 66·10 and 66·41 per cent. and the hydrogen 9·44 and 10·05. This allows of the construction of the following formula for gelsemine—$C_{11}H_{19}NO_2$.

		Calculated.	Found. I.	Found. II.
C 11	= 132	67·00	66·41	66·10
H 19	= 19	9·64	10·05	9·44
N	= 14	7·10	7·26	7·23
O 2	= 32	16·24	16·28	17·23

This formula, however, has to be doubled if it depends on the hydrochloric acid compound, since this contains 8·73 per cent. of chlorine. $(C_{11}H_{19}NO_2)_2 + HCl$ requires 8·24 per cent. of chlorine.

According to the platinum left after incineration the platinum compound must have a composition represented by $[(C_{11}H_{19}NO_2)_2HCl]\,PtCl_4$, which would explain its behaviour in water by the formation of a basic salt.

0·012 gram of the hydrochloric acid compound injected into the leg of a strong pigeon caused manifestations of cramp, followed by death in thirty-six minutes. Similar results were obtained with frogs.

SALICYLIC COTTON WADDING.

For this purpose a white wadding completely freed from fat by sodium carbonate is necessary. E. Rennard saturates in a porcelain mortar 10 parts of this wadding with a solution of 2 parts salicylic acid in 15 of alcohol, and 35 of water of 25 to 30° C. (77 to 86° F.). After the solution has been completely absorbed, and uniformly distributed through the cotton, the latter is subjected to pressure until 25 parts of the solution are recovered, which may be used for wetting a fresh portion of cotton. If it is desired to avoid expression, only one part of salicylic acid is employed, but the full quantity of liquid mentioned above, which is about the smallest quantity with which a uniform moistening of the cotton can be effected. The wadding is then dried at ordinary temperature, since a higher heat causes a reddish colour. Thiersch has recommended the addition of some glycerin, in order to fix the acid more permanently upon the cotton; but Rennard states that the addition of 10 and even 20 per cent. of glycerin will not completely prevent the dusting of the acid on beating the cotton. The above proportions furnish a wadding impregnated with 10 per cent. of salicylic acid; this strength and a wadding containing 4 per cent. are most generally employed.—*Zeitsch. Oester. Ap. Ver.*

MEETING OF CHEMISTS AND DRUGGISTS IN ABERDEEN.

A meeting of the chemists of Aberdeen, called by circular, was held in the room of the local society, on Wednesday, September 20, at which Mr. A. Strachan was elected Local Secretary of the Chemists' Trade Association.

A deputation was appointed to canvass the town with as much expedition as possible, so that its report might be presented to the Executive of the Chemists' Trade Association before the discussion on the Glasgow memorial. This deputation reports very favourably, only having received two decided refusals out of a possible thirty-one. Most persons, however, withhold their donations until they see the work proceeding. The subscriptions are given conditionally:—

1. That the Association leave no stone unturned to procure an amendment of the Pharmacy Act.
2. That an Executive, with head quarters, be appointed in Scotland, as per Glasgow memorial, having Scotch solicitors to conduct Scotch prosecutions and defences.
3. That they give their attention to cases handed them through the local secretaries and prosecute when necessary, collecting further information at the expense of the Association.

In the meantime, and until satisfactory answers to the above be received, the amount collected will be placed in the George Street branch of the North of Scotland bank on deposit receipt.

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

COUNTER PRESCRIBING.

IF it were to turn out that the vigorous words used by Professor REDWOOD at Glasgow, with respect to the composite business done in the establishments of many medical men in that city, had given rise to a certain amount of irritation, we confess that to us the result would not be unpleasing. But, on the other hand, we are more satisfied to find that the thoughtful utterances with respect to so-called counter prescribing, spoken by the Professor in his presidential address to the British Pharmaceutical Conference on the same day, have received the general approbation of the medical press. This approbation has not been won by a simple abnegation of the right of the druggist, under all circumstances and to any degree, to give advice respecting the use of the drugs in which he deals; but by his evident recognition that this advice should be limited within safe and reasonable bounds. But the difficulty of defining these bounds is acknowledged to be very great, and the "border line which separates the respective domains of the prescriber and dispenser of medicines" might be shifted over a wide area, according to the interests or prejudices which are dominant. It was forcibly urged by Professor REDWOOD that of the fourteen thousand chemists and druggists in Great Britain the greater part have at present little to do with the dispensing of physicians' prescriptions, but are principally engaged in supplying medicines to be used by the public on unprofessional responsibility; and that it would be unreasonable, whilst heads of families and others were considered justified in treating slight ailments according to knowledge empirically obtained, that men who through being continually engaged in the preparation and sale of medicines might be supposed to have a knowledge of their properties should be debarred from imparting that knowledge when appealed to. It cannot be supposed that if this were prohibited to-morrow the public would be thus driven to consult the skilled physician respecting every simple ailment. At the same time we quite agree that it is essential there should be "some control exercised over the assumption of a duty which so obviously affects the health of the public."

We need not recapitulate here all that Professor REDWOOD said, since his address was published in our columns so recently. Respecting it the *Lancet* says, "We almost entirely concur in Professor "REDWOOD'S views. . . . . Professor REDWOOD well "observes that a pharmacist who prescribes for the "sick acts with far greater responsibility than that of "an individual unconnected with any department of "medicine. . . . . It may be, as Professor REDWOOD "says, that a certain amount of counter practice is "unavoidable, and that as domestic medicine does so "little harm, counter practice will do less. This, "by the way is rather doubtful reasoning. Be "this as it may, we cannot but wish that the "distinction so admirably stated by Professor "REDWOOD were duly observed." The *British Medical Journal* considers that Professor REDWOOD'S remarks are "worthy of consideration by the "too numerous transgressors on the domain of the "physician. It is evident that he regards a certain "amount of counter practice as unavoidable rather "than justifiable; and there is much force in this "view. At the same time he is desirous of limiting "the evil as far as possible."

We do not care to cavil as to whether the words "unavoidable rather than justifiable," and "evil," represent Professor REDWOOD'S view of the "certain amount" of counter prescribing; but we freely admit, and we believe this to be the opinion of the majority of pharmacists, that this should not extend beyond the amount required for the public convenience. We cannot do better perhaps, just now, than recall the opinion of Mr. Baron BRAMWELL as to the extent to which the public convenience might be considered to modify the stringency of the law as laid down by him—quite strictly enough—in the case of the *Apothecaries' Company* v. *Nottingham*. In summing up, his lordship said, "If a man "entered a chemist's shop and asked for something to "cure a bad headache, and the chemist gave him a "draught, without doubt the chemist would techni"cally infringe the terms of the [Apothecaries'] Act, "but it would be very unreasonable if the Apothe"caries' Company were to interfere in such a case."

It cannot be denied that there are instances, and some of them very gross ones, where the chemist and druggist enters into direct competition with the medical man. For these we offer no defence; but we object strongly to their being spoken of as representative of pharmacists generally. We are of those who believe that as pharmacists and druggists become more engaged in their legitimate duties they will be less disposed to engage in those for which they have no special qualification. The *Lancet* thinks that there is far more work to be done by pharmacists whenever they will give their undivided energy and attention to the duty of preparing remedies for public use on the prescription of medical men. But for this result an important factor is at present much wanting,—the prescriptions. As soon as these are forthcoming there is little doubt that they will command the attention of pharmacists.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Tuesday, September 6, 1876.

(*Concluded from page 267.*)

The next paper was a—

NOTE ON THE BENZOATES IN SUINT.

BY ANDREW TAYLOR, F.C.S.

Chevreul demonstrated how the wool proper by no means constitutes the major portion of a sheep's fleece. Here is his analysis of merino wool:—

Earthy matter washed out by water, when the wool is washed	26·06
Suint soluble in cold water	32·74
A peculiar grease found in interior of the wool fibre soluble in alcohol	8·57
Earthy matter fixed by the fats	1·40
Wool properly so called	31·23
	100·00

The fact of the first item consisting mainly of potassic carbonate has awakened attention to the large quantity of one of our prime fertilizers annually extracted from the soil by browsing sheep, which afterwards helps to pollute our streams. A new source of potash salts has thus been recognized. Of the 48,000,000 kilo. potash salts annually made, 1,000,000 kilo. is derived from wool washing. Though the fatty matters form a larger percentage of the wool than the earthy matters soluble in water, they are not reckoned profitable raw material for the special industrialist. The pioneers of this new industry, MM. Mauméne and Rogelet, first concentrated the wash waters from the wool to a treacly consistence. They next distilled it in cast-iron retorts, recovering the ammonia water thus formed; and lastly, lixiviated the dry ash for the potash salts. But, since, the exigencies of manufacturing convenience have developed a simpler plan, collecting only the latter bodies. The suint is concentrated to a sp. gr. of 30·13, in a series of brick evaporators, the flame being drawn along the top of the liquors by an exhauster. The thick suint is then burnt off for the potash. Havrez, indeed, has indicated that suint mixed with other fatty matters forms an excellent source of prussiate of potash. This application may adapt itself better to the specialities of an intricate manufacture rather than to public utility. Theoretical research, on the other hand, has demonstrated the existence in the wool of bodies, if isolated, demonstrably of general use in the arts. Thus cholesterin and isocholesterin have much higher melting points than paraffin, and seem likely to compete with it if introduced into commerce; but still remain chemical curiosities. I suspect they cannot be obtained profitably from suint as at present manufactured. The boiling down to a syrup of the wool-wash waters may be suitable to the recovery of potash alone; but it chars the fats, and gives pitch as the highest product in a distillation, as of palm oil with superheated steam. An experiment of this kind on the large scale yielded unsatisfactory results. The material operated on yielded 50 per cent. of water, 32 per cent. of mineral matter, and only 18 per cent. of fatty matter, so burned as to render only a very small proportion available for the purposes of the soapmaker. I suspect that the wool must be treated in different fashions to obtain special materials, as cholesterin, demonstrated by laboratory experiments as present in it. In such methods washing in alcohol, ether, or acetic acid, has always been employed. It might destroy the value of the wool for its primary uses so to treat it.

Messrs. Schulze and Allrich announce that they found that the portion of the suint remaining undisturbed by the action of alcohol consisted of benzoates: one the benzoate of an ether which crystallizes from acetone or ether in needles, and separates from it in flocks or jelly-like masses. Desiring to test this practically, I employed an 80 gallon steam-jacketted still, working at a pressure of 20 lbs. to the square inch, and distilled in it equal mixtures of petroleum spirit and suint, until I had operated on a ton of the latter substance. As it stood 15 lbs to the gallon, 150 gallons were thus gone through. I recovered nearly all my petroleum spirit, or might have done so with suitable precautions, and besides a yellow fatty liquid of a sp. gr. 1·2. Every five gallons of suint used gave one of this fat; this is in the proportion of 30 gallons to the ton. This liquid gave characteristic tests for benzoic and hydrocyanic acids. On heating eight gallons of this fat in a steam jacket, after mixing with it about a gallon of hydrochloric acid, for about an hour and half, during which the boiling shed was filled with ammoniacal and other vapours, I found remaining a brown liquid filled with benzoic acid crystals; the sides of the vessel were covered with these shining needles. Fully, three-quarters of a pound of dried substance were collected from the drainings besides; or nearly three pounds to the ton of suint. I believe the whole available benzoic acid was not collected, and from laboratory experiments I find the water washed from the wool yields nearly 3 per cent. more benzoic acid than the concentrated suint.

I desire to record this somewhat imperfect experiment, because whatever economic difficulties may surround the commercial recovering of potash salts from suint, such a ready source of benzoic acid ought to bring it into much more general use, specially as a preservative agent for organic substances. It might be easily collected at every sheep-washing station.

The PRESIDENT said he was sure the Conference would thank the author of this paper. It afforded an indication of an additional source from which benzoic acid was derivable. Already in commerce there was benzoic acid derived from two or three, if not more, sources, presenting peculiarities which were very obvious to the senses. In fact at certain periods it was found that the benzoic acid of commerce was by no means so suitable as it used to be for use in medicine. That, for instance, which was prepared in Germany from cows' urine retained most persistently the odour which was quite characteristic of it. Whether such a disadvantage appertained to any extent to benzoic acid derived from this source, he was not aware. The subject, however, was of interest to the pharmacist, who might sometimes be in doubt as to the cause of slight differences in the odour presented by this therapeutic agent. Of course it was known that benzoic acid derived from benzoin, which was most suitable for medicinal purposes, and was alone recognized in the Pharmacopœia, would vary in its physical characters,—in the odour especially—according to the manner in which it was prepared. The old method of obtaining benzoic acid by sublimation had been to a great extent modified by getting it by precipitation. But then unless it were sublimed finally it lacked to a great extent the peculiar odour which was so characteristic of benzoic acid.

The next paper was on—

A NEW BASIS FOR CANTHARIDES PLASTER.

BY A. W. GERRARD,

Teacher of Pharmacy to University College Hospital.

In a report upon the official plasters presented by me before the meeting of our Conference held in London in 1874, the cantharides plaster was omitted from the list, as my experiments upon it were not then concluded. Mr. T. Groves, who was the president of the Conference for that year, remarked, in his discussion of my report, that the blister plaster was the only one in which he believed, therefore I thought it too important a matter to overlook, and am now in a position to lay the subject before you.

The basis of our present cantharides plaster, as is well known, consists of a mixture of wax, prepared suet, resin, and lard. In my experience with this basis, the most important faults it possesses are insufficiency of adhesiveness and flexibility, and by reason of this, after it has been spread a few days, and more especially during the winter months, it becomes brittle, cracks, and peels from the surface of the material upon which it is spread. To overcome these objections it was necessary to alter the proportions of its present ingredients, or seek a new formula. I chose the latter, for I consider the presence of a granular body like mutton fat a quite unnecessary and useless ingredient, and to be the main cause of the objections urged. After numerous trials with mixtures of various proportions of wax, resin, fats, and oils, most of which answered my object but indifferently, I tried Canada balsam, and found that when mixed with wax and lard in the following proportions it gave a very good result.

Take of—

Cantharides in fine powder	6	ounces.
Canada Balsam	8	"
Yellow Wax	5	"
Lard	1½	"

Dissolve the wax, lard, and balsam over a water-bath, add the cantharides, and allow them to macerate at a gentle heat for one hour, then stir till cold; during the winter months the lard may be doubled with advantage.

In deciding upon the above proportions, I have borne in mind that the plaster should be only just sufficiently adherent, that on its removal from the patient the blister is not torn.

Plaster prepared according to this form has been on its trial for some time, it produces a good blister in from four to eight hours, and I have had no complaints concerning it. For experiment I placed a small plaster of this formula, and one of the B.P., upon my own arm, the former was seven hours and the latter nearly eight hours producing the desired result.

Canada balsam is, I consider, well adapted for the purpose I have chosen it, as from its terebinthinate character it has a solvent action upon the wax, which imparts to the mixture the desired qualities of adhesion and flexibility; it is also probable that it aids the extraction of the cantharidin from the flies.

A German pharmacist, whose name I am unable to call to mind, has stated that an advantage is gained by treating the cantharidies by the following process before making them into plaster. Digest the powdered flies with caustic soda, cantharidate of soda is formed, neutralize this with hydrochloric acid, cantharidin is liberated and chloride of sodium produced: the mass is then dried and mixed with the bases, the chloride of sodium being in no way detrimental. I tried the experiment, but obtained no apparent advantage.

A blistering plaster may sometimes fail from the bad quality of the flies, and in this matter if there is any suspicion, I think the judgment would be much aided by the use of a microscope. There are other causes of failure, such as the plaster being insecurely applied, or the patient's skin may be of that nature that vesicants will not effect it; these matters are outside our control. I have only attempted that which is within it, and believe the form I have given for cantharides plaster will be found an improvement on that to which we have been accustomed.

The President said he presumed that Mr. Gerrard's special object in proposing this modification in the form of the cantharides plaster had been to adapt it for hospital use. He was not aware, through his own experience and observation, that it had been customary to keep cantharides plaster ready spread. It was usually understood when a plaster was ordered that it should be spread at the time, therefore the objection urged by Mr. Gerrard would hardly apply, namely, that of its becoming brittle with keeping. The cantharides plaster now ordered in the Pharmacopœia had been in use so long and had acquired so completely the confidence of the medical profession that it would require a good deal of consideration before an attempt should be made to alter it in the direction indicated. At the same time, of course, the Conference was obliged to Mr. Gerrard for having paid attention to the subject, and it was at any rate now within its knowledge, founded upon the result of Mr. Gerrard's observation that the plaster can be rendered more suitable for use, where it is to be kept spread for a length of time by a little modification of the materials which are introduced into it.

Mr. Martindale said it was of great advantage to keep a cantharides plaster spread in hospitals where there were many patients. The B.P. plaster had this disadvantage, that it often cracked and separated from the material upon which it was spread. He had seen samples of American cantharides plaster in which the basis was spread upon a fabric which could be crumbled up without the plaster separating from what it was spread upon. He had also seen mustard plasters spread upon the same material, which really seemed to be everything that could be desired in the way of a good mustard cloth.

Mr. Proctor said there were two distinct sides to the question, the hospital side of the question being one. He thought they might leave the hospitals to take care of themselves. The hospitals were not bound to follow the Pharmacopœia. They could make any modification to suit themselves, but the British Pharmacopœia—as the guide to pharmacists—ought to be kept quite distinct from hospital practice. The formula of the British Pharmacopœia gave a plaster which was somewhat crumbly. If that difficulty could be got over it would be a great gain. He thought in that respect Mr. Gerrard's modification would give an improved plaster. But it would be a serious consideration if they were compelled to have one form of plaster for summer and another for winter, which seemed to be Mr. Gerrard's suggestion; that would be a serious inconvenience.

Mr. Groves said he thought it was an annoyance in carrying on the routine of a chemist's business to be called upon to spread this plaster extemporaneously. It was very messy and dirted the fingers. He had hoped that Mr. Gerrard would propose something that could be kept in stock and be of the same consistence in summer and winter. D'Albespyre's blister appeared to him to fulfil those conditions. He would like that some one should make experiments in that direction.

Mr. Greenish said that by this method an adhesive margin, which was always required to a blister, could not be obtained. He had never experienced any difficulty with the present formula, and, with reference to brittleness, the plaster only required to be worked in the hand before being spread. Mr. Martindale had alluded to mustard paper; perhaps he was not aware that in the original patent benzole was used to extract the fixed oil from the mustard, and benzole in which some caoutchouc had been dissolved was used to give the mustard paper its elasticity.

Mr. McKenzie said he had always looked upon the operation of plaster making as the most crude operation in a dispensing shop, wetting your fingers and straining your thumbs. It would be a good thing to get a plaster that could be easily spread. Many know in spreading a plaster the difficulty there is to get it spread with comfort, and a uniform thickness was seldom obtained. Plasters were spread all thicknesses. In some parts they were spread upon leather, and in other places upon the ordinary substance.

Mr. Cutting said he found as a rule that the Pharmacopœia form had acted well, and as regarded the manipulation he had found it workable. He did not know that they could adopt a better plan. He found the spatula to be very serviceable in spreading plasters.

Mr. Rimmington said that by using a slightly warmed spatula the plaster could be spread without dirting the fingers.

Mr. LONG said that in preparing such plasters he always took a slab and worked the material till it was of a sufficient consistence to use. In that way he never soiled his fingers. Using a brown paper shape, he spread the plaster with a spatula, and thus obtained a nice clean shape; then he rubbed a little olive oil over it. He doubted the advisability of the plaster being made adhesive. The plaster was put on with the intention of causing a blister to rise, and if it were stuck down with an adhesive edge this action would be interfered with. The better plan was to fasten the plaster on with a bandage.

Mr. GERRARD said his object had not been to provide a plaster for hospital uses, but one for general purposes, and if by a modification of the present form it could be improved so as to suit all parties an advantage would be gained. The material upon which the plaster should be spread should not be too unyielding—such as brown paper or leather; he thought calico best adapted from its flexibility. There was no occasion to use the fingers if the plaster had been warmed and a spatula used. The blister did not run upon a heated skin in the slightest.

The next paper read was on—

A PROPOSED SOLUTION OF CITRATE OF IRON AND QUININE.

BY J. F. BROWN.

Just two years ago I was led to consider the possibility of preparing at home the citrate of iron and quinine. To this course there were two strong inducements: its importance, and the difficulty of testing its quality. Quite recently the latter has been materially lessened by the published researches of Messrs. Allen, Palmer and Cownley; but at that time manufacturers were more eager to proclaim that their preparation fulfilled the official tests than practised in the art of applying them.

One eminent firm wrote me that "The B.P. instructions, even when very carefully followed, generally give different results, although the samples be taken from the same bottle and worked under precisely the same circumstances."

At the outset I abandoned any idea of scaling the salt as beyond the scope of my time or appliances, and taking, on Mr. Umney's authority (see *Pharmaceutical Journal*, August 30, 1873), four and a-half ounces as the yield of the quantities ordered to be used, I so far modified the formula as to obtain a solution containing five grains in each fluid drachm.

As preservatives I tried first sugar and glycerine, and found both answer very well, the only perceptible difference being that the solution with glycerine changed from the reddish-brown colour, common to both when fresh made, to a much more pronounced green colour than did the syrup.

I use now chloroform in the proportion necessary to convert the solution into Aqua Chloroformi, and find it unexceptionable, preserving it quite clear and bright for months, and serving, also, to render it more palatable.

The precipitated quinine should not be suffered to dry upon the filter after washing; nor should it be added to the solution of citrate of iron until the latter has cooled, or it will fuse into soft, tenacious lumps, which dissolve very slowly.

The addition of the ammonia, according to the Pharmacopœia process, is a tedious operation, involving a good deal of labour; but by diluting it to rather more than the volume of the citrate solution, and mixing in a large bottle, with brisk shaking, the combination is very speedily effected, the separation of the quinine being scarcely visible, so rapidly is it redissolved.

The only modifications of the official directions which I propose in order to adapt them to the solution are these:—Dilute twelve fluid drachms of solution of ammonia with twenty-five fluid ounces of distilled water, and add to the cooled solution contained in a stoppered half-gallon bottle, agitating briskly; filter, make up the measure to forty-nine fluid ounces with distilled water, and add two fluid drachms of pure chloroform; shake briskly at intervals for twenty-four hours. Each fluid drachm contains five grains of the citrate.

I have tested the solution so made both by the Pharmacopœia process, and by agitating twice with ammonia and ether, pipetting off the latter and evaporating in a tared watch glass; the results were not satisfactory, 14·9 per cent. of quinine by the former and 15 per cent. by the latter process. But I believe that this deficiency arose either from my inexperienced manipulation or from faults in the methods employed, as the results compare favourably with those obtained by testing, under similar conditions, the usual scaled product.

A speculation on the chemical constitution of this salt is perhaps scarcely worth attention, but I may note in conclusion that—

3·00 oz. citric acid,
·70 oz. anhydrous quinine,
·14 oz. ammonia gas, and
·66 oz. metallic iron,

contribute to the 4·5 oz. obtained; and these quantities correspond nearly to the formula—

$$(C_{20}H_{24}N_2O_2)_3, 2\,C_6H_5O_7, Fe'''C_6H_5O_7, NH_4H_2C_6H_5O_7,$$

also that it contains 22·7 per cent. (nearly) of citrate of quinine.

The PRESIDENT said he did not exactly see what object was contemplated by Mr. Brown. Was the solution intended for use in dispensing? because if so he apprehended the presence of the chloroform would be a decided objection and render it inadmissible for the purpose.

Mr. CLEAVER said it appeared that the paper had been written to induce pharmacists to use a solution of citrate of iron and quinine instead of the ordinary scales. As a matter of fact many pharmacists had done so by dissolving the scales in water and keeping such solution ready for use; but with many scales now in the market a precipitate was gradually thrown down on standing, therefore a solution which would be quite clear and would do away with the trouble and expense of scaling would appear to be a desideratum. This thought had occurred to him some time ago, and he made a large quantity of such solution, but found it did not keep well. A small percentage of sulphuric acid, however, would make it keep for two or three months, but he did not think that that plan would be allowed if the solution was to be used for dispensing.

Mr. GREENISH said he always kept citrate of iron and quinine in solution for the convenience of dispensing; but he found it did not keep good for any length of time. He should prefer making this solution himself to being dependent on a wholesale house, and he considered that the introduction of any foreign substance, as chloroform or sulphuric acid, in order to prevent decomposition or mould would be very objectionable.

Mr. KEMP said that he added a few grains of citric acid and a little alcohol and found it kept remarkably well. In that way the mixture could be dispensed in a moment. He did not think there was any serious objection to a small portion of spirit. He added four grains of citric acid to the ounce of solution and one-eighth its volume of spirit.

Mr. ALLEN had had something to do with the estimation of quinine in the liquid and thought it would keep better if a strong solution was used. There was a similar case in tartaric acid. He understood the reader of the paper determined the amount of quinine by adding ammonia. But he himself had had great difficulty in ascertaining the amount of ammonia to be added and he did not know whether to wash, for he might wash away the quinine. But at any rate the results were constant and agreed with those when chloroform was used.

Mr. RIMMINGTON said if the solution were made of one part of citrate to two of water it would keep very well.

Mr. SMITH confirmed the remark. Perhaps the solution made by Mr. Cleaver was more dilute.

Mr. CLEAVER: It was a solution of one drachm to the ounce.

Mr. NESBIT said he had tried solutions of various strengths, but he had never found them to keep unless with the addition of a little spirit. He made a solution similar to that made by Mr. Kemp, but a little weaker—namely, one part to three. He added 15 per cent. of spirit to it, and it kept perfectly well. He had tried it of greater strengths, but not successfully. He found when spirit alone was added it kept perfectly.

The PRESIDENT said he knew that in a highly concentrated state such a solution would keep well for a considerable time. Therefore he agreed with what had been stated by Messrs. Allen, Rimmington and Smith. No doubt if it could be kept in that way, it would be the least exceptional mode of accomplishing the object. He presumed it would be subject to one little objection and inconvenience—namely the difficulty of accurately adjusting the quantity in dispensing. Such a solution would often have to be measured out in small quantities, and the determination would not be so accurate. However that would be a matter of manipulation. He wished to make a remark with reference to the method which is indicated in the Pharmacopœia for testing the strength of citrate of iron and quinine. Mr. Allen took exception to it that it was not a strictly accurate mode of obtaining an indication. It was not intended to be so. It was intended to be a method of indicating approximately the strength of a very important therapeutic preparation, the strength of which it was desirable that there should be the means afforded for ascertaining by every pharmacist. In giving that method in the Pharmacopœia, what was contemplated was, that there should be a process given there that every pharmacist throughout the country could readily apply. It was intended, and the terms in which the process was indicated were to that effect, that the precipitate should be dried, and weighed without being washed. It was—"50 grains dissolved in a fluid ounce of water, and treated with a slight excess of ammonia, gives a white precipitate (if ammonia is not added in undue excess) which when collected on a filter and dried weighs 8 grains." This test was the result of many experiments made at the time, after a good deal of deliberation as to what kind of process should be given. His object in proposing that mode of testing was, that it should be adapted to the general position and qualification of pharmacists throughout the country—that it should, in fact, be a process that all could readily apply. If strictly carried out as indicated in the Pharmacopœia, it did afford the means of approximately ascertaining the condition of the salt. He very frequently employed it himself. It was the first test he should use. At any rate it served to distinguish between a preparation that had been made practically according to the Pharmacopœia, and other preparations that did not pretend to be made according to the Pharmacopœia. He hoped the time was coming—if it had not arrived—when so important a preparation as citrate of iron and quinine would always be used by all parties, made according to the Pharmacopœia. The great difficulty for a length of time after this process was introduced into the Pharmacopœia did not originate nor exist amongst pharmacists so much as medical men. They were accustomed to use citrate of iron combined with a smaller proportion of quinine than was ordered in the Pharmacopœia and this had to be prepared for their use. Hence two preparations had been commonly made and sold, and often the weaker had found its way as well as the stronger into the hands of the pharmacist. It was important to every pharmacist who wished to act conscientiously that he should have a ready means by which he could determine whether the preparation was such as was intended to be made according to the Pharmacopœia. He was quite ready to admit that now it becomes important to go a step further and examine this preparation more critically and more strictly by processes that would give a more accurate indication.

The next paper read was—

PRELIMINARY REPORT ON THE CHEMICAL CONSTITUENTS OF THE IVY.

BY ROBERT H. DAVIES, F.C.S.,

Demonstrator in the Laboratories of the Pharmaceutical Society, and,

CHARLES H. HUTCHINSON, *Student in the Laboratory.*

Although the Conference question as to the existence or non-existence of an alkaloid in the seeds of *Hedera helix* was the starting point of this inquiry, we are not at present able to give very certain information on the point. The few chemists who have followed MM. Chevallier and Vandamme have not corroborated the discovery which those investigators considered themselves to have made, and this fact inclines us to the opinion, which is shared by one of the very few writers on the subject,* that the statement was made in error. This opinion gathers strength from the very loose manner in which the report was compiled, and the entire absence of evidence in support of the statement in question. Upon another occasion we trust to have the opportunity to state definitely as the result of our own observation whether or not, "hederine" exists.

Professor Posselt, in 1849, made some investigations into the subject dealt with in this report, and his general method of procedure has been that followed by us. Ivy berries were exhausted by continuous percolation with ether, the ethereal solution was distilled, and the residue thus obtained was found to consist of fatty matter, and has not yet been subjected to a detailed examination; the "marc" from which the remaining ether had been pressed out was twice boiled with methylated spirit (for this and some kindred operations we are indebted to Messrs. Corbyn's kindness), and the spirit distilled from the tincture thus produced. In this liquid two substances were found by Posselt, both of which he considered acids, and which he named hederic and hederitannic acid, the latter being a variety of tannin. The former so-called hederic acid is the only one which we have so far isolated and it has been but very partially examined.

It separated upon allowing the concentrated tincture to cool, as a light green powder, which by repeated solution in hot alcohol, and by boiling with animal charcoal was obtained in a colourless condition. This white powder, washed with ether and dried, was the subject of our experiments.

Some of its characteristics are as follows:—

It forms a white powder, which has proved so far uncrystallizable; is very soluble in hot alcohol, from which it is deposited to a great extent on cooling. Enough, however, remains dissolved to give the liquid a syrupy consistence. It is slightly soluble in ether, and to a less extent in carbon disulphide, chloroform, benzene and water. The solution of the pure substance does not colour blue litmus red, so that we consider the name hederic acid is probably a misnomer. Posselt seems to have found it very difficult to purify the substance from the uncrystallizable hederitannic acid, and speaks of its solution as slightly affecting litmus. We find the mother liquors decidedly acid, but the pure substance in solution incapable of action upon litmus.

When treated with sulphuric acid, this substance develops in a few minutes a splendid violet colour, which is more permanent than such colours are usually, continuing unchanged for several days. If the violet liquid be

* Dr. F. A. Hartsen, *Archiv der Pharmacie*, April, 1875.

thrown into water, a light flocculent matter separates, which is either of a brown green colour at the time of precipitation or becomes so upon drying. This is soluble in alcohol or benzene, and if the solution be evaporated the residue *instantly* assumes the fine violet tint if touched with sulphuric acid.

When treated with nitric acid the substance dissolves upon the application of a gentle heat, and if the liquid be boiled, or upon dropping the original powder into fairly hot, strong acid, copious red fumes are given off.

Dilution of the resulting liquid with water causes the separation of a yellowish white, flocculent precipitate, which, from its containing nitrogen (as proved by the detection of cyanides after heating it with sodium) and from its explosive mode of decomposition when heat is applied, is believed to be a "nitro" compound.

The so-called hederic acid dissolves in strong ammonia, and the solution if slightly diluted becomes gelatinized. Whether the transparent substance thus thrown out contains ammonia is a point not yet decided.

In the *Archiv der Pharmacie* for April, 1875, a communication appeared from Dr. F. A. Hartsen announcing the discovery of a new body in ivy leaves. From a comparison of the properties of this substance and his mode of obtaining it with those of Posselt's "hederic acid," it was concluded that they might be the same substance. Accordingly some ivy leaves were obtained and we extracted some of the "new body" after Hartsen's method, getting as result a white powder which gave the violet with sulphuric acid, so characteristic of Posselt's "hederic acid."

If the spirituous solution of this substance be largely diluted with water, the liquid froths strongly upon agitation, resembling in this respect a solution of saponin. The slight solubility of hederic acid in water is sufficient to distinguish the two, however. This property of frothing, noticed by Hartsen, led us to look for the identity of his substance with the hederic acid of Posselt. Like saponin, our substance after being boiled with dilute sulphuric acid gives a solution which reduces Fehling's copper solution, but since its solution before treatment with acid does this to some extent we do not here attach importance to the reaction.

So called hederic acid consists wholly of carbon hydrogen, and oxygen. Its formula remains to be determined after combustion.

Thanks were presented to the author of the paper.

Mr. Kingzett said the hederic acid described by Messrs. Davies and Hutchinson appeared to be a body constructed on the type of Berthelot's saccharides; that is to say, sugar, in which hydroxyl is replaced by a fatty acid. Such bodies all give the purple reaction with sulphuric acid, and on boiling with dilute acids, sugar and the original fatty acid are reproduced; such a solution should, therefore, reduce Fehling's solution.

The Conference then adjourned till the afternoon.

On the business being resumed after luncheon,

Mr. J. C. Hunter read the following paper on—

Further Experiments on the Antiseptic Action of Salicylic Acid.

BY JOHN C. HUNTER A.P.S.

Since the discovery of the antiseptic qualities of salicylic acid by Professor Kolbe, and his publications concerning it, the attention of many other scientific men, both at home and abroad, has been turned towards it for the purpose of verifying the results of Kolbe and Von Meyer, and also of assigning to it its proper place among other known and well tried antiseptics, such as carbolic acid, creosote, chromic acid, etc., etc.

Salicylic acid being only soluble to the extent of one part to the 1000 parts of water, many formulæ have been published from time to time as good solvents for it, but I think that a solution of ammonium citrate is about the best.

The formula used by me was as follows, which is a modification of one that appeared in the *Pharmaceutical Journal* about two months ago.

Citric Acid	60 grs.
Ammonia Carb	70 grs.
Water	6 ozs.

Dissolve the acid in the six ounces of water and neutralize with the ammonia, and when neutral add salicylic acid 60 grains, stirring, until it has all dissolved, and then filter. On testing the solution after the acid has dissolved, it is found to be quite acid.

From a gentleman in the wine trade, I obtained about one gallon of ginger cordial which was newly made but did not contain any alcohol to preserve it, as I wished to try the effects of salicylic acid upon it as a preventive of fermentation.

The cordial was divided into four parts—

To part 1 was added no salicylic acid.
To part 2 „ 10 grs. of salicylic acid to the pint.
To part 3 „ 15 grs. „ „ „ „
To part 4 „ 20 grs. „ „ „ „

All the bottles were loosely corked and put into a place where they would get plenty of air and light. They were examined day by day. That part containing no acid began to give way on the fifth day, a mucus forming on the surface, and shortly after carbonic acid was evolved showing that fermentation had set in. In about eight days the part containing 20 grains to the pint gave way, whilst the other two containing 10 grains and 15 grains respectively of acid to the pint gave way three days later.

I was astonished to find that the part containing the most acid was the first to give way, and the only reason that I could assign for this was, that it contained more of the ginger than the others, and that the acid was not powerful enough to overcome the decomposition of the vegetable matter.

The results from these experiments did not prove that salicylic acid was a preventive of fermentation in sugar solutions containing ginger or other vegetable matter.

In the experiments of Kolbe and Von Meyer, they employed simply sugar solutions to which they added yeast as a ferment, and from their results they inferred that so many grains of yeast could be rendered powerless to cause fermentation by a certain quantity of salicylic acid. But according to my experiments salicylic acid does not prevent fermentation in sugar solutions if they contain much vegetable matter.

Mr. Baden Benger, in his paper read before the Conference last year, mentioned the preservative action of salicylic acid on lime juice; consequently I determined to try its effect in the making up of the syrup of lemon, B.P., which is very ready to give way, a nasty white-green mucus forming on its surface.

Five grains of salicylic acid were added to the pint of lime juice used in making the syrup, and although it is now two months since the syrup was made up there is not the slightest appearance of any mucus on its surface.

The experiments of Professor Neubauer on the power of the acid to prevent grape juice from fermenting, and also for the prevention of further fermentation in wines that have fermented, prove that we possess a valuable agent in salicylic acid.

At the suggestion of Mr. Fairlie, and through his kindness in furnishing me with a supply of grape juice for the purpose of experimenting upon it with salicylic acid, I attempted to verify Neubauer's experiments. One portion with 10 grs. of salicylic acid was exposed last January as a preliminary test, and up to the present time no mucus has formed on its surface; nor has any fermentation set up, for on distilling a portion of it, chemical tests failed to detect any alcohol present in the distillate.

The second supply was obtained about two months ago; it was divided into four parts—

To No. 1 was added 10 grains salicylic acid alone to the pint.

To No. 2 was added 15 grains.

To No. 3 was added 20 grains.

These three parts contained the salicylic acid dissolved by means of the ammonium citrate solution.

To No. 4 was added 20 grs. salicylic acid to the pint.

These four quantities were all exposed under the same conditions in uncorked bottles, and have been examined from time to time. It is now two months since they were first exposed, and the grape juice contained in them is as sweet and fresh as if it was newly expressed from the grape.

These experiments confirm the statements of Professor Neubauer, that the acid is well adapted for the preservation of grape juice, as it is odourless, tasteless, and non-poisonous.

Mr. Baden Benger gave the results of his experiments last year, of its action on the infusions of the Pharmacopœia, and having tried its effects in that direction also, I find that it has a decided effect in preventing them from giving way.

Two quantities of infusion of orange and two of infusion of quassia were made by me, these infusions being selected, as they give way readily.

The two infusions of quassia and orange that contained no acid gave way first, the infusion of orange in three days, and the quassia in five days; but of the two infusions that contained the acid in the proportion 10 grs. of acid to the pint of the infusion of orange, and 5 grs. of acid to the pint of the infusion of quassia, the infusion of orange is still fresh after sixteen days exposure, whilst the infusion of quassia gave in six days a yellow flocculent deposit.

The last series of experiments undertaken by me, had for its object to determine the antiseptic action of the acid on infusions of hay and turnips used in the generation of infusorial animalcules.

I prepared four infusions of turnip.

Infusion No. 1 contained no acid
„ „ 2 1 part salicylic acid in 1000 water.
„ „ 3 1 part creosote in 1000 water.
„ „ 4 1 part of salicylic acid dissolved in 2 ammonium citrate in 1000 water.

The infusions were examined day by day with the microscope. On the third day the turnip infusion, which contained no salicylic acid, gave signs of animalcules, but the other three were still free from any. On the eighth day, infusion No. 3, containing the creosote, and also infusion No. 4, containing the salicylic acid in the ammonium citrate solution, commenced to decay, a green mucus forming on the surface of both, and on examination under the microscope, quarter-inch objective being used, animalcules were seen to be present in both; but infusion No. 2, which contained one part of the salicylic acid alone in 1000 parts of water, on being examined after a lapse of fourteen days, gave no signs of animalcules being present, and it still was quite fresh to the eyes and nose, while the other three had the mucus formed on their surface, and they all had a putrescent smell.

Three infusions of hay were prepared.

Infusion No. 1 contained no acid.
„ „ 2 „ 1 part salicylic acid to 1000 parts water.
„ „ 3 „ 1 part carbolic acid to the 1000 parts of water.

These three were also examined microscopically every day, and after a lapse of thirty-six hours there appeared in the infusion of hay, which contained neither salicylic nor carbolic acid, plenty of infusorial animalcules; paramecii, and other smaller animalcules were in abundance; and four days later, in the same solution, rotifers, or the wheel animalcules, began to appear. After four days had elapsed, infusion No. 2, containing the salicylic acid, was examined, but there was no appearance of any life. So also in infusion No. 3 containing the carbolic acid there was no appearance of life.

On the 9th day animalcules began to appear in the infusion containing the carbolic acid; these on being examined a few days later showed signs of increase in the fluid, showing that the carbolic acid had lost its power of further preventing them from multiplying; but infusion No. 2, containing the salicylic acid, had up to the thirteenth day no appearance of any animalcule, but on the fourteenth day, I was able to detect a stray small animalcule now and again. In the fluid, however, there were very few when compared with the solution containing the carbolic acid, which was also examined on the fourteenth day, and was found to contain a far greater quantity, but not so many as were to be found in the infusion that had neither salicylic nor carbolic acid.

All the infusions that had generated animalcules were alkaline to test paper, proving the well-known fact that we find animalcules present only in alkaline solutions or in vegetable infusions which are alkaline, for in the infusion of turnip which contained the pure salicylic acid, and was still quite acid to test paper, no animalcules had been generated.

Summing up the foregoing results, salicylic acid does not appear to prevent fermentation in sugar solutions containing vegetable matter.

It prevents the decomposition of lime juice, and it is also of great use in preventing the decay of syrup of lemon.

It prevents in a very marked manner the fermentation of grape juice for an indefinite period.

And, lastly, it prevents the disentegration of vegetable tissue, hence it will be found useful in preventing vegetable tissue, used for microscopic mounting, from decaying.

In conclusion, I would venture to give my opinion, "that the adaptability of salicylic acid for preserving the infusions of the Pharmacopœia is not so great as that of alcohol, when we take into consideration the many substances used conjointly that would destroy or neutralize its antiseptic action."

Mr. Siebold mentioned last year his objection to it when prescribed with salts of iron, as it would give a purple solution. Again, many medical men prescribe infusions combined with alkalies, such as bicarbonate of potass, bicarbonate of soda, liquor potassæ, etc. Consequently salicylic acid would combine with these and form salts which have a very feeble antiseptic action. Hence the infusions so preserved would in all probability begin to ferment as soon as that change took place, and the patient would find the mixture which he had obtained from his chemist becoming sour and a mucus forming on its surface before it was all taken.

The President said the results described in this paper were confirmatory of such as had been obtained by previous inquiries in the same direction. Mr. Benger had last year got a number of results and he (the President) believed that that gentleman was prepared to put the same specimens before them now that were produced on that occasion, and no doubt he would have a few words to say in reference to this communication. Their thanks were due to the author of the paper for the information he had conveyed to them.

Mr. Benger said that most of the infusions preserved by salicylic acid which he exhibited last year had kept for about six months, after which they for the most part became unfit for use. The infusions preserved with benzoic acid, ½ grain and ½ grain to the fluid ounce, had without exception kept well. They had now been prepared thirteen months, and had been kept in a hot room where the temperature was never below 70° F. In some recent experiments he had found that salicylic acid does not appear to prevent fermentation of grape sugar to the extent that had been described by some experimenters.

The PRESIDENT said he should like to ask the author of this paper why he gave a preference to citrate of ammonia for effecting a solution. There were other salts that could be used for a similar purpose, and especially borax. In making experiments in the same direction he had himself used borax and found an advantage in doing so. It was in itself an exceedingly good antiseptic, in some cases better than salicylic acid; in fact, he found it to be one of the best antiseptics for some purposes, and as it fully accomplished the object of greatly increasing the solubility of the salicylic acid it appeared to him to be suitable for that purpose.

Mr. MCKENZIE asked whether the author of the paper had made any experiments with the solution of salicylic acid with borax, and if so what results had been obtained; also, if a decomposition of the salicylic acid took place, especially when glycerine was used.

Mr. EKIN said he had found from some recent experiments on milk that he had made, the results of which were published in the last number of the proceedings of the *West of England Agricultural Society*, that boracic acid was far superior to salicylic acid in its keeping properties, and that benzoic acid ranked second.

Mr. SAVAGE wished to know how the boracic acid was dissolved when it was used with milk. He had known it used extensively by milk dealers for some time and it had been attended with decided benefit. Something like an ounce was used to ten or twelve gallons, and the milk would then keep for ten days in a large quantity. It would be a great pity to disseminate anything like an adulteration of milk, but if they got an agent so simple and which produced so admirable results it would be a great advantage.

The PRESIDENT said his experience was that borax was rather more effective than boracic acid. There was a solution very largely used in London which was a strongly alkaline solution of soda to which boracic acid has been added and that was found to be very efficient for that purpose, especially for the preservation of cream, which would keep for a week or a fortnight perfectly well.

Mr. HUNTER, in reply to Professor Redwood, said, the ammonium citrate was more soluble in water than borax, and it also had less taste. Again, the borax was not desirable in many fluids, and in using borax along with the acid they did not get to know the exact antiseptic action of the acid, as the borax itself was an antiseptic agent. He thought that the ammonium citrate was preferable as a solvent for the acid, when used to preserve either lime juice or grape juice, as the citric acid combined with ammonia forming the ammonium citrate was also one of their constituents.

NOTE RESPECTING THE STRENGTH OF COMPOUND SYRUP OF PHOSPHATES (PARRISH).

BY W. L. HOWIE, F.C.S.

The object of this paper is not to put forward any new fact or process for the preparation of any of the phosphate syrups, but simply to bring prominently before the trade through this Conference the question of what should be considered the standard strength of compound syrup of phosphates (Parrish). I need scarcely say one word of the importance of a thorough understanding being come to on this point; the extent and universality of the demand, as well as the class of ailments for which this syrup is prescribed, place it on a par in importance with any item of the Pharmacopœia, and it is to be regretted that the state of our knowledge of the subject, perhaps as much as anything else, has excluded from past editions of that work an article in such common use.

At first sight the question seems a very simple one, since Parrish, in his 'Practical Pharmacy,' attaches to the original recipe the statement that "each teaspoonful of the syrup contains about two and a half grains phosphate of calcium and one grain phosphate of iron," and this has apparently been adopted without question by various writers on the subject, who have furnished us with what was meant to be improved formulæ. On closer examination, however, we perceive that a decision is not so easily arrived at. If we consider the quantities of iron and lime salts ordered by Parrish in his formula in relation to the bulk of the finished product, we find that such a strength is absolutely impossible, and that the statement must have been the result of a miscalculation, while inaccuracy in figures is, unfortunately, not singular in the work in question. In the paper on 'Phosphate Syrups,' published in the Journals last April, I was at some pains to state this matter as clearly as I could, and trusted the question of strength might be taken up and discussed. Since then three papers have appeared on the subject, one by Mr. Ernest C. Saunders in the *Pharmaceutical Journal* for July 15, and another by an anonymous contributor in the last issue of the *Chemist and Druggist*, both of whom, on the question of strength, fall back on the statement the accuracy of which is questioned. The third paper is by Mr. E. B. Shuttleworth, in the *Canadian Pharmaceutical Journal* for August, and appeared in our own Journal for the 26th of the same month. In it Mr. Shuttleworth seems to accept the result of the formula as the standard, and to my knowledge many others hold the same opinion. In appealing to this Conference I trust we may be enabled to come to a decision which shall serve as a guide so long as we must follow an empirical formula for the preparation of this valuable remedy.

For the sake of those who may not have read the former paper I shall endeavour to state as concisely as possible the more important points. In Parrish's formula there are ordered 10 drachms sulphate of iron, which would produce 257·5 grains triferrous phosphate, were none wasted in following the process, and the finished syrup measures as nearly as possible 45 fluid ounces, or 360 fluid drachms. Were all this iron utilized we would only have ·715 grain per fluid drachm, and if allowance be made for loss through imperfect precipitation, we have almost exactly half a grain (·501) per fluid drachm. The lime, also, is over-stated. Twelve drachms of phosphate of calcium, the quantity ordered in the formula, gives exactly 2 grains per fluid drachm, and this makes no allowance for any moisture, which is present to a large extent in commercial samples, nor for loss in the reprecipitation and washing which Parrish directs. You will therefore follow me, that the syrup prepared according to Parrish's own directions cannot contain as tribasic phosphates the quantities of lime and iron which he asserts, but that something less than 2 grains of phosphate of calcium, and ½ grain phosphate of iron per fluid drachm is the extreme result of the formula. This same error is reproduced in the 'Companion to the Pharmacopœia' by Peter Squire, whose firm have long prepared what in this country is known as the genuine syrup, an examination of which I have found to bear out what has just been stated. The quantities of iron and lime obtained from the samples I have examined being somewhat under the theoretical yield of the formula. With the view of still further sifting the matter, I have lately procured through the kindness of Mr. P. S. Smith, several sealed bottles of the syrup direct from Parrish's pharmacy in Philadelphia; but unfortunately it turns out to be such poor stuff, as you will perceive by consulting the table,

PARRISH'S SYRUP. STRENGTH PER FLUID DRACHM.

	Sp. Gr.	Total Iron Calculated as $Fe_3P_2O_8$.	Phosphate of Calcium (Indefinite).	Hydrochloric Acid.
English . . .	1·320	·447 grain.	1·37 grain.	none.
American No. 1.	1·212	·160 ,,	0·87 ,,	present.
,, ,, 2.	1·235	·200 ,,	1·06 ,,	present.

that we must consider it almost out of the argument. The negative evidence, however, which may be deduced is that evidently no attempt is made to arrive at Parrish's stated strength.

It might be asked, why not discard Parrish's recipe altogether and adhere to the statement, and on it found a new formula the product of which would have a closer relation to the object aimed at? In the first place by so doing we would produce a new syrup—not Parrish's; and though it is not denied that it is quite possible to produce a syrup having this extreme strength, yet it must be borne in mind that it is not a chemical preparation we are fabricating, but a syrup the popularity of which is in great measure due to its palatable character; and further that being given to young persons and children, the extreme strength, if really existing, besides making the syrup somewhat disagreeable on account of its acidity and smaller proportion of sugar, would require to be prescribed in most cases in fractions of a teaspoonful. You will notice that this latter argument does not apply to the B. P. phosphate of iron syrup, nor to Easton's, though both of these preparations when the original formulæ are followed are not up to the stated strength, yet with them it would I think be quite consistent, as far as the dose is concerned, to improve the formula so as to make it agree with the statement; Easton's syrup being very seldom indeed prescribed for any but adults and the quantities per fluid drachm given in the statement being no more than a moderate dose.

I therefore consider that the strength of one grain of iron and two and a half of lime per fluid drachm rests only on a loose and inaccurate statement which has been freely reproduced on labels, etc., and which unless care be taken might be made a point in a prosecution under the "Sale of Food and Drugs Act" in which the sufferer might be one who on the best evidence, and believing he was doing best for both physician and patient, had closely followed the originator of the formula.

It is but right to state that on the label of the American syrup no reference to the strength is made; the name being "Parrish's Compound Syrup of Phosphates (Chemical Food) a wholesome Tonic without Alcohol," etc., which latter allusion, those familiar with the patent medicine trade of the United States will doubtless appreciate.

The PRESIDENT said this was a subject which he was sure would raise a good deal of discussion. He would then simply invite remarks upon it.

Mr. SCHACHT said that in the paper published a few months ago by Mr. Howie, when the subject was rather elaborately entered into, the conclusion arrived at was that the best strength to adopt was half a grain of the phosphate of iron and two grains of the phosphate of lime in each drachm. He had himself experienced a good deal of trouble—in fact he found it utterly impossible—to accomplish the strength declared to be that of the original preparation. He had been very glad to find that the conclusion of a gentleman who had paid so much attention to the subject was exactly like his own, and had another month gone over he would have obtruded his observations, which would have been very much of the same character as those by Mr. Howie, upon the pharmaceutical public. He thought Mr. Howie's suggestion an extremely sensible one; the strength was one that could be easily accomplished without the addition of an undue and excessive quantity of phosphoric acid. It was possible that a still greater strength of the active ingredients might be arrived at, but then it would be necessary to add so much free acid that it would render the preparation to that extent objectionable. The difficulty he found in attempting to get anything like an approach to the alleged strength of Parrish's professed preparation consisted in the tendency of some of the constituents to arrange themselves as subsalts, and to separate from the preparation. He believed Mr. Howie was perfectly right in saying that the accredited preparation never contained what was stated on the label. If the Conference could agree to recognize a preparation of the strength recommended by Mr. Howie in his first paper it would be a great convenience to pharmacists and to medical practice.

Mr. EKIN thought it was rather important to know the exact formula that was used by Mr. Howie because there were some slight modifications in the different published formulas as regards the acid. Of course they did not know how Parrish's syrup was made. In some formulas he found the ordinary phosphoric acid was used with an addition of hydrochloric acid, but when there was an addition of glacial phosphoric acid a syrup was produced which was very unpalatable and very different from Parrish's. This objection to the use of glacial phosphoric acid as an addition, however, did not apply to the use of hydrochloric acid. The strength of the syrup had to do with the way in which it was made, and in the absence of that knowledge the discussion must be somewhat hazy. He wished to know if Mr. Howie could tell the strength of the syrup referred to in his former paper.

Mr. HOWIE, with permission of the President, reminded the members that it was the question of strength only that was before them. He had gone into the chemistry of the subject in the paper already referred to, but to guide the discussion and prevent unnecessary questions he would say that he had made none of the syrups referred to in the former paper himself; they were obtained from different wholesale makers, and he thought represented what was commonly met with in the trade. At one time he had made this syrup in considerable quantity, but his later work had been wholly experimental, undertaken somewhat as an amusement, his business now taking him entirely out of the laboratory.

Mr. EKIN replied that what he had said still held good,—that the stability of the syrup depended very much on the strength and description of the acids used.

Mr. HOWIE agreed with Mr. Ekin as to the superiority of the syrupy or tribasic phosphoric acid over the glacial, and also that hydrochloric acid, as pointed out in his former paper, had a wonderful power of retaining the phosphates in solution. He at the same time called attention to a sealed bottle of the Philadelphia syrup on the table, which, despite the presence of a large proportion of hydrochloric acid, showed an abundant ferric precipitate, proving faulty preparation.

Mr. KERR said he thought it would be a pity to confine the discussion to the mere question of strength when they perhaps had opportunity of eliciting useful information concerning the preparation of the article. He had made Parrish's syrup for the last twelve years and had always kept to the one formula; but he must say that the variations in the appearance of the preparation had sometimes been very great, and he had come to the con clusion that this was caused by the sugar. Sometimes they got a very good result, and batch after batch would prove clear and bright, and keep well. He always tried to get the same sugar, but when the grocer ran out of it he had sometimes got a different sugar, and obtained very different results. He would like if some gentleman would give him an idea of how to meet this inconvenience, as he thought it had a great deal to do with the success of the preparation.

Mr. MACKENZIE said his experience had been much the same as that of Mr. Kerr. He had obtained very different results on different occasions with the same formula. He attributed a good deal of this to the sugar, and he had therefore spent some considerable time experimenting with various kinds of sugar.

Mr. GREENISH said he had made a great quantity of syrups at different times. He had tried every published formula and modifications of these formulas, but he must say the results had not been perfectly satisfactory.

Mr. SCHACHT: You have always endeavoured to make it according to the declared strength?

Mr. GREENISH: Certainly.

Mr. BORLAND said he had had some experience in the matter and had consulted with Mr. Howie on the subject. In the paper Mr. Howie had read before the Edinburgh branch last session he specially adverted to the fact that the main cause of the early precipitation that took place was due to the formation of ferric salts. To obviate that he had within the last two months been directing his attention towards making a solution of the ferrous phosphate in a direct manner without exposing it to the action of atmospheric air at all. So far as his experiments had gone, he thought there was some evidence of some little success. He dissolved calcium phosphate in phosphoric acid and to that he added a strong solution of ferrous sulphate. Double decomposition took place in a very short space of time and he had the ferrous phosphate in solution,—contaminated, he admitted, with a very small quantity of sulphate of lime. That sulphate was in such a very small quantity that he did not think it could be said to vitiate the process he was aiming at. This added to the simple syrup of the Pharmacopœia made the strength equal to what was stated to be that of the Pharmacopœia syrup. He had made syrup and had it exposed to sunlight in bottles, of course corked, and no decomposition had taken place up till the present time. He was simply aiming at forming the ferrous phosphate without exposing it to the action of the air at all. He had prepared it in a bottle, using a bottle which would exactly hold the quantity he was going to bring into combination, and in that way he thought he had been very successful. He had not yet had an opportunity of applying it to the formula of Parrish's syrup, but he thought it was a hint which might lead to further improvements in the preparation of that compound also. He thought that, so far as the simple phosphate of iron syrup was concerned, it was a decided improvement.

Mr. GREENISH said he should like to mention a circumstance which he had forgotten. His son had been making experiments for some time in the direction indicated by the last gentleman with regard to Parrish's syrup, and he knew that his opinion was that it would be quite successful.

Mr. GILMOUR said there was one point on which he would like Mr. Howie to give some explanation, viz., whether he had estimated those syrups for ferric phosphate or for ferrous phosphate alone, as he would like to know if even an attempt had been made to get in the proper percentage of iron. If they made any attempt to change the strength of Parrish's syrup they would, unfortunately, come into collision with the many other preparations of ferrous phosphate syrups. They had, for example, a B.P. syrup which was a sort of standard for all those preparations, more or less, and it would be a most unfortunate thing if they were to change the strength of Parrish's syrup in relation to the strength of the B.P. syrup, more especially as its strength, whether satisfactory or not, was generally accepted by the medical profession. He had not tried Mr. Howie's process, but be found that with a modification of the Pharmacopœia formula, taking care that no oxidation took place, a very satisfactory syrup indeed was produced, a syrup that would stand the test of strength, which would stand the test of keeping, and in every other respect be a satisfactory syrup. At the present time he had laid aside for some months a B.P. syrup prepared according to this formula. It had not deposited to any extent, that was to say the bottom of the bottle had scarcely been covered with deposit, it was quite clear, and this he took to be a very satisfactory proof that if care were taken in the matter of oxidation, and other respects, a very satisfactory syrup would be produced.

Mr. BURRELL had listened to the remarks of the various gentlemen present with very great interest, because he did not know a more unsatisfactory compound to attempt to make than Parrish's syrup. His experience had been somewhat the experience of the various gentlemen who had spoken. For one time he had succeeded he thought he had failed half a dozen times to make it what he wished; the fact was he had classed this phosphate syrup question with the Eastern question. There was one mode that he followed in making it regarding the phosphate of lime which he would mention, and which he thought was a useful way of doing it. He always made it direct. He happened to have a large quantity of a stuff called ivory dust, which at one time was used largely for stiffening bonnets—that was when ladies wore bonnets. He found he could make it very easily and simply by mixing the ivory dust with hydrochloric acid, and filtering it through paper, then precipitating with ammonia, and washing; and when he added that to the syrup and put the other ingredients into it, it was soon dissolved. It appeared to him that that syrup was better than that which he read of; at the same time he confessed that he had very little faith in any process he had ever seen or tried. He was very glad that Mr. Howie had taken the subject up, because he was sure that the profession or trade would be very much indebted to him for the time and pains he had taken in solving this very difficult question.

Mr. HOWIE, in reply, said the sugars he thought the best were Martineau's London loaves, and Finzel's crystals. There might be others, but these were first-rate sugars. Mr. Borland's original suggestion he thought a very promising one, such as could be framed into a convenient and rapid process; but he feared Mr. Burrell's success with the ivory dust was due to its not representing the full proportion of calcium phosphate. With regard to Mr. Gilmour's query, if he had estimated the relative proportions of ferrous and ferric phosphates in the syrups, he said he had not done so; he believed it could not be accomplished on account of the presence of the sugar, which interfered with the estimation of the ferrous salt, and if this sugar were eliminated, the process changed the condition of the iron. The estimations were made by his process, explained in the former paper, and represented the total iron in the syrup, and he had calculated it as ferrous phosphate. As Mr. Gilmour had said, there was little difficulty in obtaining or keeping B.P. phosphate of iron syrup, of the full strength of one grain to the fluid drachm, and he (Mr. Howie) did not deny that even a Parrish's syrup could be made of the full stated strength; but it required great skill and care in preparation, and very careful storing to ensure its stability, and even if this strength were accomplished it would be producing a new syrup. Parrish's syrup would still be made, and the new syrup would be some other person's. He thought the Conference should state a little more distinctly, if it could be done, whether the statement of strength should be adhered to, and a new syrup made, or whether the product of Parrish's formula should be taken as the standard, which he thought most natural, because were the statement adopted the old Parrish's syrup would still continue to exist.

NOTE ON SALICYLATE AND SULPHOSALICYLATE OF SODIUM.

BY JOHN WILLIAMS, F.C.S.

Salicylate of sodium has been much employed lately as an internal remedy.

It is made by neutralizing a solution of salicylic acid with caustic soda, and evaporating to dryness. It can be purified by crystallization from alcohol; the crystals formed are, however, very small and indistinct, and this method of purification is not generally adopted.

Complaints have appeared in the medical journals that the salt sometimes produces irritative effects when administered medicinally, and it has been suggested that probably a trace of carbolic acid may occasionally be retained by the salicylic acid made by artificial means, and thus the salt prepared from such acid is impure.

An examination of the salicylic acid made from carbolic acid by Kolbe's process soon proves that the product is not always to be depended upon as a pure homogeneous article; indeed it can hardly be otherwise, when we consider that the carbolic acid from which it is made is itself not an absolutely pure or definite article. Still I must observe that the salicylic acid now being supplied is much purer and more definite than that which was at first sent into the market by the German makers.

Thus salicylate of sodium—made from the artificial acid—and from the great difficulty of purifying it by recrystallization—is liable to be more or less impure, and indefinite in composition. It thus appears desirable if possible to obtain a salt which can be purified, and obtained of definite constitution.

Sulphosalicylic acid appeared to offer such a compound. It was discovered many years back by Cahours, and has been further investigated by Mendius. The process described for its production is, however, one of considerable practical difficulty.

The vapour of anhydrous sulphuric acid is passed over salicylic acid kept cool; gradually a sticky, gummy mass is produced, which contains the new acid, and can be separated by appropriate means.

I have made several attempts to produce this conjugated acid by means of ordinary sulphuric acid, and have at length succeeded in doing so, but not without several failures. I find the following process to answer.

The salicylic acid must be very pure; the unpurified commercial acid, when treated with sulphuric acid, simply yields a black mass, giving off sulphurous acid; and yielding no sulpho-salt capable of giving definite crystals.

If pure acid is employed, then about twice its weight of sulphuric acid is quite sufficient. The mixture must be gently heated in a sand-bath up to about 100° C., when action will commence in the liquid, and considerable heat be developed. The beaker must be removed from the sand-bath, and the contents stirred, so as to regulate and keep down the temperature; but the cooling must not be sufficient to altogether check the reaction. If the temperature exceeds the proper point, little or no sulphosalicylic acid is produced, but apparently bisulphocarbolic acid, which does not yield definite crystallizable salt.

When the reaction has been properly maintained, at the end of ten minutes or a quarter of an hour the temperature begins to fall and in a short time the whole becomes a solid mass, generally of a light brown colour; this will speedily deliquesce if left exposed to the air; but it can be dissolved in water at once, and treated with carbonate of barium in the usual way. I may mention that as the sulphosalicylate of barium is not a very soluble salt, it is necessary to employ a considerable quantity of water, and filter the liquid while still hot. This solution of the barium salt, decomposed by an equivalent quantity of sulphate of sodium, yields a solution of the sulphosalicylate of sodium, which upon evaporation to a small bulk yields crystals; these crystals must be pressed from the mother-liquor and purified by recrystallization two or three times from hot water.

When pure, sulphosalicylate of sodium forms hard white prisms; it is not deliquescent, although very soluble in water. It is almost insoluble in alcohol, has no caustic, but a slightly bitter taste, and is altogether a salt well adapted, I think, for medicinal use.

Salicylic acid and its salts give, as is well known, a striking reaction with perchloride of iron, producing a dark purple coloration. The sulphosalicylates produce exactly the same reaction, proving that the salicylic acid radical is still intact in these compounds, and it is fair to infer that the medicinal properties of these sulpho-salts will be found in practice to be identical with, or perhaps superior to, the simple salicylates.

We have in the analogous case of the carbolate and sulphocarbolate of soda, an instance in which the sulpho-salt possesses great advantages over the simple salt, and such may prove to be the case with the sulphosalicylates.

The acid itself is crystallizable, but deliquescent; the zinc salt is also very deliquescent. I have not paid any attention to the other salts as yet.

The PRESIDENT said the subject referred to by Mr. Williams was interesting and important. He knew, in one instance especially, in his own family, where salicylic acid had been taken internally, inconvenience was experienced from the fact of its containing an appreciable quantity of carbolic acid,—so much so in fact that the taste became an objection to further use of the remedy. He observed that Mr. Williams stated that the sulphocarbolates had a decided advantage over carbolates. Was that a confirmed fact? because he had had reason to doubt as to how far sulphocarbolic acid possessed the properties of carbolic acid.

Mr. WILLIAMS was under the impression that the sulphocarbolates were considered superior for internal administration to the carbolates. This impression was principally based upon the fact that the demand for them was increasing very considerably.

The next paper read was on—

FILTERING PAPERS.

BY THOMAS GREENISH, F.C.S.

Whilst engaged in examining some of those fungoid substances which every now and then make their appearance in solutions kept by pharmacists either for convenience in dispensing or other purposes, I have found on several occasions that the fungus had formed around a fibre, the presence of which in the filtrate was due to the paper through which the solution had passed. I observed also that those solutions which had passed through a filter were more liable to the presence of fungi than others where no filtration had been employed after solution. The paper used was the circular grey foreign filter paper. This circumstance induced me to subject the filtering papers in general use to a microscopical examination, with the view of determining the composition of each. The details I have thought may possess a certain amount of interest.

The white unsized filtering papers may be classed under Swedish, Rhenish, English, and Scotch. Sweden has obtained a reputation for filtering papers. Its manufacture has long been in the hands of the Munktell family. The supply, however, is not equal to the demand for it, consequently there is an inquiry for other papers to supply its place. The Swedish filtering paper is composed of flax fibre, and the fibres are very much crushed and broken. The linen had evidently done duty elsewhere in the rag before it found its way into the paper. The fibrillæ of the broken fibres serve to fill up the pores, and prevent solids passing through the paper. I am told that the water used in its manufacture is very pure, and contributes to its value as a chemical filtering paper. It yields a very trifling amount of ash, but recent investigations prove that the average quantity of ash has increased, pointing to the conclusion, either that the material used in the manufacture of this paper is not so pure, or that the same care is not exercised in its preparation.

The next paper is the Rhenish. This competes with the Swedish; it is a flax paper, but more fibrous in its structure and consequently less dense than the Swedish; this is due to the fibres being less broken and crushed. The fact of there being so much less fibrillæ would render such a paper quick in filtration, but not so satisfactory in results as the Swedish.

The English white filtering papers have a little cotton mixed with the flax and the fibres are very much crushed and torn. I have not had the opportunity of examining the Scotch filtering paper, which I understand to be very good, and some of the value of which is said also to be due to a very pure water used in its manufacture. These papers differ more in their physical characters than in their composition.

I now come to filtering papers of a very different character—those of foreign manufacture, grey in colour, cut circular, and of different sizes, also grey sheet filtering paper of Dutch and home manufacture. These papers are of a more composite character and have in their composition a considerable quantity of wool, said to be used to render the paper absorbent. Much of this wool is coloured and has evidently done previous duty in some textile fabric. I have also found in some samples, in addition to this dyed wool, fibres of jute and esparto, unbleached, and mixed with other fibres—in fact, to the microscopist interested in fibres it is a kind of curiosity shop. It is evident that these papers must be very unsuited for alkaline solutions and others which will suggest themselves to the pharmacist, and it is not difficult to understand that from the heterogeneous character of the material from which filtering papers of this kind are made that it may be the source from which certain impurities find their way into delicate solutions.

Here is a sample of filtering paper which has been introduced to supply a want. The Swedish is difficult to get in sufficient quantity, and some of the others are not satisfactory. This is made on the Rhine, and composed mainly of flax; it allows the fluid to pass rapidly through it. The paper being uniform the amount of ash is tolerably definite. The fibres are more torn than in the other Rhenish papers which I have examined.

It is extremely difficult to determine the fibres crushed and torn as they exist in these papers. A flax fibre where crushed resembles that of cotton, and it requires to be traced further to establish its identity. Again, the same fibre bruised only, resembles the hemp fibre. The wool is not usually much injured, with this exception, that the characteristic imbrications are sometimes nearly all obliterated.

I have here, more as a curiosity than with any practical object, a specimen of Japanese filtering paper. I do not know what the Japanese can use it for. It appears adapted only for filtering flies out of a syrup. It is prepared from the liber tissue of the mulberry *(Broussonetia papyrifera)*, a substance yielding the longest fibre of any material used in the manufacture of paper.

The PRESIDENT said the meeting had sufficiently indicated its thanks to Mr. Greenish by the way in which it had accepted his paper on filtering paper, a subject which had a good deal of practical interest to pharmacists as well as to chemists; he meant to scientific chemists. Mr. Greenish had stated that the presence of certain fungoid vegetation which was found frequently in solutions might be traced to the paper through which the solutions had been filtered. Mr. Greenish seemed to think that the commoner kinds of paper were most likely to produce such results. He must say, however, that he did not think Mr. Greenish had adduced sufficient evidence to satisfy him as to this, and his own experience was rather to the effect that papers of all kinds, of the best description as well as of the commonest description, were liable to have such substances developed in them. That was a matter which had been frequently brought under his notice both in connection with printing establishments and paper works. Not unfrequently it was found that when paper, and even paper of the very best description, such as for instance was used for the illustrations of some of our expensive books, where such paper had been kept in a moist state for any length of time these growths become largely developed in it. In old books there might be constantly observed brown spots upon the paper, which some persons had ascribed to ink spots, but they really would be found to have an entirely different origin; and those substances became developed and extended with very great rapidity, often so that a single spot at the commencement of the book would gradually creep through from page to page until it entirely permeated the book. He would be disposed to ascribe those results which Mr. Greenish had observed not so much to the character of the paper as to the condition the paper may have acquired before it was used. As far as his experience went, good filtering paper was as liable to this as the commoner kinds. The subject, however, was really a very interesting one and one which young pharmacists who were using the microscope would find to offer an opportunity for cultivating their microscopic powers of investigation. It would be found that papers were rich in substances of that description.

Mr. GREENISH said this was only a portion of a larger subject which was engaging his attention, and he hoped to be able to bring some perhaps curious results before the Conference. He thought the President in his remarks had not borne in mind the distinction between the unsized paper and the sized paper; the decomposition was generally attributed to the "size," but the unsized filtering papers were free from that unstable element.

The PRESIDENT: I have not certainly.

In reply to a question respecting the specimen of Japanese filtering paper exhibited,

Mr. GREENISH said that it was prepared from the liber of the mulberry tree. He had isolated the fibres from that liber tissue, and, having examined them under the microscope, found that they were identical with those of which this paper was composed. It was generally supposed that these Japanese and Chinese papers were made from straw. Some might be made from straw, but he had several specimens, particularly of Japanese, and all these were made from the mulberry.

Mr. EKIN said he supposed Mr. Greenish did not refer to the common mulberry tree grown in England.

Mr. GREENISH replied that he alluded to the paper mulberry tree (*Broussonetia papyrifera*) specimens of the liber tissue of which he had in his possession.

The next paper read was on—

NOTE ON THE CONDITION IN WHICH SALICYLIC ACID IS EXCRETED BY PATIENTS.

BY F. BADEN BENGER, F.C.S.

The question whether or not salicylic acid ever exists in a free, and therefore active condition, in the urine of patients being of some importance, the following experiments were made, and the results are offered as a small contribution towards a settlement of the point.

The urine of a patient who had taken 60 grains of salicylic acid during the day was collected in the evening and the following morning. It was slightly acid to test paper, and gave the purple reaction with ferric chloride characteristic of salicylic acid and its salts. A portion shaken with bitter almond meal in the proportion of two grains to the fluid ounce immediately developed the odour of bitter almond oil. In a similar portion treated with two grains of mustard flour to the fluid ounce, the odour of mustard oil was at once perceptible; mixed with forty grains of sugar and half a grain of German yeast to the fluid ounce, fermentation rapidly took place. Five fluid ounces were evaporated to half an ounce, thoroughly shaken with its bulk of ether, the ethereal solution evaporated to dryness, and the residue dissolved in one fluid ounce of sweetened water; to this half a grain of yeast was added, and fermentation immediately commenced. A portion set aside in a warm place decomposed with the same rapidity as another specimen of urine containing no salicylic acid or its salts.

Parallel experiments were then made with urine in which salicylic acid had been dissolved in the proportions of ¼ grain, ½ grain, 1 grain, and 2 grains, to the fluid ounce. Sweetened with sugar, and half a grain of yeast to the fluid ounce added, the ¼ grain and ½ grain solution fermented more or less rapidly, the 1 grain solution slightly in twenty-four hours, whilst that containing two grains to the ounce remained unaffected. Mixed with bitter almond meal, two grains to the fluid ounce, the ½ grain solution prevented the production of bitter almond oil, but with mustard flour in the same proportion a slight odour of mustard oil was apparent, nor did the 1 grain solution entirely prevent its production. Similar experiments were then made with aqueous solutions of salicylic acid, and ¼ of grain of acid to the fluid ounce was found to be sufficient to prevent the action of ½ grain of yeast on 1 fluid ounce of sweetened solution. Smaller quantities only slightly retarded the action. A larger proportion of salicylic acid was required to prevent the action of yeast on sugar than has been recorded by some experimenters, and, as might be expected, more acid was required to produce the same effect in sweetened urine than in sweetened water, some of it probably combining with the alkaline phosphates present; nevertheless these experiments, as far as they go, seem to indicate that, at all events in the case under observation, the acid was not excreted in an active condition.

In connection with this subject, some experiments were made with urine in which salicylate of sodium had been dissolved in the proportions of 1, 2, 3, 4, and 5 grains to the fluid ounce, 40 grains of sugar and half a grain of yeast were added to an ounce of each. The one grain and two grain solutions fermented rapidly, the three and four grain solutions less rapidly, and the five grain solution remained unaffected by the ferment.

Solutions of salicylate of sodium in urine appeared to exert no retarding action on the production of oil of mustard, or oil of bitter almonds. Aqueous solutions of salicylate of sodium acted in a similar manner.

It has been stated that the salts of salicylic acid do not possess antiseptic properties, but it is evident that salicylate of sodium is capable of preventing fermentation if present in the proportion named.

The next paper read was on—

The Strength of Tincture of Nux Vomica.

BY L. SIEBOLD.

Having frequently noticed a striking difference in the opalescence produced by the addition of water to tincture of nux vomica obtained from different establishments, and also a difference in the degree of bitterness quite in harmony with the difference in the opalescence, I desired to ascertain the extent to which this preparation might vary in strength as well as the cause of such variation. For this purpose I examined ten specimens of this tincture from pharmacists of very good reputation. All were perfectly clear and proved to have been made with pure rectified spirit. The solid extract was estimated in each by evaporating 10 c.c. in a platinum dish and heating the residue in a water-bath until it ceased to lose weight. The following table is arranged according to the strength of the tinctures, beginning with the weakest, and gives the weights of the dry residues calculated for 1000 c.c. of tincture:—

No. 1	2·7 grms.
No. 2	2·9 „
No. 3	4·0 „
No. 4	4·3 „
No. 5	5·5 „
No. 6	8·9 „
No. 7	9·0 „
No. 8	9·6 „
No. 9	9·6 „
No. 10	10·1 „

From this it will be seen that the strongest tincture yielded nearly four times as much extract as the weakest. As far as I could ascertain the tinctures were all made in strict accordance with the B.P. process. They varied somewhat in colour but much more in the opalescence produced on the addition of seven fluid drachms of water to one fluid drachm of tincture. On the whole the relative strength of the ten specimens was pretty well indicated by the degree of opalescence thus produced.

In the next place, I endeavoured to ascertain how far the bitter taste of tincture of nux vomica might be relied upon as an indicator of its strength, and here I obtained results which very fairly correspond with those obtained by evaporation. By adding measured quantities of tincture to 10,000 parts of water until the mixture had a distinctly bitter taste, it was found that the following quantities were required:—

14 parts of Nos. 1 and 2
10 „ „ 3 „ 4
7 „ „ 5
4 „ „ 6, 7, 8, 9 and 10.

These experiments were repeated independently by two friends of mine with the same results.

In order to see what is the proper strength of tincture of nux vomica I prepared four specimens from four different samples of the finely-powdered seeds according to the B.P. directions, and estimated the amount of solid extract in each as before. Of this they yielded 9·5, 9·9, 10·0, and 12·0 grams per 1000 c.c., respectively. As the maceration and percolation were conducted alike in each case, the difference in the result could only be due to a difference in the quality and condition of the seeds used. It will be observed, however, that three out of the four tinctures agreed very well, and that none yielded less than 9 per mille of extract. The fourth, which yielded 12 per mille was made from an exceedingly fine powder. Two tinctures made from the same powder by repeated and long continued boiling with the alcohol yielded 14·6 and 13·0 parts of extract. By this process the powder was so completely exhausted that a fresh quantity of alcohol boiled with it came off free from bitter taste. I do not advocate the uses of boiling alcohol for preparing this tincture, but merely record the two last experiments in order to show how much matter soluble in alcohol nux vomica contains.

Another series of experiments was made to ascertain whether the coarser or finer condition of the powder used is to be considered the main cause of the variation in strength of the tinctures, and also whether or not the time allowed for maceration has any appreciable effect upon the result. The B. P. directs the finely-powdered seeds to be macerated in the spirit for forty-eight hours, previous to percolation, and it appeared to me not improbable that this time is often exceeded by pharmacists under the not unnatural impression that prolonged maceration is an advantage rather than otherwise. For the experiments now to be quoted the nux vomica was used in four different states, viz., as a coarse, as a moderately fine, as a fine, and as a very fine powder. Two tinctures were made of each sample, one in strict accordance with the B. P. directions, the other by macerating for six instead of two days. The determination of solid extract gave the following results:—

B. P. Tincture.	Tincture macerated for six days.
4·2	4·3
8·9	9·1
11·1	11·8
11·7	12·0

It is evident, therefore, that prolonged maceration does not materially improve the quality of the tincture, and that leaving out of consideration such slight differences in the yield of extract as may be due to variations in the quality of the seed, the real cause of the great discrepancies alluded to is to be found in the different degrees of fineness of the powder employed. Nux vomica is a tough substance to deal with, and it is no doubt used in many instances without being reduced to a sufficiently fine powder.

Absolute uniformity of strength in tincture of nux vomica would, of course, be obtained by preparing it from a definite quantity of the alcoholic extract. But until such a process is sanctioned in a revised edition of the Pharmacopœia pharmacists must take care to prepare the tincture from the very finely-powdered seeds only. By so doing they can make sure that the tinctures obtained will contain from nine to twelve parts of extract per 1000 c.c., a result which, I believe may be considered satisfactory. Those who do not prepare their own tinctures should not neglect to test the strength of the tincture of nux vomica they purchase; 10 c.c. of the tincture should yield no less than 0·09 gram of dry extract, one fluid drachm of the tincture should impart a distinctly recognizable bitter taste to two gallons of water; and the addition of ten to twenty volumes of water to one volume of the tincture ought to produce a marked opalescence.

Tincture of nux vomica is, I believe, a weaker preparation than it is generally supposed to be. The B.P. dose (10 to 20 minims) is very small as compared to that of the extract. I have repeatedly taken a 60 minim dose of a full strength tincture without perceiving any effect. Of one of the weak tinctures referred to in this report I took a dose of 90 minims without noticing the faintest symptom and might, no doubt, have taken 200 minims of it with perfect safety. If the ordinary medicinal doses of a carefully prepared tincture of nux vomica must be considered rather small, what effect is to be expected of those specimens which fall so lamentably short of the proper strength?

The CHAIRMAN said in reference to this subject he would suggest—what Mr. Siebold had not referred to—that the discrepancy in the strength of the tinctures might be due to the fact that the tincture was made from commercial powder of nux vomica which had not been properly prepared. He had found in the examination of many specimens of commercial powder of nux vomica what appeared to him to be very strong evidence of a considerable amount of adulteration in it. In fact he had been led to make such an inquiry in the first instance from an application having been made to him by a practical grinder as to what method he would suggest for facilitating the pulverization of nux vomica, as he had found up to that time that it was absolutely necessary to make some addition in order to promote and facilitate pulverization. It was well known now, however, to practical grinders generally that by pursuing a course somewhat analogous to the course that was indicated in the Pharmacopœia, softening the nux vomica by the action of steam, and then rapidly drying it, that it could afterwards be pulverized with tolerable facility. Practical grinders got into the way of adding other substances probably partly from example and partly also possibly from the idea that nux vomica was used as a poison for poisoning vermin, and that great uniformity in its strength and composition was not of very great account.

Mr. PROCTOR would have liked to know the sources of the powders because a chemist might err from excessive caution. The fact of powdering the nux vomica himself would prevent the production of so fine powder as would be produced by a practical grinder, and thus might make his tincture worse instead of better by his care.

Mr. BENGER believed the tinctures were prepared from powders ground as Mr. Proctor suggested by pharmacists, who had found the difficulty Professor Redwood had alluded to, in obtaining a sufficient degree of comminution.

The next paper read was on—

NOTE ON THE PREPARATION OF SULPHUR PRÆCIPITATUM.

BY L. SIEBOLD.

Most chemical handbooks represent the decomposition occurring in the preparation of precipitated sulphur by the following equation:—

$$2\,CaS_5 + CaS_2O_3 + 6\,HCl = 3\,CaCl_2 + 3\,H_2O + 6\,S_2.$$

According to this explanation the whole of the sulphur originally dissolved is regained, as the sulphuretted hydrogen liberated from the pentasulphide reacts upon sulphur dioxide disengaged from the hyposulphite forming sulphur and water. This view, however, is hardly in accordance with facts, for the two decompositions do not occur simultaneously, but take place one after the other, the pentasulphide being decomposed first. If the equation given were correct there would be no disengagement of sulphuretted hydrogen. In reality, however, a very large quantity of this gas is given off, which necessitates the operation to be conducted in an open place, or under a chimney, as directed in the British Pharmacopœia. After the pentasulphide has been decomposed the hydrochloric acid begins to act upon the hyposulphite, precipitating one half of its sulphur and giving off sulphur dioxide, which is to some extent decomposed by the sulphuretted hydrogen held in solution. I believe it is not generally known to pharmacists that the sulphur precipitated during this second stage of the decomposition differs in its physical characters from that obtained during the decomposition of the pentasulphide; it is coarser, heavier, and darker in colour, and does not exhibit the same perfect globular form under the microscope. Neither is it acted upon with equal energy by chemical agents. If the precipitation be conducted with a quantity of hydrochloric acid barely sufficient for the decomposition of the pentasulphide only, so that the mixture still retains a slight alkaline reaction, the resulting preparation will be found to be much superior to that obtained by the B. P. process, in which sufficient or almost sufficient hydrochloric acid is used for the complete decomposition of both the pentasulphide and hyposulphite. Prepared in this way the product amounts to about 55 per cent. of the sulphur used. It is a pale yellowish white, thoroughly uniform, fine powder, consisting entirely of perfectly round, smooth globules; it is sure to be free from arsenic, and can never contain any persulphide of hydrogen. Solution of chlorine dissolves it immediately, forming sulphuric acid and hydrochloric acid. From its general, physical, and chemical properties, I am inclined to infer that it will be more readily assimilated than the heavier, coarser, and less uniform preparation of the British Pharmacopœia. The advantages of this partial precipitation appear to me to outweigh the not inconsiderable loss of sulphur. Pure hydrochloric acid ought to be used if a pure precipitation, free from a greyish tint, is desired, as the iron contained in the impure acid always passes into the precipitate and cannot be afterwards removed. The surface attraction between the precipitated sulphur and the sulphide of iron is so great that it is impossible to remove the latter even by long continued washing with dilute hydrochloric acid.

The preparation of precipitated sulphur by partial precipitation is a process which, I believe, deserves to be strongly recommended.

The PRESIDENT said the suggestion thrown out by Mr. Siebold was one well worthy of consideration. It presented a method by which precipitated sulphur could be obtained free from the impurities which commonly occur in it, even when prepared according to the Pharmacopœia. He thought it would be difficult to induce manufacturers to incur so great a loss as would be entailed by the adoption of the suggested process, but it would be useful to draw attention to the fact that precipitated sulphur was somewhat different from what it was often assumed to be, namely, pure sulphur. He did not think it was desirable on the present occasion when discussing this subject to mix up any other question with it. The subject before them was precipitated sulphur, which as made by the Pharmacopœia possessed certain impurities and imperfections, which Mr. Siebold suggested a method of getting rid of.

Mr. KINGZETT was glad to be able to support what had been said regarding chemical equations. He had attempted to realize the equation often given in books, but which expressed only partially the truth—viz.,

$2(H_2S)+SO_2=2H_2O+S_3$. Not only was water and sulphur produced in this way, but also pentathionic acid $H_2S_5O_6$, so that, in fact, when some years ago attempts were made to utilize sulphurous acid and hydrosulphuric acid gases derived from certain industrial processes *in this* way, one fifth of the sulphur was lost as pentathionic acid. Further, the action of hydrochloric acid upon sodic hyposulphite as generally given in books was but partially true. A great excess of hydrochloric acid, on the one hand, was required to decompose it fully, or, on the other hand an excess of hyposulphite was required to make use of all the hydrochloric acid. That is to say, there obtain certain physical and other conditions in every chemical reaction which render equations true only within limits—in other words, a chemical equation is not a mathematical equation.

The next paper read was—

Note on Flower of Tea, or Pekoe Flower.

BY T. B. GROVES F.C.S.

Some time in March this year was received at the Weymouth Custom House for export to Jersey a package containing 100 lbs. of a substance bearing the above appellation, and purporting to be a variety of tea.

Its unusual appearance at once aroused the suspicions of the "authorities," who ordered it to be detained for inquiry. A portion having been sent to the London Custom House for report, an answer was returned that the substance was really tea, and must therefore be allowed to pass; that it was not the leaf of the tea plant, but the pollen of its flower; that it was of rare occurrence in the market, and was obtained indirectly by sweeping and screening the dusty matters that collect on the extensive floors where in China teas in large quantities are "bulked." A sample was kindly sent to me as a curiosity, and having learned its history as far as it could be ascertained, I determined on making a few inquiries respecting its origin, nature, and properties.

All I could learn of its commercial source was confined to the fact that it was purchased in London of a well-known firm of brokers in Crutched Friars; but of course any one on the spot could have followed it up with more success.

That it was not the pollen of the tea flower, or of any other flower, was evident to the naked eye. It might possibly be a collection of "filaments;" but it proved on submitting it to the microscope to be composed of simple unicellular vegetable hairs, mixed with small fragments of tea leaves, together with sand, and probably other extraneous substances.

Mr. Holmes, of the Pharmaceutical Society's museum, kindly made inquiries for me at Kew and elsewhere, and by actual comparisons established the fact that the pekoe flower was really the hair of the leaf buds of the tea plant, though these, in their natural state, are white, or nearly so. The few white hairs to be found on the outside of the sepals and at the base of the petiole might possibly have contributed to the collection.

The filaments of the tea flower are, besides being of altogether different structure, much broader than the hair from the buds; the two, therefore, are quite unmistakable.

Hassall, in describing the structure of the tea leaf, states that "the *hairs* are confined to the under surface of the leaf; in the very young leaf they are very numerous, but in those of middle age they are much less abundant—and, indeed, in some cases nearly altogether wanting; they are short, and when not broken pointed and undivided." He also gives a figure of the under surface of a leaf with a hair *in situ*.

It now remained to ascertain its chemical composition. This I proposed to do in conjunction with Mr. Wigner, whose well-known acquaintance with the subject would give additional value to his results, and enable the pekoe flower to be tabulated with the very numerous other varieties of tea examined by that gentleman. It was finally, however, arranged that the analysis should be carried through by one person, and I having then but little time at my command was glad to hand the subject over to Mr. Wigner.

The following is his report:—

	"Analysis of Tea Marked Pekoe Flower.		The Average Analysis of Pekoe.
"Ash Soluble in Water	1·15	per cent.	3·30
" " " Acid	4·54	"	2·60
Silicious Matter	13·04	"	·30
Total Ash	18·73		6·20
Moisture	7·00	"	7·30
Extract (soluble in Water)	14·65	"	34·00
Ash (of ditto)	2·40	"	5·00
Theine	1·50	"	3·50
Tannin (by Ph. process)	12·00	"	28·00

The composition of the ash was as follows:—

Oxide of Iron	6·01	"	5·00
Lime	4·83	"	11·00
Magnesia	2·05	"	
Potash and traces Soda	4·97	"	32·50
Oxide of Manganese	1·02	"	
Sulphuric Acid	1·29	"	4·80
Carbonic Acid	7·39	"	12·00
Chlorine	·61	"	
Phosphoric Acid	5·33	"	16·00
Silica	66·18	"	
Loss in Analysis	·32	"	
	100·00		

"I have made several unsuccessful attempts to sift the sample. A large portion of the hair has passed through with the dust. The gross ash yielded by the sifted part corresponding tolerably with that of the original sample. The microscope shows much leaf in fragments, and some of these fragments certainly appear to belong to some plant which is not *tea*."

It will be observed that whilst its extractive is less than half that of average pekoes, its ash is three times as great and mainly silicious. The difficulty of separating the sand, might, if it were worth while, be got over, I fancy, by winnowing. It is interesting to find theine present in the hair. Doubtless some of the 1·50 found is due to the fragments of the tea-leaf present in the sample, but as those fragments certainly did not constitute more than 2 or 3 per cent. of the bulk the yield must have been mainly due to the hairs themselves.

P.S.—The above was what Mr. Groves intended to read to the meeting, but in consequence of the miscarriage of the document, an imperfect *vivâ voce* statement had at the last moment to be substituted for it.

Mr. Greenish stated that a sample of this substance had been sent to him, without a name or a history, with a request that he would determine, with the aid of the microscope, whether it was of vegetable or animal origin. On examination he found it to be mainly composed of vegetable hair, with small particles of parenchyma and spiral tissue more or less attached to it, also of minute fragments of the epidermis of a leaf. From the character of the hair, and also that of the stomata, he came to the conclusion that the substance in question formed part of the *débris* of tea leaves. On being informed that it had been offered for sale as the "pollen of the pekoe flower," he continued his investigations, and would just state the successive steps by which he had arrived at his conclusions respecting it. In the first place he would explain what was pekoe flower. Pekoe tea consisted of the young leaves of the ordinary tea plant, the first pickings, gathered in early spring; and the pekoe flower, or "pekoe tips," as known in the trade, were the youngest, unexpanded leaf buds growing on the tips of the branches, with perhaps one or two leaves attached to each. These buds consisted of two or three leaves rolled together, each of which was covered on the under surface with hair, and the leaves being rolled outwards on the mid rib. Their under and hairy surface was exposed. The buds resembled hairy pods, with a couple of leaves attached to each, and when spread on the surface of a chest of pekoe tea, they gave it a flowery appearance. He had with him as examples, some of the tips or leaf-buds, covered with grey hairs; these had been obtained direct from China. Also one, which, having been placed in water, had expanded, showing the smaller leaves enclosed forming the bud. He had detached some hair from one of these buds and found that it agreed with the hair in question; the epidermal and cellular tissue corresponded also. There still existed a difference with regard to the colour of the hair; in the sample under examination it was brown, while that on the pekoe was grey. On searching, however, a sample of Assam pekoe, he had found the buds covered with brown hair. A specimen of this also he submitted for inspection. Not yet satisfied with regard to the source of this colouring matter on the hair, he examined it more minutely and found that the colour was mainly due to particles of cellular tissue adherent to the hair, the chlorophyll of which had become more or less brown, probably from oxidation, and partly decomposed. A small quantity of the hair warmed in a dilute solution of liquor potassæ gave off a strong odour of tea, and those particles to which the hair chiefly owed its colour were removed. These facts he thought suggested the probable origin of the substance. In buildings where tea was manipulated the light hairs would be carried with the dust and lodged in different parts of the building, where it would be exposed to changes of weather. In course of time an accumulation took place, which, being swept together and collected, would eventually find its way into commerce. The fact that small particles of calcareous matter and silica were found mixed with it would favour this supposition; and he might add that the sample did not contain a particle of pollen. He had been to Kew Gardens and had seen the downy hair on the young leaves of the tea plant growing there; he had also examined in the herbarium the dried tea plants from different countries, and had come to the conclusion that the colour of the hair was a feature not special to any particular tea. He would add in conclusion that the hairs of the tea leaf offered a means of identification when, from the broken character of the leaf itself, the peculiarly serrated margin and emarginate apex could not be discovered. The hairs were conical, pointed, one-celled, slightly bent near the base, the cell walls very thick, and the central duct generally containing granular matter. The stomata also, with the cells immediately surrounding them, had certain characters, which, taken together with the hair, served to distingush the leaf of the tea from that of any known plant.

This concluded the reading of the papers.

The Bell and Hills Gift of Books.

Professor Attfield, on behalf of the Conference, presented Mr. Fairlie, as representing the local association with a number of books as a donation to the library of the association, and together with these, although having no connection with the gift, he presented two engravings, one of Dr. Pereira and the other of Jacob Bell.

Mr. Fairlie, on behalf of the local association, accepted the handsome present which had been made to them. The only thing he was sorry for was that the books were just a little too handsome to be put beside those they already had. The books were a valuable addition to their library, and he had not the slightest doubt they would be used to the best advantage by the members of the association.

Place of Meeting in 1877.

Professor Attfield said it had been the custom of the Conference, with one exception, to meet in the town in which the British Association met and on the two days preceding the meeting of that Association. The British Association, as was well known, was to meet at Plymouth next year, and he had received a letter from the Secretary of the Plymouth, Devonport, and Stonehouse Association which he would read to the meeting.

"Plymouth, Devonport, and Stonehouse Chemists and Druggists' Association.

"77, Old Town Street, Plymouth.
"August 18, 1876.

"Professor Attfield, Hon. Sec., British Pharmaceutical Conference.

"Dear Sir,—As Honorary Secretary of the above Association I am instructed to send a warm and hearty invitation to the British Pharmaceutical Conference to hold its 1877 meeting at Plymouth; and on behalf of the chemists of the three towns and neighbourhood to assure you that nothing shall be wanting on their part to cause the memory of such a visit to be one of the most pleasant recollections of the members of your Conference.

"Remaining
"Sincerely yours,
"Robert J. Huntly."

He (Professor Attfield) had very much pleasure in moving that the invitation be accepted and that the meeting of the Conference for 1877 be held at Plymouth on the two days immediately preceeding the meeting of the British Association. He was convinced from what he knew of the pharmacists of that district that the Conference would receive a warm and hearty welcome in Plymouth. One of the most prominent of these pharmacists was proposed as vice-president of the Conference. He was a visitor at their first annual meeting at Bath, where he was one of the thirty-one visiting members at the meeting. He alluded to Mr. Balkwill, and he was convinced from that gentleman's interest in and knowledge of pharmacy that they would have a successful meeting at Plymouth.

Mr. Jones had very great pleasure in seconding the motion.

The President put the proposal to the meeting and it was unanimously agreed to.

Election of Officers.

A ballot was then taken for the ensuing year, when the list proposed by the Executive Committee was unanimously elected as follows:—

President.
Professor Redwood, London.

Vice-Presidents.
A. P. Balkwill, Plymouth.
T. H. Hills, F.C.S., London.
R. Reynolds, F.C.S., Leeds.
J. Williams, F.C.S., London.

Treasurer.
G. F. Schacht. F.C.S., Clifton.

General Secretaries.
Professor Attfield, F.C.S., London.
F. Baden Benger. F.C.S., Manchester.

Local Secretary.
Robert J. Clark, Plymouth.

Other Members of Executive Committee.
M. Carteighe, F.C.S., London.
F. Codd, Devonport.

C. Ekin, F.C.S., Bath.
D. Frazer, Glasgow.
A. Kinninmont, Glasgow.
B. S. Proctor, Newcastle-on-Tyne.
E. Smith, F.C.S., Torquay.
W. A. Tilden, D.Sc., F.C.S., Clifton.
C. Umney, F.C.S., London.

Auditors.

T. Davison, Glasgow.
J. B. Turney, Plymouth.

Mr. Schacht moved a vote of thanks to the local Executive Committee for the manner in which they had arranged for the Conference. It was his conviction that the Conference had never had occasion to feel more gratitude to any such body of men than it did on the present occasion. Their thanks were specially due to Mr. Frazer, Mr. Greig, Mr. Kinninmont, Mr. Fairlie, and others, for their untiring and most successful efforts in organizing the present meeting. He would therefore move—

"That the most cordial thanks of the non-resident members be given to the Glasgow and West of Scotland members of the Conference generally, and to Mr. Frazer, Mr. Greig, Mr. Kinninmont, Mr. Fairlie, and other members of the local committee especially, for their untiring and most successful efforts in organizing the present meeting, and for the kind and thoughtful way in which every arrangement has been made."

Mr. Williams seconded the resolution, which was agreed to with acclamation.

Mr. Frazer, as Chairman of the Local Committee, acknowledged the compliment.

Mr. Gilmour moved the following resolution:—

"That the thanks of this meeting be given to the President for the ability and courtesy with which he has discharged the duties of that office, and conducted the business of the meeting."

He was sure he did not require to add one word to that resolution in support of it. From the very first,—in the able address they received from their worthy President, an address he was sure they would all remember with pleasure—down through the various papers which had been read, to the close of the meeting, the discharge of the President's duties had been characterized with an ability, address, and courtesy, which he had scarcely ever seen equalled. He had been particularly struck with the knowledge which their excellent President had brought to bear upon every subject that had been before them, and above all the practical bearings he had always sought to keep uppermost in respect to all the papers.

Mr. Proctor seconded the resolution. It was, he said, indeed a red letter day for the Pharmaceutical Conference when Professor Redwood was made its President.

Professor Redwood, who on rising was greeted with general cheering, said he felt deeply indebted to them for the very kind expression of their feeling towards him. He accepted most gratefully their vote of thanks for the slender offices which he had been enabled to fulfil during the meeting. He felt it to be a very great honour to occupy the office which he had held during the last twelve months and which they had now conferred upon him for another year. He had been greatly pleased and gratified with the manner in which the proceedings of this meeting had been carried through. The papers had been of a valuable character and the discussions had been conducted in a manner very creditable to the members of the British Pharmaceutical Conference. If anything could have been required to convince him of the great value of their institution he would have needed nothing more than the experience he had had at that meeting. He thanked them most sincerely for their expressions of good feeling towards him.

This terminated the proceedings.

Obituary.

JOHN SIMPSON.

A few months ago we had occasion to notice the death of Mr. William Tait, the then senior partner of the old established and well known firm of Duncan, Flockhart and Co., and it is now our sad duty to record the sudden and unexpected death of another partner of the same firm.

On the morning of the 22nd inst. Mr. John Simpson died after a few minutes' illness, in his house, Lauder Road. Observed to breathe somewhat unusually about 7 o'clock, medical aid was at once summoned, but he had passed away before it could be obtained. For some years he had been afflicted with valvular disease of the heart, and although he well knew how singularly uncertain his life was with such a serious and insidious complaint, yet he was able cheerfully and actively to carry on his daily occupation. He has been removed at the early age of thirty-nine and leaves a widow and five children to mourn his sad and sudden removal.

Mr. Simpson was a member of the Pharmaceutical Society, and though from his state of health he was seldom present at any of the evening meetings, he fully recognized the importance of the association and wished it well in its endeavours to promote increased education among pharmacists generally.

A nephew of the late celebrated Sir James Y. Simpson, the deceased had been connected with the business of Duncan, Flockhart and Co. for many many years, and became a partner in 1863, devoting his time and energies to that branch carried on at 52, North Bridge. From the prominent part he took in the management there his loss must be very deeply felt by his remaining partners. He was also much esteemed and respected by all who knew him, while in the more immediate circle of his relatives and friends, who were acquainted with his rare qualities of head and heart, he was greatly beloved.

The late Mr. Simpson took a deep interest in the prosperity of several of the religious and charitable institutions of the city. His heart was quick to feel for and his hand was ever ready to help the friendless and the destitute, and it is not too much to say that many, old and young, will miss in his removal a kind friend and generous benefactor.

Notice has also been received of the death of the following:—

On the 2nd of September, 1876, Mr. John Armitage, Chemist and Druggist, of Dukinfield. Aged 36 years.

On the 16th of September, 1876, Mr. Thomas Hockenhull, Chemist and Druggist, of Congleton, Cheshire. Aged 34 years.

On the 17th of September, 1876, Mr. David Atkinson, Chemist and Druggist, of North Shields. Aged 26 years. Mr. Atkinson had been an Associate of the Pharmaceutical Society since 1870.

On the 23rd of September, 1876, Mr. Joseph Wigginton, Chemist and Druggist, Long Causeway, Peterborough. Aged 36 years. Mr. Wigginton formerly represented Messrs. Richardson and Co. Leicester.

The following journals have been received:—The 'British Medical Journal,' September 23; the 'Medical Times and Gazette,' September 23; the 'Lancet,' September 23; the 'London Medical Record,' September 23; 'Medical Press and Circular,' September 23; 'Nature,' September 23; 'Chemical News,' September 23; 'Gardeners' Chronicle,' September 23; the 'Grocer,' September 23; 'Journal of the Society of Arts,' September 23; 'Grocery News,' September 23; 'Produce Markets Review,' September 23; 'Practical Magazine,' for September; 'Educational Times,' for September; 'British Journal of Dental Science,' for September; 'Journal of Applied Science, for September.

THE CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

Sir,—From your remarks and those of Mr. Mee in last week's Journal, I think there is considerable misconception of the objects and aims of the Chemists' Defence Association. The objects, as far as I see and know, are to protect the chemists and advance their interests.

You and Mr. Mee both admit that the Council of the Pharmaceutical Society is not sufficiently representative of the trade, and in my opinion it will require a far different organization than any that exists at present to accomplish so very desirable an object. The present method of election for the Council, though very broad, does not give the members an opportunity of knowing the views of those seeking election; there has been no organization of the great body of chemists, hence the majority vote haphazard or in the dark. It is also my opinion—and in this I am not alone—that the Council aim too much at the scientific, and too little at the practical instruction in the examinations of pupils for the trade. I say by all means give the highest scientific education you can to those who have the time and the means for chemical research, which is always highly estimated, and is invaluable to the community, and I think that each grade should be recognized by a higher title or reward; but the Council must not forget that ours is a trade that every one hopes to get a living by, with due attention to business.

There is very little doubt that the Act of 1868 did much good to the general body of chemists, but in many cases it is nearly inoperative. Legislation has not provided for the supply of drugs in numerous districts too small to support a chemist. These in many cases are miles apart and a great distance from any town; no doubt it was an oversight in passing the Act, but so serious that the defect makes the Act, as I said before, inoperative. I believe the movement now on foot will do much to strengthen the Pharmaceutical Society, as it will be able to take up many questions the Council cannot or is not willing to take up. It will also produce, when fairly carried out, a public opinion that will make its influence felt amongst the chemists of the country, and will, I have no doubt, complete an organization that will tend considerably to modify the present position of the Council to the trade, and will, I hope, make it have a more representative character.

It has been asked what the new association can do that could not be done by the old one. There are many things. I will briefly illustrate one of them by what we have done and propose to do in Chesterfied and East Derbyshire. Late in July, after the Birmingham meeting, we formed a branch association to embrace the eastern division of the county; it has been with us a complete success (as I have no doubt it will have been in other places where it has been tried). The trade has long been the victim of unscrupulous customers who have played upon the jealousy which has unfortunately existed so long in the trade, thereby reducing profits to the grocer's level without the grocer's rapid turn over of stock, his articles being an everyday necessity, ours only in very limited demand; and the present system of unremunerative prices will continue till there is a better understanding in the trade. Our branch association has already accomplished more than we expected in so short a time—viz., the good understanding and the determination to act together for the general good. Jealousy of each other now only excites surprise that it should have existed so long, as all that each individual wants is an honest and honourable living.

We are now engaged in arranging a schedule of prices, both for dispensing and retail, to suit our locality; we fix a minimum charge—more may be charged according to locality, the class of customers one may serve, and the expensive nature of the drugs used in dispensing. We have a private mark which is put on all prescriptions dispensed, so that if a prescription is sent to a second establishment it is charged accordingly.

Again, a chemist may have a prescription to dispense for a person in indigent circumstances; he dispenses this for less, but at the same time uses a private mark in addition to the cost mark, which shows his reason for dispensing it for less than the usual charge.

Then I may add that all our members are members of the Birmingham Association, and whilst loyal to their rules, we adopt our own, suitable to the locality; our subscription for local purposes is five shillings per annum, and has already greatly benefited its members in many ways—besides, what is worth more than all, producing a good understanding amongst them. Our secretary collects the subscriptions from the members for the general association, and remits them to their secretary, saving much trouble, time, and expense to our members and the general secretary.

If societies like ours were formed all over the country it would form one vast federation of chemists, thoroughly representative in its character, and would have force and influence upon future legislation that must be heard and attended to.

Thus it will be seen we are doing nothing that can be construed into hostility to the Pharmaceutical Society; and further, we are doing for ourselves what that Society could not do as a general body. There is room for both in their respective spheres. A. GREAVES.

Chesterfield, September 26, 1876.

A. Z.—We do not consider that the dose would be necessarily a dangerous one, but it should be given only on the responsibility of a medical man.

S. P. S.—First rub the extract up with a little warm water, sufficient when mixed to diffuse it through the liniment.

J. C. Fell.—See a paper by Mr. E. C. Saunders, in the present volume, before, p. 89.

"Pharmaceutical Chemist."—The fact of a person joining the Pharmaceutical Society as an Associate would not affect his position in respect to passing the Major examination.

"Spiritus."—By the Act 9 and 10 Vict. cap. xc. sect. 4, the Commissioners of Excise may permit a person to keep and use a still for the manufacture of any articles other than spirit or spirit mixtures, upon the person giving notice to the nearest officer of excise, and conforming to regulations laid down by the Commissioners, before commencing to use the still.

H. G.—The following formula is given by Squire in his 'Companion to the Pharmacopœia':—"Chloroform, 4 oz.; ether, 1 oz.; rectified spirit, 4 oz.; treacle, 4 oz.; extract of liquorice, 2½ oz; muriate of morphia, 8 grs.; oil of peppermint, 16 minims; syrup, 17½ oz.; prussic acid (2 per cent.), 2 oz.; dissolve the muriate of morphia and the oil of peppermint in the rectified spirit; mix the chloroform and ether with this solution; dissolve the extract of liquorice in the syrup, and add the treacle; shake these two solutions together and add the prussic acid.

J. Williams.—Solution of potassium sulphocarbonate has been recommended by Dumas as an insecticide especially effective against phylloxera. The sulphocarbonates are compounds of carbon bisulphide with metallic sulphides, which are slowly decomposed with evolution of sulphuretted hydrogen. See vol. v. p. 404.

J. D. F.—We should think not, if sold under their proper name. The only persons who can give an authoritative answer are the Inland Revenue authorities, to whom you are recommended to apply.

J. W. S.—Composition Powder.—The following recipe has been published:—

Pulv. Bacc. Lauri	℥iv.
Pulv. Zingib. Opt.	℥ij
Pulv. Pini Canadensis	℥i
Pulv. Caryophyllarum,	
Pulv. Pip. Cayenne ana	ʒij.

Mix. Dose: A teaspoonful in a cup of hot water, sweetened.

Moss.—The moss sent by a correspondent is *Marchantia polymorpha.*

Z., J. C. P., S. N. O., A. G., J. T. R., H. M. H., B. W. W.

NOTES ON PHOSPHORUS PILLS.

BY E. J. APPLEBY.

With reference to the discussion that took place at the Conference meeting at Glasgow on phosphorus pills, which is reported in the *Pharmaceutical Journal*,* I venture, at the suggestion of Mr. Ekin, to submit the results of some experiments I have made during the last twelve months, in order to find a good vehicle for the administration of phosphorus, either alone or in combination with other ingredients.

The different substances I have experimented upon have been suggested from time to time by communications to the *Pharmaceutical Journal*, and by the reports of the discussions on the subject at the meetings of the American pharmacists published about the middle of last year. It is, I think, generally admitted that the formula for phosphorus pills given in the Additions to the Pharmacopœia is anything but satisfactory. Although the pills can be easily made according to the B.P. process, they are perfectly insoluble, as I have proved, in water at ordinary temperatures even after more than a year's immersion.

Another very serious objection to the pills is, that in order to give a full dose, say of $\frac{1}{8}$ of a grain of phosphorus—a quantity I have sometimes dispensed—16 grains of the mass must be prescribed. Messrs. Allen and Hanbury recommend a solution of phosphorus in bisulphide of carbon to be added to guaiacum resin, soap, etc., to form a mass, and possibly the process answers very well. The odour, however, of the bisulphide of carbon given off whilst making the pills must manifestly be most objectionable, especially when the process has to be repeated, as must sometimes be the case, several times a day. Later, a formula by Dr. Corfe has been brought under notice by Mr. Haffenden of Brighton, as one that he has been very successful with. But Mr. Haffenden does not show that the emulsion of phosphorus can be preserved to meet the requirements of pharmacists dispensing fractional parts of a grain of phosphorus frequently.

Of the different substances I have myself used, I give the preference to cacao butter, balsam of tolu, and common yellow resin. Cacao butter I melted in a wide-mouth bottle, and having introduced the phosphorus, well agitated them until the latter was dissolved; soap and tragacanth being added, the cooled mass was rolled into pills of small size containing $\frac{1}{30}$ and $\frac{1}{16}$ of a grain of phosphorus in each.

Balsam of tolu and phosphorus, in the proportions of 24 to 1, I rubbed together in a mortar under hot water until thoroughly incorporated. A portion of this was beaten into a mass with compound tragacanth powder and treacle, and divided into pills of the same strength as above.

This experiment was repeated, yellow resin being substituted for the balsam, and a portion made into pills by the aid of compound tragacanth powder and treacle as before. In each case the pills were varnished with an ethereal solution of resin, and subsequently coated with mucilage and French chalk.

Pills thus made in October last year give even now abundant evidence of the presence of phosphorus, as they are quite luminous when crushed between the fingers in the dark.

The objections to cacao butter are, the mass requires some time and patience to prepare, and it is necessary that it should be divided into pills and coated at once. The pills also soon become rancid on keeping, and further, the butter is difficult to incorporate with other ingredients.

The phosphorized balsam of tolu is easily made, and keeps well under water; but it is difficult to incorporate with other ingredients. Pills, too, made from it, soon lose their shape, and are with difficulty soluble in water.

Phosphorized resin possesses none of these disadvantages. To sum up its advantages: it is easily prepared and may be preserved under water for any length of time; it can be quickly reduced to a fine powder, and made into a mass with compound tragacanth or other ingredients; it can be conveniently made so that twenty-five parts of the resin shall contain one part of phosphorus in solution.

As a very small portion only of the resin, therefore, is required for an ordinary dose of phosphorus, other ingredients may be combined with it without making too large a pill. I give, as an example, a formula which I frequently dispense.

℞	Phosphori	gr. $\frac{1}{30}$
	Ferri redacti . . .	gr. ij.
	Quiniæ Sulph. . . .	gr. iss.
Ft. pil. i.		

Pills properly prepared with the resin are thoroughly disintegrated by cold water in a very short time.

8, *Argyle Street, Bath.*
Sept. 28*th*, 1876.

FUCUS VESICULOSUS AND SOME ALLIED SPECIES.*

BY JOHN M. MAISCH.

Though Theophrastus already, in his history of plants, mentions several species of marine algæ, the sea wrack does not appear to have been employed medicinally before the first half of the eighteenth century; I find, at least, no mention made of it in the new 'London Dispensatory' of 1676. Russell seems to have been instrumental in introducing it into medicine through his essay, 'De tabe glandulari,' which was published in 1750, and in which he specially recommended *Fucus vesiculosus* in the form of charcoal and jelly, the former, known afterwards under the name of *Æthiops vegetabilis*, being prepared by heating the plant in a crucible closed with a perforated cover until smoke ceased to be given off, while the latter was made by expressing the mucilaginous liquid, and also by macerating the fucus in an equal weight of sea-water for two weeks, or until it was converted into a kind of jelly, which was employed both externally and internally. Upon the strength of these observations *Fucus vesiculosus* was admitted into several pharmacopœias, but was afterwards dismissed, the last one dropping it being the 'Dublin Pharmacopœia,' in the edition of 1850. The beneficial effects in scrofulous swellings and goitre of the vegetable ethiops and of the sponge charcoal, which had been introduced by Arnaud de Villeneuve near the close of the thirteenth century, and the discovery of iodine in the ashes of sea-plants, induced Dr. Coindet, of Geneva, in 1819, to study the effects of iodine, and led to the introduction of this element into medicine. Subsequently, Duchesne Duparc, and after him Godsfrey, stated (1862)

* Read at the Meeting of the Philadelphia College of Pharmacy, August 15, 1876. From the *American Journal of Pharmacy.*

that they had found this fucus to possess valuable properties as a remedy for morbid obesity, an observation which, by later investigators, does not appear to be confirmed to the full extent mentioned by the first recommenders in this complaint.

Of late, the bladder wrack, it seems, has been employed medicinally to some extent in the United States, so that a brief description of this and some allied species may be desirable.

The genus *Fucus* belongs to the sub-order *Fucoideæ* or melanosporeæ of the natural order *Algæ*. As originally constituted by Linnæus, it embraced several genera which have been separated by later authors, and among which are the genera *Laminaria*, *Sargassum* and *Cystoseira*, the last named having the thallus usually inflated into vesicles which often show a moniliform arrangement, while the vesicles of *Sargassum* are stipitate. *Fucus* has either a cylindrical (filiform) or flat, usually forking thallus, and the sporocarps inflated and usually terminating the branches. In their fresh state they have an olive or brownish-green colour, becoming blackish on drying. Several species have portions of the thallus inflated so as to form hollow vesicles.

Fucus vesiculosus, Lin., attains the length of one to three feet, and has a flat thallus one-half to one inch wide, with the margin entire and a distinct midrib running the entire length of the thallus; the vesicles are always in pairs, one being placed on each side of the midrib, spherical or oblong globular in shape, and occasionally attaining the size of a hazel nut. It grows on rocky sea-shores of the Atlantic Ocean, near high-water mark, and in marshes which are occasionally overflowed by the tide. Formerly it was known by the name of *Quercus marina*, or sea oak, its common English names being bladder wrack, sea wrack, sea ware, kelp ware, and black tang. In Scotland and other northern countries it is used in winter for feeding horses, cattle and sheep, and is eaten by deer when other food is scarce.

F. nodosus, Lin., knobbed sea wrack, grows in similar localities, but at or near low-water mark. It attains a length of four to six feet, and has a narrower veinless frond, with the branches almost filiform at the base, the vesicles single in the centre of the thallus, or frond, ovate in shape and usually quite large.

F. serratus, Lin., has a veined and serrate frond, and is destitute of vesicles.

F. siliquosus, Lin., s. *Cystoseira siliquosa*, Agardh, has a very narrow frond, two to four feet long, with short branches, articulated vesicles and lanceolate flattened sporocarps.

F. natans, Lin., s. *Sargassum bacciferum*, Agardh, the gulf-weed of the Atlantic Ocean, is often found in immense masses floating in the sea. Its frond is terete, with the branches linear and serrate and the vesicles globular and aculeate.

All these and many allied species appear to be very similar in their constituents, of which they contain mucilage, mannite, odorous oil, bitter principle and a considerable proportion of saline matter, varying from 14 to 20 per cent., calculated for the dry plants. According to Godeschen, James and others, the variation is just as great for the bladder wrack as collected in different localities, and it is not impossible that this may be, at least in part, accounted for by having been collected in different seasons, the plant being assumed to be most active when collected after the sporocarps have formed, about the month of July. E. Marchand found (1865) in the ashes of *F. vesiculosus* 0·719 per cent. iodine and 0·603 per cent. bromine; in *F. siliquosus* nearly the same amount, and in *F. serratus* 0·834 iodine and 1·007 bromine, while the ashes of the fucoideæ *Laminaria digitata*, Lamx., contained 5·352 iodine and 0·774 bromine, and *Lam. saccharina*, Lamx., about one-half these amounts (see also *American Journal of Pharmacy*, 1854, p. 438).

Bladder wrack has been employed in France in the form of extract, prepared, according to Dannecy, by exhausting the plant with 54 per cent. alcohol; it is stated to represent fifteen parts of the fucus ('Proc. Am. Phar. Assoc.,' 1863, p. 66); also in the form of syrup, suggested by Potier (*ibid.*), by exhausting 150 parts of the powdered plant with 14 per cent. alcohol, evaporating the tincture to 230 parts and dissolving in it 370 parts of sugar; 20 grams (one tablespoonful) of this syrup represents 0·6 grm. of the extract and 5 grm. of the fucus, which is the average dose. A fluid extract might doubtless be prepared by a process similar to the officinal one for fluid extract of chimaphila; the average dose of such a preparation would be about a teaspoonful. If, however, the virtues depend mainly upon the iodine and bromine present, the dose would have to be increased very considerably.

THE MILK-SAP OF CYNANCHUM ACUTUM.*

BY A. BUTLEROFF.

The author has examined a small specimen of this sap brought from the vicinity of the Oxus, where the plant (a creeper belonging to the *Apocyneæ*) is regarded as very poisonous, and especially dangerous to camels. The sap, as it reached the author, consisted of a white, soft, resinous mass, and an aqueous, nearly colourless liquid, these being probably formed by coagulation of the sap. It had a faint disagreeable odour, somewhat resembling that of infusion of tobacco.

The fluid portion of the sap deposited on evaporation a quantity of potassium chloride free from sodium chloride. The syrupy mother-liquor was treated with alcohol, the alcoholic liquid evaporated, and the residue dissolved in water. A portion of this solution injected into the veins of a dog exerted no poisonous action. On distilling the solution with potash, there passed over a strongly alkaline liquid of peculiar odour, likewise without poisonous action on a frog.

The white coagulum formed a soft resinous mass. When heated it melted and burned with the smell of burning caoutchouc. The coagulum was treated with alcohol, which dissolved the greater part: the residue dissolved almost entirely in hot carbon bisulphide. The latter solution left on evaporation a transparent yellow, sticky resin, which did not harden in the air, and smelt of burnt caoutchouc when heated. The solution in boiling alcohol deposited on cooling white granules, which, after being purified, crystallized in small needles and shining laminæ. This substance, called by the author *cynanchol*, is moderately soluble in hot, but nearly insoluble in cold alcohol. It is accompanied by an amorphous, resinous body, which appears to hinder its crystallization.

Cynanchol, when sufficiently pure to crystallize distinctly, is white, bulky, and friable in the fingers. It melts at 135°—145° to a colourless liquid, and on cooling solidifies in a transparent amorphous mass, which becomes white and opaque when moistened with alcohol. It dissolves in alcoholic potash, but is not attacked by it even on heating to 100°. It is not affected by hydrochloric acid or ferric chloride, nor by potassium bichromate and sulphuric acid. Strong sulphuric acid colours it reddish-brown in the cold, and blackens it when hot, evolving sulphur dioxide. Nitric acid acts violently upon it, giving off nitrous fumes, and ultimately forming a solution from which water throws down a yellow pulverulent resin, insoluble in ammonia. Analysis of cynanchol leads to the formula $C_{15}H_{14}O$.

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

MEANS OF STUDY.

THE question "How to prepare for the Examinations?" is one so frequently put by correspondents that we believe the remarks of Mr. BARNARD PROCTOR on this subject will be of great practical utility to many embryo pharmacists who are in the position of having still to undergo the ordeal of examination. These remarks, and the illustration of them by reference to the speaker's own experience, will also be serviceable in helping to do away with the erroneous impression that there is some amount of hardship attending the necessity of acquiring such knowledge as is demanded for the pharmaceutical qualification. It is not unfrequent to hear the examinations spoken of as if they related to subjects altogether foreign to the occupation and daily duties of those engaged in the business of a chemist and druggist, and we have reason to believe that many who look forward to passing them entertain the idea that they are rather obstructions to be overcome, than a means of proving that those who pass them are in a fair way to become creditably competent members of the trade. As Mr. PROCTOR tersely put it, in reference to the Minor Examination, "All that passing indicates, is, that you are not too ignorant, or too stupid, to be entrusted with the practice of your trade."

As to the means by which this minimum amount of knowledge is to be acquired, it is a mistake to suppose that attendance at a school of pharmacy is by any means an indispensable necessity. The shop and its ordinary duties afford a wide scope for the acquisition of knowledge by anyone who is disposed to seek it; and it is no disadvantage that the growth of knowledge thus acquired is slow. The articles with which an apprentice has constantly to do, together with the brief account of their character and natural history, should suggest to an inquiring mind the desirability of searching for further details respecting them, their sources, mode of preparation, and chemical composition. Three or four years thus spent in the study only of such articles as trade routine brought an apprentice in contact with, could not fail to raise him to the position of having a fair knowledge of the materia medica, and of being able to satisfy the requirements of the examiners in that respect.

In regard to chemistry, also, the systematic carrying out of the tests prescribed by the Pharmacopœia, together with the preparation and use of the various standard volumetric solutions, would not only afford considerable opportunity for acquiring the art of conducting such operations with dexterity, but would also suggest innumerable questions for study in leisure moments, with the result of familiarizing the mind with the details and general tenour of chemical science.

We believe that any young man of ordinary intelligence, who is engaged in performing the ordinary work of a chemist and druggist's establishment has in all cases within his reach ample material for study, and opportunity for obtaining sound knowledge of two of the most important subjects upon which he would have to undergo examination before gaining the legal title to carry on business himself. All that is necessary in order to render useful the means at his disposal, is to have a due appreciation of the possibility of helping himself by constant and diligent use of the faculty of observation.

The account Mr. PROCTOR gives of his own course of study at a time when there were not only no Schools of Pharmacy, but none of those aids to study in the shape of students' materia medica cabinets and scientific manuals which recent progress has produced, ought to dispel entirely the idea that without the opportunity of attending lectures on materia medica, and classes of practical chemistry, nothing is to be done towards qualifying for the examinations. It will, we trust, encourage many a one to follow his example, instead of remaining apathetically under the impression that the sciences of chemistry, physics, and botany can be studied after his apprenticeship is completed, and enough learned about them by a few months' grinding just to float him clear of rejection.

Another useful hint given by Mr. PROCTOR to the student was that in dealing with numerous scattered facts he should endeavour to arrange them in order and find out the law of their relation. Although the example given was an arithmetical one, it might have been supplemented by many others in sciences more nearly allied to pharmacy. That advantage would result to the student by exercising his thinking faculties in this direction is manifest.

THE SALE OF POISONS.

WE are glad to observe that the *Lancet* has promptly adopted the correction we had occasion to make in reference to certain statements made as to the sale of opium and its preparations without registration. At the same time the opinion is expressed that it is neither just nor wise to allow poisonous doses of opium to be sold freely while a dose of arsenic or aconite may not be sold. The same opinion is expressed in regard to the distinction between the sale of belladonna and atropine. It cannot be denied that there is an apparent incongruity in the imposition of restriction in one case and the permission of free sale in the other, but a very little reflection should be sufficient to suggest the existence of sound reasons for the distinction drawn between such articles as the preparations of belladonna and atropine, or between opium and arsenic. It is scarcely possible to avoid the adoption of an arbitrary distinction in accordance with the applications to which the articles are put. With all reasonable desire to restrict the illegal use of poison, would it be expedient to apply regulations that would cause inconvenience in the use of every-day remedies? The *Lancet* is of opinion that restriction should be put on the sale of opium and its preparations, and as a reason for this opinion it is alleged that their use as agents of self-destruction probably exceeds the illegal use of all other poisons put together, and that there is more accidental poisoning with opium than with any other agent. It is therefore suggested that opium should not be sold in larger quantities than two drachms, except on medical prescription.

The *British Medical Journal*, in referring to our remarks on the Spalding case, says it is hardly in the public interest that others should concur in the hope we expressed that "local officials will be restrained from commencing vexatious prosecutions against unoffending chemists and druggists." This remarkable comment is only to be understood on the assumption that the sale of laudanum without registration was supposed by the writer to be a breach of the law. That, no doubt, was the view of the Coroner at Spalding, but these officials possess a super-human capability of error, and we do not doubt that if our contemporary will take the trouble to refer to the Schedule of the Pharmacy Act, and the sections relating to it, he will concur with the hope we expressed, so far at least as the actual state of the law is concerned.

THE FRENCH INTERNATIONAL EXPOSITION IN 1878.

ACCORDING to the *Répertoire de Pharmacie* the chemical and pharmaceutical products, materials etc., exhibited at Paris in 1878, are to be classed in the following order:—

GROUP V., CLASS 47.—*Chemical and Pharmaceutical Products.*—Acids, alkalies, and salts of all kinds; marine salts and products of the working of mother-liquors. Various products of industrial chemistry; wax and fatty bodies; soaps and candles. Primary materials for perfumery; resins; tars and derivatives; essential oils and varnish. Various lubricants; blackings, etc. Products of the india-rubber and gutta-percha industry. Dyeing substances and colours. Natural and artificial mineral and aerated waters. Pharmaceutical substances. Simple and compound medicaments.

GROUP VI., CLASS 47.—*Material of the Chemical, Pharmaceutical and Tanning Arts.*—Laboratory utensils and apparatus. Apparatus for industrial and commercial tests. Materials and apparatus used in manufactories of chemicals, soaps and candles. Materials and processes of manufacture of essential oils, varnishes, and objects in india-rubber and gutta-percha. Materials and apparatus for gas manufactories. Materials and processes of bleaching. Material and preparation of pharmaceutical products. Materials used in tanning and leather dressing. Materials and processes used in glass works.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, October 4, 1876.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atherton, Atkins, Betty, Bottle, Cracknell, Frazer, Greenish, Hampson, Hanbury, Hills, Mackay, Owen, Rimmington, Robbins, Sandford, Schacht, and Shaw.

The minutes of the previous meeting were read and confirmed.

METHYLATED SPIRIT.

The PRESIDENT stated that in accordance with the decision arrived at at the last Council meeting he, accompanied by Mr. Stacey, Dr. Paul, and the Secretary, had waited on the Secretary of the Board of Inland Revenue. That gentleman received them very politely, and as the result of a long interview desired them to place their views in writing for presentation to the Board. A memorial had therefore been drawn up and sent to the Board, but no answer had yet been received.

The memorial was as follows:—

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, W.C.
"August 16, 1876.

"To the Honourable the Commissioners of the Board of Inland Revenue, Somerset House.

"Gentlemen,—The Council of the Pharmaceutical Society of Great Britain would respectfully draw the attention of your Honourable Board to a question of difficulty which has arisen amongst chemists and druggists, consequent on a recent order issued, virtually prohibiting the use of methylated spirit in the preparation of all medicinal compounds intended for external use, with two exceptions only—viz. 'compound liniment of soap,' and 'compound liniment of camphor.'

"Having carefully examined the various Acts passed to allow spirit of wine to be used duty free in the arts and manufactures of the United Kingdom, your Memorialists observe that the one prohibition running through them all is, that in no case shall methylated spirit form part of any article to be used as a beverage, or of any article to be used internally as a medicine.

"It is within the knowledge of your Memorialists that a general permission has been granted for the use of methylated spirit in the preparation of the two liniments above named, and it seemed but a natural inference that these two well-known compounds were to be taken only as types of the class of external remedies for which methylated spirit would be legally applicable, consequently that other liniments might be so prepared. As examples, those of belladonna and aconite; both of them so highly poisonous that it would be utterly impossible to convert them into beverages and thereby defraud the Revenue. Both of them are so expensive, when made with pure spirit, that their cost would be a bar to their use in hospitals and other charitable institutions, as well as in the medical practice of poor districts.

"Other external applications might be enumerated, but these two may suffice to illustrate the difficulty, the more especially as they have lately been called in question.

"Your Memorialists are aware that the permission of your Honourable Board to use methylated spirit in the preparation of the external remedies ordered by the British Pharmacopœia (even in the soap and camphor liniments) cannot override the 15th section of the Pharmacy Act, 1868, which renders it penal to compound any medicine of the British Pharmacopœia except according to the formularies of the said Pharmacopœia.

"Nevertheless, in the interest of charitable institutions and of the poorer classes, they would respectfully submit that to allow the continuance of the use of methylated spirit in such external remedies as by reason of their poisonous nature or offensive flavour could not possibly be converted into beverages, would be a great boon and no infringement or evasion of the methylated spirit Acts. Such articles, although equal in efficacy, could not be sold or dispensed as those of the Pharmacopœia, and therefore would not obtain generally.

"I have the honour to be,
"Gentlemen,
"Your obedient Servant,
"JOHN WILLIAMS,
"*President.*

"On behalf of the Council of the Pharmaceutical Society of Great Britain."

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

Baikie, Peter .... Armagh.
Duberly, George Smith .... Luton.
Jones, James Parry .... Cwm Coy.

Chemists and Druggists.

Cottingham, Joseph John ...... Dartford.
Duncalfe, Richard .... Urmston.
James, Hamilton .... Truro.
Olive, William Thomas .... Burry Port.

ASSOCIATES IN BUSINESS.

The following having passed the Minor examination, being in business on their own account and having tendered the subscription for the current year, were elected "Associates in Business" of the Society:—

Beverley, Robert Henry .... Nottingham.
Blades, Josiah Brunt .... Leek.
Harris, Francis George .... Liverpool.
Jones, William Henry .... Islington.
Rowcroft, Albert Edward ...... Maidstone.
Squire, Frank Robert .... San Remo, Italy.

ASSOCIATES.

The following having passed the Minor examination and tendered their subscriptions for the current year, or having already paid the same as Apprentices or Students, were elected "Associates" of the Society:—

Brooks, Charles T. .... London.
Collingwood, John Henry ...... Little Gonerby.
Collitt, William .... Gainsborough.
Craske, Thomas Augustus ...... Tunbridge Wells.
Evans, Thomas .... Cwmbach.
Hues, William Richard .... Everton.
Radford, Charles .... Nottingham.
Ridgley, Thomas .... Newport, I. of W.
Tompsett, Leighton Stovold ... Strood.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination were elected "Apprentices or Students" of the Society:—

Boor, Jonathan .... Manchester.
Brown, Thomas .... Hull.
Butterfield, Joseph Wm. .... Blackburn.
Corfield, Edward .... Birmingham.
Cowpe, John .... Southwell.
Cutts, Joseph Nix .... Chesterfield.
Foggitt, John Blackett .... Thirsk.
Gibbons, Walter .... Manchester.
Gourd, William .... Stoke Devonport.
Hogg, Henry Scott .... Glasgow.
Marshall, Charles William ...... Devonport.
Matthews, John Henry .... London.
Pond, George Peter .... London.
Powell, Ernest Geo. B. .... Cheltenham.
Richards, Randolph H. .... London.
Roderick, Thomas A. H. .... Pontypool.
Sangster, John Graham .... Southsea.
Southee, Wm. Jennings .... London.
Toms, Alfred .... Swansea.
Tuck, Walter Barber .... Eastbourne.
Wale, George .... New Malden.
Williams, John Wynn .... Mold.

Two persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Mr. Wm. Wright, an Associate of the Society before 1842, was elected a Member of the Society.

The names of John Henry Walker of 23, Mytongate, Hull and John Swain of 249, Mill Street, Liverpool, were restored to the Register of Chemists and Druggists.

THE NORTH BRITISH BRANCH.

Mr. STENHOUSE was re-appointed Assistant-Secretary to the North British Branch for the ensuing year.

Mr. HILLS moved,

"That two Members of the Board of Examiners in Scotland and the Assistant-Secretary to the North British Branch be invited to attend the meeting of the Board of Examiners in London during the present month, their travelling expenses to be paid, and the two Examiners be also paid a sum equivalent to Examiners' fees for two days, and Mr. Stenhouse the necessary sum to defray his expenses in London."

He said he thought such interchange of visits between the two Boards was of the greatest value in promoting uniformity of examination.

Mr. BOTTLE seconded the motion. He held it to be of the utmost importance that the examination in London and Edinburgh should be precisely the same, and with that view an interchange of visits was highly desirable.

Mr. MACKAY thought these interchanges of visits should take place at least once a year, and therefore strongly supported the proposition.

The motion was unanimously agreed to.

Mr. MACKAY said there were a great many candidates coming up at the next examination in Edinburgh, and after this resolution he should propose that the examination be deferred until after the deputation had visited London.

Mr. BOTTLE said a few weeks ago Dr. Fowler, a member of the Board of Examination of the Apothecaries' Company, expressed to him his desire of visiting the examination held by the Pharmaceutical Society, with a view to rendering the examination in dispensing held by the Apothecaries' Company equally searching. His impression was that the Apothecaries' Company was perhaps doing the Pharmaceutical Society injustice, by giving young men a qualification to dispense medicine after an examination below that required by the Society.

The PRESIDENT said he believed he had the privilege of inviting any one to attend the examinations, and he would, therefore, direct the Secretary to write to Dr. Fowler informing him when the examination would be held, anp inviting him, or a deputation from the Examining Board of the Apothecaries' Company, to attend.

REPORTS OF COMMITTEES.

LAW AND PARLIAMENTARY.

The report of this Committee was very long, referring to several matters of importance. It contained letters from the Solicitor, stating the progress of cases on which he was engaged in connection with breaches of the

Pharmacy Act; and also suggesting with reference to a question which had been raised as to the right of the Society to receive the penalties imposed by magistrates for breaches of the Pharmacy Act, that a written application should be made to the Commissioners of the Treasury on the subject. The Committee recommended that this course be adopted, and a draft letter was submitted for the approval of the Council.

A lengthy correspondence had taken place between Mr. Selby, deputy-coroner at Spalding, and the President and Secretary of the Society, with regard to the construction of section 17 of the Pharmacy Act, 1868. The coroner at Spalding having expressed his opinion that it was the duty of a chemist to register the names and addresses of all persons to whom poisons of any description were sold, Mr. Selby wished to know if the Society had ever taken counsel's opinion on the section, and if the coroner's was the correct interpretation of it. The Secretary having replied that such interpretation was not correct or there would have been no necessity to have two parts of the schedule, but that no opinion had been taken as the question had never been raised, Mr. Selby again replied to the effect that he had written on the subject to *The Justice of the Peace*, the response being that the interpretation by the coroner was the correct one. He therefore suggested that the Society should obtain the opinion of the law officers of the Crown upon the matter. The Committee recommended that Mr. Selby's last letter be simply acknowledged, and that he be informed that the Council sees no necessity for taking counsel's opinion on the question submitted.

A letter from a member of the Society at Nottingham had been received, stating that a private detective had lately been employed by the Nottingham Medical Defence Association, to visit various chemists' shops, and under the pretence of having a cold or sore throat had obtained a bottle of mixture; and that it was understood that proceedings were in some cases to be commenced for a breach of the Apothecaries Act. The Committee had considered the matter but deferred coming to any resolution.

The Committee had also considered the following resolution passed at the Chemists and Druggists' Trade Conference, held at Birmingham, July 11, last:—"That this Conference of chemists and druggists urge upon the Pharmaceutical Society the necessity of testing the legality of co-operative traders selling and dispensing poisons." The Committee decided to recommend the Council to invite a deputation from the executive of the Association to meet the Parliamentary Committee, when the latter would explain their views more fully than they could do in any other way.

Mr. Atherton said that Mr. Jones, the President of the Trade Association had come up to London for the purpose of seeking an interview with the Council as to the mode of procedure with regard to the threatened prosecution of chemists and druggists in Nottingham.

Mr. Hampson moved,

"That Mr. Jones be invited to attend the Council."

Mr. Atherton did not see what would be gained by the invitation.

Mr. Sandford said he should be very happy to see Mr. Jones, if he had anything to say, but it would be very irregular to discuss business in the presence of anyone not a member of the Council.

Mr. Atkins asked if Mr. Jones had made a *vivâ voce* or a written application to see the Council; if the latter, he should like to know the terms of it, in order to learn the special purport of his visit.

A considerable amount of discussion ensued as to the propriety of admitting Mr. Jones, but ultimately on that gentleman sending in a written request, it was resolved,

> "That Mr. Jones be admitted to make his statement respecting threatened prosecutions regarding alleged infringements of the Apothecaries Act, and that the Council resolve itself into committee for that purpose."

Mr. Jones was then introduced, and stated that he was desirous of obtaining the advice of the Council as to the steps to be taken by his Association in view of the threatened prosecution of chemists in Nottingham for prescribing. The Association had been informed that summonses had been applied for but had not yet been served.

The President informed Mr. Jones that the subject was at present under the consideration of the Council and that the decision arrived at would appear in the report of the day's proceedings.

Mr. Jones then withdrew.

A discussion next ensued on the portion of the report which dealt with the memorial from the Chemists and Druggists' Trade Association, asking the Council to take steps to test the legality of co-operative societies dispensing poisons. There was no difference of opinion as to the decision come to by the Committee and after some conversation as to the form in which it should be expressed, it was resolved on motion of Mr. Sandford,

> "That the report of the Law and Parliamentary Committee, so far as regards the communication from the Chemists and Druggists' Trade Association, be adopted."

The President said the next point for consideration was the letter from Nottingham, with regard to which the Committee had made no recommendation; but the matter was of some urgency, and it was for the Council to say whether it thought it necessary to pass any resolution upon the subject.

Mr. Atherton said he had made inquiries, and could get no definite information. He thought it very important that the matter should receive the careful attention of the Council, as a principle was involved.

Mr. Hampson suggested the following resolution in order to elicit the opinion of the Council:—

> "That it is desirable that in any case of prosecution, arising out of the action of the Medical Defence Association or otherwise, being brought against a registered chemist and druggist for simple prescribing, that the said chemist and druggist be defended by the Society."

Mr. Atherton would not say that every case should be defended.

Mr. Robbins thought the Council might come to a unanimous opinion that if the legitimate business of a chemist and druggist was interfered with by the Medical Defence or any other association, it would defend the case. It was known that there was a large number of chemists who tried to sail too near the wind, and trespassed on the province of medical men; such men, of course, the Council could not defend, but if the legitimate trade were interfered with it ought to do something. It was difficult to say what was legitimate trading, and therefore the Council could only deal with each case as it arose.

Mr. Mackay thought Mr. Robbins had chosen a very unfortunate word in saying "legitimate." If he had used the words "ordinary business" it would have been better. He had no doubt the Council would express in some tangible way its sympathy with any one who was vexatiously interfered with for giving simple remedies across the counter, and that such a person would receive the sympathy of the public also, but he saw considerable difficulty in framing a suitable resolution. It was known that some men not only prescribed but visited patients; but it was not necessary even to do that to trespass on the province of the medical practitioner, and until the Council had all the details of any particular case it could do nothing. If the members of the trade were made aware that the Society was both willing and able to protect them when unfairly interfered with he thought that was all that could be done at present, leaving further details to the Council.

Mr. RIMMINGTON said he understood there was a clause in the Apothecaries Act which secured to chemists and druggists all their previous rights and privileges, and if that were looked up and carefully examined it might be useful.

The PRESIDENT remarked that there had been an expression of a very eminent judge's opinion upon the question.

Mr. SCHACHT, being a comparatively young member, was not quite clear what principle the Council had adopted in previous cases. The details of particular cases must of course vary very much, but the question at the present moment seemed to be whether the Society should defend any case at all, whether its energies and resources should be devoted to such purpose at all. He could not remember that the Society had ever appeared in the capacity of defendant in any such case. It might be perfectly right, or it might be very unwise, and he should like the abstract question discussed first.

Mr. HAMPSON did not wish to be at all rash, and he was quite sure that the Council, representing pharmacy in its true sense, would object to anything like indiscriminate and reckless prescribing. But there was a certain privilege which custom seemed to have made almost into law, which must be maintained. This privilege was very difficult to define, but from the time chemists and druggists existed at all they had been accustomed to give advice in simple matters with respect to the use of drugs. While he would maintain this privilege intact, he would protest against a chemist and druggist exercising the functions of a medical man. He believed it was immoral in every sense for a man to undertake that which he was not capable of performing, and to obtain money for it. But still existing conditions must be recognized, and the condition was that the public expected to receive certain advice from chemists and druggists, and they were not prepared to give up that privilege at the dictation of any medical association. The motion might read as follows:—

> "That it is the opinion of this Council that it is desirable in the event of a chemist and druggist being prosecuted for simple prescribing that the Pharmaceutical Society should defend the case if it should be found to be unobjectionable."

Mr. ATKINS would prefer to discuss the general question before committing himself to a resolution, and therefore thought it desirable that Mr. Schacht's question should be answered.

Mr. SANDFORD said he believed there had never been a case in which the Council had appeared to defend an accused person; but there had been cases in which it had indirectly supported and given pecuniary assistance to a man in his own defence. In Berry's case the Council had supported the defendant in appealing against a conviction which was eventually quashed. The Hull "Pick-me-up" case would also be remembered, respecting which the Council sent a deputation to the authorities at Somerset House and the result was that the case was carried no further, and other threatened prosecutions were abandoned.

Mr. OWEN thought the Council would be treading on delicate ground if it gave the country to understand that it would defend any man who had violated the law. It ought not to defend unprincipled men who really broke the law; but on the other hand there was probably not a gentleman present who had not at some time or other given some sort of advice. He could only say that he often did so, and yet he never had any misunderstanding with his medical friends.

Mr. HILLS thought the Council should take no action of any kind until a definite case came before it.

The VICE-PRESIDENT agreed with this view. The clause in the Apothecaries Act referred to by Mr. Rimmington was very plain. It referred to the privileges exercised and carried on by chemists and druggists before the passing of the Act.

The PRESIDENT: It says nothing about prescribing.

The VICE-PRESIDENT: No; but it speaks of the privileges they enjoyed before; and there was no doubt, on the evidence of the *Lancet*, that chemists went much further in prescribing formerly than they did now.

The SECRETARY said when the Pharmacy Bills of 1865 were under the consideration of Parliament, Dr. Quain, in his evidence before a Select Committee of the House of Commons, said he considered a chemist who systematically treated diseases by giving advice day after day would be infringing the privileges of the medical profession; it was—he said—the systematic going out and visiting, and treating diseases at home, which were injurious to the public.

Mr. BETTY, in seconding Mr. Hampson's motion, said he felt it was desirable before asking the Council to decide on any proposition, however unobjectionable, in the first instance to decide whether it was wise to move at all in the matter. On behalf of taking some action he would urge that the Council had been asked to do so by a very important body, and that proceedings had virtually been commenced against certain gentlemen, who were in great perturbation of mind as to what the consequences might be. He saw no inconvenience that could arise from the opinion of the Council being stated, as to the course to be adopted if certain events should arise. It was possible also that an expression of opinion on the part of a powerful and organized body might at least be a practical protest against any vexatious actions. He did not believe the general body of the medical profession throughout the country desired that any chemist and druggist should be proceeded against, unless he systematically assumed the functions of the medical man. At the same time, advantage might be taken of the technical wording of the Act of Parliament to seriously annoy chemists and druggists. He contended that the powers of the Society could not be better employed than in combating any such attempts. They knew very well that these proceedings were taken in consequence of the remarks of Baron Bramwell in a recent case. Those remarks had been much canvassed, but he assumed the very wording of his judgment would guide the Council in the way of carrying out the resolution which he had much pleasure in seconding, and which it was now proposed by Mr. Hampson should read as follows:—

> "That in the opinion of this Council it is desirable in the event of a chemist and druggist being prosecuted for prescribing or advising on the action of remedies, so far as long usage and the public benefit and convenience should warrant him, that the Council should defend the case, should such a case prove unobjectionable."

The merits of each individual case would of course be judged of by the Council. There was a difference between the technical wording of the law and the practice which had long prevailed, which he believed made the common law. He only advocated that their practice should be shaped in accordance with the opinion of Baron Bramwell, the pith of which was that although a chemist could be proceeded against for prescribing in the most superficial way, it would be unreasonable to do so. If the Council could frame a resolution in accordance with that opinion, it would show that the Pharmaceutical Society, was determined that a custom so far as it was for the public convenience was not to be swept away. Possibly the attempt would not be made, but if it were he would urge that no effort should be spared to protect the interests of every chemist and druggist who carried on his business in such a way that it would be against all reason to prosecute him.

The PRESIDENT said he would ask the Council to very carefully consider this resolution before deciding on passing it.

Mr. ATKINS thought the Council must bark back to the question put by Mr. Schacht, which was one of vital importance. It was certain that large establishments such as those with which many gentlemen present were most familiar, were perfectly safe, but that was not the case with many other places, and if the question had not yet arisen, it must arise ere long, and probably on a considerable scale. The Council, representing pharmacy in its most cultured and thoughtful aspect, would desire to hold the scales equitably between pharmacists on the one hand and medical men on the other; but it would be as absurd as to try to stop the course of the sun in the heavens, to try to prevent such prescribing as was represented to have been practised in Nottingham in the case of the private detective. He thought in such cases the Secretary might fairly render assistance. A man with a limited purse, and a limited knowledge of the world, was frightened when a summons was served upon him, and would pay a fine rather than make a fight; but if he knew he had the assistance of a large body, who were determined to see that he had fair play and just treatment, he would feel in a much stronger position.

Mr. HAMPSON said he would ask permission to substitute the following form for his previous motion:—

"That this Council is prepared to consider the case of any chemist or druggist who is threatened with prosecution for prescribing according to long usage and, if the circumstances warrant, to defend the same."

The PRESIDENT having read from the *Pharmaceutical Journal* the words of Baron Bramwell already referred to,

Mr. SCHACHT said he thought it would be unwise for the Council to declare its intention, or to lead any individual to infer that the Society would defend any case, until the case was distinctly before the Council. It appeared from what the President had read that in the opinion of Baron Bramwell if anybody chose to prosecute for such an action as he described, the defendant must be convicted, but it would be most unreasonable for such a prosecution to take place; and he thought, therefore, the best course would be to endeavour to persuade the Medical Association not to prosecute in such cases. He would rather not undertake to defend any individual in any case whatever. He would not wish the Society to defend himself, if he were proceeded against for the most clearly innocent action, such as dispensing a physician's prescription, if such a thing were possible. He understood that Dr. Richardson was President of the Association, and he was quite sure that gentlemen would take a reasonable view of the matter.

Mr. FRAZER said he was once prosecuted but he did not ask the Society to assist him.

Mr. MACKAY said others were not so fortunately circumstanced as to be able to dispense with assistance.

Mr. ATKINS said that he found, on reference to the Charter, that the Pharmaceutical Society was established in 1841 for the purpose, amongst other things, of protecting those who carried on the business of chemists and druggists. He had told many persons who advocated the claims of the new association that the Society had the capacity to deal with all such cases as they arose, and if a case occurred where there appeared to have been no real infringement of the Apothecaries Act, and no trespassing on the manor of medical men, he thought the Society was bound to give the individual attacked pecuniary and moral support.

Mr. SANDFORD remarked that long usage in a wrong direction did not legalize it. It was known that druggists had for many years prescribed to a certain extent, and that in ordinary cases they had not been molested. Judges had to administer the law according to the spirit of it, not strictly to the letter, and therefore he had no fear of the result if chemists and druggists confined themselves fairly to their regular business. The Society was originally a voluntary one, but it had progressed step by step, and under the Act of 1868 was in a very different position. He therefore viewed the formation of the trade association somewhat favourably, as he believed it would be perfectly within its province to take up the case of members of the trade who were prosecuted vexatiously. It could not be denied that there was an immense deal of prescribing in druggists' shops which the law forbade, and the Council could not set itself up to oppose the law. The Society would lose its prestige and influence if it went forth that it was prepared to do anything of the kind. He would therefore move as an amendment—

"That it is undesirable for this Council to express any abstract opinion on the policy of employing the organization of the Pharmaceutical Society in defence of persons generally who may at any time be prosecuted for infringements of the Apothecaries Act, but that should vexatious prosecutions be instituted the Council hereby desire the Parliamentary Committee to watch and report on such cases."

Mr. HILLS seconded the amendment.

Mr. ATKINS said of course it would be understood that the Council would not in any way support the practice of illegal prescribing.

Mr. BETTY hoped the amendment would not be passed, since it started with assuming what was not a fact, that the motion was an abstract one, and ended by agreeing with it.

Mr. SCHACHT thought the motion was an abstract one.

Mr. BETTY contended that it was not.

Mr. SCHACHT said it was general if not abstract. He saw a clear distinction between it and the amendment, for which he should vote.

The amendment on being put was lost by nine votes to eight.

On the original motion being put several members objected to the word "prescribing," and, on the suggestion of the President, it was ultimately adopted in the following form by nine votes to eight:—

"That this Council is prepared to consider the case of any chemist and druggist who is threatened with vexatious proceedings for alleged infringement of the Apothecaries Act, and, if the circumstances warrant, to defend the same."

The report and other recommendations of the Law and Parliamentary Committee were then received and adopted.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation that the following grants be made:—

£10 to a registered chemist and druggist, aged 68, formerly in business, but latterly in temporary employment, and now unable to obtain even that.

£10, in two instalments at an interval of three months, to a registered chemist and druggist, aged 75. Applicant failed in business about two years ago, and has now no resources nor friends to whom he can apply.

£10 to a registered chemist and druggist formerly in business, but ruined by a partner. Now unable to obtain employment owing to deafness, brought on by nervous debility.

£10 to the widow of a former member in very poor circumstances, and suffering from chronic ill health.

£10 to the widow of a former member, having three children dependent upon her; the assistance being asked in order to enable her son to obtain a situation.

£10 to a registered chemist and druggist, formerly in business for forty-one years, but obliged to dispose of it owing to ill health.

£10 to an associate suffering from severe illness, whose case was considered in August last, when a temporary grant of £5 was made, pending further inquiry.

Several other applications were deferred for further information.

The report and recommendations were adopted unanimously.

NORTH BRITISH BRANCH.

It was decided that an estimate which had been obtained for two cases to contain the collection of minerals given by the late Mr. David R. Brown be accepted, and the specimens arranged therein as soon as possible.

THE CHEMISTS' TRADE ASSOCIATION.

The SECRETARY read a letter from the secretary of this association, asking for a complete file of the *Pharmaceutical Journal*, and for duplicate copies of the Register. The Secretary stated that the Register was out of print.

It was resolved that a set of the third series of the Journal, as far as possible, be sent, and that future numbers be forwarded as published.

THE MUSEUM.

The SECRETARY read a letter from Mr. W. L. Bird, of Castle Street East, for several years Vice-President of the Society, offering the Society a herbarium which he had collected some years since. He was directed to write to Mr. Bird accepting his offer, and thanking him for the donation.

Mr. SCHACHT suggested that a communication be sent to Dr. Richardson, President of the Medical Defence Association, with a view to a mutual understanding being arrived at as to the practical bearing of the Apothecaries Act on the usual conduct of the business of chemists and druggists.

Mr. HILLS thought it would be better for the President to see Dr. Richardson personally on the matter.

Many members having left, Mr Schacht, in deference to the views of those remaining, said he would bring the matter forward at the next meeting.

PHARMACEUTICAL MEETING.

Wednesday Evening, October 4, 1876.

The Opening Meeting of the Session, 1876-7, was held at 17, Bloomsbury Square, on Wednesday evening last. The chair was taken at half-past eight o'clock by the President of the Society, Mr. JOHN WILLIAMS.

The minutes of the previous meeting having been read and confirmed, the following Donations to the Library and Museum were announced, and the thanks of the Society voted to the Donors:—

To the Library.—'Science made easy: a Series of Familiar Lectures,' by T. Twining, from the Author; 'Ueber Carvol,' von Professor Flückiger, 'Documente zur Geschichte der Pharmacie,' von Professor Flückiger and 'Neue Beiträge zur Kenntuiss des Elemi, I. Ueber das Amyrin,' von Dr. E. Buri, from Professor Flückiger; 'Calendar of the University of Durham,' from the University; 'Calendar of the University of London,' from the University; 'Calendar of the University of Glasgow,' from the University; 'St. Thomas's Hospital Reports,' new series, vol. 6, from the Hospital; 'Guy's Hospital Reports,' 3rd series, vol. 21, from the Hospital; 'Statistical Tables of the Patients under Treatment during 1875,' from St. Bartholomew's Hospital; 'Pharmacopœa Helveticæ Supplementum, 1876,' from the Swiss Pharmaceutical Society; 'A Catalogue of Plants Cultivated in the Garden of John Gerard, 1596–1599, edited with Notes, References to Gerard's Herball, the addition of Modern Names, and a life of the author,' by B. D. Jackson, F.L.S., from the Editor; 'Science Papers, chiefly Pharmacological and Botanical,' by D. Hanbury, F.R.S., edited, with Memoir, by J. Ince, F.L.S., from Thomas Hanbury, Esq.; 'The Flora of British India,' by J. D. Hooker, etc., part iv., from the India Office, per Dr. J. Forbes Watson; 'Rapport sur le mémoire "Histoire des progrès de la médecine mentale depuis le commencement du xix^e siècle jusqu'a ce jour,"' Morel, rapporteur, and Analyse chimique de quelques Drogues actives et de leur Préparations pharmaceutiques,' par le Dr. G. Dragendorff, traduit par le Dr. J. Morel, from Dr. Morel; 'Du M'Boundou ou Poison d'Epreuve du Gabon,' par L. Kauffeisen, from Dr. Soubeiran (?); 'Medical and Surgical History of the War of the Rebellion,' part ii., vol. ii., from the Surgeon-General, U. S. War Department; 'Brief Considerations on the Diseases of the Ear,' by L. Thomas, M.D., second edition, from the Author (?); 'Introduction to the Study of Chemical Philosophy,' by W. A. Tilden, D.Sc., from the Author; 'Versuch einer vergleichenden Analyse der in den Monaten April, Juli und October, 1874, in der Umgegend Wolmars gesammelten Rd. filicis maris,' von Provisor Kruse, from Professor Dragendorff.

To the Museum.—Specimens of the flowers of *Spilanthes oleracea*, or Para Cress, from Messrs. Godfrey and Cooke; Specimens of the root of *Garuleum bipinnatum* (Cape of Good Hope), from Mr. F. M. Hyman; Specimen of Para Rhatany, from Professor Flückiger; Fine specimens of Magnesite of crystals of Iodide of Potassium and of Phosphate of Sodium, from Messrs. Huskisson and Son; Specimens of Nitrate and Phosphate of Pilocarpine, from Mr. A. W. Gerrard; Specimen of Chrysophanic Acid extracted from Goa Powder, from Messrs. Young and Postans; Fine specimen of a Musk Pod, from Nepaul, taken from a Deer shot during the Visit of H.R.H. the Prince of Wales to India, from Messrs. Battley and Watts; Cone of Mannite, from Mr. J. M. Broad; Specimens illustrating the Phenomenon of Fluorescence, from Mr. Lettsom; The Collection of Materia Medica Specimens and Pharmaceutical Portion of the Herbarium belonging to the late Daniel Hanbury, from the Executors; Specimen of Anthraquinone, from Mr. Richardson, Laboratory Student.

To the Herbarium.—Specimens of *Campanula latifolia* from Mr. Mordue; Herbarium, consisting of about 100 Specimens, from Mr. W. L. Bird.

The PRESIDENT called upon Professor BENTLEY (in the temporary absence of Professor REDWOOD) to make his—

REPORT ON THE BOTANY AND MATERIA MEDICA CLASS.

Professor BENTLEY said everything he had to report with regard to the class of Botany and Materia Medica was of a satisfactory nature. In regard to numbers he had not had so good a class for many years, over 100 students having attended during the last session. This was a great fact and, considering that the attendance on the classes was optional, spoke much in favour of the desire of pharmacists to get the best knowledge they could obtain by attending lectures. A large number attended throughout the entire course of ten months, and he hoped that it would become the practice for all to do so as far as possible. On the present occasion he could conscientiously say, as he had had to say for the last twenty-five years, that his class had been everything that could be desired; regular in attendance, and punctual; and the progress made had been well shown at the weekly examinations, to which he attached great importance. It was very desirable to bring the student not only into the lecture room, but into intimate relations with the Professor in the examinations. He had some little experience in teaching, having been Dean of a large Medical School for fourteen years, and he attributed any success he had had especially to the friendly intercourse which he was always desirous of establishing with his students. It was always his pleasure, as well as his duty, to explain after the lecture any points which seemed difficult to the students, and he hoped they would in future take full advantage of such opportunities. Speaking next of the competitive examinations for the bronze medals at the end of the two courses, and the silver medal at the end of the session, which he termed the blue ribbon of the Society, so far as his lectures were concerned, he had to state that at the end of February there were 22 competitors, Mr. F. W. Place being the successful candidate. At the end of the second course Mr. Charles Edward Palmer was the bronze medallist, and with regard to both gentlemen he could say that their honours were well earned and richly deserved. The competition for the silver medal was very severe, there being 16 candidates, and it was awarded to a gentleman bearing a name well known in pharmacy and wherever microscopic research was carried on, Mr. Henry George Greenish. The same gentleman had to receive other medals so that there was no doubt of the name being well supported. Certificates of honour were also given to three gentlemen, whose names will be found below, two of whom—Mr. A. W. Wheatly and Mr. T. D. Wright—had on a former occasion been successful competitors for the Herbarium prize. He would again urge upon his hearers the importance of practically studying botany during the term of their apprenticeship. Having mentioned the names of the gentlemen who had honourably obtained certificates of merit, Professor Bentley concluded by expressing a hope that for many years to come he might be able to attend there and present as satisfactory a report as on the present occasion.

The following are the names of the prize takers:—

TEN MONTHS' COURSE.

Silver Medal ....Henry George Greenish.

Certificates of Honour ... { Arthur William Wheatly. / Thomas David Wright. / Samuel Newbury. }

Certificates of Merit ...... { Augustus Frederick Dimmock. / Charles Edward Stuart. / James Hart. }

FIVE MONTHS' COURSE.

FIRST COURSE.

Bronze Medal.................Frederick William Place.

SECOND COURSE.

Bronze Medal.................Charles Edward Palmer.

The following were the questions for the examinations:—

MATERIA MEDICA AND BOTANY.

THE BRONZE MEDAL. FIRST COURSE.

Time allowed: Three Hours.

1. Describe the general properties and structure of the cell-membrane of plants; and distinguish between parenchymatous and prosenchymatous cells.
2. Define the following:—Starch, chlorophyll, vessel, cuticle, receptacle of secretion, cambium, spine, prickle, bulb, corm, stipule, and bract.
3. What is the fruit? Distinguish between small fruits and seeds.
4. What are the botanical and geographical sources of the official jalap and Tampico jalap? Describe their physical characters, and show how they may be distinguished from each other. Enumerate the official preparations of jalap.
5. Describe the physical characters of dandelion root, pointing out especially how it can be distinguished from other roots; also mention the period usually regarded as the best for its collection, and the data upon which such an opinion is founded. State the official preparations of dandelion.
6. What are the botanical and geographical sources of senega root and serpentary roots? Describe their physical characters, and enumerate their official preparations.
7. What are the botanical and geographical sources of buchu leaves? Describe the leaves of the official species, and state their official preparations.

THE BRONZE MEDAL. SECOND COURSE.

Time allowed: Three Hours.

1. What are parenchymatous and prosenchymatous cells, and in what parts of plants are they to be found.
2. Define the following:—Bulb, corm, rhizome, epiphyte, parasite, tuber, and the following terms as applied to leaves:—Serrate, pinnatifid, pinnate, mucronate, emarginate and retuse.
3. Define the following:—Bract, cupule, involucre, epicalyx, spathe, glume, spike, spadix, umbel and cyme.
4. What are the botanical and geographical sources of gamboge? How is it obtained, what are its physical and chemical characteristics, and how may its purity be ascertained?
5. What are the botanical and geographical sources of the official kinds of senna? What are the common adulterants of Alexandrian senna, and how may they be detected?
6. Describe the physical and chemical characteristics of kamala, and state its properties, uses and doses.
7. Distinguish the ranunculaceæ from the rosaceæ; the atropaceæ from the solanaceæ; and the liliaceæ from the melanthaceæ.

THE SILVER MEDAL AND CERTIFICATES.

Botany.

Time allowed: Three Hours.

1. What is chlorophyll? Where is it found, and what are its physical and chemical characteristics?
2. Give a general sketch of the structure of a palm stem.
3. Define the following terms as applied to leaves:—Connate, decurrent, amplexicaul, fascicled, equitant, obvolute, palmate, palmatifid, spine, tendril, ligule and phyllode.
4. Distinguish between determinate and indeterminate inflorescences; and define an umbel, panicle, locusta, capitulum, scorpioid cyme, and verticillaster.
5. Give the essential characters of the following natural orders, and enumerate the official plants which they respectively contain:—Iridaceæ, polygonaceæ, labiatæ, oleaceæ, rutaceæ and papaveraceæ.

Materia Medica.

Time allowed: Three Hours.

1. What are the botanical and geographical sources of quassia wood and simaruba bark? Describe their physical and chemical characteristics. What is Surinam quassia?
2. What are the botanical and geographical sources of Peruvian and Savanilla rhatany? How may they be distinguished from each other? And what are the official preparations of rhatany?
3. Describe the method by which opium is obtained. State the characters of good opium, and mention the official preparations into which it enters as an ingredient, and their doses.
4. Enumerate the official plants of the gentianaceæ

Describe the characters of the official chiretta, and show how it may be distinguished from spurious kinds.

5. How is aloes obtained in the greatest purity? What kinds of aloes are official? Distinguish between, and explain the characters of, socotrine, hepatic, and Barbadoes aloes.

6. Give the general and chemical characters of larch bark, and mention its properties, uses, and preparations.

The PRESIDENT then called upon Professor Redwood to make his—

REPORT ON THE CHEMISTRY AND PHARMACY CLASS.

Professor REDWOOD said he did not regret having been accidently detained a few minutes, so as to allow his colleague, Professor Bentley, to take precedence in explaining the facts relating to the progress of the school and the results of the examinations. Before announcing the results in his own class, he would only say that one of the most agreeable duties which the Professors had to perform was that of announcing at the commencement of each session the achievements of the past. These occasions were always very pleasant ones; in the first place because these were the only meetings which were graced with the presence of ladies, and also because every one seemed to come prepared to be pleased and to give pleasure to others. Young, middle-aged, and old, all seemed to agree in having for their special object the encouragement of those who were the recipients of the prizes. He should no doubt have to repeat some names which his colleague had already mentioned, though the gentleman who took the bronze medal at the end of the first five months' course was not the same as took a like honour in Botany. He might state that, as his examinations were conducted entirely in writing, the names of the successful candidates were not known to him until they were published in the *Journal*, the values only of the answers being communicated by him to the Council, who opened the sealed envelopes bearing the motto of the successful competitor to ascertain the name. In the case referred to the name was that of Mr. Samuel Newbury, and if more than one prize had been awarded, there were several others who would have been entitled to them. But no doubt the decision of the Council was a wise one not to hold out too much inducement to those who attended the shorter courses of lectures, but to offer more prizes at the end of the session. Consequently at that period there were a greater number of recipients, whose names he would next mention. The bronze medallist for the second short course—though it must be remembered that as there were sixty lectures given of an hour and a half each it was really as long as the courses delivered at most medical schools—was the son of a man well known to all practical pharmacists, and who had for many years been one of the advocates and foremost supporters of advanced pharmaceutical education, Mr. Abraham, of Liverpool. The silver medal was won by the same gentleman who received that distinction in Professor Bentley's class, Mr. Henry George Greenish, and he thought nothing would more clearly indicate the genuine and satisfactory manner in which the decisions were arrived at, than the fact that without knowing the names at all, they found the best man standing foremost in more than one department. Whether he also stood first in the third branch would be seen presently. Professor Redwood concluded by reading the names of those entitled to certificates of honour and of merit. The complete list of prizes taken in this class is as follows:—

TEN MONTHS' COURSE.

Silver Medal....Henry George Greenish.

Certificates of Honour... { Arthur William Wheatly. Samuel Newbury.

Certificates of Merit ... { Thomas Ridgley. William Champley Kidd. Frederick William Place.

FIVE MONTHS' COURSE.

FIRST COURSE.

Bronze Medal....Samuel Newbury.

SECOND COURSE.

Bronze Medal....Alfred Clay Abraham.

The following were the questions for the examinations:—

CHEMISTRY AND PHARMACY.

THE BRONZE MEDAL. FIRST COURSE.

Time allowed: Four Hours.

February 29th, 1876.

1. State the weight in grains of a pint, a fluid ounce, a fluid drachm, and a minim of water.
2. State the weight in grains of a fluid ounce of nitric acid of the Pharmacopœia.
3. Describe the method of determining the specific gravity of a piece of wax.
4. Name some of the best and some of the worst conductors of heat, also radiators of heat, and absorbers of heat.
5. State the latent heat of water and of steam, giving the latter at different temperatures.
6. Describe the processes of the Pharmacopœia for the extracts of colchicum, hemlock, liquorice, poppies, and liquid extract of opium, explaining the objects for which the special instructions are given.
7. Describe the preparation and properties of nitrous oxide.
8. Describe the process by which zinc is obtained from its ores, the properties possessed by the metal, and the different methods by which the oxide may be prepared.
9. Describe the process for the preparation of chloroform, and explain the reactions which may be supposed to occur in its production.

THE BRONZE MEDAL. SECOND COURSE.

Time allowed: Four Hours.

1. What are the values in English weight of a decagramme and centigramme?
2. What is the weight of a cubic inch of distilled water at a temperature of 62° Fahr.?
3. What are the weights respectively of a fluid drachm and of a minim of distilled water?
4. What is the specific gravity of a liquid a fluid ounce of which weighs 440 grains?
5. Explain the process of dialysis, and illustrate the results of the application of the process by a reference to examples.
6. Explain what occurs in the slaking of lime with water, referring all the phenomena to their causes.
7. Describe the production of an emulsion, specifying the ingredients used, the change, if any, which they undergo in the process, and the objects with which any of the ingredients are used which are introduced with a special object.
8. Describe the Pharmacopœia process for the prepara-

tion of diluted phosphoric acid, giving a full explanation of every part of the process.

9. Give the composition of cane sugar and grape sugar. Explain the characters by which these sugars may be distinguished, and especially point out what their respective solubilities and sweetening powers are.

SILVER MEDAL AND CERTIFICATES.

Time allowed: Six Hours.

1. Define the terms "density" and "specific gravity."
2. Explain the phenomena of capillarity.
3. What are the principal ascertained facts and phenomena relating to gaseous and liquid diffusion?
4. What are the principal characteristic features of a crystal belonging to the dimetric or square prismatic system? and how would you define this system according to the axial classification?
5. Explain the difference in properties between common light and polarized light, and state what these differences are supposed to be due to.
6. Describe the production, composition and properties of nitric oxide and peroxide of nitrogen.
7. Give the Pharmacopœia process and tests for iodide of potassium.
8. How is hypophosphite of lime prepared and what is its composition?
9. Give a sketch of the methods by which artificial alkaloids have been prepared.
10. What are the essential conditions for the production of ether, and how are these provided in the process given in the Pharmacopœia?

The PRESIDENT then called upon Professor Attfield for his—

REPORT ON THE PRACTICAL CHEMISTRY CLASS.

Professor ATTFIELD said that in reporting as to the state of his class in practical chemistry during the past session he was proud, for once, to be ahead of his colleagues as regards numbers, having had 123 pupils in the laboratory last session, or ten more than ever worked there since it was opened thirty-four years ago. These students entered for various periods, averaging about five months per head, and worked on an average four hours daily. He had in his report to the Council in August given a table showing the number attending for the different periods of study. The increase in the entries during the past session had been chiefly due to men who worked three hours daily for five months; all those also attended the lecture-classes. A considerable number worked for longer periods, some also for shorter periods; the latter had attended in the previous, or intended to enter again in the succeeding, session. He had explained in his report that three hours' attendance in the laboratory was about a fair proportion of the student's time if he were also attending the other classes, and if he wished to qualify as a "chemist and druggist" only, and not as a "pharmaceutical chemist." It was interesting to note that about 25 per cent. of the students might be fairly considered as resident in the metropolis, while 75 per cent. came up from the country on purpose to work in the school. As usual he had to testify to the diligence and gentlemanly conduct of the students. At the close of the session fourteen pupils competed for the Council prizes. The questions set included a synthetical one, two in qualitative analysis, one in quantitative analysis, and a chemico-physical question. At the termination of the two days' work the results were as follows. Out of 100 possible marks 84 were obtained by Mr. Greenish, whose name had been already twice mentioned. And he would say this, that it was not difficult for a man of fair average ability, if he devoted his whole time to one of the classes in the school, to take a first prize, but to take a first prize in each class a man must possess first-rate ability. Next came Mr. Kidd with 79 marks and Mr. Newbury with 78, taking bronze medals; Mr. Pollard and Mr. Campbell with 77, and Mr. Severs and Mr. Wheatly with 75, receiving certificates of honour, while Messrs. Wright, Gardner and Dimmock obtained respectively 70, 65, and 60 marks, entitling them to certificates of merit. The remaining four did not obtain the requisite number of marks for a certificate, but the gentlemen he had named well deserved the respective distinctions awarded to them.

The prize taken in this class were as follows:—

Silver Medal	Henry George Greenish.
Bronze Medals	William Champley Kidd. Samuel Newbury.
Certificates of Honour	Frederick E. Pollard. Henry Campbell. Samuel Thomas Severs. Arthur William Wheatly.
Certificates of Merit ...	Thomas David Wright William Gardner. Augustus Frederick Dimmock.

The following were the questions for this examination:—

PRACTICAL CHEMISTRY.

Two Days' Examination. Hours: Ten to Five each Day

(*Books and memoranda permitted. Standard number of marks,* 100.)

1. Prepare five fluid ounces of *Liquor Bismuthi et Ammoniæ Citratis*, B.P., from the materials in the laboratories.
2. Make a qualitative analysis of the fluid labelled "*Liquor Bismuthi.*"
3. Analyse the powder marked "Impure Carbonate of Bismuth."
4. Ascertain the proportion of bismuth in the "Solution of Bismuth" given to you.
5. Estimate the present weight of the air in the adjoining room "A"—assuming that furniture and fittings are removed. State, also, what the weight would be on a winter's day (temp. 5° C.; barom. 745 mm.)

NOTE.—Manipulation as well as results will be scrutinized.

The PRESIDENT then requested Professor Bentley to make his report respecting—

THE BOTANICAL PRIZE.

Professor BENTLEY said that he had not referred, when making his previous report, to the presence of the ladies because he knew that would be done more gracefully by his colleague, Professor Redwood, and also because he wished to take the present opportunity of stating that two ladies in his class had very highly distinguished themselves, and he hoped many others would follow their good example. One lady had obtained a high certificate in botany, and another was about to enter on an appointment in one of the largest schools for ladies. As he had frequently stated, he believed there was no training equal to that obtained by collecting herbaria, and any one who did this during his apprenticeship would find the value of it not only in the information he obtained but in the strengthening his powers of observation and discrimination. The Herbaria prizes on the present occasion had been conferred on two gentlemen who well deserved their distinctions, Mr. Buck, of Sandgate, winning the silver medal with a collection of 500 specimens, and Mr. A. H. Cooper, of Bradford-on-Avon, a bronze medal with 446 specimens. He would urge on any future competitors the importance of seeing that the specimens were not only carefully named, but well selected, so as to represent the plants in all their botanical aspects, that they should be well dried, each plant on a separate sheet, and the sheets all of the proper recognized size. A great deal of uncertainty had arisen from this not being understood, and if any intending competitors would communicate with him, he should be glad to afford them all requisite information.

Silver Medal ....Charles Burton Buck.
Bronze Medal..............Albert Henry Cooper.

The PRESIDENT then requested Mr. Carteighe to say a few words in reference to the—

COUNCIL EXAMINATION PRIZES.

Mr. M. CARTEIGHE said the competition was commenced for the first time this year under new conditions. Formerly certain prizes were given periodically on the reports of the Board of Examiners, somewhat informally; but the Council, conjointly with the Board of Examiners, had thought it wise to alter the arrangement, and under the present system a large number of Major candidates might, if they thought fit, compete for what he ventured to say was really the blue ribbon of the Pharmaceutical Society. The examination for these prizes covered the whole of the subjects taught in the school, and on that point he should like to state a fact presently which had only come to his knowledge that evening, which was peculiarly interesting. The Pereira Medal was founded in honour of the distinguished professor whose name it bore, who was known not only to pharmacists in Great Britain, but throughout the whole civilized world. It was therefore a very great honour to obtain this medal. The Council had also, by way of encouragement to those who failed to attain that high distinction, offered a silver medal; and to each of these medals, through the generosity of a former president of the Society, Mr. Hills, was attached a prize of books of substantial value. Lastly, there was a bronze medal as a sort of consolation stakes for those who failed to obtain the first and second prizes; also accompanied by a gift of books. The first process in the examination was one of sifting, for although a great number of gentlemen were eligible to compete, circumstances prevented many from attending. Some were at too great a distance; others, perhaps, thought they had had quite enough of examinations; and there was, besides, a general feeling on the part of the students that a certain number of them only would have much chance in the competition. In certain universities on the north of the Tweed, he understood that it was the practice for the students themselves to select the prize winners, thus saving the examiners all trouble, and so here, they generally arranged amongst themselves that a certain number of men were best qualified to sustain the honour of the class to which they belonged. The result was that only nine actually competed, and though this did not seem a large number he thought it very encouraging, for they had not before had so large a number of good men, or so many good papers to read through. Of those nine the first prize was awarded, on the recommendation of his colleague, Mr. Linford, and himself, to Mr. A. W. Wheatly; the second prize to Mr. Harry Alma Thomas, and the third prize to Mr. Newbury. Since he came into the room he had learned for the first time that all these gentlemen were students of the institution. The examination was open to all Majors, and as examiners they did not inquire where the candidates obtained their knowledge. They had simply to put certain sets of questions, and gauge the merits of the competitors by the answers. The fact that in this first competition the three successful gentlemen were honour bearers in the Society's School augured very well for its future prosperity.

Council Examination Prizes.

FIRST PRIZE.

The Pereira Medal (Silver) and Books value £5.

Arthur William Wheatly.

SECOND PRIZE.

Pharmaceutical Society's Medal (Silver) and Books value £3.

Harry Alma Thomas.

THIRD PRIZE.

Pharmaceutical Society's Medal (Bronze) and Books value £2.

Samuel Newbury.

The following were the questions for the examination:—

CHEMISTRY.

Time allowed: Three Hours.

1. ·1483 gram of an organic compound gave ·3799 gram of CO_2 and ·1575 gram of water. Its vapour density (air =1) was 2·951. Calculate a rational formula.

2. The analysis of the barium salt of an organic acid gave the following results:—

I. ·2065 gram of substance gave ·1297 gram of $BaSO_4$.

II. ·1377 gram of substance gave ·1307 of CO_2 and ·0300 of H_2O.

Calculate the formula of the salt and the corresponding acid.

3. A body having the composition $C_5H_{12}O$ is an alcohol. Express by equations the probable action upon it of acetic acid, oxalic acid, and oxidizing agents.

4. How are carbolic and picric acids respectively obtained? State the properties of each, and show the chemical relations assumed to exist between them.

5. A mineral contains sulphur, arsenicum, cobalt, nickel and iron. State minutely how you would analyse it.

6. What is the average composition of coal gas? How is it prepared and purified? How would you detect sulphur in it?

BOTANY AND MATERIA MEDICA.

Time allowed: Three Hours.

1. Give a short account of the principles of classification of plants under the Linnean and Natural Systems.

2. State the characters that determine the sub-orders of the compositæ, giving an example of each.

3. What is the difference in structure of the fibres of hemp, cotton, and New Zealand flax, and in what portions of the plant are they found?

4. What are the alkaloids yielded by the plants of the order melanthaceæ and how are they distinguished?

5. Describe the different drugs imported as pareira and state how they are distinguished?

6. What is gamboge, state its sources geographical and botanical as far as known and its characters?

7. How would you detect the adulteration of essential oil of almonds with nitro-benzol?

The PRESIDENT then proceeded to distribute, with a few appropriate words in each case, the various prizes and certificates. He afterwards introduced to the meeting the successful competitors for the—

Jacob Bell Memorial Scholarships.

George William Bullen.
George Frederick Gutheridge.

The following were the questions for this examination:—

CHEMISTRY AND PHARMACY.

Time allowed: Two Hours.

1. State all you know of the element chlorine, and describe processes for its production.

2. Describe the action of nitric acid (Brit. Pharm.) upon mercury and bismuth; also the action of *boiling* oil vitriol upon mercury and carbon.

3. How many grammes of oxygen could be produced from a kilogramme of chlorate of potassium? and about how many litres would it occupy at 0° Cent.?

4. Give the symbolic formulæ for emetic tartar, salts of tartar, tartarated soda, red and yellow chromates, and red and yellow prussiates of potassium.

5. Describe the official processes for the production of the liquid extracts of cinchona bark, and liquorice.

BOTANY.

6. Define a stem and a root, and explain the difference between the stem and root of an endogen and those of an exogen.

7. Explain the meaning of the terms determinate and indeterminate, as applied to the inflorescence of plants.

8. Give examples of the following fruits:—sorosis, etœrio, galbulus, legume, drupe, pome, pepo, achœnium and capsule.

LATIN, ETC.

Time allowed: Three Hours.

Virgil—Æneid, Lib. I., II., or III.

Translate into English:—

1. Portus ab accessu ventorum immotus, et ingens
Ipse: sed horrificis juxta tonat Aetna ruinis,
Interdumque atram prorumpit ad aethera nubem,
Turbine fumantem piceo, et candente favilla;
Attolitque globos flammarum, et sidera lambit:
Interdum scopulos, avolsaque viscera montis,
Erigit eructans, liquefactaque saxa sub auras
Cum gemitu glomerat, fundoque exaestuat imo.

2. Contra, jussa monent Heleni, Scyllam atque Charybdim
Inter utramque viam, leti discrimine parvo,
Ni teneant cursus, certum est dare lintea retro.

Grammatical Questions on the above:—

3. Give the present, the perfect, the infinitive, and the supine of *tonat, prorumpit, attolit, lambit, erigit, glomerat.*

4. Parse fully *accessu, immotus, fumantem,*

ARITHMETIC.

5. Find the value of $16\frac{3}{8} - 3\frac{1}{4}$ of $3\frac{1}{5}$.

6. Add together 1·234, 12·34, 123·4, 1234, and multiply the product by ·1234.

7. Subtract ·06789 from ·6789, and divide the product by 6·789.

8. A druggist borrowed of his neighbour a quantity of rose water, which was filled into a rectangular vessel, each side of which measured 12 inches; when he returned the rose water he sent *two* smaller vessels, the sides of which each measured 6 inches only. How many pounds did he borrow, and did he return the same amount? (1 cub. foot = 62·5 pounds).

ENGLISH.

9. Parse the following lines:—

Errors, like straws, upon the surface flow;
He who would search for pearls must dive below.

10. Write a short essay on *The Value of Time.*

FRENCH AND GERMAN.*

1. Translate into French:—

In one of the most beautiful regions of Spain, not far from Seville, and on an eminence as rich in vegetation as agreeable to the eyes of the traveller, was situate the castle of the Count of Bellamore.

And translate into English:—

Ma fille, tendre objet de mes dernières peines,
Songe au moins, songe au sang qui coule dans tes veines;
C'est le sang de vingt rois, tous Chrétiens comme moi;
C'est le sang des héros défenseurs de ma loi;
C'est le sang des martyrs.——O fille encore trop chère!
Connais-tu ton destin? sais-tu quelle est ta mère?
Sais-tu bien qu' à l'instant que son flanc mit au jour
Ce triste et dernier fruit d'un malheureux amour,
Je la vis massacrer par la main forcenée,
Par la main des brigands à qui tu t'es donnée?

Or translate into German:—

On a smooth table-rock surrounded by trees and shrubs, every leaf of which had been washed by the night's rain as clean as it could have appeared on the day of its birth, there were seated in front of their wigwam, and close to a fire, the white smoke from which was gracefully meandering upwards through the trees, an Indian's family, composed of a very old man, two or three young ones, about as many wives, and a most liberal allowance of joyous looking children of all ages.

Books, to the value of £5 each, were also presented to the Bell Scholars of the past session.

HENRY GEORGE GREENISH.
JOHN LEAVER WEST.

MR. BARNARD S. PROCTOR, of Newcastle-upon-Tyne, then proceeded to deliver—

THE INAUGURAL SESSIONAL ADDRESS.

STUDENTS OF PHARMACY,—

The "few words of encouragement and advice" which it is this evening my duty to address to you must of necessity be in many respects like the addresses which have been delivered in former years with the same object, so much so that I feel no small difficulty in imparting to them anything like freshness and vitality.

My simple duty is to tell you all to be good boys and learn your lessons well, and that then you will reap the reward which all good boys receive. That is a plain statement of the case with the great merit of brevity. Why should I say more? I do not much

* The Candidate is at liberty to choose either French or German, and is not required to show a knowledge of both.

like sermonizing, and I may add I do not like sermonizing much. My belief is that too frequent repetitions of good advice are debilitating rather than strengthening to the moral tone of any but those of very tender years. Now I expect you have all cut your double teeth, past your Preliminary, and do not require to be fed upon any of those insipid foods so highly recommended for infants and invalids. Do not mistake me; though I do not like sermonizing, yet I heartily admire excellence in moral and intellectual life. I enjoy to express my admiration of it, I also enjoy right heartily to give a vigorous thrust at any evil doing.

In performing the duty which lies before me I will endeavour to address you in a homely and friendly way, as I would old acquaintances, and thus avoid the distant or formal manner which too often separates the monitor from his audience.

You have chosen a particular road for your life's journey and are about to start upon the track which I have travelled for more than twenty years, and you are desirous, I doubt not, of profiting by the experience of myself and others, with the view of making your journey with as much comfort and success as is attainable.

Your Professors are your guides, and your text books teach you the language and topography of the district through which the path you have chosen to follow will take you; but there is still room to hear, and perchance to profit by, the tale of a traveller who has had some of the same experiences which you are about to undergo.

But, if I tell you about *my* journey, I must talk about myself—and that is egotistical. Well, suppose it is, I fear the fact must be admitted; I *am* and I intend to be egotistical, and if that requires excuse, my excuse is that I wish to convey to you the benefit of my experience, and to speak only that which I know. I will therefore keep pretty much to my personal experience, as by so doing I can express myself with the greater confidence.

Speaking now of the pursuit of pharmaceutical studies as the one thing which it is more particularly my province to dilate upon, I will say a few words first upon the mode of learning, and then upon the kind of learning, which is desirable.

You may have heard of a learned pig which could point to the number 18, when asked, How much is twice 9? That is the very lowest species of learning. It had learned, but it did not know. And from this upwards we have all grades, to the highest of which the human mind is capable. Learning, knowing, understanding, and that combination of intellectual faculties by which new truths are evolved from old ones.

It is quite necessary for any one who would excel that he should exercise all these powers.

Let me for a moment further illustrate the difference between learning and knowing. You have all learnt the multiplication table, and could say it from beginning to end, and if I were to ask you how much is five times seven, or eleven times twelve, you could give me the answer without consideration, in which case you may be said not only to have learned it, but to know it. Probably also you have all learned a verse which commences

"Thirty days hath September;"

But I rarely find any one who can tell the number of days belonging to each month, without a moment's consideration, and often, only by the aid of repeating the verse, and noting anew that the months containing thirty days are September, April, June, and November. In this case they have *learned*, but do not *know*, how many days there are in August.

All facts having a direct and practical bearing upon your daily routine work should be known as you know your multiplication table. With regard to facts which meet with application only once a month, it may suffice if you know them as you know how many days there are in August. Learn them, and if possible retain such a clue as will bring the knowledge to your mind by a moment's consideration. Information which is only wanted at long intervals is sufficiently in your possession if you retain the outline and know where to refer for the details. If you were all men of remarkable genius, it might be unnecessary thus to discriminate between the more and less important items of knowledge; but most men have a limit to their capacity, and must economize their power of learning and retaining knowledge. In all cases where you desire to retain a useful outline of a subject, take care that you understand it thoroughly at the time you read it, as in that case the impression left will be much clearer and more permanent.

Knowledge which is permanent is almost invariably of slow growth, more especially if it be in any branch of knowledge for which you have not a natural aptitude or liking. I believe I shall enforce this most effectually by giving you a page from my own history.

When I was a boy I had a taste for mechanics and physics, and my desire was to be an optician and philosophical instrument maker; but my father said I had to be a chemist and druggist and help him. I had no great dislike to the business, so without much reluctance I made up my mind to follow it and help him to the best of my abilities. I had some liking for chemistry, but none for botany, pharmacy, nor materia medica, and Latin was always drudgery to me. After I entered the business I continued for twelve years to wish and to hope that I should some day be released from it to follow a more congenial occupation; but I never ceased the endeavour to make the best of the position to which I was bound by circumstances which had more weight with me than my personal inclinations. In the days I speak of local schools of pharmacy were unknown, the guidance of any one who had passed the ordeal of a pharmaceutical examination was not within reach. I remember with what reverence I looked up to an associate who passed through our town after having accomplished his Minor, at the second attempt, and how great an advantage I thought it to hear from him what books I should read. If you note all these circumstances you will perhaps admit that it may be worth while to know by what method of study I was able to pass my examination without the usual preparation of a few weeks' or months' grinding.

The first and most important thing was that I began my apprenticeship with the intention of making myself as well acquainted with my business as any man in Newcastle, and commenced from the first to pick up information whenever I had an opportunity, for I anticipated that it would require all the study I could take during a seven years' apprenticeship to pass my Minor, and then I hoped to go to London to prepare for the Major, in which hope, however, I was disappointed. I had but few books, and those probably not in all cases the best; but I took care to keep their contents constantly before me and to understand them as I went along. I should like to impress you strongly with the importance of diligent husbandry in the cultivation of knowledge.

"True knowledge is of slow growth."

"He who would woo wisdom must work and weary not."

More students fail through making haste to get on than from slowness of perception. It is not the want of finish but the want of beginning and of going on where the weakness lies. If there are little hollow corners in your foundation the superstructure is sure to be shaky, but it is almost as difficult to build a ricketty reputation on a good foundation. Students' materia medica cabinets were not known during my apprenticeship, but I made the shop my cabinet, and put on the backs of the bottles and drawers labels indicating the botanical names and natural orders of vegetables, and the formulæ and equivalents of chemicals. So that my daily dealing with drugs, and my dusting of bottles and shelves, became a perpetual reminder of what I learned by reading. He who does not let his thoughts run idle while his hands are at routine work can afford to give his mind a holiday when his body is at liberty.

Now, here I am disposed to run counter to a common item of so-called good advice. I have repeatedly heard the classical scholar advise that we should pursue Latin for the pleasure it affords; and the botanist dilate upon the enhanced pleasure of a walk in the country if your vasculum be strapped to your shoulder and your flora under your arm. I do not consider that is at all the right light in which to view the matter. It is like telling a child that its medicine is not nasty, and the natural reply is, "Yes it is nasty and I won't take it." But I am speaking to men, not to infants, and I would say if you can enjoy your Latin and your botany by all means do so, and thank heaven that your path is made pleasant to you. But if these subjects be uncongenial, study them conscientiously, a little more than you think can be reasonably expected of you, and then thank Heaven yet more fervently that you can do your duty, be it a pleasure or a pain. If botany be not to you both a pleasure and a relaxation, do not spoil a holiday for the sake of a little half-hearted study. When you do study let it be with earnestness and industry, and when you take holiday let your pleasure be pure and hearty, let it be a bumper full to the brim. And if you must have a flora with you let it not be Babington's or Bentham's, but your sister Flora. If you take your study into your recreation, you will become impatient of such a spoil-sport, and jump to a wrong conclusion for want of patience to get at the right one. Now I have no objection to jumping; I have seen a great philosopher jump, though he was one of the most cautious men the world ever knew, as regards jumping to a conclusion. When I was a boy Faraday challenged me to a jumping match, and with a hop, step, and a jump, he cleared the length of a grass plot in my father's garden, while I could only accomplish two-thirds the distance. I do not think he was studying all the while. No, he was taking a holiday, and having a game with the children. It is only small men who must be always studying, and who are afraid of their reputation suffering by the enjoyment of light-hearted pleasures.

I was speaking of study, and I have taken a little holiday digression. Now let me return to the point where I advised that when you are occupied upon uncongenial subjects, you should go a little deeper into them than you think can be reasonably expected of you, and I will illustrate again by a little personal experience.

In the days when I became an apprentice, it was the custom to accept, in lieu of the Preliminary examination, a certificate from any competent person stating that the candidate had a sufficient knowledge of Latin, arithmetic, etc., to fit him for entering upon the technical studies of the trade. My father obtained this certificate from my schoolmaster, and on presenting it, was informed that it would have been more satisfactory if it had come from an unprejudiced witness. Nevertheless I had gained my status and then went to an evening school to grind up my Latin, lest the full status had been purchased with a short measure of qualification. I take no credit to myself for this; it was my father's doing, not mine; but the lesson was a good one, and afterwards I had an opportunity of doing the same on my own account as regards botany.

I went through my seven years' apprenticeship, slowly and steadily picking up such knowledge as I thought ought to qualify me for carrying on the business, and always looking forward to the finishing touch which was to be effected by the professors at Bloomsbury Square. But when the time came I met with the grievous disappointment of being told that my services were so much wanted at home that I could not be spared for a few months' study, and must wait a few years for a more convenient season. With this I commenced a more systematic study of chemistry, especially analysis, leaving botany and materia medica, not to be forgoten, but only attempting to keep up what I had acquired, for I wished to get into chemical works where these would not be required; but I did not let them slip, lest I should continue to be baffled by circumstances which, as I said before, had more weight with me than my personal inclinations. So things went on till, in the spring of 1853, I got leave for a ten days' holiday, and I availed myself of the opportunity for presenting myself before the examiners. I went to London almost without notice and quite without grinding, and, as a preparation for the ordeal, I spent the better part of two days in the museum at Bloomsbury Square. There I made acquaintance with the seeds of croton tiglium and ricinus communis, and filled up one or two other gaps which trade experience had left. But, more important to me than this, I met a number of students, some of whom had passed their Minor examination, and by conversation with them felt my way as to how far I might trust to my knowledge and experience to carry me through. At that time there was in force a pass examination something like the Modified of more recent date; with this I determined to have nothing to do. I would apply for the Minor, and if successful immediately put up for the Major, a policy which by a reference to the Journal of that date I find my friend Mr. Kinninmont successfully carried through, but which in my case miscarried, I believe, because my weak voice could not penetrate the poor deaf secretary's ears. I understood him to say I could pass both at once, and it was greatly to my mortification, when the day of examination arrived, to find that I was entered for the pass examination, for I thought myself thus doomed to be a second class chemist after all.

Among other things that I heard in the museum, there was a pretty free criticism of the board of examiners, of the examination specimens, and of the questions that were asked. I heard how well one got through who knew the formulæ for quinine, morphia, etc.; how another was plucked just because he could not answer one little question which escaped his memory at the moment. I heard how savage Mr. Squire was, how sulky was Bell, how particular was Deane, and how lucky I might think myself if I had nothing to do with any of them. I heard it all with a somewhat incredulous ear, and I said to myself, "I know that I cannot remember the formulæ for the alkaloids and organic acids, but I know that I have a good general knowledge of my business, and I will trust that is better than formulæ committed to memory." Probably many of you will at times hear such things said, as I heard, and I beg you will turn to them an incredulous ear, as I did. If you have a good knowledge of your business, and no memory of the formulæ of the alkaloids, I trust the examiners will find out your merits, and if you have great stores of chemical formulæ at your finger ends, and are superficial as regards other things, I trust the board will still find out your merits; and your demerits also. Remember, that a bad student never has a good examiner. It was my lot to fall into the hands of Mr. Squire first thing. He examined me in vegetable materia medica and botany; he found me with a moderate amount of information on the former subject and a deficiency in the latter; in fact, he told me so, and I agreed with him, which was very pleasant, and I thought him a very agreeable gentleman. He asked me many questions, and I asked him some, and got from him some information and advice as to how I should pursue my botany a little further when I returned home. So in botany as in Latin, after I had passed my examination I began to grind. The other parts of the examination were easily got through; pharmacy had occupied my days and chemistry the majority of my evenings, so these departments I passed through comfortably, though not without a feeling that in some cases the questions were unreasonably severe, considering that I was entered for the pass examination, and that rejection would disqualify me from membership of the Society. For example, I remember the chemical examiner, after a great many other questions, said, "Suppose I were to give you a white powder insoluble in water and not dissolved by boiling with nitric and hydrochloric acid, what could it be?" And when I enumerated chloride of silver, silica, and sulphate of baryta or strontia, he pushed me further as to the method of discriminating which of these four a given specimen might be. I made a mental note, "this is not the kind of knowledge that can reasonably be demanded of an ordinary chemist and druggist," and proceeded to describe to the best of my ability the usual process for such an analysis. He pointed out to me one particular in which I had gone astray, and then with the remark, "Very good!" passed me on. I looked at Mr. Bell with a feeling of pity and half regret that I had not to pass under his hands also. He sat there with an expression of patient suffering on his face. I wished for the honour of his approbation and the pleasure of saying he was not sulky, but I did not get that privilege, nor was I examined by Mr. Deane, for he was chairman of the board that day. However, that gave me the advantage of hearing, in his kindly words, what the examiners thought of me. Now, if I were a modest man, I could not tell you what he said, but as my argument would not be complete without it I will give my modesty leave to withdraw for five minutes.

He told me that the gentlemen through whose hands I had passed had been comparing notes about me, and that each had found me better informed than the majority of the candidates for the pass examination, that they had consequently pushed their questions a little further to ascertain how far my knowledge extended. He reminded me that as I had entered for the pass examination I had not gone through the part of their programme which was conducted in writing, but that the examiners were satisfied from the way I had answered the oral questions that I should have passed the whole of the more stringent examination to their satisfaction, and they felt that under the circumstances it would be unfair not to give me the honorary certificate which they felt sure I deserved. He also told me I must not conclude that my examination being passed, my education was finished. It was the duty of every one with ability to work, and to give some portion of his work to the public good. I might, for example, work out some subject connected with my daily occupations and publish the result in the Journal; they would be glad to see me a contributor to its pages.

I did not see Mr. Deane again for ten years, when I met him as a fellow councillor; by that time he had forgotten all about it, no doubt having given similar advice and encouragement to many other students, but I had neither forgotten it nor failed to act upon it. I now echo his sentiments and advise you all to profit by them as I have done. But that is not just the point of my story; I tell it you as an illustration of the falsity of the reports circulated by unsuccessful students about the sulkiness, the hardness and the savageness of the examiners. I tell it you to show how they even went out of their way to confer an honorary distinction which was not asked for, lest the omission would be unfair to a willing student. I found all with whom I spoke pleasant, gentlemanly, and kind, and though we have not the same men, we have the same spirit in the board still.

Now I will tell you a secret which will help you to pass your examination with pleasure and comfort. Be prepared to give your examiners about 50 per cent. more of good solid information than you think they have a right to expect, and depend upon it you will find, as I did, that they are all remarkably pleasant gentlemen.

While I earnestly commend diligence and persistence in the prosecution of your studies I must also add this further injunction, that you be not students in pharmacy only. Do not give your whole soul to this one study, for your duties as pharmacists will not be worse performed, but better, for the cultivation of refined tastes and the following of intellectual pursuits. Keep a little corner of your soul free from the bricks and mortar of pharmacy—there the daisies will blossom and your hobby may be turned out to grass.

Three months' training cannot make a sedentary man into an athlete, neither can three months' grinding make a tyro into a philosopher.

The growth of physical power comes by daily work, battle against resistance, alternated with food and rest. By no other means can you develop bone and sinew, muscle and nerve, in a healthy and vigorous condition.

The growth of moral and intellectual power takes place upon precisely similar principles. It is the daily battle with difficulties, little difficulties, the daily learning of little facts, the daily exercise of observation and judgment; it is the daily struggle and the nightly rest that makes the moral and intellectual powers grow strong and healthy.

I have no fear of error in your judgment of what it is desirable you should become in the course of the next ten or twenty years. If I had a power to give you I would give you strength of will. The picture drawn by hope is bright and fair. What is wanted for its realization is the determination that every day shall record some definite progress, however small.

Learning commences in the cradle, it goes on always and for ever. Going to school and leaving school, passing an examination and entering business, are not to be regarded as aims or ends, but only stages in an endless journey.

The necessity for a compulsory curriculum is a question which has often been debated by leading men in our Society; the necessity for it only exists inasmuch as you fail to be a law unto yourselves. Voluntary work is both better and less irksome than that performed under compulsion, but it must be work of that quality with which a taskmaster could find no fault. Be your own task masters, and practice upon yourselves that rigorous discipline to which you would like to subject me.

If you do so we should hear no more of cram, or of students who crowd their efforts into a three months' course of study, and convert their brains into deposits for dry rubbish.

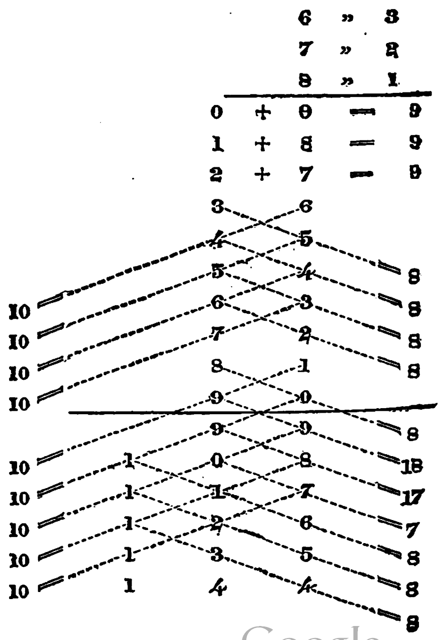
And when you have passed your examination remember you have not done any great thing; do not grow conceited on the strength of so small an achievement. All that passing indicates is that you are not too ignorant, or too stupid, to be entrusted with the practice of your trade. Do not think that, having learned enough to merit this first mark of confidence, you may then rest from active exertion. Rest is only given us to restore our power. Prolonged rest is neither useful nor agreeable. Activity is life, stagnation is death—death such as no Christian should acknowledge. The glory of the Christian faith is going on in all good works, and knowing no end. It is the mark of unworthy aims and narrow views to look forward to an achievement which is an end to work and progress.

> "Glory of warrior, glory of orator, glory of song,
> Paid with a voice flying by, to be lost on an endless sea.
> Glory of virtue, to fight, to struggle to right the wrong.
> Nay, but she aimed not at glory; no lover of glory she!
> Give her the glory of going on and still to be!
>
> The wages of sin is death: if the wages of virtue be dust,
> Would she have heart to endure for the life of the worm and the fly?
> She desires no isles of the blest, no quiet seats of the just,
> To rest in a golden grove, or bask in a summer sky;
> Give her the wages of going on, and not to die!"

I have endeavoured to show the importance of the gradual and persistent accumulation of facts and of their consequent assimilation and permanence in effect when thus slowly acquired. But this acquirement of facts is a very poor kind of education unless it be accompanied by a general development of faculties which raises it to a higher level, far above that parrot-like power of giving certain answers to certain questions. I am perfectly aware that it is not possible to cultivate this or any other branch of education without developing in some degree all the others, but for a satisfactory cultivation of your powers all the faculties of the mind and heart should have full and healthy play. You learn to remember what you read, you must learn to understand it also. You learn to remember the objects you see, you learn to observe accurately, to compare and to classify. You endeavour to remember the phenomena that take place in the operations you perform, and you learn to observe, to compare, to judge. You try to overcome a difficulty or to understand a failure, and you learn to imagine, and to theorize. Not only must your minds have received an ample store of useful facts, but all those faculties must also have received a large development before you can be regarded as in any complete sense well educated and intelligent men.

To make a carpenter you want wood and tools, and skill to use them So to make a learned man you should have knowledge of facts and laws, and power to use them.

Probably many of you are not aware how imperfectly you exercise these faculties upon facts or circumstances which are presented to you. I will take an illustration. Suppose I write down in vertical column the series of units 0, 1, 2, 3, etc., up to 9. You observe that I have written down the whole series. You observe and would readily remember the order in which I have placed them, because the order is regular, and with one exception it is probably the order in which you were were required to write them when you learned to write. Suppose I write a second column beside these in the reverse order;



you would have equal facility in observing and remembering the units and their order. But there are now several other things which may be noticed with regard to them. Some would be noticed by all of you if you regarded the figures long enough, but you would not all observe them equally soon; it would depend upon the innate faculty and the degree of educational development of the individual. The first thing you would notice is that the double column represents the nine column in the multiplication table; next you might notice that if we place a plus mark (+) between these two columns, and an equal mark after them, we would be led to putting down a third column all nines, 0+9=9, and the same with all the others down to 9+0=9. And if you take their sums diagonally they are all eights one way and all tens the other. In making these observations we should not say you had discovered a law, though we might say you had detected a rule applying to the arrangement, and you would naturally say, "Where there's a rule there's a reason." And in the search for the reason you exercise the higher faculties of the mind. You do not continue your observations upon these figures alone; you commence considering, speculating, and testing speculation with experiment. You may extend the column upwards and downwards and find nine times nine tenths is 8·1, and nine times eight tenths is 7·2. So of the remainder, the sum of the two figures continues to be nine. You may then carry your extension downwards, and find nine times eleven are ninety-nine, the sum of which two figures is not nine but eighteen. Then nine times twelve equal 108, in which case the sum of the three numbers gives us nine, as also is the case with the following numbers, 117 and 126, etc. You will observe the hitch at eleven times nine in the sum taken horizontally, and that there is no hitch in the sums taken by the right-hand diagonal, and three hitches in the left hand diagonal. This will lead you to observe that in stepping from decimals into units the rate of progression is altered, and that it is not altered in passing from units to tens, because we take in the teens between ten and twenty. It is not my object to teach you arithmetic, or to explain the law which governs these phenomena, but I would just suggest for any one curious in figures to note that nine is the highest number in units, and that comparable phenomena may be observed if he takes eleven as the highest number of pence, not a shilling. The products in the eleven column expressed in shillings and pence give eleven as the number of coins. Seven being the largest number of pints, not a gallon; the seven column expressed in gallons and pints gives seven as the sum of the measures, etc. How much more interesting arithmetic becomes when the reason for a rule is found. How much more interesting and useful every branch of science becomes when it is followed with intelligence instead of being learned merely by memory.

In all cases when you have numerous scattered facts, endeavour to arrange them in order, and to find the law of their relation.

I regard it as one of the weak points of the pharmaceutical examinations, as at present constituted, that though they inquire into the student's knowledge of facts and power of memory, they do not sufficiently test his power of thought, judgment, and originality: I trust the day is not far distant when a change will be made in this respect.

All of you to whom I am now speaking are destined to be Square men; let me urge upon you the importance of being both able and willing to fill a round hole, or any kind of a hole in which fortune may place you.

The use of the laboratory and the guidance of professors are your great privileges. Such aids often make a little man stand fairly well, and enable a man of good abilities to distinguish himself, but they alone never make a great man, and they even risk the dwarfing of great characteristics by bending habits of thought into the established forms. This is a word of encouragement to many who may read my words, but who like myself have to do the best they can without the advantages you enjoy. The dwellers in little country towns often have the advantage of shorter hours and of more leisure behind the counter, and if they have the wisdom to make good use of these, and their opportunity of gathering a few indigenous herbs, they stand a good chance of developing individual characteristics, which is a great boon in a world of common-place men, and at a time when individuality is scarce, and every day becoming a scarcer commodity. Comparative ignorance and inexperience in the case of the home student, and slavish conformity to custom, and to a regulation pattern on the part of the collegians, are the dangers of the two positions to be avoided if possible. It may not be in the power of many in the country to choose between their circumstances and yours; but to both I would offer a piece of good advice, in the words of somebody who says, "Of two evils choose, neither." Do not neglect cultivation, but do not let cultivation convert you into a locomotive engine, which can run only on the line upon which it is placed.

Your studies will cost you something, so will your pleasures. If the cost of study be burdensome, take care that the cost of pleasure be the less. Do without expensive pleasures; whether the expenditure is much money, much time, or much energy.

Cultivate those pleasures which leave you better able for duty, shun those which leave a bad after taste. There is one cheap pleasure I would commend to you all, I mean the habit of cheerfulness and of making the best of the unpleasant duties which are sure to fall to your lot. We often hear complaints—sometimes a chorus of complaints—about the hard fate of the pharmacists; how hard it is that they should be learned and poor. Now let me caution you; the learning did not make them poor unless they learned to be idle, to be above drudgery, to be negligent of common duties; but these are things you ought not to learn in any school or you will have to unlearn them in the school of adversity. Instead of thinking how hard it is to be poor and learned, think how much harder it would to be poor and ignorant, as the bulk of pharmacists were fifty years ago.

Much has been said about our professional status. We have repeatedly seen it suggested by writers in the journals that we should rise above our trading character; and we have seen communications from young men apparently not yet come to years of discretion, asking if the wearing of an apron were not degrading to gentlemen of their professional status.

I had almost resolved to say nothing on a subject so little worthy of our attention; but I must just give it a word in passing to express my contempt for men who, having entered the business, are ashamed to take upon themselves some of the duties of their position. I care not to address such superfine gentlemen, any more than Hotspur cared to discourse with the perfumed popinjay who said that he, too, would have been a soldier were it not for the villanous saltpetre and the vile guns. If you would prosper in the battle of life be a Hotspur rather than a kid-gloved courtier. You should be so full of work, and of desire to do what is right and to be what is right, as to leave neither leisure nor inclination to trouble yourselves about such petty matters further than to acknowledge once for all their fitness and the fitness of conformity to discipline. Such dainty dislike to rough work springs from idleness, for there is nothing truer than that Satan provides mischief for idle hands.

As you would exclude the evil one keep your hands full of honest work, your heads full of useful knowledge, and your hearts full of pure affections.

Pure motives and earnest work give dignity to every duty. As regards the mere name (trade or profession), true worth is satisfied with any title conveniently descriptive.

Your business will include some things which you may feel to be drudgery, but should not include anything really derogatory. The drudgery will be much lightened by your culture enabling your minds to be occupied with thoughts which are pleasant, pure, refined, and elevating, while your hands are occupied with the so-called menial work of making the shop clean and orderly.

My subject has grown in treatment more lengthy than I intended, but I trust it has not grown dreary or unprofitable.

I have endeavoured to enforce the importance of beginning, at once and in earnest, that course of moral and intellectual development which is one perpetual achievement, but knows no end. I have listened to the teaching of the generation which has gone to the front, and I have endeavoured to reflect upon you an echo which has not lost vitality in its passage. I look to you in the future to roll on this echo to another generation—not like the echoes of the physical world, which grow fainter and fainter as they pass from hill to hill, but strengthened by your earnest and your honest work, by your love of truth and your zeal for progress.

Thus shall—

> "Our echoes roll, from soul to soul,
> And grow for ever and for ever."

At the conclusion of the Address, the PRESIDENT said it was hardly necessary to move a vote of thanks to Mr. Proctor for his excellent and telling address, but they were all much obliged to him for it. Not only the young but the oldest amongst them might draw valuable lessons from it, and he trusted the example he had set before the students would not be lost on those whom of course it was Mr. Proctor's desire most to encourage.

The meeting then adjourned.

Notes and Queries.

[527]. COMPOSITION POWDER (Dr. COFFIN'S). We have received from a correspondent the following recipe for this preparation:—

Powd.	Bayberry Bark	8 ozs.
„	W. Poplar „	4 „
„	Ginger	2 „
„	Cinnamon	1 „
„	Pip. Cayenne	1 „

Correspondence.

"*Aide-de-Camp.*"—(1) One of the numerous cultivated species of *Aster*, known under the name of Michaelmas Daisy; (2) *Centranthus ruber*; (3) *Œnothera biennis*; (4) *Tanacetum vulgare*; (5) Possibly *Spiræa salicifolia*: it is not possible to say with certainty from so small a specimen; (6) *Eupatorium cannabinum*; (7) *Lithospermum officinale*; (8) *Origanum vulgare.*

H. M. Hadfield.—Your specimen is the seed of some species of *Amomum*. It comes nearest in size and appearance to that of *Amomum Clusii*, Sm. The Curator of the Society's Museum would be glad to receive an entire fruit, or specimens of the seed in a recent state.

"*Apprentice.*"—Squire's 'Companion to the Pharmacopœia,' published by J. and A. Churchill.

J. G. Candy.—The only difference in the composition is in the substitution of treacle for conserve of red roses.

"*Saline.*"—The powders must be dried separately, either in a hot water oven or upon a pan heated by a water or steam bath. Each to be passed through a fine hair sieve separately, and finally mixed and put into bunged jars or stoppered bottles.

A. L. F. B.—*Lycopsis arvensis.*

J. H. A.—(1) *Ranunculus sceleratus*; (2) *Scrophularia aquatica.*

"*Fides.*"—We believe that a little turmeric or saffron is used.

"*Hampton.*"—We cannot understand from the terms of your question what is precisely the information you seek.

B. W. W.—The difference in behaviour is due to the fact that the preparation which precipitates with water has been properly prepared, while the other is but an imitation of the officinal preparation. We believe cinchona barks containing only cinchonidine and cinchonine are often used for the official fluid extract instead of quinine-yielding cinchona bark. The difference is important, and in this respect the precipitation upon dilution with water is no distinguishing test.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Morris, Mr. Clarke, Mr. J. Garrett, Mr. Butt, Mr. J. Wright, "Ignorans," "One who has known the Drug Trade more than Thirty Years."

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 190.)

BRIEDELIA MONTANA.—*Local name*, ASAUNA.

A short thick tree with spreading branches. The bark is externally of a light brown colour, and has little fungous protuberances of dead suber; internally it is smooth and fibrous and of a light cinnamon colour; taste purely astringent. If soaked in water it gives out much mucilage. The fibrous portion of the bark is very tough and strong. Sections placed under the microscope show the outer portion to be made up of thin-celled reddish parenchyma; in the inner portion there are numerous vessels the external surface of which is incrusted with large crystals arranged in regular columns. Briedelia bark is not mentioned in the Indian Pharmacopœia, but it is well known as a valuable astringent in the Bombay Presidency.

BERGERA (MURRAYA) KÖNINGII.—*Local name*, KURWA NIMB or KARIPAK.

The bark and leaves are mentioned in the Indian Pharmacopœia. The leaves are in common use, but more as a condiment than as a medicine; they enter into the composition of curries and green chutnies. The leaves are pinnate, the leaflets 19 to 21, 1¼ inch to 2 inches long, alternate, unequally oblique at the base, irregularly ovate, serrated, pubescent, upper surface dark-green dotted, under surface of a lighter colour, venation reticulated prominent, petioles red, odour powerful penetrating, and peculiar taste, moderately pungent, bitter, and acidulous. The bark has the same taste and odour as the leaves; the thin walled cells of its parenchyma contain numerous minute oil globules.

The leaves of *Murraya exotica*, a small evergreen shrub, with large white sweet smelling flowers, smell like box leaves, and have a very pungent taste. They have from 5 to 8 elliptic, ovate, tapering leaflets, acute at the base, shining, coriaceous, and dotted with prominent venation. The bark of this shrub is insipid, but its parenchyma abounds in oil globules.

CISSAMPELOS PAREIRA, TINOSPORA CORDIFOLIA, and COCCULUS VILLOSUS,

Are all three very common in this neighbourhood. *C. Pareira* is seldom used, its local name is Mibishee. *T. cordifolia* has a very peculiar habit; if a portion of the stem be severed and hung upon a bush, it will remain alive during the dry season, and as soon as the rains commence send forth shoots and long aerial roots about the size of a piece of whip cord; these eventually reach the ground and develop into stems. The local name is Goolwail. The drug is described in the 'Pharmacographia,' and is much used in this country. *C. villosus* is seldom used, the leaves are sometimes employed to make an emollient fomentation; the local name is Lamtanee. The structure of the root and stem of all three plants is of a similar character.

AILANTHUS EXCELSA.—*Local name*, MAHAROOK.

The bark is very brittle and granular, the external surface brown, marked with scars formed by the exfoliation of dead bark, internal surface of a cinnamon colour; numerous nodules of stony cells are visible to the naked eye. Under the microscope the bark is seen to consist of an outer reddish-brown epidermic layer, the cells of which appear to contain resin, a parenchyma of thin-walled cells which are loaded with starch granules, and which, towards the outer part of the bark contain much green colouring matter; the inner circle of the bark is mostly occupied by the masses of stony cells already mentioned. The odour and taste resemble that of cinnamon. The bark has been strongly recommended as a tonic in dyspepsia. The alcoholic tincture when evaporated yields a dark reddish-brown extract which appears to consist of a wax and resin mixed. It has a strong cinnamon odour.

GYMNEMA SYLVESTRE.—*Local name*, KAVLEE.

A shrubby climbing plant. Upper surface of leaves dark green, shining, under surface pale green; their shape varies from ovate-lanceolate to obovate; the venation is transverse and reticulate with a marginal vein; length four to five inches; taste saltish and acrid. The root is about the size of the little finger or less, not unlike Hemidesmus; it has a tough central wood, and when fresh a soft spongy bark, which is reddish brown and fissured longitudinally; it loses much bulk in drying and becomes loose and transversely fissured; the taste is acrid and saltish; the whole plant abounds in milky juice. Under the microscope the central woody portion of the root is seen to have a radiated structure and to be traversed by large vessels; the extension of the medullary rays into the bark is distinct; the latter is made up of a thin-walled parenchyma, the cells of which contain much starch and tolerably numerous crystalline concretions. There are many laticiferous vessels, especially towards the inner part. The epidermis consists of several layers of flattened cells of a deep reddish brown colour. I am unable to confirm Mr. Edgeworth's statement that chewing the plant destroys the power of the tongue to appreciate the taste of sugar. Sugar taken into the mouth after chewing the fresh plant, more especially the root bark, has a saltish taste. The medicinal properties of Gymnema require investigation.

VITIS (CISSUS) LATIFOLIA.—*Local name*, KOLE ZAN.

A large climbing plant, with perennial tuberous roots; fruit exactly like bunches of small black grapes; very common in this part of India. The whole appearance of the plant reminds one of the vine. The roots form large bunches of tubers attached to a central root-stock; the tubers are from one to two feet long, tapering at both ends, with a maximum diameter, when fresh, of from two to three inches; externally they are covered by a light brown epidermis, and marked with small wart-like protuberances arranged in circular rings; internally they are red and juicy. A section shows a thick stringy cortical portion easily separable, and a central fleshy part of the consistence of a parsnip. Under the microscope the root is seen to be made up of a thin-walled parenchyma, the cells of which contain large oblong starch granules and numerous bundles of needle-shaped crystals; the outer portion of the root and root-bark is traversed by numerous very large fenestrated vessels. The taste is sweetish, mucilaginous and astringent. This drug is used by the country people as an alterative; they consider that it purifies the blood and renders the excretions healthy. The form of administration is a decoction of the dried tubers.

ASPARAGUS ASCENDENS?—*Local name for the dry tubers*, SUFFED MOOSLI.

I place a query after the botanical name, as I have not seen the plant. The drug consists of shrivelled decorticated tubers, from two to two and a half inches long, the largest being about a quarter of an inch in diameter; they are of an ivory white colour, often twisted, hard and brittle; adhering to some of the pieces may be seen portions of a yellowish epidermis; when soaked in water they swell up and become spindle-shaped, the thickest part being about the size of a lead pencil. Under the microscope these tubers present a delicate cellular structure, the cells of which contain nothing but a little fine granular matter; this surrounds a central vascular column the middle part of which is entirely occupied by jointed vessels, the outer portion consisting of scalariform—the portions of adherent epidermis already mentioned are silicious. Suffed Moosli has an agreeable mucilaginous taste; it contains no starch. I have used it largely as an article of diet; it is far nicer than Salep, and is generally relished by Europeans. To prepare it, take 200 grains of the powder, 200 grains sugar, pour upon them slowly a large teacup of boiling milk, stirring constantly all the time. Two varieties of asparagus are found in this neighbourhood; *A. sarmentosus* which has a woody root stock, to which are attached a number of ovate tubers, and *A. racemosus* having also a woody root stock and bearing a large number of fleshy vermicular tubers. The local name of the first is Makhee, of the second Satawree.

ARISTOLOCHIA INDICA.—*Local name*, SAPSUN.

The drug as found in the shops consists of the root and stem, the latter principally. It is in pieces about three inches long and one quarter of an inch or more in diameter, and has a central woody column made up of about ten wedge-shaped portions. The bark is thick and corky, marked with longitudinal ridges and numerous small warty projections; it is of a yellowish brown colour. Under the microscope the central wood is seen to be traversed by large vessels, the medullary rays are distinct and easily traced into the bark; in the latter, which consists of a corky parenchyma loaded with starch, there is a circular zone of large yellow stony cells. Sapsun is very bitter and has a pungent camphoraceous taste; it is met with in all the shops. The plant grows in this neighbourhood but is not very common; it is largely used as a stimulant tonic. An alcoholic tincture evaporated yields a quantity of yellow bitter resin, and some yellow colouring matter soluble in water.

ARISTOLOCHIA BRACTEATA.—*Local name* KEERAMAR.

The drug consists of the leaves, stem, root, and ripe capsules. The portions of stem are striated, slender, and about as thick as a piece of whipcord; the root is of the same size but not striated; the leaves are uniform, glaucous when fresh; the capsules are ovate, three-quarters of an inch long, ribbed, depressed at the apex, six-celled; each cell contains a column of heart-shaped flat seeds, closely packed. The appearance of the seeds is peculiar; they look as if they had been cut out with a punch; one side is flat, black and rough from a number of irregular projections; the other is almost entirely occupied by two brown, comparatively smooth lobular projections of a soft corky structure; these, under the microscope, are seen to be entirely made up of ovate empty dotted cells. The whole plant is nauseously bitter; it is much used as an anthelmintic. Its reputed antiperiodic properties require investigation.

BALSAMODENDRON ROXBURGHII.

Through the kindness of Mr. Woodrow, in charge of the Botanical Gardens at Hewra, in the Deccan, I have been favoured with fresh specimens of the stem and exudation of this tree, collected near Prit, about thirty miles north of Poonah. Description: The epidermis consists of several rows of delicate elongated cells containing a little granular matter; the cells beneath this, which form the green bark, are loaded with chlorophyll and starch. Proceeding inwards the chlorophyll gradually diminishes, and a few bundles of liber cells are met with, forming a broken irregular zone. Within this the cells contain granular matter, starch, and globules of balsam; the cells throughout the bark are of an oblong form; laticiferous ducts permeate the bark at intervals, and the medullary rays are distinctly traceable; a few conglomerate crystals are met with. The wood which is white, soft and brittle, consists of elongated thin-walled cells, divided into zones; in the zone next the bark the cells (eighteen to twenty rows) are empty or contain a little starch; in the next they are smaller and loaded with large starch granules. The same structure is continued to the central pith, which consists of similar cells full of starch. The examination of sections of the wood and bark is much facilitated by coloration with an aniline dye. The exudation of this tree is at first opaque and milky; as it dries it becomes greenish and translucent, and very closely resembles the gum resin sent to me from Sind as the produce of *B. Mukul*, the only difference I observe is that it has a more terebinthinate odour; I identify it as forming part of the Bysabol Googul of the shops, which I have described in "Some Remarks upon Myrrh and its allied Gum Resins," as Indian Bdellium. I think it quite possible that the same trees in Arabia may produce genuine Bdellium. Carter, in his 'Geography of the South East Coast of Arabia,' mentions "the Moql tree, the gum of which is called Tabka, and its companion the *Balsamodendron pubescens*." In Arabic and Persian works on Materia Medica, the different kinds of Bdellium are described under Moql, and Googul is sometimes given as the Indian equivalent. In a former article I have shown that true Googul is the produce of *Boswellia serrata*. In some parts of India the term appears to be applied to different kinds of dammer.

(*To be continued.*)

FERRIC CITROPHOSPHATE.*

BY R. ROTHER.

Citric acid is one of the most remarkable of the organic acids. Its constitution is so peculiar and unintelligible that synthetic chemistry has failed to produce it; neither has any process of disruption yielded it from more complicated compounds. It is, in our present knowledge of the substance, most emphatically an organic acid. It is, however, a noticeable fact that, considering the interest and importance attaching to the citrates as a class, they have been but imperfectly studied.

The marvellous property possessed by citric acid of rendering metallic bases insusceptible to many of the ordinary reagents has long been known. This action has been interpreted in various ways, and given rise to some most striking theoretical speculations. From the time that H. Rose first observed the ready solubility of dry ferric citrate in presence of normal monad citrates to the present, no definite and reliable knowledge existed in regard to the constitution of these compounds. The opinion largely prevailed that they were but mechanical mixtures; that is, mere solutions of one salt in the other without reference to equivalency. The first step in the direction of a comprehensive view of this heretofore hopelessly intricate subject was made by the writer (*Laboratory*, February, 1876), in showing that ferric salts with monobasic radicals formed, by a combination of double decomposition and additive affinity, a peculiar green double citrate of iron and the monad metal, whilst the monobasic or dibasic radical passed to the base of the citrate actually decomposed. By means of dialytic experiments (*American Journal of Pharmacy*, April, 1876), the writer added further proof in confirmation of this result, but also showed that in case of the citrophosphoric compounds a rearrangement of more complicated character takes place. All compound salts may be divided into two classes. Double, triple and quadruple salts are formed from dibasic, tribasic and tetrabasic acids when each individual unit of equivalency is saturated by a distinct basic radical. Secondary, tertiary and quarternary salts are produced when each independent unit of equivalency of a polyatomic metal is saturated by distinct acid radicals of corresponding basicity.

The writer's process for preparing ammonio-ferric citrophosphate (*Pharmacist*, August, 1871) indicates that two equivalents of ferric orthophosphate and one equivalent of triammonic citrate react upon each other in the production of a soluble amorphous compound readily obtainable in splendid brown green scales. The solution, when subject to dialysis, gave no evidence of dissociation, showing that no crystallizable salt is present. The formation of the compound, therefore, determines a basic condition made apparent by the presence of ferric oxycitrate or free ferric hydrate (*Pharmacist*, May, 1876). Its generation may then be represented as follows:—

$$4(FePO_4)+2\,(NH_4)_3C_6H_5O_7+3\,(OH_2)=FeC_6H_5O_7(NH_4)\\C_6H_5O_7,\ Fe(OH)_3+2\,(FePO_4),\ (NH_4)_3H_3(PO_4)_2.$$

As this reaction assumes the production of an ammonio-ferric phosphate in which one equivalent to each monammonic and diammonic phosphate are seemingly united, the writer endeavoured to produce this double phosphate independent of the citrate by dissolving freshly precipitated ferric phosphate in a mixture of the two ammonium phosphates, but no solution appeared to take place. Ferric citrate was then substituted for the ammonium phosphates, when rapid solution was effected, thus enabling the writer to add one more interesting iron salt to the list of those already discovered by him. The ferric citrophosphate obtained by this combination is a secondary anhydrous salt having the composition $Fe_2(PO_4)\ (C_6H_5O_7)$, and easily obtainable in beautiful brown green scales. It forms in long slender blades, a shape characteristic of ferric citrate. In concentrated solution it is absolutely permanent, showing also, in this respect, one of the properties of ferric citrate. It has a sweet, acidulous taste, free from metallic flavour and the saline nauseousness of some of the ferric double citrates now in use. There can be no doubt of its complete superiority over all other citroferric phosphates at present so largely employed, either in a pharmacal or therapeutic aspect. On the assumption that this salt is one of the components of the ammonio-ferric citrophosphate above described, the formation may be written as follows:—

$$2\,(FePO_4)+(NH_4)_3C_6H_5O_7=\\Fe_2(PO_4)\ (C_6H_5O_7)+(NH_4)_3PO_4.$$

This result seems quite probable, since, as the basicity of the acids is apparently alike, a possibility of closer union is not precluded, and hence we may have the actual combination of the two constituents in the condition of a secondary double salt,

It is a remarkable fact, worthy of note in this connection, that ferric pyrophosphate is practically insoluble in ferric citrate. This property, therefore, supports the writer's constitutional formula of the officinal pyrophosphate, making it a mixture of ammonio-ferric pyrophosphate, ammonio-ferric citrate and free ferric citrate.

As previously suggested by the writer (*American Journal of Pharmacy*, April, 1876), it was found that the most practical and expeditious process of preparing the ferric citrophosphate consisted in precipitating the iron as a mixed phosphate and oxycarbonate, and dissolving the mixture in citric acid. Ferric oxycarbonate (*Pharmacist*, December, 1873) is so incomparably superior in every respect to the ordinary ferric hydrate that no operator who has once employed it will ever abandon its use. The compact ferric phosphate (*Pharmacist*, December, 1873,) is equally an improvement on the gelatinous kind. In the production of ferric citrophosphate the writer combined the processes of the two iron salts as follows:—

Take of Solution of Ferric Sulphate ...one pint.
Disodic Orthophosphate Cryst. 7 troy ozs.
Disodic Carbonate „ ...9 „ „
Citric Acid „ ...3 „ „
Water sufficient.

Add the sodic phosphate to the solution of ferric sulphate and apply heat until solution is effected; now place the sodic carbonate into a capacious vessel, pour on half a pint of water and apply heat until the salt has dissolved; then add in rapid succession the former solution, one-fourth at a time, and maintain the heat, with constant stirring, until effervescence has ceased; dilute the mixture with water to the measure of eight pints, and when the precipitate has perfectly subsided decant the supernatant liquid, and mix the sediment again with a fresh portion of water, as before; after three or four washings in this manner, pour the precipitate upon a muslin strainer and press it thoroughly; place the residue into a porcelain capsule, add the citric acid and apply a water bath heat until perfect solution has occurred; finally, pour the liquid upon plates of glass or porcelain and expose it in the open air to dry. The yield is about 6½ troy ounces.

In this formula a slight excess of sodic phosphate is employed, since the sodium carbonate has a tendency to take away the acid of the ferric phosphate. Hence, the two precipitates may also be prepared separately, mixed after washing, and dissolved as above. With the adjusted quantity of sodium phosphate, as directed in the above formula, the final result, however, agrees very closely with the theoretical yield.

If desirable, the salt may be retained in solution, which, if sufficiently concentrated, will remain absolutely

* From the *Pharmacist* for September, 1876.

permanent. A solution containing one-half a troy ounce of the salt in the fluid ounce appears to be the most convenient form.

This salt, similar to the officinal pyrophosphate, when mixed with any acid stronger than the citric, is completely decomposed, ferric phosphate being precipitated. The officinal pyrophosphate, when mixed with orthophosphoric, pyrophosphoric, metaphosphoric, chlorhydric, nitric or sulphuric acid, is instantly precipitated. The white gelatinous precipitate is insoluble in either of the phosphoric acids, but any of the latter three acids, when in sufficient excess, again dissolve it. The erroneous belief is still abroad that the officinal pyrophosphate of iron should form a clear solution when mixed with diluted phosphoric acid. It is, however, about time now that it was generally understood that any citrophosphoric compound is incompatible with free orthophosphoric acid, by reason of the fact that any citrate present will be decomposed, its acid being liberated; and as free citric acid fails to dissolve the various ferric phosphates, these must of necessity be thrown out of solution.

EXTRACT OF MALT.*

Extract of malt has become a popular dietetic remedy, and is particularly esteemed as a demulcent and nutritive food for children. Its syrupy appearance, however, offers many inducements to fraud. The simplest and cheapest adulterant is glucose (syrup), which is in general use by brewers to increase the amount of extractive matter in beer. But there is no ready method known to detect this admixture. And as a complete analysis is in most cases impracticable, the consumer must generally rely upon the honesty of the manufacturer.

Hager reports having received a sample of malt extract, which in external appearances resembled the genuine completely, although it had a peculiar faint foreign taste.† From its behaviour towards reagents, in which it greatly differed from the genuine, it was judged to be a mixture of glucose, glycerine, and about thirty per cent. extract of malt. To confirm these results, comparative reactions were made with three samples of extract of malt, one of which had been evaporated in an open vessel, and had a darker colour than the others. The main difference between extract of malt and glucose (syrup) is probably the amount of soluble modifications of proteïn-bodies in the former. It might be conjectured that the adulteration with glucose would produce a greater amount of reduction in alkaline copper solution. But the results obtained do not permit any such conclusion to be drawn; one gramme of the three last named extracts reducing respectively 43, 44·5, and 46 c.c. of the copper solution, while the submitted sample (X) reduced 48·5 c.c.

The presence of glycerine in moderate quantity, say up to 10 per cent., cannot be called an adulteration, as it is no doubt added for the purpose of preserving the extract; but then the glycerine must be employed in a pure state. The above mentioned sample of extract (X), however, contained 26 per cent. of glycerine (extracted by ether-alcohol), which could not have been very pure, owing to the considerable quantity of calcium chloride present.

Hager considers the examination of the following points sufficient to decide on the genuineness and qualities of a malt extract.

1. The extract must have its own peculiar sweet taste and the refreshing odour of fresh bread.

2. The watery solution must be nearly clear. On dissolving 5 gms. of the extract in 45 gms. of distilled water, under stirring and without heat, a slightly cloudy solution is obtained, which may be filtered without difficulty. The insoluble matters were found to be different under different circumstances, and consisted of amorphous coagulum, ferment-bodies, and columnar, four or six-sided (sometimes also star-shaped) crystals.

3. 10 c.c. of the filtered solution, prepared as just stated, are placed into a test-tube, 1·5 cm. (= $\frac{3}{5}$ inch) wide, and mixed with 10 cc. of an aqueous cold saturated solution of picric acid. In the case of good extracts, a strong cloudiness appears at once, which gradually increases, and after ten minutes has become so intense as to prevent the passage of daylight through the liquid. The adulterated sample (X) showed only a slight cloudiness with picric acid, nor did it after ten minutes become so intense as to be impervious to light.

If it is desired to determine the quantity of the protein compounds in solution, 10 gms. of the extract are digested for half an hour at a gentle heat in 100 gms. of cold saturated aqueous solution of picric acid, and the whole set aside to allow the precipitate to deposit. The latter is collected in a tared filter, washed and dried in the water-bath. Its weight, divided by 2, is approximately equal to the quantity of the proteïdes.

4. Another portion of the filtered 10 per cent. solution is mixed with tincture of galls in excess, and well shaken. A copious whitish precipitate, remaining suspended in the liquid, and making it impervious to light, must make its appearance. Sample X gave only a slight cloudiness.

The same relationship which exists between pepsin and fibrin, or other animal proteïn-compounds, holds good between the diastase of extract of malt and vegetable starches. The latter, which form a main constituent of our vegetable diet, are converted by diastase into dextrin. Extract of malt, therefore, owing to its proteïdes and to diastase, is an excellent adjunct in the nutrition of infants.

Various other remedies have been combined with the extract of malt, to modify its action, or it is used as a pleasant disguise for disagreeable medicines. But since those agents which are capable of arresting or preventing fermentation would exert the same influence upon the diastase, and consequently would prevent the latter from acting upon starch, they should not be given in combination with malt extract, or at least only in very small quantities. Tannic acid, salts of quinine, salts of iron (ferric) with organic acids, and potassium iodide should be given in comparatively large quantities of the extract. Hager mentions the following compounds or preparations as in use in Germany:*

Extractum malti chininatum (or *quinatum*), *Malt extract with quinia*, was formerly prepared by adding 1 part of quinia sulphate to 250 parts of the extract; but the bitterness of the mixture caused it to be frequently rejected by children. At present the usual method is to add 1 part of quinia tannate to 100 parts of the extract. A trial with a perfectly neutral extract, prepared by J. D. Riedel, yielded a solution, which had not deposited any sediment after eight days, and which exerted but a very slightly diminished action upon starch. Hager proposed to call this *Extractum malti tannochinatum*.

Extractum malti ferratum, *Ferrated malt extract*. A formula for this preparation is given by the German Pharmacopœia. It is best prepared by dissolving 2 parts of soluble ferric pyrophosphate in five parts of pure glycerine, and adding it to 93 parts of the extract. The taste of the resulting product is, however, slightly modified, and Hager recommends to use saccharate of iron 3 parts, glycerine 7 parts, and extract 90 parts.—This would be *Extractum malti saccharoferratum*.

Extractum malti iodatum, *Iodized malt extract*, is a solution of 1 part of potassium iodide in 10,000 parts [rather dilute! Ed. N. R.] of extract.

Extractum malti pepsinatum, *Malt extract with pepsin*, is said to be more nutritious than the simple extract, and

* From *New Remedies*, August, 1876.

† In the course of the paper, this sample is distinguished by X.

* A number of preparations, besides those enumerated above, are in use in the United States.

to be especially valuable in dyspeptic complaints. For this purpose a saccharated pepsin of 50 per cent. is recommended. Two parts of this are rubbed with 5 parts of glycerine, and added to 93 parts of the extract. It is best to prepare this mixture only when wanted.

Extractum malti lupulinatum, Extract of malt with hops, is a preparation made by J. D. Riedel, of Berlin. Although originally intended to be added to weak malt liquors or beers for the purpose of giving "body," it may be used medicinally. It has an agreeable aromatic taste, and is probably a solution of alcoholic extract of hops in extract of malt.

NOTES ON THE GENUS TEUCRIUM.*

BY JOHN M. MAISCH.

In the search for remedial agents, physicians sometimes resort to drugs which have been formerly employed medicinally and have fallen into disuse on account of their indifferent properties, or because other more active and reliable medicines have taken their place; occasionally a remedy is neglected and forgotten, and its valuable qualities have to be, as it were, rediscovered, or it comes to the surface once more, merely, as it seems, for the purpose of proving that we can well get along without it. Such thoughts came to my mind when, a short time ago, a prescription was shown to me calling for *Extractum Teucrii scordii fluidum,* an almost obsolete European remedy in an American form.

Teucrium scordium, Lin, *germandrée aquatique* of the French, *Lachenknoblauch* of the Germans, is usually called water germander in English, because it grows in moist, swampy meadows, near ponds, etc. It is found in Western Asia, and throughout a large portion of Europe. Forty years ago it was officinal in most pharmacopœias of continental Europe, but since then has been dismissed in the revised editions of nearly all, retaining a place in a few only.

The plant belongs to the natural order of Labiatæ, a family of plants which is characterized by the complete absence of deleterious properties, the active constituents found in them being chiefly volatile oil, associated in many with more or less of a bitter, non-alkaloidal principle, and occasionally with a little tannin. The medical properties of the labiatæ are therefore mainly carminative and stimulant, and frequently tonic and stomachic. They are mostly indigenous to the temperate regions of the old world, the number indigenous to the United States being comparatively small; but many species have been introduced here from Europe, and completely naturalized in some sections of the United States.

The genus Teucrium is classed with the tribe *Ajugoideæ,* which has the upper lip short, or deeply notched and turned forward so as to appear wanting, the four ascending stamens projecting through the slit in the upper lip. Several of the European species formerly enjoyed a high reputation, among them the one mentioned, which, together with the allied species *T. scordioides,* Schreb., is regarded to be the Σκόρδιον of Dioscorides. The plant is softly pubescent, attains a height of twelve to eighteen inches, has sessile, oblong, serrate leaves, and rose-coloured flowers, two or three of which are found in the axils of the leaves. The second species differs mainly by being villous and having cordately ovate, somewhat clasping leaves. Both possess a bitter taste, and, in the fresh state, a distinctly alliaceous odour; it was formerly in repute as an antiseptic and diaphoretic internal remedy, for gargles, and as a dressing for foul ulcers. 'The New London Dispensatory,' printed in 1676, says of it: "It is lyptintick, abstersive, traumatick, alexipharmick, sudorific, anodyne and pectoral; it opens obstructions of all the principal parts, cleanseth the intrails and old ulcers; provokes urine and the terms; expectorates rotten matter out of the chest; helps old coughs, asthmas, pleurisies, inward ruptures, biting and stinging of serpents, and potently resists poison, plague, and all pestilential diseases. It exhilarates the heart, cures the bloody-flux, comforts the stomach, and drives out the small pox and measles. Outwardly, it cleanseth and heals wounds and ulcers, and cures pains of the gout. The essence is most effectual to the intentions aforesaid."

Similar but more feeble virtues were attributed to *T. scorodonia,* Lin., s. *Scorodonia beteromalla,* Moench, likewise a European plant, which differs from the former in having petiolate, cordate-ovate leaves, a more distinctly two lipped calyx and yellow corolla.

The fluid extract of water germander may be made by the U.S. officinal process for fluid extract of chimaphila, and may be given in doses of one-half to one teaspoonful.

The following European species were formerly employed medicinally for their stimulating and tonic properties, and some still enjoy some popularity as domestic remedies in localities where they occur.

T. polium, Lin., with sessile, linear-lanceolate, crenate and tomentose leaves and terminal white flowers.

T. montanum, Lin. Leaves similar, with a revolute margin and terminal yellowish flowers.

T. creticum, Lin., resembling the preceding, but the bluish flowers axillary and single. The closely allied *T. rosmarinifolium,* Lam., has the branches longer and more slender, and the flowers in cymules of three in the axils of the bracts.

T. flavum, Lin., has its greyish-yellow flowers similarly arranged; but the petiolate leaves are ovate and crenate.

T. fruticans, Lin., is the *Erba di S. Lorenzo* of Southern Italy, and has entire, oblong or oval, sub-coriaceous leaves, and single axillary flowers with bluish corolla.

T. chamædrys, Lin., the χαμαίδρυς of Dioscorides; leaves short petiolate, ovate to obovate, cuneate at base, crenately serrate; flowers, one to three, axillary with purplish-red corollas.

T. botrys, Lin. Leaves triangular-ovate in outline, pinnatifid; flowers axillary, in threes; corolla pale red, punctate in the throat.

These and a few other species, indigenous to Southern Europe and the basin of the Mediterranean, most probably do not differ in their medicinal properties from *Teucrium Canadense,* Lin., the wood sage or germander of the United States and Canada.

Somewhat different properties are met with in *T. marum,* Lin., cat thyme, or Syrian herb mastich, which is found in the countries bordering on the Mediterranean. Its leaves are petiolate, ovate or ovate-oblong, rather acute, white tomentose beneath; the rose-red flowers are single in the axils of the bracts, and form a terminal one-sided, raceme. It has a strong aromatic, somewhat camphoraceous odour, and an aromatic, bitterish and acrid taste. It has been employed internally, in doses of twenty to sixty grains, in various spasmodic and other nervous disorders, and externally chiefly for its errhine properties; it constituted the active ingredient of the *Pulvis sternutatorius* of some old European 'pharmacopœias,' which was composed of sweet marjoram three parts, cat thyme, lily of the valley and orris root, of each one part. Cat thyme is prescribed in Europe under the name of *Herba mari veri.*

SANTONATE OF SODA*.

BY M. LEPAGE.

The author having failed to get satisfactory results with either of two published processes for preparing santonate of soda, proposed the following mode of operating, which he finds to give a satisfactory result:—

* Read at the Meeting of the Philadelphia College of Pharmacy, held August 15th; from *Amer. Journ. Pharm.*

* Abstract of a paper in the *Journal de Pharmacie* [4], vol. xxiv. p. 311.

Take—

Powdered Santonin	100	grams.
Alcohol (90°)	500	„
Distilled Water	500	„
Unslacked Lime	80	„
Carbonate of Soda	90	„

Dissolve the santonin in the alcohol and water at the temperature of a water-bath; then add the lime, previously slacked and suspended in a very small quantity of water, and stir frequently. The liquid immediately takes a magnificent rose colour, but after about ten or fifteen minutes it loses its colour and presents the appearance of a clear soup. This is due to the formation of santonate of lime, which is but slightly soluble in the alcohol and water. Allow the mixture to remain in the water bath some minutes longer, to ensure the complete combination of the calcium oxide and santonin; then pour in the carbonate of soda dissolved in double its weight of pure water, agitate briskly, allow the liquor to deposit, and filter. Distil the filtrate in a water-bath to recover the alcohol; concentrate the residue in a dish placed in hot water until of the consistence of a syrup, weighing 200 or 220 grams. After about twelve hours, when it has solidified, powder it and suspend it in 800 grams of 90° alcohol; agitate frequently to facilitate solution, and after some hours of contact decant the clear liquid. Wash the portion remaining undissolved (excess of carbonate of soda) with 200 grams of fresh alcohol and add this to the other alcohol, filter, distil to recover about three-fifths of the alcohol, and terminate the operation by concentrating the residue in a water-bath until reduced to about 400 grams. Let this stand, and at the end of twenty-four to thirty-six hours it will form a crystalline mass of small prismatic needles, which after drying will weigh 150 to 160 grams. The mother-liquor, by further concentration will still yield 20 to 25 grams of the salt.

The santonate of soda thus obtained is perfectly white, and contains, according to the author's analysis, 51 per cent. of santonic acid. It dissolves completely in three parts of water at the ordinary temperature and in four parts of alcohol at 90° C. The aqueous solution possesses a marked bitter taste and presents an alkaline reaction with litmus paper. No turbidity or precipitation should be caused by oxalate of ammonia, chloride of barium, or carbonate of soda. Acids added in slight excess precipitate the santonic acid.

Syrup of Santonate of Soda.

The author recommends the following formula for a vermifuge syrup, which from its taste resembling sugar syrup could be administered without difficulty to children:—

Powdered Santonate of Soda	5	grams.
Simple Syrup	900	„
Syrup of Orange Flower	100	„

Suspend the santonate in 250 grams of the simple syrup and heat it over a spirit lamp until dissolved; add the remainder of the syrup, then the syrup of orange flower; and mix carefully. A tablespoonful, or 20 grams of this syrup, will contain 10 centigrams of santonate, or the equivalent of 5 centigrams of santonin. For adults the dose might be doubled, or a syrup made containing 20 centigrams to the tablespoonful.

THE PREPARATION OF SOME COLOURED FIRES (BENGAL LIGHTS) USED IN PYROTECHNY.*

BY SERGIUS KERN, ST. PETERSBURG.

In preparing coloured fires for fireworks by means of the usual formulæ given in many manuals of pyrotechny it is often very necessary to know the quickness of burning of coloured fires, as in some cases, such as decorations and lances, they must burn slowly, in other cases, as wheels, stars for rockets, and Roman candles, they must burn quicker. Working for some months with many compositions of such kind, I prepared three tables of coloured fires (red, green and violet), where every formula with a higher number burns quicker than a fire with a lower number. For instance, No. 5 burns quicker than No. 6, and slower than No. 4. These tables will, I think, be of much assistance in the preparation of fireworks:—

Green-coloured Fires.

No.	Potassium Chlorate. Per cent.	Barium Nitrate. Per cent.	Sulphur. Per cent.
1.	36	40	24
2.	29	48	23
3.	24	53	23
4.	21	57	22

* From the *Chemical News*, September 29, 1876.

THE PHARMACOLOGICAL GROUP OF PIPERIN.*

Professor R. Buchheim has shown, several years ago,† that black pepper contains two substances which are of analogous chemical constitution, and have similar action. One of these is piperin, which was discovered by Oerstedt in 1819, and was first supposed to be the acrid principle until Pelletier (1821) showed that it was tasteless, when quite pure, and that the biting taste resided in the accompanying resin. To settle this question, Professor Buchheim lately exhausted 2000 gms. of black pepper with alcohol, removed the alcohol from the percolate by distillation, and treated the residue with water, which dissolved only traces thereof, without assuming any sharp taste. The extract was now shaken with ether as long as the latter became coloured thereby. The residuary part of the extract consisted almost wholly of impure piperin, which was deprived of a little adhering resin by potassa solution, then dissolved in hot alcohol, decolorized by animal charcoal, and re-crystallized from hot alcohol and petroleum ether. The pure piperin thus obtained consists of almost colourless rhombic cylinders, with a faint yellowish tint, which could not be removed. They were tasteless when merely placed upon the tongue, being entirely insoluble in aqueous fluids, but exhibited the sharp taste of pepper when chewed, or when introduced in alcoholic solution.

The ethereal solution obtained above was then shaken with solution of potassa, which removed chlorophyll, fatty acids, and an acid resin. On distilling off the ether a residue of an intense yellow colour was left behind, which was dissolved in alcohol and treated with animal charcoal. It was, however, impossible to decolorize it entirely; and, besides, a little piperin accompanied it, from which it was exceedingly difficult to separate it. In this condition the residue appeared as a yellowish-brown mass of the consistence of thick turpentine, and of extremely biting taste. The yield was about two-thirds of that of piperin. Treatment with alcoholic potassa and supersaturation with sulphuric acid produced from it a substance which was recognized as piperidin sulphate.

There exist, therefore, in black pepper, two bodies, which yield piperidin with alcoholic potassa—namely, *piperin*, and the new body here obtained, for which the name *chavicin* is proposed, from *Chavica officinarum*, Mign., or long pepper. On account of its amorphous condition this substance has heretofore been denoted merely as "resin," and had not been investigated. While *piperin*‡ may be regarded as piperidin, $C_5H_{10}HN$, in which one H is replaced by piperic acid—$C_5H_{10}(C_{12}H_9O_3)N$—we may consider *chavicin* in a similar manner as piperidin, in which one H is replaced by *chavicic* acid.

These piperidin compounds exist in nature, also, in other plants. Pellitory (*radix pyrethri*) contains a body, which Professor Buchheim has named *pyrethrin*, and which he ascertained to be decomposable into piperidin and pyrethric acid. *Herba spilanthis* (from *Spilanthes oleracea*, Jacq., paracress) also contains a body which may be split up into an acid and piperidin.

CYPRESSUS PYRAMIDALIS.§

BY N. HARTSEN.

The author has published a note relative to an amorphous and a crystalline substance that he has found in the *Cypressus pyramidalis*. The amorphous substance was obtained by macerating the stems in alcohol, then distilling off part of the alcohol until the resinous matters were precipitated, separating the liquid and further heating it to drive off the alcohol. A yellowish powder was precipitated that was insoluble in water, acetic acid, and ether (the last could be used for separating it from adherent resinous matter); in alcohol it was slightly soluble.

Sulphuric acid converted it into a brown substance. It was dissolved by ammonia, forming a citron yellow liquid. Its alcoholic solution gave a yellow precipitate with an alcoholic solution of acetate of lead.

The crystalline substance was obtained from ripe or nearly ripe fruits, by macerating the peeled fruits in alcohol, and allowing the tincture to evaporate spontaneously, when the crystals were left mixed with resinous matter. This substance crystallized in beautiful prisms, which had a light emerald green tint; treatment with animal charcoal failed to remove this colour. When heated upon platinum the crystals melted and afterwards volatilized, giving off irritating vapours. The crystals were insoluble in water, but soluble in alcohol and ether. An alcoholic solution was precipitated by an alcoholic solution of acetate of lead.

NEW ITALIAN VARIETY OF LIQUORICE EXTRACT.

In the *Pharmaceutische Zeitschrift f. Russland* (vol. xv., p. 257), A. Peltz notices a new variety of liquorice extract which he had received for examination from a Russian wholesale house. It occurs in irregular masses, is rather tough, but can be cut with a knife, has a dull appearance, and possesses a purely sweet, not burnt, taste. On dissolving it in water it leaves only a very small residue. whilst the solution evaporated over a water-bath yields 75 per cent. of extract dried at 90° C. The undissolved residue was washed with a weak solution of ammonia, then boiled in water, and the liquid then gave indications of starch with tincture of iodine.

To ascertain the amount of glycyrrhizin 10 grams of the liquorice were dissolved in water, filtered, the filtered solution mixed with a sufficient quantity of dilute sulphuric acid, and the precipitate collected on a filter and washed. As this did not give the glycyrrhizin sufficiently pure, the precipitate was again dissolved in weak solution of ammonia and reprecipitated with sulphuric acid. This precipitate was dried, triturated with one-third of its weight of barium carbonate, and extracted with hot absolute alcohol. The alcoholic extract evaporated to dryness gave 1·5 gram of glycyrrhizin.

The amount of sugar was ascertained by means of the copper solution to be 10 per cent.; the loss in moisture when dried at 100° amounted to 14 per cent.

The following table shows the position of the new substance in relation to other commercial liquorices:—

Variety.	Moisture Per cent.	Dried Extract Per cent.	Glycyrrhizin. Per cent.	Starch. Per cent.	Sugar. Per cent.
English .	1·2	38	2·44	27·10	13
Calabrian	2·0	47	1·33	35·50	11
Bayonne .	3·7	48	2·19	35·10	14
Astrachan	7·3	50	18·14	1·33	12
Spanish .	4·12	55	3·15	8·35	14
Kasan .	4·5	57	14·74	2·62	14
Sicilian .	4·1	60·5	4·67	5·00	16
Baracco .	3·7	67·5	4·95	13·12	15
Morean .	—	79·0	11·88	5·33	16
Italian .	14·0	75·0	15·0	2·50	10

It will be seen that though the Morean variety yields more extract it is accounted for by the amount of sugar; whilst the Kasan variety which contains almost the same amount of glycyrrhizin as the Italian has the disadvantage of an unpleasant, almost tarry taste. The new article, notwithstanding its good qualities, is said to have been offered at a low price.

* From *New Remedies*, September, 1876.

† *Archiv f. Pathol. Anatomie*, LVI., 9.

‡ The formula of piperin is $C_{17}H_{19}NO_3$, or doubled, $C_{34}H_{38}N_2O_6$.

§ *Journal de Pharmacie* [4], vol. xxiv. p. 304.

THE BRUSSELS CONGRESS.

USE OF DEFINITE CHEMICAL PRINCIPLES IN MEDICINE.

We have been favoured with the following letter upon the above subject by Dr. Julius Morel, of Ghent:—

"My dear Editor,—I wish to chat with you for a few minutes to-day respecting one of the questions discussed at the Medical Congress, held at Brussels last year. It is only within the last few days that the *Compte-Rendu* of the sittings has appeared, and that the interested public and the press, who did not take part in the sittings, have been able to make acquaintance with scientific discussions which there took place.

"The question is, 'Is it necessary to extend the medical use of chemically definite immediate principles and to multiply the preparations of them in the Pharmacopœias?' Mr. Van Bartelaer, who presented to the pharmacy section the report upon this question, stated the following conclusions:—

"'(1) That it is eminently desirable that the employment in medicine of chemically definite immediate principles should be extended in such a manner that, progressively, the usage should become established of substituting for the employment of the crude vegetable substances that of their isolated active principles.

"'(2) It would be useful, with this object, to multiply in the Pharmacopœia formulæ suitable to aid the movement.

"'(3) The medicinal forms which would lend themselves best to the employment of immediate principles and facilitate their administration to the sick are—For internal use: the *grain* and *granule*, containing one milligram of active substance; and, for external use: the *alcoholate*, 1 in 50, which would correspond pretty closely with a milligram per drop measured by the *compte-goutte*.'

"Warm partisan as I am of the extension of the use of the active principles in medicine, I cannot, as a medical man, hide from myself the great difficulties that would arise from the too general adoption of the first conclusion of the reporter. Mr. Van Bartelaer, whilst admitting the differences which exist between an active principle of a plant and the official preparations of it as given in the Pharmacopœias, shows himself to be a zealous defender of the generalization of the administration of active principles, and seems to have a very limited confidence in the pharmaceutical preparations of the present day. He alleges the confusion and want of clearness in the action of complex medicines, and the variability in the therapeutic power of plants, dependent upon collection. He refers to the small confidence which the first principles of the art of pharmacy inspire in respect to the time at which a plant should be collected. He asks,—Do you know the age of the plants which you use as a drug? Do you know the conditions, the soil, the climate, in which the plant has lived? The flowers, fruits, roots, etc., have they been collected at the time ordered by the Pharmacopœia? Does the drug come from a plant that has been cultivated or one that has grown wild? Have the extracts always the same strength, or do they possess always the same therapeutic value? I comprehend easily the different arguments with which the honourable reporter defends his thesis, and, with him I also say that there is a variability in the therapeutic power of plants, due to the Galenical preparation, and that the same Galenical preparations have a variable action dependent on their preservation.

"But all these arguments have not convinced me, and notwithstanding the eulogy uttered upon the facility with which active principles can be administered to the sick,—a facility which no one contests,—I cannot admit, or believe, that at this moment there is any urgency for the modification of our ordinary mode of procedure. We know well, and Mr. Van Bartelaer admits, that there are medicines which hitherto it has not been possible to replace by active principles and that it would be necessary in respect to them to make exceptions. Unfortunately these exceptions would be so numerous that the nineteenth century would not see the complete abandonment of barks, roots, etc., in favour of medicines of a simpler composition.

"No person more than myself, I repeat, is a partisan of the generalization of active principles in medicine, and I watch with pleasure the incessant labours of chemists, pharmacologists, and toxicologists, who make known to us from time to time fresh information upon the composition of drugs and new experiences in the action of medicines. I admire the splendid modern investigations of the chemists who help to give us the chemical composition of drugs as completely as possible, who seek to isolate and to introduce their active principles into therapeutics. But a consideration of the different arguments has induced me to rest *in statu quo*; that is to say, not to recommend the generalization of the active principles except so far as experiments shall have shown, in an irrefutable manner, that these substances present an action identical with that of the drug from which they are derived, or, to speak more clearly, answer the same therapeutic object. I am convinced that all professors entrusted with the teaching of therapeutics, will look upon the question in the same light.

"Another point in the report of Mr. Van Bartelaer that deserves to be challenged, is that where he speaks of the unfaithfulness of the Galenical preparations and the impossibility of exercising any control over their value. This is an error, a profound error. It is sufficient to recall the fact that on the occasion of the Pharmaceutical Congress held at St. Petersburg in 1874, Dr. Dragendorff, professor at the University of Dorpat, presented a *brochure* entitled, 'The Chemical Valuation of some Active Drugs and of Medicinal Preparations made from them' (*Die chemische Werthbestimmung einiger Starkwirkender Droguen und der aus ihnen angefertigten Arzneimischungen*), which has already been translated into French; and in which fourteen drugs and their preparations are examined, not only from the qualitative point of view, but from the quantitative. Professor Dragendorff is pursuing his work, and soon we shall have another memoir dealing with the chemical study, qualitatively and quantitatively, of another series of drugs. Besides this, information is now met with scattered throughout most periodical pharmaceutical works which make it possible for the pharmacist who desires to assure himself of the value of his products to examine a large number of Galenical preparations. Science is always progressing, but while hoping in a prompt renaissance of the art of pharmacy, I believe that we should be taxed with exaggeration and exclusiveness in trying at present to generalize the use of active principles to the extent desired by the reporter. The control of Galenical preparations is for the most part possible, and it is for the pharmacist to exercise this in his laboratory. Further, modern Pharmacopœias, which have been compiled both by medical men and pharmacists, prove sufficiently that the second conclusion of Mr. Van Bartelaer,—that it would be useful to multiply in the Pharmacopœias formulæ suitable to promote the movement—would not receive an unanimous adhesion.

"What shall be said of the third conclusion, recommending for internal use the grain and the granule containing a milligram of active matter, and for external use the alcoholate, 1 in 50°? Here, without consulting the medical profession, every serious pharmacist would see the impossibility of adhering to such a conclusion. He knows, on the one hand, that the use of such granules would only favour the development of industrial pharmacy, and on the other, that the pharmacist prefers to leave the preparation of the medicines to the decision of the physician, who prescribes them according to the particular circumstances of which he alone can be the judge. As to the employment of the alcoholate for external use, experiments would have to be instituted to ascertain which is the best menstruum to facilitate the absorption of the medicine. Concerning this Mr. Van Bartelaer is silent."

The Pharmaceutical Journal.

SATURDAY, OCTOBER 14, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

POISON SCHEDULES AT HOME AND ABROAD.

A SIMILAR question to that which has been mooted in this country, as to the desirability of extending the existing restrictions of the sale of poisonous articles, has, during the past few years been under consideration in France with regard to the proposed addition of nux vomica to the list of articles which are not allowed to be sold except on the order of a medical practitioner.

The Sanitary Committee of the Government having been appealed to, came to the conclusion that before taking any decisive measures, and at the same time with the view of making at once any other necessary alterations in the list of articles subject to restriction, the Departmental Sanitary Committees throughout the country should be consulted on this matter, and with that object a circular was sent out requesting communications in reply to the question, "Whether it would not be opportune to include in a supplementary decree, not only nux vomica, but also some other poisonous substances which do not appear in the list, and which should be included out of regard to the public safety?"

The result of this inquiry has recently been made public, and a *résumé* of the different opinions expressed will not be without interest at the present time. In the first place it will be necessary to state that the present state of the law relating to this subject in France is as follows:—

Previous laws relating to poisons were superseded by the articles 34 and 35 of the law of 21st Germinal an XI.

The 34th article refers in a general way to all poisonous substances, but does not give any definition of them; it does not contain any schedule of the articles to which it relates, but merely indicates, for illustration, arsenic, corrosive sublimate, and realgar; moreover, this article applies only to pharmaciens and grocers, without any mention of the other vendors of poisonous substances, such as wholesale dealers and manufacturers who employ poisonous substances and have considerable quantities of them at their disposal. Lastly, it imposes a uniform penalty of about £120 for any infringement of its provisions—a circumstance that caused difficulty in enforcing the penalty in minor cases of infringement or of mere negligence, which on this account frequently escaped the degree of punishment they merit.

In order to remedy these defects the law was supplemented with a subsequent enactment, the special object of which was to establish a scale of penalties proportionate to the various circumstances under which the law relating to poisonous substances might be disregarded, and it left the duty of regulating the sale, purchase, and use of those substances to be dealt with by the Government.

The penalty of infringement was according to this law from £4 to £120, with a term of imprisonment varying from six days to two months, and in all cases confiscation of the articles sold contrary to law.

In conformity with this law regulations were laid down in 1846, and they specify under three distinct heads all the obligations affecting commercial transactions relating to poisonous substances, the sale of such substances by pharmaciens, and the general arrangements and proceedure fitting to ensure the observance of the regulations in question. They comprise, moreover, a schedule of the particular articles to which they apply, numbering in all sixty-two, which are specially named, but in reality comprising many more, since in many instances the names include all the preparations into which the scheduled substances enter as ingredients.

The schedule was greatly modified by the decree of 1850, and the number of articles specially named was reduced to twenty. Lastly, a decree in 1864 added to this schedule coculus indicus, which was used for killing fish. It is to this modified schedule that the Ministry has called the attention of the Departmental Sanitary Committees by inviting them to specify the substances which they think should be added to it.

The alterations that have already been made in the schedule of poisons, and the necessity of revision, which is now deemed to be desirable, are in themselves sufficient evidence of the difficulty that is experienced in reconciling the requirements of trade and industry with those of public safety. If, from the latter point of view alone, it be desired to have a schedule of all poisonous substances that are capable of being misused with criminal intent, it would be necessary to add to the schedule salts of lead and of copper and a host of articles which are staple commodities of the drysalter, colour dealer, and chemical manufacturer, as well as a great number of materials employed in the arts or in domestic economy, and even then the object in view would be far from being attained.

If, on the contrary, the question be regarded merely from a free trade point of view, there is a tendency to limit as much as possible the restriction and to do away altogether with formalities which are in any way troublesome to those who use, sell, or purchase poisonous articles.

An official schedule, whatever may be its scope, will therefore always appear to some to be insufficient, while it is regarded by others as being to a great extent superfluous, if not altogether so, and it is precisely this conflicting result that has been arrived at by the inquiry instituted by the French Government.

The greater number of the reports sent in by the Departmental Sanitary Committees express the opinion that the schedule appended to the regulations of 1846 is incomplete and that it should be to some degree extended, and at the same time a smaller number demand on the contrary that it should be reduced, while some others, but it is true only three, demand that it shall be altogether done away with.

The principal argument put forward against the existing state of the law is to the effect that the regulations of 1846, having for their object the prevention of criminal poisoning and having failed to attain that object, are to be regarded only as useless hindrances of trade which ought to be removed. This view of the matter, however, leaves out of consideration the fact that it is not only criminal poisoning that is sought to be prevented, but likewise those accidents which may result from mistakes, ignorance, or negligence on the part either of the vendors of poisonous substances or of those who make use of them. It is to the point that the regulations are directed where it is provided that manufacturers using poisonous substances shall control their application in their establishments and register the use of them as directed by law; also that poisonous substances shall always be kept by dealers, manufacturers and pharmaciens in a place that is locked up. These precautions cannot always prevent the misuse or accident, but they impose a great responsibility upon those persons who have the control of poisonous articles, and in case of crime or accident they afford means of ascertaining whether reasonable care has been taken.

On the whole, one of the most striking results of this inquiry is the evidence afforded by the reports of the Sanitary Committees as to the slender confidence inspired by the law, and the little zeal that is exercised to carry it out. It is evident, too, that considerable ignorance prevails as to the actual state of the law, for in some instances recommendations are made to add to the schedule articles which are already comprised in it. In this respect the state of affairs seems to be much the same in France as in this country, where there is constantly occasion to remark that the provisions of the law relating to the sale of poisons are misunderstood or ignored by public officials.

ANALYTICAL DISCORD.

SINCE the establishment of the analyst as a public official his existence has not been a very peaceful one, and the recognition of his labours for the public good has certainly in most cases secured for him more kicks than halfpence. Of late, less has been heard of analytical cases and contests than when those proceedings had the charm of novelty: but the habit of fighting developed on butter, milk, and bread, appears to have become so inveterate that these officials, having started a Journal of their own, are now commencing to attack one another, and their natural enemy, Mr. HOLBORN, may eventually have the satisfaction of seeing them share the fate of the proverbial cats of Kilkenny. For some time past, a contest has been going on about an analysis of butter, and in reference to some comments on this matter in the *Analyst* a letter appears in the *Chemical News* of last week, from Mr. WANKLYN, in which he takes the "opportunity of making known that the Society of Public Analysts has no real control over the *Analyst*, which is the property of Mr. WIGNER and Dr. MUTER, who alone are responsible for the contents of the paper." We are at a loss to understand the announcement from Mr. WANKLYN, since his name appears on the title-page of the *Analyst* as a member of the Committee of Publication. Still more remarkable is the statement in the same letter that an indirect vote of censure on the Committee of Publication was passed at the Glasgow Meeting of Public Analysts, for Mr. WANKLYN, we believe, presided at that meeting, and would appear to have superintended the condemnation,—partly of himself,—which he now tells us was not half so severe as he thinks it should have been.

LIVERPOOL CHEMISTS' ASSOCIATION.

WE are informed by the President of the Liverpool Chemists' Association that Mr. THOMAS WILLIAMS, F.C.S., will deliver a Course of Lectures on Chemistry, at the Laboratory, 23, Lord Street, Liverpool, on Friday evenings, commencing the 13th instant. Arrangements have also been made for the teaching of Practical Chemistry.

AMERICAN PHARMACEUTICAL ASSOCIATION.

THE twenty-fourth annual meeting of the American Pharmaceutical Association was commenced on Tuesday, September 12th, in the Lecture Room of the Philadelphia College of Pharmacy, under the presidency of Professor MARKOE. About 250 members were present. The programme extended to the following Tuesday. We hope to be able to give further details of the meeting in the Journal for next week.

PHARMACY IN NEW SOUTH WALES.

WE are glad to learn that a Pharmaceutical Society has been established in New South Wales for the purpose of uniting the chemists and druggists in the colony "in one ostensible, recognized, and independent body, for protecting their general interests, and for the advancement of pharmacy by furnishing such a uniform system of education as shall secure the profession and public the safest and most efficient administration of medicines." The new Society has speedily obtained legislative recognition, and an Act has been passed entrusting to a Board of Pharmacy elected from the Council of the Society power to control all matters relating to the conduct of pharmacy, sale of poisons, etc., throughout the colony.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

The Opening Meeting of the above Society was held on Friday, September 23. The chair was taken by Mr. G. C. Druce. The election for Council and Class Conductors was first taken, when the following were chosen :—*President*, Mr. G. C. Druce; *Vice President*, Mr. G. C. Osborne; *Secretary and Treasurer*, Mr. J. Townsend; *Council*, Messrs. Holdgate, Holloway, and Northen; *Class Conductors*, Mr. Mayger (Botany); Mr. Holdgate (Materia Medica; Mr. Druce (Chemistry); and Mr. Townsend (Pharmacy).

The President said he was not prepared that evening with an address, but he must express his thanks to so many members for their support and assistance during the time he had been Secretary. Nor could he allow the kindness and help rendered by the principals to pass unnoticed. He greatly regretted the Association could not show better results after the initiation of earlier closing last winter, but from various causes the number of assistants in the town had been reduced by 20 per cent. in the last three years, and as it happened some three or four were rendered comparatively useless to the classes by the *pons asinorum* of pharmacy, which they had to cross; so that after Christmas the attendance at the classes had become so bad as to render it necessary to discontinue what might have been a good programme. But an analytical class was carried on for some time weekly. He believed, judging from the present meeting, that a desire was now felt to keep the Association going by making the classes a success. He concluded by thanking the members for electing him and by welcoming the new members.

The Secretary thanked the members for electing him as secretary, and expressed a hope that the ensuing session would be a success in every respect. He then read the following:—

"REPORT.

"The Council in placing the report of their fifth year's work before the members, regret that the attendance during the past year was so poor that a great portion of the classes had to be omitted, a result perhaps partly owing to the comparatively few who were eligible to prepare for the minor examination. But in the opinion of the Council it would be unwise to let the partial failure of a session be the cause for a discontinuation of the classes; it has therefore arranged a series of classes on botany, materia medica, pharmacy, prescriptions, practical and theoretical chemistry, which will be alternately studied on Mondays and Thursdays. The room will also be available for use on any other week night. The Council takes this opportunity of thanking the principals for meeting the wishes of the members by closing their establishments at 7·30 last winter, and trusts that they may not find it detrimental to business if they give the same advantage in future. Thanks are also due to P. Jeyes, Esq., for the continued use of room; to James Barry Esq., for gift of 20 bound vols. of *Pharmaceutical Journal*; to the Pharmaceutical Society for gift of Journal and Calendar, and to the Mechanics' Institute for loan of Oertling's Balance. The Council sincerely hopes that the members will give their support to the Association by regularly attending the classes, thus showing to the class conductors that their efforts are appreciated."

Mr. Holdgate in a short speech alluded to the way in which the Minor examination was conducted, and said it only needed determination and work, to successfully pass it.

The meeting then terminated with the usual vote of thanks to the Chairman.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A numerously attended meeting of members of the above Association was held on Thursday, the 21st inst., at the Halford Street Chambers, in order to listen to a lecture on the microscope, delivered by Mr. James Edwards. The President, Mr. W. B. Baron, occupied the chair. As the optical portion of the subject had been fully treated upon by the President near the close of the last session the lecturer confined himself to the elucidation of the mechanical principles involved in the construction of the microscope, the precautions to be observed in its manipulation, and to an enumeration and illustration of the various uses to which it might be advantageously applied. He lucidly explained the construction and method of using not only the ordinary binocular, but also some of its more important accessories, including polarizing prisms, paraboloid illuminator, graduated mechanical stage, camera lucida, micrometer, etc. The manifold uses subserved by the microscope in the prosecution of physiological research, both in the animal and vegetable kingdoms, its value to the anatomist in making minute dissections, to the physician in tracing the progress of renal and kindred diseases, to the analyst in enabling him to detect impurities in food and drugs, and as a means of mental discipline, inducing in the observer habits of carefulness, exactitude, and close observation, were all enlarged upon by the lecturer. Finally, a collection of objects was exhibited, including among other things the circulation of the blood in the foot of the frog, also specimens of Sarcoptes scabiei, Stylops Spencii, elytron of Curculis imperialis, spermatozoa, crystals of salicin, chlorate of potash, etc. The whole of the lecture was admirably illustrated by a very fine binocular by Crouch.

On the termination of the lecture a hearty vote of thanks was moved by the Chairman to Mr. Edwards for his services, and the motion was carried by acclammation. The meeting then broke up after spending a couple of hours in a most profitable manner.

At the meeting of the Association on the 28th of September, Mr. Cocking, of Sittingbourne, Kent, exhibited his double-action pill machine to the members.

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of this Society was held on Wednesday, August 2, under the presidency of M. Marais.

Action of Phosphorus upon Iodates in Presence of Atmospheric Air.—Amongst the papers read was one by M. I. Corne on this subject. On a former occasion the author had stated that the reduction of iodine observed when a fragment of phosphorus is brought into contact with a solution of an iodate was not due to the phosphorus, but to a phosphorus acid. This statement having been challenged by M. Pollacci, fresh experiments have been made by the author. A solution of pure potassium iodate, some starch paste and chloroform, were placed together in a barometer bulb, any air contained in the liquids driven off by ebullition, and the whole covered with naphtha. A piece of phosphorus being introduced, no sign of blue coloration took place, although the chloroform dissolved a sufficient quantity of the phosphorus to have allowed it to have taken place had it been possible. But the blue colour became clearly manifest five minutes after the introduction of a few bubbles of air, and the reduction appeared to be complete in ten minutes. A similar result was obtained when phosphorus that had been dipped into oil of turpentine to prevent oxidation was brought into contact with a solution of an iodate and starch mucilage. These experiments the author considers to authorize the conclusions (1) that phosphorus is absolutely without action upon iodates, and (2) that where reduction of the iodate does take place it is subsequent to an oxidation of the phosphorus. Phosphorus and phosphoric acid being excluded from being the cause of the reaction, the author is engaged in ascertaining whether it is due to the action of phosphorous acid or of some other oxygenated compound.

Glass Cotton.—M. Limousin brought before the notice of the meeting a specimen of glass cotton (*Glaswolle*) which is now used in Germany, and especially in Austria, for filtering purposes. It consists of very finely spun glass, and the advantages gained by its use are that filtration takes place through it rapidly, that it is not acted upon by concentrated acids or alkaline solutions, and that there is no danger of organic substances being injured by its use.

Protosulphide of Iron.—Dr. Méhu exhibited a sample of protosulphide of iron which had been prepared by heating together in a crucible for half an hour at a red heat two parts of finely divided pyrites and one part of unoxidized iron filings. The reaction that takes place is represented by the equation $FeS_2 + Fe = 2FeS$. A greyish mass is thus obtained, which is easily powdered, and which disengages torrents of sulphuretted hydrogen when treated with hydrochloric acid.

Tayuya.—M. Yvon presented a note in which he assigned the following percentage composition to tayuya root, recently referred to in this Journal*:—Water, 11·57; organic matter, 79·96; inorganic, 11·47. The organic portion consists of—

Glucose	0·84
Crystallizable matter, soluble in Alcohol	0·24
Bitter Resin	1·17
Essential Oil	—
Starch	17·32
Organic Acids, Ligneous Matter, and Loss	57·39

The inorganic portion consists of—

Silica	1·02
Lime	4·71
Iron and Alumina	1·23
Potash and Soda (by difference)	1·39
Sulphuric and Hydrochloric Acids not estimated.	

The resin slightly resembled bees-wax in consistence. It was greenish-yellow in colour, had an excessively bitter taste, and melted at 49° C. It had an acid reaction, dissolved partly in alkalies, microscopic crystals being perceptible in the solutions. The author considers the resin to be the active principle of the plant. The root, exhausted with alcohol, imparted to the solvent a clear yellow colour; the tincture had a freely acid reaction, and when concentrated by evaporation deposited crystals after several days. Like M. Martin, the author failed to detect the presence of an alkaloid in the root.

* Vol. vi., p. 401.

BRITISH ASSOCIATION.

Address to the Chemical Section.

BY WILLIAM HENRY PERKIN, F.R.S.,

President of the Section.

There can be no doubt that chemistry and the allied sciences are now being recognized to a much greater extent in this country than in former years; and not only so, the workers at research, though still small in number, are more numerous than they were.

In 1868 Dr. Frankland, in his address to this Section at the meeting at Norwich, commented upon the small amount of original research then being carried on in the United Kingdom; but, judging from the statistics of the Chemical Society, this state of things became even worse; for in 1868 there were forty-eight papers read before the Society, but in 1872 only twenty-two. Since then, however, there has been a considerable increase in the number; and at the anniversary meeting in March last it was shown that the number of communications for the session had risen to sixty-six, or three times as many as in 1872.

Of course these figures only refer to the Chemical Society; but I think they may be taken as a very safe criterion of the improved state of things, though it would be very gratifying to see much greater activity.

It is also very pleasing to find that the aids to and opportunities for research are increasing, because it must be remembered that, in a pecuniary sense, science is far from being its own rewarder at the time its truths are being studied, although the results very often become eventually of the greatest practical value; hence the wisdom of a country encouraging scientific research.

But little, however, has been done in this direction in past years—the grants made for general science by this Association, and that of the Government of one thousand pounds annually to the Royal Society, being the most important.

The Chemical Society has also been in the habit of giving small grants for the purpose of assisting those engaged in chemical research. In the future, however, it will be able to do much more than hitherto. One of the original members of the Society, Dr. Longstaff, offered in the early part of the year to give one thousand pounds provided a similar sum could be raised, the united amount to be invested and the interest applied for the encouragement of research. I am happy to say that rather more than the required sum has been raised, and it is hoped that it may be still further supplemented.

In addition to the Royal Society grant the Government have given this year a further annual sum of four thousand pounds. Of course this is for science generally.

Mr. T. J. Phillips Joddrell has also placed at the disposal of the Royal Society the munificent sum of six thousand pounds to be applied in any manner that they may consider for the time being most conducive to the encouragement of research in physical sciences.

When we consider how much of our science is of a physical nature, we must be grateful for this bequest; and it is to be hoped that these helps will more and more stimulate research in the United Kingdom; and if we have any hope of keeping pace with the large amount of work now being carried on in other countries, we must indeed be energetic.

The employment of well-trained chemists in chemical works is now becoming much more general than heretofore, especially on the continent, where in some cases a considerable staff is employed and provided with suitable appliances, etc., for the purpose not only of attending to and perfecting the ordinary operations which are in use, but to make investigations in relation to the class of manufacture they are engaged in. A conviction of the necessity of this is gaining strength in this country, though not so quickly as might be desired; nevertheless, these things are encouraging.

With reference to the progress of chemistry and what have been the fruits of research of late years, it will be impossible for me to give even a general outline, the amount of work being so large; in fact, to recount the list of investigations made during the past year would take up most of the time at my disposal.

Amongst the most interesting, perhaps, are those relating to isomerism, especially in the aromatic series of organic bodies; and it is probable that a more intimate knowledge of this subject will be found of really practical value.

As I am unable to give an account of the work done during the past year on account of its quantity and diversity, I propose to refer to some of the practical results which have already accrued from organic chemistry, as a plea for the encouragement of research; and those I intend to speak of are of special interest also on account of their close connection with the textile manufactures of Great Britain. I need scarcely say I refer to the colouring matters which have been obtained from the products found in tar.

It was in 1856, now twenty years since, that this industry was commenced by the discovery of the "mauve," or "aniline purple;" and it may be of interest to state that it was in Scotland, in the autumn of the same year, that the first experiments upon the application of this dye to the arts of dyeing and calico-printing were made at Perth and Maryhill.

I need scarcely remind you of the wonderful development of this industry since then, seeing we now have from the same source colouring matters capable of producing not only all the colours of the rainbow, but their combinations. I wish, however, to briefly refer to the date and origin of the products which have served to build up this great industry.

It was in 1825 that Faraday published in the 'Philosophical Transactions' his research on the oily products separated in compressing oil-gas, and described a substance he obtained from it—a volatile, colourless oil, which he called bicarburetted hydrogen. Mitscherlich some years afterwards obtained the same substance from benzoic acid, and gave it the name it bears—viz., "benzol." This same chemist further obtained from benzol nitrobenzol, by acting upon it with nitric acid. Zinin afterwards studied the action of reducing agents upon nitrobenzol, and obtained "aniline," which he at that time called benzidam.

Again, Pelletier and Walter discovered the hydrocarbon toluol in 1837. Deville produced its nitro-compound in 1841; and Hofmann and Muspratt obtained from this "toluidine," by the process used by Zinin to reduce nitrobenzol.

I might mention other names in connection with these substances, such as Runge, Unverdorben, etc.; but I would now ask, did any of these chemists make these investigations with the hope of gain? was it not rather from the love of research, and that alone? and now these products, which were then practically useless, are the basis of the aniline colours. But to go further: Doebereiner a long while ago obtained from alcohol a substance which he called "light oxygen ether," now known as aldehyd. Gay-Lussac produced iodide of ethyl in 1815. Dumas and Peligot discovered the corresponding substance, iodide of methyl, in 1835; but, as in the cases I have previously referred to, these bodies had no practical value, and were never prepared but in the laboratory. Hofmann, in his researches on the molecular constitution of the volatile organic bases, discovered in 1850 the replacement compounds of aniline containing alcohol radicals.

All these compounds have now been manufactured on the large scale and used in the further development of the industry of these artificial colouring-matters.

Other substances might be mentioned; but I think these are sufficient to show how the products of research which, when first discovered and for a long period afterwards, were of only scientific interest, at last became of great practical value; and it is evident that, had not the investigations and discoveries I have referred to been made as they were solely from a love of science, no aniline colours would now be known.

The colouring-matters I have hitherto spoken of are nitrogenous, and derived from benzol and its homologues. There are a few others, however, of the same origin which contain no nitrogen; but they are of secondary importance.

I now pass on to another class of colouring-matter, which is obtained from anthracene, a coal-tar product differing from benzol and toluol in physical characters, inasmuch as it is a magnificent crystalline solid.

The first colouring-matter derived from anthracene which I wish to draw your attention to is alizarin, the principal dyeing agent found in madder-root. This substance was for a long time supposed to be related to naphthaline, inasmuch as phthalic acid can be produced from both of them; and many were the experiments made by chemists in this direction; it was not, however, until 1868 that this was proved to be a mistake, and its relationship to anthracene was discovered by Graebe and Liebermann, who succeeded in preparing this coal-tar product from the natural alizarin itself.

Having obtained this important result, they turned their attention further to the subject, hoping to find some process by which alizarin could be produced from anthracene; in this they were soon successful.

The discovery of the artificial formation of alizarin was of great interest, inasmuch as it was another of those instances which have of late years become so numerous, namely the formation of a vegetable product artificially; but the process used by Graebe and Liebermann was of little practical value, because too expensive for practical purposes.

Having previously worked on anthracene derivatives, it occurred to me to make some experiments on this subject, which resulted in the discovery of a process by which the colouring-matter could be economically produced on the large scale; Messrs. Caro, Graebe, and Liebermann about the same time obtained similar results in Germany; this was in 1869. Further investigation during that year yielded me a new process, by which "dichloranthracene" could be used in place of the more costly product anthraquinone, which was required by the original processes. I mention this, as most of the artificial alizarin used in this country up to the end of 1873, and a good deal since, has been prepared by this new process.

It was observed that when commercial artificial alizarin prepared from anthraquinone, but more especially from dichloranthracene, was used for dyeing, the colours produced differed from those dyed with madder or pure alizarin; and many persons therefore concluded that the artificial colouring-matter was not alizarin at all. This question, however, was set at rest by separating out the pure artificial alizarin from the commercial product and comparing it with the natural alizarin, when it was found to produce exactly the same colours on mordanted fabrics, to have the same composition, to give the same reactions with reagents, and to yield the same products on oxidation.

But whilst examining into this subject it was found that a second colouring-matter was present in the commercial product, and in somewhat large quantities, especially when dichloranthracene had been employed in its preparation; and to this was due the difference in shade of colour referred to.

This substance, when investigated, was found to have the same composition as "purpurin," also a colouring-matter found in madder, but of very little value on account of the looseness and dulness of some of the colours it produces. This new substance, being derived from anthracene, was named anthrapurpurin; unlike its isomer purpurin, however, it is of great value as a colouring-matter. I do not think I shall be going beyond the results of experience if I say it is of as great importance as alizarin itself; with alumina mordants it produces reds of a more scarlet or fiery red than those from alizarin. In fact so fine are the colours produced that, with ordinary alumina-mordants on unoiled cotton, it gives results nearly equal in brilliancy to Turkey-red produced with madder or garancine; and I believe the rapid success of artificial alizarin was greatly due to its presence. Most of that consumed at first was for Turkey-red dyeing; and the colours were so clear that it was mostly used in combination with madder or garancine, to brighten up the colours produced by these natural products

The purple colours anthrapurpurin produces with iron mordants are bluer in shade than those of alizarin, and the blacks are very intense. Its application is practically the same as alizarin, so that they can be used in combination.

As already noticed, the commercial product called "artificial alizarin" first supplied to the consumer was always a mixture of alizarin and anthrapurpurin; and various mixtures of these two colouring-matters are still sent into the market; but, owing to the investigations that have been made and the study and attention that have been given to it by manufacturers, nearly pure alizarin and anthrapurpurin are also sent into the market—the first being known as "blue-shade alizarin," and the second as red or "scarlet alizarin."

The formation of anthrapurpurin in the manufacture of alizarin may to some extent be said to have arisen from a want of knowledge of the true conditions required for the production of the latter.

It is now well known that alizarin is a dioxyanthraquinone, or, in other words, anthraquinone in which two atoms of hydrogen are replaced by hydroxyl.

$$\underbrace{C_{14}H_8O_2}_{\text{Anthraquinone.}} \qquad \underbrace{C_{14}H_6(HO)_2O_2}_{\text{Alizarin.}}$$

If we want to introduce hydroxyl into a compound, there are several processes which can be used; but I will only refer to those connected with the history of this colouring-matter.

The first process which I will refer to has been used by chemists for a long period. It consists in first replacing the hydrogen by bromine, and then treating the resulting body with potassic or other metallic hydrate; and according as one, two, or more atoms of hydrogen have been replaced by the bromine, so on its removal by the metal of the metallic hydrate, a compound containing a corresponding number of atoms of hydrogen replaced by hydroxyl is obtained.

Graebe and Liebermann acted upon this principle in their experiments on the artificial formation of alizarin; and as it was necessary to replace two atoms of hydrogen in anthraquinone, they first of all prepared a dibrominated derivative, called dibromanthraquinone,

$$C_{14}H_6Br_2O_2.$$

By decomposing this with potassic hydrate at a high temperature, they obtaimed a violet-coloured product, which, when acidified to remove the alkali, gave a yellow precipitate of alizarin,

$$C_{14}H_6(HO)_2O_2.$$

The second process I wish to speak of for the replacement of hydrogen by hydroxyl in a compound is by converting it into a sulpho-acid (usually by means of sulphuric acid), and subsequently decomposing this with potassic or other hydrate; and according as a mono- or disulpho-acid is employed, it yields on decomposition a compound with one or two atoms of hydrogen replaced by hydroxyl.

The discovery of sulpho-acids of anthraquinone, and their use in place of the brominated derivative originally employed by Graebe and Liebermann, constituted the great improvement in the manufacture of alizarin already referred to.

From what has just been stated, it was naturally supposed that a disulpho-acid of anthraquinone would be required to produce alizarin; and this was believed to be the case for some time; but further experiments have proved it to be a mistake, and shown that the monosulpho-acid is required to produce alizarin, the disulpho-acid yielding anthrapurpurin.

But how are we to explain this apparent anomaly? It would take up too much time to enter into a discussion respecting the constitution of the sulpho-acids of anthraquinone in reference to the position of the HSO_3 groups. I will therefore confine my remarks to their decomposition.

Monosulphoanthraquinonic acid,

$$C_{14}H_7(HSO_3)O_2,$$

when heated strongly with caustic alkali, as potassic or sodic hydrate, decomposes in the ordinary way, and we get "monoxyanthraquinone,"

$$C_{14}H_7(HO)O_2,$$

which is a yellow body possessing no dyeing properties. On further treating this, however, with caustic alkali it changes, being oxidized, and yields alizarin,

$$C_{14}H_6(HO)_2O_2.$$

Disulphoanthraquinonic acid,

$$C_{14}H_6(HSO_3)O_2,$$

when subjected to the influence of caustic alkali, at first changes into an intermediate acid,

$$C_{14}H_6(HO)\ (HSO_3O)_2,$$

and then into a dioxyanthraquinone,

$$C_{14}H_6(HO)_2O_2,$$

now known as "isoanthraflavic acid,"—a substance having the same composition as alizarin, but being only an isomer of that body and possessing no affinity for mordants; like monoxyanthraquinone, however, when further heated with alkali it becomes oxidized and yields a colouring-matter, which is "anthrapurpurin,"

$$C_{14}H_5(HO)_3O_2.$$

Looking at these reactions, it appears rather remarkable that Graebe and Liebermann should have succeeded in preparing alizarin from dibromanthraquinone. It can only be explained on the assumption that the hydrogen atoms replaced in the disulpho-acid are different in position from those replaced in the dibromanthraquinone; and of course it is possible that a disulpho-acid isomeric with that now known may be discovered that will yield alizarin as a first product on treatment with alkali.

In the reaction which takes place when monoxyanthraquinone or isoanthraflavic acid become oxidized and change into alizarin and anthrapurpurin nascent hydrogen is formed; and this causes a reverse action to take place—ordinary anthraquinone, or its hydrogen derivative, being formed, and a loss of colouring-matter resulting. A small amount of potassic chlorate is now used with the caustic alkali, just sufficient to overcome the reducing action, which has resulted in an increased yield of colouring-matter, the percentage obtained being now not very much below the theoretical quantity.

When the process for making commercial artificial alizarin by treating anthraquinone with sulphuric acid was first adopted, the product from that treatment was a mixture of the mono- and disulpho-acids of anthraquinone. Consequently the colouring-matter prepared in this manner was a mixture of alizarin and anthrapurpurin; and the reason why dichloranthracene, when used in place of anthraquinone, yields a product very rich in anthrapurpurin, is on account of the readiness with which it forms a disulpho-acid of dichloranthracene, which afterwards changes into the disulpho-acid of anthraquinone.

At first it was supposed by many that the quantity of coal-tar produced would not yield a sufficient supply of anthracene for the manufacture of artificial alizarin. Experience has, however, proved that this supposition was groundless, as now the supply is greater than the demand.

Moreover some very interesting experiments have lately been made, by which anthraquinone and its derivatives have been obtained without the use of anthracene. The most interesting are those in which phthalic anhydride is employed with benzolic derivatives; for example, this anhydride gives with hydroquinone a colouring-matter having the same composition, as well as most of the other properties of alizarin. It is called quinizarin. Baeyer and Caro have also obtained from phthalic anhydride and phenol oxyanthraquinone; and by using pyrocatechin in place of phenol they got alizarin itself.

Although these products have not been obtained in sufficient quantities by these processes to be of any practical value, we do not know what further research may do. Already one of the substances used is being prepared on the large scale for the manufacture of that beautiful colouring-matter "eosine;" I refer to phthalic anhydride.

Now, with reference to the origin of the products which are used for the manufacture of artificial alizarin, we find the first researches made in reference to anthracene were by Dumas and Laurent in 1832; subsequently Laurent further worked upon this subject, and obtained, by the oxidation of this hydrocarbon, a substance which he called anthracenuse; he also obtained dichloranthracene. Dr. Anderson also made an investigation on anthracene and its compounds in 1863, and assigned to it its correct formula; he re-examined its oxidation-product, which Laurent called anthracenuse, and named it oxyanthracene, the substance we now know as anthraquinone.

All these substances were without any practical value until 1868; but we now find them of the greatest importance, and used daily in immense quantities.

But to bring out more clearly the practical importance of these fruits of scientific research, it will be well perhaps to see what has been their influence on the colouring-matters which were in use before them, and also the extent of their present consumption.

The influence of the so-called aniline colours on dye woods, etc., has been remarkably small. It is true that at first magenta had a depreciating influence upon cochineal; but this has passed away, and now the consumption of that dye is as great as ever; certainly its price is much lower than it used to be; but this is due to a variety of causes, especially the great increase in the cultivation of the insect at Teneriffe. And perhaps this want of influence is not so very remarkable, when we consider the aniline colours are entirely new products, differing in composition and properties from the old colouring-matters, and therefore could only displace them to a certain extent.

But whilst this is the case, the aniline colours have been more and more used, until at present it is computed that their annual sale in the United Kingdom and on the Continent exceeds £2,000,000. This is probably due to new applications and increase of trade.

When, however, we come to consider the influence of the anthracene colours alizarin and anthrapurpurin, more generally known as "artificial alizarin," we find we have a very different tale to tell.

Here, in the case of alizarin, we have a competition, not between two colouring-matters, but the same from different sources—the old source being the madder-root, the new one coal-tar. And when we introduce the consideration of anthrapurpurin, which produces such magnificent reds, much brighter than alizarin or ordinary purpurin, we see we have not only a replacement but an improvement, so that these new colouring-matters throw the old ones into the shade. The products being purer, the clearing processes for goods dyed with them are also necessarily easier and simpler.

It will be interesting to examine into the statistics of the madder and garancin trade in a brief manner, to see what has been the influence of artificial alizarin on their consumption. The following figures are mostly calculated from the Board of Trade returns.

During the ten years immediately preceding the introduction of artificial alizarin the average annual imports of madder into the United Kingdom were 15,292 tons, and of garancin 2278 tons. Estimating the value of the former at £2 2*s.* 6*d.*, and the latter at £8 per cwt., which were about the average prices during that period, the annual value in round numbers was about one million sterling.

The introduction of artificial alizarin, however, has so influenced the value of madder that its price is now less than one half; and thus a saving of over half a million sterling per annum has been effected to the manufacturers of the United Kingdom, one half of which may be put down to Glasgow.

So much for its effect in reducing prices; but what has been its influence on the consumption of these dye-stuffs?

I have already stated the average quantity of these substances imported per annum prior to the discovery of the artificial product, and will now compare it with the imports of last year and this. That for the present year of course will be an estimated quantity, and calculated from the returns for the first seven months.

	Average Annual Imports.		
	1859-1868.	1875.	1876.
	tons.	tons.	tons.
Madder . . .	15,292	5014	3653
Garancin . . .	2,278	1293	813

These figures speak for themselves.

The money value, which was formerly £1,000,000 per annum, is now, calculating from the estimated quantity for the year, only £138,105, say £140,000, taking garancin at £4 per cwt. and madder at £1 per cwt., prices slightly in excess of their present value.

At the present prices the cultivation of madder-roots is unremunerative; and it is to be expected that madder-growing will soon be a thing of the past, thousands of acres of land being at the same time liberated for the growth of those products we cannot produce artificially, and without which we cannot exist. The quantity of madder grown in all the madder-growing countries of the world prior to 1868 was estimated to be 70,000 tons per annum; and at the present time the artificial colour is manufactured to an extent equivalent to 50,000 tons, or more than two-thirds of the quantity grown when its cultivation had reached its highest point.

I might have referred to other subjects besides the coal-tar colours which have resulted from scientific research; but I know of no other of such interest and magnitude. From the brief history I have given, we see that the origin of these colouring-matters is entirely the fruit of many researches made quite independently by different chemists, who worked at them without any knowledge of their future importance; and on looking at the researches which have thus culminated in this industry, it is interesting to notice that many, if not most of them, were conducted for the purpose of elucidating some theoretical point.

These facts certainly ought to be a great encouragement to chemists, and stimulate them to greater activity. It would be very pleasing to see more work emanating from the chemical schools of the United Kingdom; and I think no student should consider his chemical curriculum finished until he has conducted an original research. The knowledge obtained by a general course of instruction is of course of very great value; but a good deal of it is carried on by rule. In research, however, we have to depend upon the exercise of our judgment, and, in fact, of all our faculties; and a student having once conducted one, under the guidance of an efficient director, will find that he has acquired an amount of experience and knowledge which will be of the greatest value to him afterwards.

It is hoped these remarks will encourage young chemists to patiently and earnestly work at whatever subject they may undertake, knowing that their results, although sometimes apparently only of small interest, may contain the germ of something of great scientific or practical importance, or may, like a keystone in an arch, complete some subject which before was fragmentary and useless.

Parliamentary and Law Proceedings.

Suspected Poisoning by Strychnia.

On Tuesday last, Mr. W. Carter, the Coroner of East Surrey, resumed at Vauxhall an adjourned inquiry relative to the death of Ellen Sloper, aged 27, who died on the 11th ult., under circumstances leading to the arrest of a man named Silas Barlow, *alias* Smith, for murder. It appeared that the deceased woman had cohabited with the prisoner Smith and had had a child by him, that he visited the woman twice at her lodgings, and that after each visit she became sick and convulsed, dying in his presence, apparently from poison. The day after her death he took away the child, saying he was about to put it under the care of his cousin. The baby was not again seen until its dead body was discovered in a reservoir at Battersea, and at the inquest on the body a verdict of wilful murder was returned. The child was subsequently identified, the prisoner arrested on suspicion, and an inquest opened on the body of the woman and adjourned for an analysis of the contents of the stomach and of the lees in some bottles found in the lodgings of the man Barlow. Mrs. Jessie Wilson, the wife of a waiter, deposed that on the 21st of August last the deceased came to her house with a baby, and representing that she was married, engaged a room giving her name as Mrs. Smith. The prisoner came to the house on the 2nd of September, and stopped all night. On the 3rd of September the prisoner visited deceased, and stopped with her for nearly two hours, but after he left she became suddenly ill; she said the prisoner had given her some sarsaparilla to strengthen her. On the 10th the prisoner again visited her, and she was then perfectly well. About 9·30 that night the prisoner came down to witness and said that his wife, meaning deceased, had had two fits. On going upstairs she found deceased lying across the bed apparently in a fit. She was very stiff, and her feet were getting white, and the moment she was touched she had a strong convulsion. She became conscious shortly afterwards and said to the prisoner, "Oh, it is the sarsaparilla water you gave me." The prisoner replied, "Oh, no; I took more of it than you did." A doctor was sent for, who came and prescribed for her. Shortly after she appeared to be drawn backwards, and her back to become arched, and she died apparently in great agony. Mr. James Miller, M.R.C.S., said that when he was called to see the deceased he found her conscious. She complained of pains in the head and cramp in the lower limbs. He found her hands clenched, muscles rigid, and the feet turned inwards, and he prescribed for epilepsy and hysteria. She died shortly after he left. There was no arching of the back while he was there. He had seen the result of tests made by Dr. Lees, and was of opinion that strychnine had been found in one of the bottles of sarsaparilla. Dr. Joseph Lees, of Walworth Road, deposed that he had analysed the contents of the bottles found at the prisoner's lodgings, and in the small one, which was almost empty, had discovered the strychnine crystals produced. The jury, after half an hour's deliberation, returned a verdict of "Wilful murder" against Silas Barlow, *alias* Smith, and the Coroner issued his warrant committing the prisoner for trial at the next Old Bailey Sessions.—*Times.*

Poisoning by Chloral Hydrate.

An inquest was held in Carlisle on Wednesday September 27, before Dr. Elliott the City Coroner, respecting the death of John James, aged 70. It appeared from the evidence that the deceased had for some time suffered severe pains through illness, and was in the habit of taking chloral hydrate to obtain sleep. A bottle was produced which it was believed had contained the chloral taken by deceased. On the bottle was the instruction, "One-half to be taken to-night and the other half to-morrow night." Deceased had stated that it contained twopence worth.

John Richard Raffles said he was 18 years of age, and had served three and a half years as an apprentice druggist. The assistant druggist of Mr. James Shaw Pattinson, Botchergate, having gone to spend his holidays, witness, a week past last Wednesday, went to the shop in Botchergate to work there. (Shown the bottle which contained the chloral.) He remembered having seen it. He served deceased with chloral several times, he could not say positively how often. He half filled the bottle about five or six times, and filled it twice. The first time he got the bottle filled was on Saturday night last, and the second time on Monday night. The strength of the chloral was always ten grains to a drachm of syrup.

The Coroner here explained that chloral hydrate was a preparation of chloroform with pure alcohol, which was very much stronger than spirits of wine. It was a white crystallized substance. If they were to weigh that substance by any kind of weights that could be divided by a hundred, or say by ten, which would answer their purpose just as well, then eight-tenths of the whole would be chloroform. It really was chloroform. It could be dissolved in water, and sold as had been stated. When swallowed and distributed over the body, the blood sustained serious injury, in fact, it was not really blood for a very considerable time afterwards. He could only express his deep regret that it was sold so freely, and so much used as a means of procuring sleep. Laudanum and other preparations of opium were assuredly bad enough, but chloral seemed to be still worse.

A Juror asked if there were any restrictions upon the sale of chloral.

Witness: No. He had seen none. The same label which was put on the bottle when Mr. James got twopence worth was allowed to remain when he got double that quantity.

The Coroner: Suppose the label remained and a double quantity supplied, the deceased would take half each night.

A Juryman: Thus doubling the dose.

Another Juryman: But the deceased would know what the dose was.

Witness continued: He did not put the label on the bottle; it was on when it was first presented. When deceased came for the chloral he brought no prescription. Deceased explained to witness what he was taking chloral for. He gave him his opinion. He could not say how long the deceased had been in the habit of taking chloral. On Monday night, when deceased was leaving the shop after being supplied with a bottleful, he raised his hand to get hold of the door to steady himself. He did not see deceased take anything out of the bottle. He did not look like a person the worse for drink. On Tuesday at dinner time he got a note from Mr. James S. Pattinson, asking if the deceased had got any chloral, and witness sent an answer saying that he had. He did not supply many persons with chloral.

A Juryman: If deceased got a bottleful on Monday night, that would be four doses?—Yes.

Another Juryman: And if he got the bottle filled on Saturday night that also would be four doses?—Yes.

The Foreman: That means that he had eight doses within forty-eight hours.

Witness continued: Mr. Pattinson was from home at the time the chloral was sold to the deceased, and the only person in the shop when Mr. James came into the shop was the errand boy. He was not aware of any restrictions on the sale of chloral. There was a list of the name of the drugs on which restrictions were placed in the shop, but chloral was not mentioned. The list was a leaf in the poison book which had to be signed by people getting poison. If choral had been mentioned in the list he was sure he would have seen it.

Dr. Walker said deceased suffered from a painful disease in the bladder. He never prescribed chloral for deceased, and lately he had not given him any narcotics for the purpose of making him sleep. When he saw deceased on Tuesday morning he was quite insensible and breathing rather heavily. Witness tried to rouse him, but could not. (Shown bottle). It would contain about an ounce, that was about 8 drams, or 80 grains of chloral. He thought 80 grains was not an excessively fatal dose, but such a dose had proved fatal. The last dose taken by deceased would be all the more likely to prove fatal on account of his having taken some before. He was of opinion that an overdose of chloral had caused the death of Mr. James. He was satisfied with this, and he did not think that a *post mortem* examination was necessary.

The Coroner summed up the evidence, excluding the idea of suicide, and strongly advising that chloral should be included in the list of poisons named in the Act of Parliament.

A Juryman: Are you sure that this chloral is not on the list?

The Coroner: I am not acquainted with the list. It is sent to all druggists not to medical men. The boy says it was not on the list. Of course if it be on the list it would alter the case most materially against himself.

A Juryman: We might recommend that there should be more restriction put upon the sale of chloral. It appears to be very carelessly sold.

Another Juryman: This chloral is much used in the south of England under the sobriquet of "pick-me-up"—evidently a misnomer.

The Foreman: I am inclined to condemn the practice of selling such large quantities of that deadly drug.

The Jury returned the following verdict:—Deceased died from an overdose of chloral taken for a relief from pain."—*Carlisle Express.*

Singular Death of a Chemist and Druggist.

On Monday last an inquest was held at Bradford, by Mr. Thomas Taylor, Coroner, on the bodies of Edward Clarkson Pearson, chemist and druggist, and William Pearson, his son.

Mr. Robert Soppitt said he was a chemist's assistant, and resided at Kensington Street, Girlington. He last saw Mr. Pearson alive about five minutes to four o'clock on the previous Friday afternoon. He had with him the deceased child, William Pearson. Mr. Pearson said he was going to Leeds to buy drugs, and he promised to be back at a quarter past seven, but as he did not return at the time witness locked up the shop and went away at his usual time. For months the deceased had complained about pains in his head and feet. In consequence of a message which he had received he went to Mr. Pearson's house in Hanover Square. A woman gave him a screw-driver and he prized open the door of Mr. Pearson's bedroom. Witness thought there was no one in the room at first, but on going to the far side of the bed he saw Mr. Pearson lying with the child underneath him. He was lying partly on his side. He was in his night-dress. Witness moved Mr. Pearson and got the child from under him, and then Mr. Pearson was lying on his face. The child was lying on his face. Both the deceased were quite cold and very stiff. There was a mark on the child's face. There was a child's cot near the bed, and the deceased was lying between it and the bed, so that they could not move without going under the bed. Witness then went for Doctor Taylor, and after his arrival he requested witness to put the child on the bed. Witness had never seen Mr. Pearson tipsy, but he had seen him when he had had drink. The deceased had been in bed, because the bed-clothes were disordered and lying on the opposite side to which the deceased were. The disease from which Mr. Pearson suffered would make him appear to be intoxicated. There was nothing whatever in the room. He had often complained at the shop of pains in the head, and witness had given him potash and sal volatile. He had seen Mr. Pearson take potash and sixpennyworth of brandy. There was a will of Mr. Pearson's on the floor near his clothes. It was ordinary parchment. There was no reason that witness knew of to cause Mr. Pearson to commit suicide. There was no trouble about the business. He was particularly fond of his youngest child (the deceased), and said that if he had a leaning to any of his children it was to that one. Mr. Pearson had money in gold and silver in his pockets.

Dr. C. H. Taylor, in the course of his examination, deposed that he had known Mr. E. C. Pearson about ten years, and had attended him professionally about four or five years ago. On Saturday, about noon, he was called to Mr. Pearson's house. Witness went into the bedroom and found the deceased in much the same position as described by the previous witness. He was laid on his left side with his head on his left arm, and his right arm was under the bed. The bodies were very rigid. The child was lying on the floor a little distance away from Mr. Pearson. Witness examined them to see if there were any external wounds or anything to cause the deaths. He came to the conclusion that the deceased must have been dead about eight or ten hours. He looked round the room to see if he could find any bottles or anything else. In the room he did not find anything of the sort. He made a *post mortem* examination of the bodies on Saturday. There were no external bruises on anything to account for death. There was blood oozing from the right ear. With regard to Mr. Pearson he found the scalp congested, and on opening the skull he found the brain very much congested. There were about four ounces of bloody serum on the base of the brain. The brain substance was normal and healthy. The extravasation of the blood and serum was entirely independent of external violence. The liver was very much enlarged, weighing nearly 15 lbs., and of a very dark colour. There were no marks of inflammation. He could not trace any irritant poison, either by what he saw or could smell. He had placed some of the principal organs in the hands of Mr. Rimmington, so that an analytical investigation could be made if it was thought desirable. He could see no other cause of death than congestion of the brain, caused by the flow of blood to the head. From the state of Mr. Pearson's liver it was probable he had taken stimulants for a length of time, which had, to some extent, accelerated the congestion of the brain and liver. When he saw the bodies on the Saturday there was a strong smell of brandy. There was nothing inconsistent with death from natural causes. The deceased might have walked about the room feeling unwell before he died, and have fallen down. If he had taken some preparations of opium the same *post mortem* appearances might have been produced.

Emily Leach, domestic servant, said the boy went to bed about half-past nine and Mr. Pearson about ten. The boy slept in the same bed with his father. Mr. Pearson was perfectly sober and witness could not say that he had anything to drink before going to bed.

George Edward Pearson said he was nine years of age. About three o'clock on Saturday morning he heard his brother William screaming for about five minutes. Witness went to the servant's bedroom to wake her, but he could not. He could not get into his father's bedroom because the door was locked. He told the servant next morning that he heard the screaming. Just as his brother had given up screaming he heard a noise as of something falling in the bedroom.

The Coroner briefly summed up, and asked the jury if they were not satisfied that the death of Mr. Pearson was the result of natural causes, and that the boy was smothered by his father falling on to him. If the jury wanted more information they could have the contents of the stomach analysed.

The jury consulted for about three-quarters of an hour, and it was then decided to adjourn the inquiry until Monday evening next, so that in the meantime the contents of the stomach could be analysed by Mr. Rimmington.—*Bradford Daily Telegraph.*

Reviews.

ΕΛΛΗΝΙΚΗ ΦΑΡΜΑΚΟΠΟΙΙΑ *κατα Βασιλικην Διὰταγην και κατ' εγκρισιν του Β. Ιατρικοὺ Συμβουλιου εκδοθεισα. Συνταχθεισα δε παρα Ιοαννου Βουρου, Ξανεριου Λανδερερου καὶ Ιωσηφ Σαρτοριου. Εκδοσις β'.* Athens: K. Antonias. 1868. From Professor Landerer.

Having lately received a copy of the Greek Pharmacopœia from Professor Landerer, of Athens, it was with some degree of curiosity that we opened it, to see if it would throw any light upon the state of pharmacy in that country, for a national pharmacopœia should always to a certain extent reflect the existing state of both medicine and pharmacy. The work before us is written in modern Greek and a Latin translation is placed side by side with the Greek text. It is the second Pharmacopœia which has been issued in Greece under government sanction, and differs from the first in the following particulars. It contains an appendix which includes many new remedies, with description and formulæ for their manufacture, as well as for several known patent medicines; a short list of poisons and their antidotes; and an etymological lexicon explaining the derivation of the names of various plants, metals, and technical terms. The index is less full than in the previous edition, the synonyms not being separately indexed. One curious feature in the Greek Pharmacopœia is a Greek-Latin and Latin-Greek lexicon of the terms used in the body of the work. The Pharmacopœia, as was formerly the case in this country, is divided into two principal parts, the one being a list of the materia medica and the other a list of preparations, with formulæ for making them, the pharmaceutist being expected to prepare himself unless he can obtain them equally pure and good in commerce, but of which in any case he is expected to test before using.

In the first part the drugs are classed alphabetically first according to their commercial names, then their scientific names; in the case of plants, the Linnæan class and order as well as the natural order to which they belong are given, also their synonyms in the Italian, French English, German, and Turkish languages. Following these comes a description of the drug, with appropriate tests for ascertaining its purity. As a rule the English synonyms are well rendered, but in a few cases they would hardly be recognized. Thus fike-leaved, sharp, small barnett, dried pitch, vomiting nut, cherry bay tree, would hardly be considered, in this country, the English names for *Œnanthe Phellandrium; Rumex obtusifolius, Pimpinella Saxifraga, Resina alba, Nux vomica* and *Prunus Lauro-cerasus.* Printers' errors are very numerous throughout the work, and the matter is much more crowded in the last edition; the arrangement of the type also is not good, so that it is rather difficult to distinguish the headings from the text. The pharmacology is not quite up to date in many instances. Thus we find Chinese rhubarb attributed to "*Rheum australe* seu *R. Emodi,*" and ammoniacum is attributed doubtfully to *Heracleum gummiferum* and *Ferula orientalis,* while the description of the drug applies rather to Persian than to African ammoniacum. It would be interesting to ascertain whether African ammoniacum is really used in Greece to the exclusion of the Persian. Camphor is attributed to *Dryobalanops Camphora* and *Laurus Camphora,* so that both Borneo and Chinese camphor must be official; kino is said to come from the East Indies and to be derived from *Eucalyptus resinifera.*

In the list of materia medica many of our wild plants still esteemed by herbalists in this country, as well as numerous garden herbs, find a place, among which may be mentioned masterwort, tansy, hedge hyssop, elecampane, soapwort, feverfew, fumitory, German chamomile, greater celandine, scurvy-grass, buck-bean, centaury, ivy leaves, ground ivy, dock-root, burdock-root, wormwood, mugwort, yarrow, and many others. A trace of ancient pharmacy is seen in the presence of such articles as crabs-eyes, teucrium marum, oyster-shells, Roman nettle, white agaris, flea seed, gypsum, graphite, and other remedies now found in this country only in museums or the collections of the curious. Other articles are still used to a certain extent in this country, such as Galangal, China root, *Triticum repens, Anemone Pulsatilla, Phellandrium aquaticum,* etc., while others are used on the continent in several countries although not at all in England.

In a few cases the botanical sources of drugs differ slightly from those of this country; thus, oak bark is derived from *Quercus Œgilops* and aconite root from *A. neomontanum* as well as from *A. Napellus.* As no botanical authority follows the name, and as the name *neomontanum* has been applied to nine different species by different botanical writers, it is rather difficult to say which species is here intended. In Greece, salep appears to be obtained from *Orchis mascula, O. pyramidalis, O. longibracteata* (*O. Robertiana.* Desleng?) and *O. latifolia;* spearmint is replaced, as in Germany, by *Mentha crispa.*

The second part, containing the preparations, presents several points of interest. The nomenclature used is very old, but nevertheless leaves little room for mistakes to be made. Thus, calomel is called hydrargyrum muriaticum mite; and corrosive sublimate; hydrargyrum muriaticum corrosivum; carbonate of potassium, kali subcarbonicum, and the bicarbonate, kali carbonicum acidulum. Certain preparations appear to be much more in favour than others; thus we find no pill masses so called, very few liniments, infusions, spirits, wines, or confections, while there are more than fifty each of extracts, plasters, and waters, and a large number of tinctures, liquors, syrups, and oils. A few preparations much used in this country are conspicuous by their absence, such as spirit of sal volatile, ipecacuanha wine and the scaled preparations; while others, such as the serums or wheys made with vinegar, alum, or cream of tartar, and the soaps of jalap, resin, guaricum, and sulphide of antimony, the elæosaccharums and robs or inspissated pulps of fruits, have no representatives in this country.

As might be expected from a work which is only the second of its kind that has been published in that country, the Greek Pharmacopœia still retains a number of old and comparative useless or absurd preparations, such as cephalic water, theriaca, spiritus formicarum, pulvis antiepilepticus (composed of mistletoe, crabs'-eyes, and peony root), and some others.

On the other hand, some preparations which have only lately been added to our own Pharmacopœia have been official in that of Greece since 1837, such as acetic ether, phosphorated oil, and compound liquorice powder; while the facts which recent researches have brought to light concerning compounds of ammonia and glycyrrhizin have had a practical application for many years past in the elixir e succo liquiritiæ.

The processes prescribed for making some of the preparations vary somewhat from those of the British Pharmacopœia. Thus, acetic ether is made by distilling a mixture of alcohol, acetate of lead, and sulphuric acid, and rectifying the product after treatment with lime water. Sweet spirit of nitre is directed to be rectified from hydrate of calcium and preserved in small bottles quite filled, and containing a small quantity of calcined magnesia. Sulphur præcipitatum is made by precipitating a potassic solution of sulphur with sulphuric acid. It would be desirable to know whether the Greek preparation is free from the objections lately raised against the B.P. article. Many other interesting details will be found in perusing the work.

Of preparations bearing names or synonyms familiar to English ears, several differ either in composition or strength. Thus oleum camphoratum is only half the strength of the B.P. article, while tinctura opii is considerably stronger, six parts representing one part of opium, and oleum phosphoratum is said to contain about 9 grains of phosphorus in one drachm of the oil. Prussic acid is an alcoholic solution of the acid made by decomposing Prussian blue with phosphoric acid. Compound decoction of sarsaparilla is of two strengths; the one known as "fortius" contains mercury probably in the state of perchloride, the other distinguished as "mite" differs considerably in flavour from the B.P. preparation, since it contains cinnamon, cardamoms, and other aromatics.

The number of agreeable vehicles and dietary articles manifest an evident tendency in the direction of elegant pharmacy. Most of the disagreeable medicines appear to be given in the form of pills as far as possible, since they enter largely into the extracts, while the syrups of raspberries, almonds, cinnamon, balsam of Peru, various palatable jellies, Iceland moss chocolate, pâte de guimauve, numerous aromatic tinctures and elixirs, all testify that the Greeks possess quite modern notions with regard to agreeable medicines. The appendix manifests an endeavour to keep pace with other countries in the use and knowledge of new medicines. These seem to have been culled from various pharmacopœias as well as from other and perhaps questionable sources. A certain amount of want of judgment is displayed in the selection of the formulæ here given. Everything that could be called for, from chloral and digitalin down to well-known patent medicines, find a place here. Benzine, mineral waters, bisulphide of carbon, caffeine, tooth stopping, James' powder, Vienna paste, pepsine, Holloway's pills and ointment, powder for hydrophobia, propylamine, and Blancard's pills follow one another in a most heterogeneous fashion. We must confess to a little curiosity as to the cases in which the formulæ for Holloway's pills are intended to be used. Are pills thus made prescribed by Greek physicians? Are they to be supplied when Holloway's pills are asked for? Or are they used to avoid the sale of patent medicines? These are questions which naturally occur, but which must remain unanswered until we know more of the state of pharmacy and medicine in Greece.

Chloral is latinized as chlorelayllum, and glycerine appears to be used chiefly as a solvent for the alkaloids. We fear that those who desire a universal pharmacopœia would of necessity spend a considerable time over the Greek Pharmacopœia, and that there would be considerable difficulty in reducing some of the preparations to anything like uniformity with other pharmacopœias. Those who are interested in the progress of pharmacy in different countries will find much that is suggestive and interesting in the perusal of this work, and particularly in that portion relating to the preparations.

The Chemists and Druggists' Trade Association.

Sir,—However strange it may appear, it is no less a fact, that a great number of the trade most determinedly hold aloof from giving any support to the Pharmaceutical Society or to its Benevolent Fund, and as I can testify, whenever appealed to on behalf of either giving the one or assisting the other, the reply generally given seemed to have something of the spirit of those mentioned in your leader as belonging to the "ignoble army of grumblers." Whether Mr. Mee will be able to educate us into a better state of things, or what system he may adopt, I cannot say, but if he be the divinity or spirit that is going to collect together every member of the trade into one great comprehensive unity—in fact to make this pharmaceutical wilderness to blossom like the rose—there is a great work before him and all must wish him success.

I cordially coincide with your other correspondent, Mr. Greaves, that there does seem a need for "The Trade Association." Many of his reasons seem to me unanswerable; at the same time, whilst it is my clear conviction that this association, if adequately supported and judiciously carried out, may, and ought to strengthen the Pharmaceutical Society, still I strongly agree with you that the great need of the body at large is want of union.

Certainly one does not exactly see why the happy state of things just brought to pass in Chesterfield and East Derbyshire could not have been equally as well done, although the Birmingham meeting had never taken place; but be this as it may, the great thing needed is to follow this example.

Mr. Greaves, strangely enough, speaks of the trade being the victims of unscrupulous customers, but it always seems to me under similar circumstances that we are rather the victims of reckless members of the trade, for if we have not sense enough to look after our own interests the public will not be likely to do so.

It was thought years ago by Mr. Bell and others that this ruinous competition in starvation prices would cease when men became better educated, and consequently more appreciative of their position; but such is not the case, for "Mr. Parnassus after having done the Square," seems to have just as little respect for his calling and to be less versed in political economy than his neighbour.

Two instances in this somewhat aristocratic city (having somewhere about six practising physicians), which have just occurred, may perhaps illustrate what I desire to say. A short time since one of the largest and handsomest shops in the place, and of some years' standing, having changed hands, a notice duly appeared that the new-comer was a pharmaceutical chemist by examination, certificates of which, nicely framed, stood in the window, but there was very little else of pharmaceutical pretensions—hair brushes, combs, soap, occupying a good share of the remainder of the space. Another handsome shop, where the business has been larger and of many years' standing, also just lately found a new owner; pharmaceutical chemist by examination again appears, this time with a notice that the occupier intends to apply for a magistrate's licence to sell beer (wine and spirits being already introduced); the handsome plate-glass windows are filled with bills offering orange quinine wine in wine bottles at 1s. 10*d*. "made of Howard's quinine, and in strict accordance with the British Pharmacopœia." Happy is Mr. Greaves that his town and neighbourhood have learned to see the folly of such miserable work, and that a good understanding and determination to act together for the general good has been arrived at.

This is the want of the trade, as much elsewhere as in Chesterfield. I wish every member of the trade would study and consider what Mr. Greaves says about our foolish jealousies. The truth is, we want protection from gross inroads upon our trade rights; we want protection from medical illiberality and tyranny; we want to protect ourselves from wholesale houses, who fill the windows of grocers and others with drugs; but more than anything else we need a proper feeling amongst ourselves, and getting this all the others will be attainable either directly or indirectly. On former occasions, as well as the present, my object in writing to the Journal has ever been to promote the interests of a trade in which more than thirty-five years of a somewhat laborious life has been spent. I would then state that the two great curses of our business are just these, low prices and long hours. The only cure for them that I can see is the abandonment of indifference, the forming in each town associations similar to that mentioned by Mr. Greaves, and whilst we may see our need of a trade association, never allowing the claims of the Pharmaceutical Society or its Benevolent Fund to be placed upon so low a footing as "what do we get out of it?" Perhaps in this, as in many other things, we get just a proportion as we desire and strive for.

For the well-being of the trade at large, for our own personal good, for the interest of those we have educated and are introducing into the business, do let the "ignoble army of grumblers" haul down their flag and disband themselves forthwith.

Mr. Greaves says the Act of Parliament of 1868, did not provide for the supply of drugs in districts too small to support a chemist, nor did the Medical Act provide for the supply of medical advice under similar circumstances. The fact is, no Act of Parliament could do this; it must almost entirely be left to individual management; the house separated by distance from the market needs to be provided beforehand with goods for emergencies. If the Act is a failure at all it is the same in all cases and under all circumstances so, and just because it is not sufficiently restrictive. This, however, requires great consideration, and it ought to be one of the great questions with the trade association.

Mr. Mee has evidently not had a very extensive range of vision, or he would see that there are numerous places and even districts where the carrying on of pharmacy pure and simple could never be done, and if it could I fear the greed of gain would influence men more than the love or pharmacy.

Some time since I was engaged with a friend upon the purchase of a very extensive concern in the North of England, the shop large and lavishly fitted up, and it will startle some of your readers to learn that out of returns of about £2000 per annum, £600 was from the sale of gingerbread nuts. At the annual fair great quantities were exhibited in the window, an illumination, and a band of music in the window of an upper room.

One Who has known the Drug Trade more than Thirty Years.

Sale of Poisons by Unregistered Persons.

Sir,—The sale of laudanum and other poisons seems to have largely increased of late. The remedy is in the hands of the chemist himself, and I think if the following suggestion were acted upon we should soon have little to complain of under this head. That each local secretary should wait upon the chemists in his district and obtain their signatures to a form stating, "That they would not supply any unregistered person—being a shopkeeper—with laudanum, or any of the poisons mentioned in the Act," I think there would be very few who would decline signing it.

Grantham, September 26, 1876. Jno. Cox.

Effects of Long Hours.

Sir,—The Obituary notices on Saturday week were a sad record of the shortness of a chemist's life. Five—and all under forty years—viz., 26, 34, 36, 36 and 39. This ought to be a warning to the advocates of long hours. I am often shocked by hearing of the death of young chemists, who, when I last saw them, were fine hearty looking fellows. And the cause—"want of fresh air and daily exercise."

Wolverhampton. Robert Henry Lowe.

A New Pill Excipient.

Sir,—May I be allowed a little of your valuable space in reply to the objections urged by Mr. Greenish against my paper on a new pill excipient, read at the recent Conference Meeting at Glasgow, and published in your issue of the 23rd ult.

I beg leave to say there is a wide difference between a mixture of tragacanth and glycerin and the excipient in question; and I have yet to learn that it is a matter of no moment which of the two is employed.

A mixture of 1 part of powdered tragacanth and 19 parts of glycerin does not gelatinize in the cold; but, upon heating in a water-bath, forms a jelly of similar consistency to that which I still designate "the new excipient."

Fifteen gr. of the former mixture are requisite to form a coherent mass with ℨij P. Ipecac. Comp. which is a little in excess of the amount needed of "new excipient." If, however, it be attempted to roll the mass thus formed into pills, the difference in the properties of the two "mixtures" will be at once apparent. While one rolls out with the greatest ease, the other forms a kind of tube which is very much larger in the middle than towards the extremities,—a pleasing and peculiar formation, doubtless; not, however, conducive towards pill-making. This behaviour of a mixture of tragacanth and glycerin is sufficient to demonstrate that it possesses but little adhesive properties.

As to the observation that "oil of pimento is unnecessary and a bar to its general employment," I have to say that if the trouble be taken to make the excipient from month to month it is unnecessary,—but not otherwise,—as "mould" forms upon it when kept for some months exposed to air. The excipient, however, forming the subject of the paper at Glasgow, will keep good for "five years" at least, and the amount of oil of pimento contained in it is so infinitesimal as to be of no account whatever, since in a few weeks its odour is barely perceptible.

It is scarcely necessary to enter into the question as to whether the "excipient" is new or old, but, I may say that at all events it was new to me.

The Dispensary, Grantham. George Welborn.

S. N. O.—(1) According to Professor Wayne, in the United States the extemporaneous sugar coating of pills is effected by making the pill as dry and hard as possible, coating it with a solution of tolu, and then covering it with a powder containing equal parts of milk sugar and ordinary sugar, and drying. (2) See a paper on arsenical sheep washes in *Pharm. Journ.* (o.s.), vol. xviii., p. 511.

"*Improver.*"—There is no method by which you can dispense your mixture with those ingredients. Consult the prescriber and tell him the quinine is sure to be precipitated, and will coat the sides of the bottle as a resinous substance—pure quinia.

W. H.—The use of the title Pharmaceutical Chemist by such a person in Great Britain would be illegal.

"*Chemicus.*"—Section 12 of the Pharmacy Act, 1852, makes it illegal "for any person, not being duly registered as a Pharmaceutical Chemist according to the provisions of this Act, to assume or use the title of Pharmaceutical Chemist or Pharmaceutist, in any part of Great Britain, or to assume, use, or exhibit any name, title, or sign implying that he is a person registered under this Act."

"*Pax.*"—Candidates for the office of Dispenser in Her Majesty's Naval Hospitals must make written application to the Director-General of the Medical Department of the Navy, Admiralty, Whitehall.

E. Nuthall.—In a memoir published in the *Neues Repertorium f. Pharmacie*, 1868, pp. 513—534, Dr. Urner discusses the value of chloracetic acid as a medicinal agent, and states that he found dichloracetic acid to be a powerful cauterizer, well adapted for large and small surfaces.

"*Cathcart.*"—Divide it into five equal parts, and allot three-fifths to one person and two-fifths to the other.

"*Registered Apprentice.*"—(1) We were not aware that salicylic acid was yet used in cattle medicine. (2) We are obliged to you for the particulars. (3) Probably your solution of ammonia was too weak. The making of the preparation requires care, as there is some iodide of nitrogen formed which settles to the bottom of the bottle, and should be separated. This is a very explosive substance when dry, and it is to it your explosion was due.

Y. Z.—It is probably grape sugar that is formed and crystallizes out. Try heating a little carefully, set aside to cool, and then see if it crystallizes out again. Be careful not to employ too much heat.

Pharmacist.—There seems to be some resin and essential oil in the pills which absorbs the ether causing expansion so that in time this mixture will crack the coating and the pill mass will exude. Try a solution of gum arabic.

Communications, Letters, etc., have been received from Mr. Martin, Mr. Jackson, Mr. Corder, Mr. Gilmour, Mr. Proctor, Pen Gwyn, Hampton, S. P. A., "Juvenis."—Try almond oil,

TEST FOR SPERM OIL.

BY W. GILMOUR.

In the course of some recent investigations into the properties and reactions of some of the fixed oils I had occasion to observe their behaviour on the addition of sulphuric acid in certain proportions and under various circumstances. Some of the experiments were exceedingly interesting, and brought out features in these oils quite characteristic, and not observed hitherto, so far as I am aware, by other investigators, and which after further verification I may take another opportunity of pointing out. What I wish, however, in the meantime to suggest is the probability of the purity of sperm oil being determined in a very simple manner by the amount of *cetin* which it contains, and which I found might be liberated by the action of sulphuric acid.

The cetin thus proposed to be estimated is not derived from any artificial mixture of spermaceti with the oil due either to imperfect exhaustion or clarification. It is apparently, judging from all the experiments which I have made, a proper constituent of the oil itself in the natural state, and present in genuine oils nearly always in a uniform proportion. According to Hofstadter, sperm oil contains spermaceti, oleic, valerianic, and physetoleic acids, whilst, according to Stenhouse, its composition appears to be isomeric with spermaceti fat. I have not, however, been able to ascertain that the relative proportions of the several constituents are anywhere stated, probably owing to the fact that this oil, like most of the other fatty oils, is somewhat unstable in character. In the samples which I have examined I have recovered from about 4 per cent. of cetin downwards, according, I believe, to the genuineness of the oil; and the proportion in several experiments on the same sample was in every case nearly uniform.

The mode of procedure, which is very simple, is as follows:—Take one part by weight of sulphuric acid, sp. gr. 1·84, to four parts of oil, and mix thoroughly. Let it stand for about twenty minutes, shaking once or twice in the interval, and then add about three ounces of distilled water. On now shaking the mixture a very thick saponaceous-like compound will be formed which should be throughout of uniform colour, showing that the mixture is complete. After letting this stand for about eight hours it will be found to have separated into two layers, the one underneath being clear and colourless, and the one above a dark-brown viscous mass, in which the cetin, if present, will be found floating, giving it a mottled appearance. It should now be set aside for a further interval of eight or twelve hours so that all the cetin may separate, on which it should be transferred to a larger vessel containing three or four times its volume of water, and the whole thoroughly shaken. The cetin will now be found floating on the surface of the liquid and should be filtered out and thoroughly washed until the filtrate ceases to have a milky appearance, and then dried spontaneously. As thus obtained the cetin is light, crystalline, pearl-white, not unlike quinine in appearance, but more glistening, and has neither taste nor smell. According to Christison, it is a pure proximate principle, intermediate between wax and the concrete oils, and presenting all the leading properties of spermaceti, but less greasy and fusible only at the higher temperature of 120°. It undergoes partial saponification when boiled with caustic potash solution, forming a brittle soap only in part soluble in water and composed chiefly of palmitate of potash, oleate of potash, and a crystalline principle called ethal.

The following table gives the amount recovered from one ounce by weight of ten different samples, with the specific gravity of each oil respectively:—

Sample.	Spec. Grav. 60° F.	Cetin in grains.
1.	·884	16·2
2.	·880	15·5
3.	·886	11·
4.	·883	7·1
5.	·881	6·5
6.	·884	6·
7.	·889	4·2
8.	·885	3·
9.	·882	none.
10.	·896	none.

As already stated, all the foregoing oils have been tested in the manner indicated more than once (in most instances repeatedly) with nearly uniform results, so that it appears reasonable to assume the utility of this mode of determining their purity.

I may state that I have endeavoured to extract the spermaceti, previously known by this means to be present in some of these oils, by boiling in rectified spirit and subsequent crystallization. Spermaceti, it is well known, is soluble in boiling rectified spirit, whilst sperm oil is not, and therefore I thought it might be obtained by dissolving in that menstruum and afterwards crystallizing out. I have, however, failed in every attempt thus to extract the spermaceti; but whether from some adulterations of these oils with other oils soluble in rectified spirit, or from other impurities still, or from some defect in the manipulation, I have been unable to determine. It shows, however, not only how prevalent adulteration is in this valuable oil, but also how defective the means are for its detection, when dealers in every case prudently refrain from giving any opinion on its purity, and when further *it is known that the annual consumption is much in excess of the amount actually imported.* In circumstances such as these the test may prove of some practical utility; but be this as it may, it is put forward in the meantime more as a suggestion, in the hope that some one with greater facilities for investigation may be induced to take the matter up and carry it to a proper conclusion.

NOTE ON SUMBUL.*

BY KARL WITTMANN

After referring to a notice which appeared last year in the *Pharmaceutical Journal* (vol. vi. p. 43), respecting the blooming of the Sumbul plant at Kew, the author, who is Secretary to the Military Medical District Administration of East Siberia, gives the following information.

The *Euryangium Sumbul* is found in large quantities in the neighbourhood of Chabarowka, a military post on the river Amur, in the province of Küsten, East Siberia, 9000 versts from St. Petersburg. It is a perennial umbellifer, and grows to the height of from 3 to 5 feet. Its root is branched, fleshy, about 11 inches in circumference at the base, and

* From the *Pharmaceutische Zeitschrift für Russland*, vol. xv. p. 545.

3⅝ inches in diameter, with numerous rootlets and covered with a brown bark. The root has a strong smell of musk, which by moistening with water is considerably increased. The stalk of the plant is always fleshy, equal in circumference at the base with the root, becoming gradually more slender towards the top. The leaves are more than twice pinnatifid, the pinnæ lancet-shaped, sharply serrate; the umbels with 30 to 50 rays; the flowers white and small.

Besides the *Euryangium Sumbul*, the author has met with another umbellifer, which resembles it very much in its entire habit, but may be distinguished by its smaller size, lighter leaves, and the absence of the musk-like smell of the root.

The Eastern Russian inhabitants call the *Euryangium Sumbul* "Bärenklaue" (bears' claw), and use the root as a medicine. The Chinese living in the district use the root of the plant against various diseases and call it "Lsóuma-tschen-tuk." It is also used by the natives internally as a remedy for swellings; with them it bears the names "Ofuokgi" and "Ouchi."

The author promises a future communication, giving the results of an examination of the separate constituents of the root as it is found in the district of Chabarowka.

REGENERATION OF SPENT ALBUMIN BY MEANS OF PEPSIN*.

BY J. WAGNER AND G. WITZ.

The property of an aqueous solution of albumin to deposit the albumin in the insoluble form on application of heat is applied to the fixing of a variety of important colours upon cotton. Both soluble and insoluble colours are mixed with the cold solution, printed on the cotton-piece, and the latter is then steamed, which converts the soluble albumin into the insoluble variety, forming a kind of fixed and elastic varnish upon the cloth, and mechanically fixing the colouring matter. Both egg- and blood-albumin pass into the insoluble form, *either wholly or partially*, if the temperature of the drying chamber has passed 35°, or even if exposed to the sun accidentally, or after allowing it to stand too long. Now the problem has been, "How to recover albumin which has thus become insoluble and is lost, so as to obtain it again in the soluble form for further service." Dilute alkaline carbonates or hydrates could bring such albumin into solution again, but such a solution lacks the power of coagulating on application of heat; in fact the constitution of the albumin is altered by the alkalies, a portion of its sulphur being abstracted, and the substance in solution is therefore not albumin at all. This prejudicial action of alkalies is at times experienced in working; thus if the basic lead chromate be not completely freed, by washing, from adhering lime, and be then thickened with albumin and printed, not a bright orange is obtained on the cotton on steaming, but, through presence of lead sulphide, a muddy-brown. At length J. Wagner devised the following successful method:—He brought 350 to 400 grams of such unserviceable albumin into contact with 30 grams of calf's stomach, cut into little pieces and distributed through 1 litre of water. The water was treated with 10 grams of concentrated hydrochloric acid, and had a temperature of 37·5°. After 24 to 36 hours' standing the whole was passed through a fine sieve, and the filtrate neutralized with ammonia, and thus an albumin solution was obtained which answered every purpose completely. Witz uses a sheep's stomach, and to 1 litre of acidified water nearly 125 grams of dry insoluble albumin. He states that pigs' stomachs are even more active than sheep's. He further digests for 40 hours at a temperature of 35° to 40°, whereby somewhat more than half the albumin goes into solution. The dissolved portion being separated by a sieve, the insoluble portion is treated once more with acidified water in the same manner, to bring a further portion of albumin into solution. The solution so obtained is without odour, and but little coloured, a fact worthy of note as regards blood-albumin. It has also the property, after neutralization by ammonia, to become coagulated either by boiling or by addition of alcohol. Experiments as to the use of this albumin in ultramarine printing, showed that on steaming, a pure, fast blue is obtainable, unaffected by boiling soap solution. There is one reaction which marks a difference between albumin recovered by pepsin and ordinary albumin. The former treated with acetic acid, before or after neutralization with ammonia, either does not at all become turbid, or only slightly, and in no case gelatinizes, even after long standing. On the contrary, one part of egg-albumin dissolved in ten parts of water, so that the filtered solution has a sp. gr. of 1·027, and treated with an equal or half volume of acetic acid of sp. gr. 1·050, immediately forms a solid, transparent jelly. This also takes place if hydrochloric acid be added. Witz has proved conclusively that under no circumstances whatever is coagulated albumin soluble in acetic acid. The text-books usually state that albumin-solutions are not precipitated at all by acetic acid, and are thus in great error. Digestion with pepsin is thus a certain method of bringing coagulated albumin again into solution. Just as cloth, which has undergone some injury in finishing, may be quite freed from its size by digestion with malt, and much more easily than by long treatment with boiling water, so by the help of pepsin, printed albumin colours, even after steaming, can be completely removed from the fabric.

For this purpose the piece is placed in warm, slightly acidified water, together with some pieces of the membrane of a calf's stomach. The pepsin in presence of the dilute acid dissolves the albumin, and the colouring matters, as chrome-green, lamp-black, chrome-yellow, ultramarine, ochre, etc., are now readily removed by washing. Pepsin can bring about the solution of albumin coagulated by boiling, as well as that of otherwise insoluble albumin, but the two solutions differ, as the former will not coagulate on boiling, but the latter will. The presence of a small quantity of free hydrochloric acid is indispensible in aiding the solution of the albumin by the pepsin. Dilute hydrochloric acid (1 part of sp. gr. 1·169, in 100 of water) alone, after some days, at a temperature of 38°, can effect the solution of insoluble albumin. The solution will coagulate on boiling, and answers well in printing. By digesting blood-fibrin in dilute hydrochloric acid, a fibrin solution is obtained, which coagulates on boiling, exactly as the albumin solution above mentioned does. It is thus possible that fibrin would make a good substitute for egg-albumin. Coagulated fibrin, like albumin, on treatment with acidified pepsin-solution, dissolves, but apparently in an altered or modified form, as the solution will not coagulate on boiling. Coagulated fibrin can also be dissolved gradually, by dilute hydrochloric acid (1 part of sp. gr. 1·169 to 100 of water). On heating, the solution precipitates the fibrin as a thick, solid jelly.

* From *Journal of the Chemical Society*, August, 1876 (*Dingl. polyt. J.*, ccxix, 166–171).

NOTE ON THE GUMS OF SENEGAL.*

BY DR. A. CORRE.

In commerce the gums of Senegal are distinguished according to the district which yields them, or the port from which they are exported.† They are (1) GOMMES

* *Journal de Pharmacie* [4], vol. xxiv., p. 318.

† These gums are not very often met with in general commerce, the greater part of them being imported into and used in France.—ED. PH. J.

BAS-DU-FLEUVE (Bas-du-fleuve, Degana, and Podor; gums from the desert of Bounoun and the country of the Braknas); and (2) GALAM GUMS, or GOMMES HAUT-DU-FLEUVE (Galam, Podor, Bakel, and Medina). These gums, when carefully sorted, yield very different products, which the author classifies as follows:—

A first group includes the gums in round pieces (*en boules*, so called because of their form). The subdivisions of this group are regulated by the degree of consistence and resistance, size and colour, of the balls.

A. *Hard Gums* (*Gommes dures*), of firm consistence, with large, clear, shining fracture:—(1) *grosse blanche:* pieces large or medium sized, entire, white or yellowish-white; (2) *petite blanche:* pieces small, entire or in fragments, generally whiter than the preceding; (3) *grosse blonde:* pieces large or medium sized, entire, yellowish or reddish-yellow; (4) *petite blonde:* pieces small, entire, or in fragments, yellowish or reddish-yellow; (5) *deuxième blonde:* pieces more or less large, entire or in fragments, reddish; (6) *fabrique:* pieces more or less large, entire or in fragments, reddish or brownish, moderately limpid, grumous or tearlike on the surface, with a fracture often resinoid, uneven, and dull.

B. *Soft or Friable Gums* (*Gommes molles ou friables*).—(7) *blanche;* (8) *blonde;* (9) *fabrique.*

In a second group the author places the gums occurring in elongated masses, a form which results, doubtless, through delay in the solidification of the gum upon the tree, caused by rains or humidity of the atmosphere:—(10) *larmeuse:* in mammillated or undulated masses, clear light yellow colour, shining at the surface, fracture clean, hard; (11) *vermicelle:* rather dull white, surface corrugated, fracture pretty clean and shining, friable; this gum is remarkable for its convolute form, which resembles that of vermicelli.

To a third group belong the gums in fragments and powder, the *débris* and residue of the preceding:—(12) *gros grabeaux;* (13) *moyens grabeaux;* (14) *menus grabeaux;* (15) *grabeaux triés;* (16) *grabeaux fabrique;* (17) *poussière.*

To a fourth group is allotted (18) *marrons* or *bois*, a largish gum, frequently of resinoid aspect, yellowish or brownish, mixed with, or adherent to, fragments of bark.

The Senegal gums are collected from a great variety of plants. The acacias (*Acacia nilotica*, *Verek*, *Adansonii*, *albida*, *dealbata*, *Sing*, *Seyal*, etc.) yield the greater part, and the finest qualities. They are also obtained from the *Khaya senegalensis*, certain *Spondias*, some *Sterculiaceæ*, and perhaps *Bassia*, etc.

As the result of the study of the mode in which the gum is produced from the verek, the author is of opinion that the starting point is certainly in the cambium. When a transverse incision is made in a young branch, there is observed at first a sort of exudation, badly defined, between the wood and the bark. As the exudation becomes more considerable it raises the bark, and makes its way to the exterior through any cracks or fissures. But as there are two layers in this zone—a ligneous and a cellular layer—the question arises in which layer does the gum take its origin? For the following reasons, the author believes it to be formed in the ligneous layer at the expense of the crude sap circulating therein.

(1) Upon different specimens of verek he has observed that at the level of the base of the gummy exudations the exterior woody bundles become deviated in the form of a capsule, and present traces of an erosive or destructive action. In very young branches, by the aid of a microscope, these bundles may be distinguished, dissociated and jagged, in the midst of the gummy matter.

(2) The balls of gum are frequently marked with very regular cavities, similar to those produced in a viscous mass by blowing air into it through a slender tube. These cavities cannot be due to the penetration of a gas coming directly from without, for they face inwards, *i.e.*, towards the base of the exudations; they could only be produced by the air from the vessels of the sap wood, ruptured and dissociated at the same time as the woody fibres.

(3) The mineral elements of gum (lime, etc.), belong to the crude sap.

Gum, however, is not simply water charged with salts, neither is it a highly concentrated saline solution. It is a product that presents great analogy of chemical composition with lignose. The author, therefore considers gum to be the result of a kind of liquefaction of the elements of the sap wood by the crude sap.

It is incontestable that the formation of gum is connected with an anomalous state due to excess of nutrition. It is observed more particularly at the points of budding, and at the bifurcation of the branches, and it acquires a remarkable development upon abnormal nodosities—in fact, wherever the nutritive action exists in the greatest intensity. Beyond certain limits, this energy in the rising of the sap is accompanied by a slackening of the circulation, which leads to a stagnation of the liquid through the engorgement of the channels; hence, perhaps, by absorption, leading to the softening and liquefaction of the fibrous and vascular element of the sap wood.

In this phenomenon the easterly winds have a share, their high temperature and dryness favouring the determination of the sap to the exterior. Their influence, is not, as often stated, limited to the production of cracks in the bark. It will be seen that there is a great analogy between the mode of the formation of verek gum and that of the gum of Rosaceae, as described by Trécul.

Recently an important part in the production of the Senegal gums has been attributed to a loranthaceous parasite, which is met with frequently in eastern Africa, not only on gum trees, but also on guava trees, palms, etc. The author has never observed the least exudation of gum at the points of implantation of this parasite, which itself takes up sap and leaves no excess for the plant on which it is developed. The nodosities, which have probably been attributed to the action of this parasite, and thus led to the suggestion, the author considers to be the results of insect punctures.

ARICINE AND ALLIED SUBSTANCES.*

BY O. HESSE.

The author reviews the experiments made by Pelletier and Coriol in 1829 on a bark of doubtful cinchona nature, from which these chemists obtained a base crystallizing in white transparent crystals soluble in alcohol and ether, insoluble in water, and capable of forming an acid and a neutral sulphate; by Leverköhn, who obtained from false calisaya bark (cinchona from Cusco) a gelatinous apparently non-crystalline sulphate of a base termed by Buchner *cusconine*; by Manzini, who extracted from pale tenchina bark an alkaloid which he called *cinchovatine*, but which the author subsequently found to contain also cinchonine, and which was subsequently found by H. Bourchardat and Winckler to be identical with aricine; and by David Howard, whose results the author considers to be due to his having obtained an impure *paricine* (containing cinchonine ?).

The alkaloids of a Cusco bark obtained from De Vrij were extracted by the author in the ordinary way; the concentrated neutral sulphuric acid solution yielded crystals of cinchonidine sulphate, and then gelatinized to a mass of microscopic prisms of the same containing a little quinine sulphate; the filtrate from these contained cinchonine and amorphous bases from which nothing characteristic could be isolated. Other samples of Cusco bark yielded only cinchonidine and traces of amorphous bases; the author considers De Vrij's bark not to have

* From the *Journal of the Chemical Society*, September 1876 (Liebig's *Annalen*, clxxxi, 58).

been genuine Cusco bark. Another Cusco bark (*China de Cusco vera* of Wiggers) identical with that employed by Pelletier and Coriol yielded cinchonine, a little cinchonidine, and amorphous bases, but no other crystallizable alkaloid.

Commercial "pale tenchina" bark carefully examined and selected by Wiggers yields no cinchovatine or aricine, but only cinchonine and traces of quinidine (the conchinine of the author), and amorphous bases. Other pale tenchina barks from France yielded cinchonidine also; but this bark appeared to contain an admixture of other varieties, although specimens could be readily picked out agreeing in all respects with the sample obtained from Wiggers.

Cinchovatine prepared by Winckler and examined by the author gave no blue fluorescence when dissolved in sulphuric acid; it formed fine white prisms which gave numbers agreeing with those required for cinchonidine; it melted at 208° (not corrected) and gave the rotation $(\alpha)_D = -107{\cdot}25$, whilst pure cinchonidine melts at 205° (not corrected) and gives the rotation $(\alpha)_D = 106{\cdot}89$ under the same conditions. It gave a hydrochloride indicated by $C_{20}H_{24}N_2O.HCl.H_2O$, a platinum salt $C_{20}H_{24}N_2O.2HCl.PtCl_4$, a sulphate $(C_{20}H_{24}N_2O)_2H_2SO_4$ anhydrous after drying in the air, and giving the rotation $(\alpha)_D = -172{\cdot}20$, whilst pure cinchonidine sulphate gave $(\alpha)_D = -172{\cdot}37$, and finally the hydrochloride and the sulphate gave with phenol water compounds precisely resembling those obtained with cinchonidine.

Aricine sulphate of commerce consisted mainly of a sulphate forming on recrystallization a gelatinous mass of minute needles, together with some cinchonine and quinine sulphates and a trace of resinous matter insoluble in water. The base in these small crystals gave on analysis numbers agreeing with cinchonidine; it melted at 205°, and gave the rotation $(\alpha)_D = -107{\cdot}25$; the sulphate crystallized from a large bulk of water, formed crystals containing $(C_{20}H_{24}N_2O)_2H_2SO_4.3H_2O$; with phenol water and Seignette salt it formed difficultly soluble compounds precisely agreeing in all respects with those from cinchonidine.

Hence the author concludes that the bodies described as aricine and cinchovatine are simply more or less pure cinchonidine, as is also a lævo-rotatory crystalline base extracted in 1873 by De Vrij from Jamaica bark.

EARTH-NUT, OR GROUND-NUT, CAKE.*

BY RICHARD V. TUSON, F.C.S. LONDON AND BERLIN,

Professor of Chemistry and Toxicology in the Royal Veterinary College.

Having, in the course of my analytical practice, had occasion to examine some samples of Marseilles earth-nut cake, I take the opportunity of communicating the results obtained, in the hope of furnishing interesting information respecting a material which is chiefly employed in the sophis tication of the more expensive feeding cakes, but which I think might in some instances be with advantage substituted for them.

The seeds from which earth-nut cake is manufactured are the product of a leguminous plant growing in the East, and which, according to Lindley, is called the *Arachis hypogœa*, or under-ground kidney bean. It is so named from the circumstance of its pods forcing their way into the ground and there ripening.

Arachis seeds constitute one of the varieties of food termed pulse, and the oil, which exists in them to the extent of from 40 to 50 per cent., is much used in India as a substitute for olive oil. The oil is also an article of the Indian Pharmacopœia, and is rapidly being introduced in the making of soap in this and other countries.

By pressure the seeds yield all but about 7 per cent. of their oil, and the material which remains after the expression of the greater part of the oil is sent into commerce as earth-nut, or ground-nut, cake.

Sometimes the husks of the seeds are first removed and only the kernels subjected to pressure for the sake of the oil, the cake so produced is called "decorticated earth-nut cake," at other times the entire seeds are submitted to this treatment, and then the resulting cake is known as "undecorticated earth-nut cake."

The following table shows the composition in 100 parts of both descriptions of cake, as well as that of linseed cake of first rate quality; the last analysis being added for the sake of comparison.

Table showing the Centesimal Composition of Decorticated and Undecorticated Earth-Nut Cake and Linseed Cake.

		Decorticated Earth-nut cake.	Undecorticated Earth-nut cake.	Linseed cake.
Moisture		9·58	9·28	11·72
Fat and Heat producers	Oil	7·40	6·99	12·09
	Starch, digestible fibre, etc.	27·63	23·67	*25·29
Flesh-formers (Albumenoids)		†42·81	‡32·81	32·64
Indigestible fibre		7·87	23·80	11·79
Ash		4·71	3·45	6·47
		100	100	100

From the foregoing analyses it will be seen that both descriptions of earth-nut cake are exceedingly rich in flesh formers, and that they contain a moderately large amount of oil. They also possess a sweet agreeable flavour, and are, I believe, very digestible. As these may, I am informed, be bought at from £6 to £8 per ton, it is evident that farmers would do well to give earth-nut cakes a trial in the feeding of their stock.

SURFACE BIOLOGY.§

BY ALFRED RUSSEL WALLACE, F.R.G.S., F.L.S.

The range of subjects comprehended within this Section is so wide, and my own acquaintance with them so imperfect, that it is not in my power to lay before you any general outline of the recent progress of the biological sciences. Neither do I feel competent to give you a summary of the present status of any one of the great divisions of our science, such as Anatomy, Physiology, Embryology, Histology, Classification, or Evolution—Philology, Ethnology, or Prehistoric Archæology; but there are fortunately several outlying and more or less neglected subjects to which I have for some time had my attention directed, and which I hope will furnish matter for a few observations of some interest to biologists, and at the same time not unintelligible to the less scientific members of the Association who may honour us with their presence.

The subjects I first propose to consider have no general name, and are not easily grouped under a single descriptive heading; but they may be compared with that recent development of a sister science which has been termed Surface geology or Earth-sculpture. In the older geological works we learnt much about strata, and rocks, and fossils, their superposition, contortions, chemical constitution, and affinities, with some general notions of how they were formed in the remote past; but we often came to the end of the volume no whit the wiser as to how and why the surface of the earth came to be so wonderfully and

* Reprinted from the *Veterinarian*, October, 1876.

* Pure linseed cake does not contain starch, but in its stead mucilage. The feeding qualities of starch and mucilage are, however, very similar.

† Containing 6·85 of nitrogen.

‡ Containing 5·25 of nitrogen.

§ Presidental Address delivered to the Biological Section of the British Association, at Glasgow, on September 6th, 1876.

beautifully diversified; we were not told why some mountains are rounded and others precipitous; why some valleys are wide and open, others narrow and rocky; why rivers so often pierce through mountain-chains; why mountain lakes are often so enormously deep; whence came the gravel, and drift, and erratic blocks so strangely spread over wide areas while totally absent from other areas equally extensive. So long as these questions were almost ignored, geology could hardly claim to be a complete science, because, while professing to explain how the crust of the earth came to be what it is, it gave no intelligible account of the varied phenomena presented by its surface. But of late years these surface-phenomena have been assiduously studied; the marvellous effects of denudation and glacial action in giving the final touches to the actual contour of the earth's surface, and their relation to climatic changes and the antiquity of man, have been clearly traced, thus investing geology with a new and popular interest, and at the same time elucidating many of the phenomena presented in the older formations.

Now just as a surface-geology was required to complete that science, so a surface-biology was wanted to make the science of living things more complete and more generally interesting, by applying the results arrived at by special workers to the interpretation of those external and prominent features whose endless variety and beauty constitute the charm which attracts us to the contemplation or to the study of nature. We have the descriptive zoologist, for example, who gives us the external characters of animals; the anatomist studies their internal structure; the histologist makes known the nature of their component tissues; the embryologist patiently watches the progress of their development; the systematist groups them into classes and orders, families, genera, and species; while the field-naturalist studies for us their food and habits and general economy. But till quite recently none of these earnest students, nor all of them combined, could answer satisfactorily, or even attempted to answer, many of the simplest questions concerning the external characters and general relations of animals and plants. Why are flowers so wonderfully varied in form and colour? what causes the Arctic fox and the ptarmigan to turn white in winter? why are there no elephants in America and no deer in Australia? why are closely allied species rarely found together? why are male animals so frequently bright-coloured? why are extinct animals so often larger than those which are now living? what has led to the production of the gorgeous train of the peacock and of the two kinds of flower in the primrose? The solution of these and a hundred other problems of like nature was rarely approached by the old method of study, or if approached was only the subject of vague speculation. It is to the illustrious author of the 'Origin of Species' that we are indebted for teaching us how to study nature as one great, compact, and beautifully adjusted system. Under the touch of his magic wand the countless isolated facts of internal and external structure of living things—their habits, their colours, their development, their distribution, their geological history,—all fell into their approximate places; and although from the intricacy of the subject and our very imperfect knowledge of the facts themselves, much still remains uncertain, yet we can no longer doubt that even the minutest and most superficial peculiarities of animals and plants either, on the one hand, are or have been useful to them, or, on the other hand, have been developed under the influence of general laws, which we may one day understand to a much greater extent than we do at present. So great is the alteration effected in our comprehension of nature by the study of variation, inheritance, cross-breeding, competition, distribution, protection, and selection—showing, as they often do, the meaning of the most obscure phenomena and the mutual dependence of the most widely-separated organisms—that it can only be fitly compared with the analogous alteration produced in our conception of the universe by Newton's grand discovery of the law of gravitation.

I know it will be said (and is said), that Darwin is too highly rated, that some of his theories are wholly and others partially erroneous, and that he often builds a vast superstructure on a very uncertain basis of doubtfully interpreted facts. Now, even admitting this criticism to be well founded—and I myself believe that to a limited extent it is so—I nevertheless maintain that Darwin is not and cannot be too highly rated; for his greatness does not at all depend upon his being infallible, but on his having developed, with rare patience and judgment, a new system of observation and study, guided by certain general principles which are almost as simple as gravitation and as wide-reaching in their effects. And if other principles should hereafter be discovered, or if it be proved that some of his subsidiary theories are wholly or partially erroneous, this very discovery can only be made by following in Darwin's steps, by adopting the method of research which he has taught us, and by largely using the rich stores of material which he has collected. The 'Origin of Species,' and the grand series of works which have succeeded it, have revolutionized the study of biology; they have given us new ideas and fertile principles; they have infused life and vigour into our science, and have opened up hitherto unthought of lines of research on which hundreds of eager students are now labouring. Whatever modifications some of his theories may require, Darwin must none the less be looked up to as the founder of philosophical biology.

As a small contribution to this great subject, I propose now to call your attention to some curious relations of organisms to their environment, which seems to me worthy of more systematic study than has hitherto been given them. The points I shall more especially deal with are—the influence of locality, or of some unknown local causes, in determining the colours of insects, and, to a less extent, of birds; and the way in which certain peculiarities in the distribution of plants may have been brought about by their dependence on insects. The latter part of my address will deal with the present state of our knowledge as to the antiquity and early history of mankind.

On some Relations of Living Things to their Environments.

Of all the external characters of animals, the most beautiful, the most varied, and the most generally attractive are the brilliant colours and strange yet often elegant markings with which so many of them are adorned. Yet of all characters this is the most difficult to bring under the laws of utility or of physical connection. Mr. Darwin—as you are well aware—has shown how wide is the influence of sex on the intensity of coloration; and he has been led to the conclusion that active or voluntary sexual selection is one of the chief causes, if not the chief cause, of all the variety and beauty of colour we see among the higher animals. This is one of the points on which there is much divergence of opinion even among the supporters of Mr. Darwin, and one as to which I myself differ from him. I have argued, and still believe, that the need of protection is a far more efficient cause of variation of colour than is generally suspected; but there are evidently other causes at work, and one of these seems to be an influence depending strictly on locality, whose nature we cannot yet understand, but whose effects are everywhere to be seen when carefully searched for.

Although the careful experiments of Sir John Lubbock have shown insects can distinguish colours—as might have been inferred from the brilliant colours of the flowers which are such an attraction to them—yet we can hardly believe that their appreciation and love of distinctive colours is so refined as to guide and regulate their most powerful instinct—that of reproduction. We are therefore led to seek some other cause for the varied colours that prevail among insects; and as this variety is most conspicuous among butterflies—a group perhaps better known than any other—it offers the best means of studying the subject. The variety of colour and marking among these insects is something marvellous. There are probably about ten thousand different kinds of butterflies now known, and about half of these are so distinct in colour and marking that they can be readily distinguished by this means alone. Almost every conceivable tint and pattern is represented, and the hues are often of such intense brilliance and purity as can be equalled by neither birds nor flowers.

Any help to a comprehension of the causes which may have concurred in bringing about so much diversity and beauty must be of value; and this is my excuse for laying before you the more important cases I have met with of a connection between colour and locality.

Our first example is from tropical Africa, where we find two unrelated groups of butterflies belonging to two very distinct families (Nymphalidæ and Papilionidæ) characterized by a prevailing blue-green colour not found in any other continent.* Again we have a group of African Pieridæ which are white or pale yellow with a marginal row of bead-like black spots; and in the same country one of the Lycænidæ (*Leptena erastus*) is coloured so exactly like these that it was at first described as a species of *Pieris*. None of these four groups are known to be in any way specially protected, so that the resemblance cannot be due to protective mimicry.

In South America we have far more striking cases; for in the three subfamilies *Danainæ, Acræinæ* and *Heliconiinæ*, all of which are specially protected, we find identical tints and patterns reproduced, often in the greatest detail, each peculiar type of coloration being characteristic of distinct geographical subdivisions of the continent. Nine very distinct genera are implicated in these parallel changes—*Lycorea, Ceratinia, Mechanitis, Ithomia, Melinæa, Tithorea, Acræa, Heliconius,* and *Eueides*, groups of three or four (or even five) of them appearing together in the same livery in one district, while in an adjoining district most or all of them undergo a simultaneous change of coloration or of marking. Thus in the genera *Ithomia, Mechanitis,* and *Heliconius*, we have species with yellow apical spots in Guiana, all represented by allied species with white apical spots in South Brazil. In *Mechanitis, Melinæa* and *Heliconius*, and sometimes in *Tithorea*, the species of the Southern Andes (Bolivia and Peru) are characterized by an orange and black livery, while those of the Northern Andes (New Granada) are almost always orange-yellow and black. Other changes of a like nature, which it would be tedious to enumerate, but which are very striking when specimens are examined, occur in species of the same groups inhabiting these same localities, as well as Central America and the Antilles. The resemblance thus produced between widely different insects, is sometimes general, but often so close and minute that only a critical examination of structure can detect the difference between them. Yet this can hardly be true mimicry, because all are alike protected by the nauseous secretion which renders them unpalatable to birds.

In another series of genera (*Catagramma, Callithea,* and *Agrias*), all belonging to the Nymphalidæ, we have the most vivid blue ground, with broad bands of orange-crimson or a different tint of blue or purple, exactly reproduced in corresponding, yet unrelated species, occurring in the same locality; yet, as none of these groups are protected, this can hardly be true mimicry. A few species of two other genera in the same country (*Eunica* and *Siderone*) also reproduce the same colours, but with only a general resemblance in the marking. Yet, again, in Tropical America we have species of *Apatura* which, sometimes in both sexes, sometimes in the female only, exactly imitate the peculiar markings of another genus (*Heterochroa*) confined to America; here, again, neither genus is protected, and the similarity must be due to unknown local causes.

But it is among islands that we find some of the most striking examples of the influence of locality on colour, generally in the direction of paler, but sometimes of darker and more brilliant hues, and often accompanied by an unusual increase of size. Thus in the Moluccas and New Guinea we have several Papilios (*P. euchenor, P. ormenus,* and *P. tydeus*) distinguished from their allies by a much paler colour, especially in the females, which are almost white. Many species of *Danais* (forming the subgenus *Ideopsis*) are also very pale. But the most curious are the Euplœas, which in the larger islands are usually of rich dark colours, while in the small islands of Banda, Ké, and Matabello at least three species not nearly related to each other (*E. hoppferi, E. euripon,* and *E. assimilata*) are all broadly banded or suffused with white, their allies in the larger islands being all very much darker. Again, in the genus *Diadema*, belonging to a distinct family, three species from the small Aru and Ké islands (*D. deois, D. hewitsonii,* and *D. polymena*) are all more conspicuously white-marked than their representatives in the larger islands. In the beautiful genus *Cethosia*, a species from the small island of Waigiou (*C. cyrene*) is the whitest of the genus. *Prothoë* is represented by a blue species in the continental island of Java, while those inhabiting the ancient insular groups of the Moluccas and New Guinea are all pale yellow or white. The genus *Drusilla*, almost confined to these islands, comprises many species which are all very pale; while in the small island of Waigiou is found a very distinct genus, *Hyantis*, which, though differing completely in the neuration of the wings, has exactly the same pale colours and large ocellated spots as *Drusilla*. Equally remarkable is the fact that the small island of Amboina produces larger-sized butterflies than any of the larger islands which surround it. This is the case with at least a dozen butterflies belonging to many distinct genera,* so that it is impossible to attribute it to other than some local influence. In Celebes, as I have elsewhere pointed out,† we have a peculiar form of wing and much larger size running through a whole series of distinct butterflies; and this seems to take the place of any speciality in colour.

From the Fiji Islands we have comparatively few butterflies; but there are several species of *Diadema* of unusually pale colours, some almost white.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, OCTOBER 21, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

XANTHIUM SPINOSUM.

SOME little interest having been excited with respect to the *Xanthium spinosum*, which has lately been lauded as a remedy for hydrophobia, it may be of use to our readers to present them with a short description of the plant, and such particulars as may help those who are called upon to make preparations of it, to obtain and recognize the right plant.

Xanthium spinosum, L., is a common weed in the south of Europe, growing in waste places, at the foot of walls, and by roadsides. In this country it is not a native and is very rare, but it has been found in waste places near Kenilworth and Hereford, and in Wales. The stem grows from 2 to 3 feet high, and is branched at the base. The dark green leaves, greyish-white beneath, and the long yellow spines at the base of the leaves at once mark out the plant. The leaves are alternate, from 2 to 4 inches long, and about ½ to 1 inch broad in the middle, and taper at both ends. About the middle of the leaf there are two or more teeth, usually one on each side of the leaf, which thus give the lower half of the leaf a wedge-shaped outline. The leaf is dark green above, with a distinct midrib, and usually two well marked lateral veins, one running to each tooth. These veins are whitish, and contrast strongly with the dark green colour of the leaf. The under side of the leaf is white and downy.

On each side of the base of the leaf, and occupying the place of stipules, are sharp yellow spines, usually in pairs; each spine is branched into three from near its base like that of the barberry, but the bright yellowish colour and polished appearance render them much more conspicuous.

The plant belongs to the Compositæ, but is a somewhat anomalous member of that large and usually well marked family. It is remarkable for having monœcious capitula and for the pistillate capitulum consisting of only one or two flowers: these are without a corolla and are enclosed in an involucre, the scales of which become welded together into what looks like a capsular fruit. This capitulum is about the size of a horsebean or rather larger, and is sessile either in or near the axils of the leaves. When the capitulum occupies the place of the stipule it usually replaces the branched spine on the side on which it occurs. It is covered with small hooked bristles, which are about half as long as the capitulum is wide.

The plant flowers in July and August and could probably be obtained from any port in the south of France or Italy. A specimen of the plant, collected near Kenilworth by Mr. A. WHEATLEY, is in the Herbarium of the Pharmaceutical Society, Bloomsbury Square.

It will be remembered that in a paper printed in this Journal a few weeks since (before, p. 249), M. GUICHARD gave the results of treatment of the plant with alcohol and with water, and that from these he was induced to believe that an alcoholic extract would probably prove the most active preparation. M. GUICHARD also considered that his experiments demonstrated the presence of an alkaloid, which, however, he had not succeeded in isolating. Since then, in a note on the analysis of *Xanthium spinosum* M. YVON has expressed a doubt as to the existence of such an alkaloid, he considering the indications that might lead to such a supposition to be due to a resin, soluble in ether and in alcohol, which occurs to the extent of two per cent. M. YVON found 76½ per cent. of organic matters (including 10 per cent. of starch), 11½ per cent. of mineral matters, and 12 per cent. of moisture.

ERYTHROXYLON COCA.

THE uses of the leaves of the coca plant (*Erythroxylon coca*) have occupied so much attention of late that some details on the characters of the different kinds and of the traffic in these leaves may be of interest. The coca plant, as is well known, is very largely grown in Peru. Peru nevertheless takes large quantities from Bolivia, where the coca is said to be of a much superior quality; to such an extent are the Peruvian purchases that in one year the value of introduced coca amounted to 205,600 francs. In the two provinces of Salta and Jujui the consumption is enormous; in the former it is usually sold for seven francs the pound of sixteen ounces, but the price varies according to the quality and condition of the harvest; latterly, however, the price has risen considerably and the cultivation has very much extended.

Thus, though coca is chiefly at the present time used in Peru and Bolivia, and in the two provinces of Salta and Jujui in the Argentine Confederation, it is being gradually introduced into other provinces, and it is considered very probable that in a few years its use may extend over the whole of the Argentine Republic. It has been asserted that coca is used as a currency in Peru, but this seems doubtful; indeed, modern travellers do not mention it as a fact. It has also been stated that the revenues of the cathedral of Cuzco were entirely derived from the tithes on coca. With regard to quality, the best coca is said to be produced in the province of Yungas. Some of it is sold at a very high price; the most inferior quality is that produced in Peru. Good quality coca should have its leaves unbroken, of a medium size, bright green in colour, and of an odour somewhat combining those of hay and chocolate. The taste is bitter, and when masticated coca is said to yield easily to the teeth. Infused in hot water it has a beautiful green colour, which, however is much darker from inferior leaves. A decoction made in the form of tea is said to have a pleasant taste peculiar to itself. An infinite number of varieties are recognized between the best and the lowest quality, which has a disagreeable smell and a colour resembling roasted coffee. The leaves are also bent and broken, scarcely a whole leaf being found amongst them. It is stated that the numerous varieties "cannot be distinguished except by connoisseurs, who bring to this matter a delicate taste, acquired by indulging in a luxury and studying its effects for many years. The inexperienced European druggist who wishes to deal in coca must judge it by its two most appreciable qualities, the green colour, and the small delicate leaf."

CHINESE VIEWS ON ENGLISH PHARMACY.

Now and then, when English pharmacists have been favoured with a glimpse of the style of Pharmacy that obtains favour with their Celestial brethren, their interest has been somewhat tinged with surprise and amusement at the nature of some of the preparations. But a letter from the Shanghai correspondent of *The Times*, published last week, seems to indicate that the Chinese have been enjoying a *quid pro quo* in this respect. It appears that an anti-Christian book, called the "Ki-Kinglu," has been published in the province of Szechuen, in which it is stated that the skill and intelligence of foreigners have been obtained by robbing the Chinese. One method of doing this, it is there represented, has been the making of an extract from the eyes of Chinese who have become Christians, and touching the eyes of foreigners with it, by which they have been enabled to understand astronomy and perceive the mineral wealth of the earth. Another valuable medicine for the promotion of intelligence has had for one of its ingredients the brains of a Chinese girl who has embraced Christianity. Other medicines have been mixed with the brains and the compound made up into pills, which received their final touch in the shape of certain incantations instead of a sugar coating. The *bona fides* of the author is attested by his statement that he has himself lived three years in England, during which time he had three princesses given him to wife by the Queen, and that he was only permitted to return to China upon giving a promise not to expose the improprieties he had witnessed in this country.

A PRICE LIST FOR THE WEST OF ENGLAND.

At a large and influential meeting of the Chemists and Druggists of Plymouth, Devonport, and Stonehouse, held at Plymouth at the end of June last, it was resolved to form a Chemists and Druggists' Association for the district, and Mr. F. Codd was elected President, Mr. A. P. Balkwill, Vice-President, and Mr R. J. Clark, Honorary Secretary and Treasurer. One of the first things done by the new Association was to send an invitation to the British Pharmaceutical Conference to meet next year at Plymouth, which was accepted. Another resolution was that a Price List should be published. The work of compiling this List was entrusted to a committee, by whom it had been promptly issued with a wish—which we fully endorse—that as the prices adopted in it are fairly remunerative, it will prove acceptable to the trade and be widely adopted and generally adhered to. Where the prices suggested are higher than those hitherto obtained it is not expected that an immediate and abrupt advance shall be made, but that each chemist and druggist shall endeavour to work as nearly as possible up to the standard, so that some approach to uniformity may be gained. One useful piece of advice is also given, that, when necessary, the public should be given to understand that, dispensing being skilled labour of a high class, involving the gravest responsibility, the mere retail price of the ingredients in a prescription would be very inadequate remuneration to the competent dispenser. We congratulate the young Association on the vigorous signs of life it is showing.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

A circular has been issued by the Council of the above Association announcing the following arrangements:—(1) That a "Tutorial Class" for instruction in English, Arithmetic, and Latin, conducted by Mr. Archibald Fairlie, C.M., will be held on Tuesday and Friday evenings, from 8·45 to 10·45 o'clock, from the beginning of November to the end of April; fee for the entire course, 10*s.* 6*d.* (2) A Practical and Theoretical Pharmaceutical Chemistry Class will be held under the superintendence of Dr. A. T. Machattie, on Tuesday and Thursday evenings, from 8·30 to 10 o'clock, from the beginning of November to the end of April; fee for the course, £2 2*s.* Should there be a satisfactory number of entries to the above classes, a Materia Medica and Pharmacy Class will be commenced early in the New Year, and a Botany Class in the Spring. The opening meeting of the Association for the session will be held on Wednesday, November 8th, when the introductory address will be delivered by the President, Mr. Daniel Frazer.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The First Meeting of the above Association for the session of 1876-77 will be held at 17, Bloomsbury Square, on Thursday evening, October 26th, Professor Attfield, President, in the chair.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

October 2, 1876.

Two hundred and thirty-five candidates presented themselves for examination of whom *one hundred and twenty* failed. The following *one hundred and fifteen* passed and have been duly registered as Apprentices or Students (arranged alphabetically):—

Adamson, Wm. Stuart............Edinburgh.
Akers, John ....Leighton Buzzard.
Allison, William Alfred ....Harrogate.
Appleyard, John ....Bradford, Yorks.
Atkins, Alfred Edward ....Newport, Mon.
Audus, William George ....Dumbarton.
Austin, Alfred ....Birmingham.
Bailey, John Henry...............Wanstead.
Barnett, Walter James ....Coventry.
Beckett, Harry Rumbold ......London.
Beckett, Louis ....London.
Bellingham, Benjamin............Dawley.
Blakie, James A. ....Newbury.
Blaylock, Richard ....Maryport.
Bloodworth, Thomas ....Bourn.
Bright, Richard H. D.............Peterborough.
Caldecott, Clement Guest ......Whitchurch, Salop.
Carter, Henry Ayling ....Winchester.
Clarke, Richard ....Ruthin.
Clarke, Wm. Henry...............Sleaford.
Clayton, John William ....Preston.
Colam, Fred.........................Hull.
Coleclough, John Arthur.........Tiverton.
Colegrove, John Thomas F......Liverpool.
Cooper, George Townson.........Church.
Cutmore, Frank ....Totnes.
Dix, James Edward...............Croydon.
Dyer, Sidney Reginald............Chiswick.
Elstob, John ....Richmond, Yorks.
Evans, Richard.....................Dinas Mawddwy.
Farnsworth, Percy Harrison ...Codnor.
Fisher, John Hutcheson ....Edinburgh.
Fleming, Ebenezer ....Castle Douglas.
Foster, Morris ....London.
Foster, William.....................Dewsbury.
France, James Mead ....Clapham.
Gordon, William George ....Aberdeen.
Granger, Harold ....Nottingham.
Griffiths, John ....Carmarthen.
Griffiths, John ....Newcastle Emlyn.
Guest, George Robert ....Brentwood.
Gwyn, William Alexander ......Taunton.
Hague, Fred..........................Lees.
Hall, John Thomas ....Manchester.
Heath, Robert Philip ....Norwich.
Heynes, Sydney Gawler ....Bromsgrove.
Holifield, Edward Joseph ......Faringdon.
Houfe, Robert William ....York.
Hughes, Edward ....Sarn.
Hughes, Evan ....Chelmsford.
Hughes, James ....Liverpool.
Humble, Charles Henry ....London.
Hunter, William ....Stockton-on-Tees.
Innes, David.........................Stalybridge.
Joyner, Arthur George ....Cheltenham.
Lowe, Moses H. ....Great Barr.
Lowe, Sam. Peter ....Sheffield.
Loxton, James Stokes ....Cannock.
Lyon, Thomas ....Edinburgh.
Marshall, Percy Wm. ....Uxbridge.
Martland, Thomas ....Wigan.
Mathias, James R. H.............Tenby.
Matthews, Charles William......London.
Metcalf, Rowland Alfred.........Uxbridge.
Millson, William Jarvis ....Boston.
Morkill, Arthur James ....Leicester.
Nance, William Clarke de ......Glasgow.
Nethercott, Walter John.........Stroud.
Norman, William Francis ......Towcester.
Owen, Robert ....Dowlais.
Parish, Henry ....Birmingham.
Peat, Joseph ....Accrington.
Perkins, Thomas Frampton ...Bristol.
Pilsbury, William..................Eccleshall.
Pope, Albert Harry ....Southport.
Power, William.......................Greenwich.
Presbury, Herbert Henry ......London.
Radford, James Alfred ....Birmingham.
Rees, David ....Haverfordwest.
Richards, John William ....Pontypridd.
Sagar, Hartley ....Nelson-in-Marsden.
Shacklock, James Harvey ......South Cave.
Shaw, Frank...........................Nottingham.
Silk, Thomas..........................Burton-on-Trent.
Smith, Frederic William ....Wellington (Salop).
Smith, Norman Sellers ....Birmingham.
Snell, Charles James B. V. C...Brookwood.
Stableforth, John William ......London.
Steel, Alexander ....Torquay.
Stevens, Charles ....Upper Norwood.
Stevens, Robert ....Bristol.
Stott, Walter Henry ....Wednesbury.
Stredwick, Augustus ....Bristol.
Suart, George ....Lancaster.
Sumner, John ....Wilmslow.
Swan, Michael Edward ....London.
Taggart, Herbert Wm. Ashton.Manchester.
Taylor, Arthur Bertie ....Sheffield.
Thomas, James Morris............Whitland.
Thomas, Joseph Arden ....Cambridge.
Thompson, Arthur Stevens......Barking.
Thompson, Frederic ....Scarborough.
Trezise, William Augustus .....Sheffield.
Trickey, Robert Harding.........Weston-super-Mare.
Tyndall, Francis ....Newcastle, Staffs.
Tyson, Thomas Balmforth ......London.
Walker, Charles ....Birstwith.
Warrell, Edmund ....London.
Watts, John Manning ....London.
Williams, James Boden ....Manchester.
Williams, William Jesse ....Crickhowel.
Wilson, Samuel.......................Hanley.
Wood, William Arlington ......Bradford.
Worts, Harry Augustine.........Harwich.
Young, William Ferguson ......Elgin.

First or Preliminary Examination.

October 2, 1876.

(*Time allowed: Three hours for the three subjects*).

I. LATIN.

1. Translate into English:—Genus hoc erat pugnæ, quo se Germani exercuerant. Equitum millia erant sex: totidem numero pedites velocissimi ac fortissimi; quos ex omni copia singuli singulos, suæ salutis causa, delegerant. Cum his in prœliis versabantur, ad hos se equites recipiebant: hi, si quid erat durius, concurrebant: si qui, graviore vulnere accepto, equo deciderant, circumsistebant: si quo erat longius prodeundum, aut celerius recipiendum, tanta erat horum exercitatione celeritas, ut, jubis equorum sublevati, cursum adæquarent.

2. Decline throughout *genus, pugnæ, equites, cursum,* and together *graviore vulnere.*

3. Select in the above passage the adjectives and adverbs which are in the comparative or the superlative degree, and give the three degrees of comparison in each instance.

4. Give the present, the infinitive, the perfect, and the supine of *exercucrant*, *delegerant*, *recipiebant*, *concurrebant*.

5. In what case will you put the place (*a*) *where*; (*b*) *whither*; (*c*) *whence*?

II. ARITHMETIC.

(The working of these questions, as well as the answers, must be written out in full).

6. Find the value of 3 oz. 5 drams 2 scruples at £1 6*s*. 8*d*. per oz.

7. Simplify $\frac{\frac{21}{22}}{97} \div \frac{2}{3} \times \frac{7}{13}$.

8. Reduce $\frac{10}{21}$ to a decimal. Divide 3·7514 by ·067.

6. Define the *gramme* and the *litre* of the Metric System. How many cubic inches does the *litre* contain?

10. What is the sum of $\frac{1}{7}$th of a yard, $\frac{1}{7}$th of a foot, and $\frac{1}{7}$th of an inch? Express the answer—1st, in inches; 2nd, as a fraction of a yard; 3rd, as a decimal of a yard.

III. ENGLISH.

11. How does an adjective differ from an adverb?

12. Give the past indefinite tense, and the complete participle of each of the following verbs: *sting*, *shoe*, *fly*, *flee*, *lay*.

13. Parse the following lines:—

> "We look before and after,
> And pine for what is not:
> Our sincerest laughter
> With some pain is fraught."

14. Write a short account of William the Conqueror, *or* Queen Elizabeth, *or* a short essay on Coal, *or* Telegraphs, *or* the War in Turkey.

The following is a list of the Centres at which the examination was held, showing the number of Candidates examined at each Centre, and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	3	1	2	Leeds	11	5	6
Aberystwith	1	1	0	Leicester	3	1	2
Barnstaple	1	0	1	Lincoln	3	1	2
Birmingham	28	11	17	Liverpool	6	1	5
Boston	2	1	1	London	45	26	19
Brighton	4	0	4	Macclesfield	1	0	1
Bristol	6	4	2	Manchester	13	8	5
Cambridge	4	2	2	Newcastle	4	0	4
Canterbury	1	0	1	Northampton	1	1	0
Cardiff	3	2	1	Norwich	2	1	1
Cardigan	2	1	1	Nottingham	3	3	0
Carlisle	4	1	3	Oxford	2	1	1
Carmarthen	4	4	0	Peterborough	1	1	0
Carnarvon	1	1	0	Plymouth	3	1	2
Cheltenham	2	2	0	Preston	7	4	3

Inverness	1	1	0	Worcester	3	1	2
Leamington	1	0	1	York	4	1	3

Addendum.—To the list of persons on p. 298, col. i., to whom a Certificate of Merit was awarded in respect to the Ten Months' Course in Botany and Materia Medica, add—Thomas Ridgley.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The annual meeting of the twenty-seventh session of the Liverpool Chemists' Association was held at the Royal Institution, September 28, the President, Mr. A. H. Mason, F.C.S., in the chair.

After confirmation of the minutes of the previous meeting, the Honorary Secretary, Mr. Thomas Williams, F.C.S., read the report of the council for the past session, of which the following is an abstract:—

In reviewing the proceedings of the twenty-seventh session of the Liverpool Chemists' Association, the council congratulated the members upon its steady progress. It was stated that the great impetus which has been given of late years to scientific inquiry had evidently extended itself to the business of the meetings, and that the session had been marked by increased activity and a larger attendance. During the past session one honorary member, seventeen ordinary members, and one associate, had been elected, and one of the most esteemed honorary members, Dr. Inman, had died. The council also paid a tribute to the memory of one of the founders of the Association, Mr. Robert Clay, who had been called away, and who was president during the first two sessions of its existence. The chemistry classes in connection with the School of Pharmacy had been conducted by Mr. Thomas Williams, F.C.S., and the number of students had been above the average of recent sessions. An examination had been conducted, in which Mr. W. H. Edwards had been the successful candidate, and he had since passed the Minor examination of the Pharmaceutical Society. By permission of the committee of the Liverpool Royal Infirmary School of Medicine, students of the Liverpool School of Pharmacy had been admitted to the lectures on botany conducted by Dr. Carter, and the lectures on materia medica conducted by Dr. Nevins. The papers read at the meetings and the published proceedings of the Association were reported to have attracted more than usual interest, and much information had been elicited during the discussions which followed. Miscellaneous contributions, which have always formed an attractive feature of the proceedings, have been numerous and valuable, some original. The question box had been used more frequently during the session.

The museum had been enriched by a handsome contribution of specimens of rare chemicals, from Messrs. T. Morson and Son, of London; by a valuable collection of opium alkaloids and their derivatives, from the President, and several novelties from the discoverers or proprietors. The librarian reports that 230 books have been taken out during the session. The twelfth conversazione is considered to have been a success, and the council expressed its indebtedness to several scientific friends for their services.

A suggestion that it may be desirable to alter the title of the Association had received the consideration of the council, but it was felt to be a question to be decided by the members. The following members of council retired by rotation:—Messrs. Armstrong, Davies, Murphy and Williams.

The treasurer presented his report of the finances of the Association, which showed a credit balance of £3 11*s*. 1*d*.

The President moved "That the reports, as read, be adopted, and, together with the list of members and abstract of proceedings of the past session, be printed and circulated among the members." He reviewed the various paragraphs in the report, and impressed upon the members the importance of doing their utmost to maintain the position of the Association, inviting the students to use all diligence to render the session of the School of Pharmacy successful. He also congratulated the Association upon the success of the past session, and upon the satisfactory change in the condition of the finances of the Association.

Mr. W. H. Edwards seconded the motion, which was carried *nem. con.*

The meeting then proceeded to the election of four members of council. Messrs. E. Davies, F.C.S., Thomas Williams, F.C.S., James T. Armstrong, F.C.S., and Martin Murphy, F.C.S., were duly elected.

Mr. Joseph Woodcock moved "That the best thanks of the meeting be given to the donors to the library and museum, and to the authors of papers during the past session."

Mr. E. Davies, F.C.S., seconded the motion, which was carried unanimously.

Mr. Haddock moved—"That the best thanks of the meeting be given to the officers and council for their services during the past session."

Mr. E. F. Morton seconded the motion which was carried by acclamation.

The President, Treasurer, and Honorary Secretary returned thanks.

The President then presented to Mr. W. H. Edwards the prize awarded by the council for chemistry. It consisted of a handsomely re-bound copy of Hanbury and Flückiger's 'Pharmacographia."

This concluded the business of the session.

The first general meeting (twenty-eighth session) was held at the Royal Institution, Colquitt Street. The President, Mr. A. H. Mason, F.C.S., in the chair.

After the minutes of the previous meeting had been read and signed, the Honorary Secretary announced the list of officers for the session.

President, Mr. A. H. Mason, F.C.S.; Vice-President, Mr. Joseph Woodcock; Council, Messrs. J. Abraham, J. T. Armstrong, F.C.S., E. Davies, F.C.S., Charles Jones, Martin Murphy, F.C.S., E. W. Parnell, F.C.S., A. Redford and J. Shaw; Hon. Treasurer, Mr. R. Sumner, 50, Lord Street; Hon. Sec., Mr. Thomas Williams, F.C.S., 23, Lord Street.

The donations received during the recess were announced and the thanks of the Association unanimously accorded to the donors.

Messrs. Conroy, Sumner, Bevan, Hughes, and Longshaw, were elected members. Messrs. Evans, Ellis, and Taylor, associates.

The President then delivered his inaugural address.

President's Address.

Gentlemen,—As the first occupant of this chair elected by the members of your Association under the altered law, permit me to thank you most sincerely for the elevated position which by your kindness I have the honour to hold. Labouring under a deep sense of my obligation to you and feeling the additional responsibility of delivering an address under these circumstances worthy your Association, I crave your indulgence, conscious of my insufficiency to discharge the duties of so important an office.

During the twenty-seven years your Association has been established it has experienced the various vicissitudes of time and progress. The records show that in 1855 half the members and associates of the Pharmaceutical Society of Great Britain in this neighbourhood were members of this Association, and it was at that time your museum was formed. For this object a grant of fifty pounds was made by the Council of the Pharmaceutical Society, subject to the condition that the members and associates of the Pharmaceutical Society have free access to the museum. This privilege was granted by the Committee of the Royal Institution, subject to the applicants holding an admission from our Secretary. This donation was about one-fourth the cost of the museum; other donations of money and specimens were liberally provided by pharmacists, chemists and druggists, medical men, and scientific and manufacturing chemists in the town and neighbourhood. Your library was built up by donations of books from the same sources and from the funds of the Association. At first your assumed objects were strictly pharmaceutical, and your government was confined exclusively to chemists and druggists, but the papers read were not all of this nature, and I find your circulars after 1855 announced "meetings" and "pharmaceutical meetings;" hence outsiders lectured and read papers and were eventually admitted as members, and it is probable had not this been the case that your Association would not have maintained the high position and scientific reputation it now holds. Its constitution, perhaps fortunately, is now almost as comprehensive as the science with which we are so intimately associated. At the same time it still fills its mission and provides quite as much information for the pharmacist as it did formerly. Having suggested the desirability of altering our title you will at once perceive my object in the foregoing observations. I have on previous occasions stated reasons for my suggestion; since then it has been decided to form one hundred and thirty chemists' associations throughout the kingdom, united in one object—self-defence and protection of trade interests. I now leave this matter entirely in your hands, simply stating that probably substituting the word "society" for association would accomplish the desired result. We stand now in connection with the Pharmaceutical Society as an educational body (having a recognized school of pharmacy), and related to the Pharmaceutical Conference, and the Chemical Society of London, in the various qualifications of our members and in the practical results of our meetings.

Having thus far trespassed upon your time, I purpose inviting your attention now to some of the more important results of the investigations which are of interest to us, which have been announced since I had the honour to address you twelve months ago; and although I fear I can only refer to what is well known to you, I hope we may all profit by freshening our memories and perhaps be stimulated to follow up the investigations of some of those champions of our profession of whom we may well feel proud.

Salicin and Salicylates have occupied considerable attention, the announcement that salicin was proved a specific against rheumatism caused the demand for that substance to be greatly in excess of previous production. Hence an enormous advance in pecuniary value, and as fresh supplies cannot be produced until the spring, probably the administration of salicylic acid as a substitute was suggested. You are aware that according to Laveran and Millon (*Ann. Ch. Phys.* [3], xiii. 145) that after the ingestion of salicin into the animal body, salicylol and salicylic acid are found in the urine.

Salicin ($C_{13}O_{18}O_7$) (Leroux, *Ann. Ch. Phys.* [2], xliii., 446) exists ready formed in the barks of several species of willow (17) and poplar. It appears also to be contained in the flower buds of meadowsweet (*Spiræa ulmaria*) and in the green parts of this and other herbaceous spiræas, inasmuch as these plants yield salicylol by distillation with water (Buchner, *N. Repert. Pharm.* ii. 1). Salicin is produced artificially in several ways, see 'Watts,' vol. v. 147).

Salicylic Acid ($C_{14}H_{10}O_4$) may be obtained in various ways. The specimens I exhibit are (*a*) from Ol. gaultherii (oil of wintergreen) in which it exists as salicylate of methyl. The oil is heated with strong potash ley till no more methylic alcohol is given off from it and the residue is precipitated with hydrochloric acid; the precipitate is washed with cold water and crystallized from alcohol. (*b*) Artificial salicylic acid from phenol, by Kolbe's patent process, to which I alluded in my address last year. English physicians have been testing the efficacy of this medicine, and Dr. Maclagan of Dundee, and others, have clearly proved its efficacy, whilst the observations of

Fürbunger, Reiss, Tischer and Stricker have proved that salicylic acid is equally efficacious. On the other hand, English experimenters object to salicylic acid on account of its being caustic, and causing irritating sensations in the throat. (Probably artificial salicylic acid has been used.) As a remedy against this the substitution of sodic salicylate, or of salicylic acid combined with carbonate or phosphate of soda, has been experimented with, and on account of its being soluble and much less nauseous is preferable. At the same time experiments made by Mr. John Williams, F.C.S.,* show that the artificial productions are not easily obtained at present of definite constitution. He therefore suggests *sulphosalicylate of sodum* as a substitute, and in the paper referred to details his method for production. Salicylic acid and its salts give as is well known a striking reaction with perchloride of iron, producing a dark purple coloration. The sulphosalicylates produce exactly the same reaction, proving that the salicylic acid radical is still intact in the compounds, and it is fair to infer that the medicinal properties of these sulpho-salts will be found in practice to be identical with or perhaps superior to simple salicylates.

Kolbe's artificial acid has proved a commercial success, its efficacy as an antiseptic and to arrest fermentation being established.

Alkaloids of Aconitum Napellus.—Dr. Wright has renewed his chemical examination of aconite, and the ultimate conclusion he arrives at is, that the method which ought to be adopted for the production of a pharmaceutical product of constant composition and properties is 1st, percolation by alcoholic tartaric acid and evaporation to a small bulk of the percolate at as low a temperature as possible, probably in a vacuum pan would be best; 2nd, crystallization from ether of the base separated by sodium or potassium carbonate from the aqueous solution of the extract, after separation of resin, etc.; in this way the crystallizable alkaloid if present will be separated; and 3rd, participation by conversion of the crystalline salt, for which purpose the hydrobromide is well fitted; in this way small quantities of another base which obstinately adheres to aconitine when crystallized from ether are separated. The base obtained in this way is a simple body expressed by the formula $C_{33}H_{43}NO_{12}$ in a state of great purity and possessing high physiological activity.†

Erythroxylon Coca.—Whether this is likely to become an important article of materia medica, or not, remains to be proved. Sir Robert Christison has published some interesting details respecting its action, and is, I believe, making further practical investigations. Its chemical analysis shows that it contains a crystallizable basic substance, *cocaine*; a volatile odoriferous alkaloid, *hygrine*; a peculiar tannin, *coca-tannic acid*; a waxy body named coca wax. It is also said to contain a substance analogous to *theine*. To an exhaustive paper by Mr. B. Shuttleworth I refer you for further information.‡

Gelsemium sempervirens.—Chemical examination shows that it contains an alkaloid, *gelsemine* ($C_{11}H_{19}NO_2$), and an organic acid, isolated by Dr. Wormsley, which he named *gelseminic acid*, but Sonnenschein has proved that this acid is perfectly identical with æsculin, and has the formula ($C_{30}H_{34}O_{19}$).§

Jaborandi.—Continuing Gerrard's investigations, Kingzett has proved the formula of pilocarpine to be $C_{23}H_{34}N_4O_4$, and has discovered and analysed a crystalline salt of formula $C_{23}H_{34}N_4O_4 2HCl,PtCl_4$.

Aloin.—Dr. Tilden‖ has proved that this substance, whether obtained from Barbadoes, Socotrine, or Natal aloes, has the chemical composition $C_{16}H_{18}O_7$; this substance has been worked upon by chemists abroad with very trifling deviation from the same result. Mr. Dobson, M.R.C.S., has tested the therapeutic value and concludes that all three are decidedly uncertain and variable in their action, and that they seem to possess no advantage over an equal dose of aloes, excepting, perhaps, that griping was rather less common than when aloes alone were given.

Capsaicin.—Thresh has isolated this active principle of capsicum fruit, but has not yet given its formula.

Cortex Rhamni Frangulæ.—The fact that this bark requires to have been gathered twelve months before its therapeutic virtues are developed is rather remarkable, and suggests that it may be a desirable substance for chemical investigation,

Ergot.—Tanret claims to have discovered the active principle of ergot, a new alkaloid which he designates *ergotinine*. Professor Dragendorff does not agree that this represents a chemically distinct substance, and states that the active principle is an acid which he names *sclerotic acid.*

Opium Derivatives.—Beckett and Wright still continue their valuable researches on the opium bases, from which we trust in time to learn the constitutional formula of these interesting compounds. I called your attention to these researches as far as they had gone, last year; since then "narcotine" ($C_{22}H_{23}NO_7$), "cotarnine" ($C_{12}H_{13}NO_3$), hydrocotarnine ($C_{12}H_{15}NO_3$) have been investigated by them, and their experiments show that it may be inferred that these bases yield definite ethiodides and other ethyl compounds like most other alkaloids, and that they are nitril bases. In these investigations the authors found that on repeating the experiments of Matthiessen and Foster, of fusing opianic acid with caustic potash, as they had stated, it is converted into meconin and hemipinic acid, but that the latter contains a small quantity of another acid, which gives a blue tint with ferric chloride, and which is methylnormeconin ($C_9H_8O_4$). On heating dry sodium hemipinate with dry soda-lime, a heavy oil was obtained, which on examination proved to be dimethyl-pyrocatechin, the reaction being—

$$(COOH)_2C_6H_2(OCH_3)_2 = 2CO_2 + C_6H_4(OCH_3)_2,$$

when treated with strong hydriodic acid the dimethyl-pyrocatechin is converted into pure pyrocatechin with simultaneous formation of methyliodide. If hemipinic acid is fused with caustic potash the following reaction takes place:—

$$C_{10}H_{10}O_6 + 3KHO = C_7H_5O_4K + K_2CO_3 + 2CH_4O,$$

potassium protocatechuate being produced. These results conclusively prove that hemipinic acid is a carboxyll-dimethyl-protocatechuic acid $(COOH)_2C_6H_2(OCH_3)_2$. It seemed probable from the results obtained with hemipinic acid that on heating sodium opianate with soda-lime methyl-vanillin $(COH)C_6H_3(OCH_3)_2$ would be produced, and on making the experiment such was found to be the case, although the yield was comparatively small. By the action of oxidizing agents, methyl-vanillin is converted into dimethylprotocatechuic acid, $COOH,C_6H_3(OCH_3)_2$, and when treated with hydrochloric acid it yields *vanillin*, $COH,C_6H_3(OCH_3)(OH)$, and methyl-chloride. The action of hydriodic acid on hemipinic acid has also been studied by these investigators, and they find that methyl-norhemipinic acid $(COOH)_2C_6H_2(OCH_3OH)$, is first produced, and that by a continuance of the action this is then converted into methyl-protocatechuic acid, and finally into protocatechuic acid; somewhat analagous results were obtained with hydrochloric acid. The decomposition which methyl-norhemipinic acid undergoes when fused with potassic hydrate results in the formation of protocatechuic acid, and when heated alone it yields methylprotocatechuic acid.

The concluding portion of the paper of which the foregoing is an abstract (see *Journal of the Chemical Society* for March, 1876) describes the action of fused potash on meconin with similar results.

Tiemann and Haarmann when publishing their paper announcing the discovery of artificial vanillin from coniferin ('Proceedings Royal Society,' June 18, 1876.

* *Pharm. Journ.* [3], vol. vii., p. 280, 1876.
† *Pharm. Journ.* [3], vol. vii. p. 259.
‡ *Pharm. Journ.* [3], vol. v., p. 483.
§ *Pharm. Journ.* [3], vol. vii., p. 269.
‖ *Pharm. Journ.* [3], vol. vii., p. 264.

vol. xxii) demonstrated that their vanillin is the methylated aldehyde of protocatechuic acid. The importance of these investigations, therefore, I trust needs no apology for my troubling you with so much detail. It is probable that a further important result will accrue from this investigation. On examining this specimen of crude vanillin from opianic acid you will perceive crystals; it occurred to me that these crystals might be identical with those yielded by or exuded from the natural pods of vanilla. Hitherto, I believe, the true chemical constitution of these crystals has not been definitely demonstrated; they are, however, supposed to consist of benzoic or cinnamic acid or coumarin. The suggestion has been submitted to Dr. Wright, and he believes them to be identical, reserving demonstration for the next meeting of the Chemical Society.

Dr. Wright has further succeeded in obtaining a new opium alkaloid. During the preparation and purification of narceine from opium liquors an indistinctly crystalline mass is often left undissolved on boiling the partially purified narceine with water; the results of experiments tend to show that this crude product contains the new alkaloid, bearing to narcotine the relationship of benzoic acid to benzoic aldehyde. Dr. Wright calls the new base *oxynarcotine*. Oxynarcotine crystallizes in micaceous sandy crystals, whose composition is $C_{22}H_{23}NO_8$. It forms a hydrochloride, $C_{22}H_{23}NO_8HCl\ 2H_2O$. Oxynarcotine differs from narcotine in containing the carboxyl group instead of the aldehyde group. (Full details of these investigations will be found in the *Journ. Chem. Soc.*, April.)

Of course you are aware that the object of these investigations is to endeavour to find a method of building up the constituents of the natural alkaloids by synthesis, and thus produce morphine artificially, and it is believed that ultimately success will follow; meanwhile we must all admire the persevering energy with which Messrs. Beckett, Wright, and others are labouring to accomplish this result. I desire to acknowledge the courtesy with which Dr. Wright has enabled me to exhibit those specimens to you. The other derivatives are specimens which illustrate the investigations of the anhydrides on bases.* In a paper which Mr. David Brown, F.C.S., read to the Conference at Glasgow, he announced the presence of free *acetic acid* in opium, and he has kindly enabled me to exhibit to you a quantity that he has extracted; he also confirms by independent investigations the statement made by Professor Flückiger in 1869, regarding the presence of a member of the pectin series in opium.

There is a general tendency to the supposition that natural alkaloids will supersede the administration of crude drugs, and we, perhaps, have no more formidable instance of the necessity of an uniform standard in the administration of therapeutic agents, such as the use of alkaloids would secure, than the drug opium. The variable percentages of morphia to be found in the tincture, extract, and liquid galenical Pharmacopœial preparations were demonstrated by Mr. Dott, in a communication read at Glasgow, and whilst I would with some reserve advocate the administration of active principles whenever it can be shown that their effects are identical, it is necessary to add that care should be taken these bases are absolutely pure, otherwise the same danger will be present; for instance, morphia might not be entirely free from codeia, etc., in which case its potency would be modified—a resinoid such as podophyllin might be reduced by admixture with the powdered root; of course these constitute frauds, but, unfortunately, some foreign competitors are not too scrupulous in this matter. This leads me to ask your consideration of an hypothesis which may not be unreasonable. It is known in some instances, take opium and the cinchonas as examples, that the crude drugs have a specific therapeutic action; they yield different alkaloids of different proportions in different samples, whereas the total amount of alkaloids may be with slight deviation of the same percentage. It has been shown that these different alkaloids produce modified effects from the principal one. Is it fair to assume that nature has not had time to develop these alkaloids when the crude substance is gathered,—for instance, one poppy capsule may be in a more matured state than another when tapped,—and will not the statement that our new Indian cinchona plantations only yield the inferior alkaloids, but that it is supposed that age will develop the more formidable properties, help to substantiate the hypothesis? Of course we must not overlook nature's assistance in the quality of the soil and the climate. It is only fair to add that I have not any practical experience to bring to bear upon the question.

* See *Journ. Chem. Soc.*, 1875.

Butyl-Chloral.—Kramer and Pinner, in the course of their researches on the substance commonly called crotonchloral, have ascertained that it contains two more atoms of hydrogen than was supposed, and that it is in fact butylchloral. When soda or another alkali is mixed with it it undergoes decomposition, chloride of sodium, formate of soda, and bichlorallylene being produced, $C_4H_5Cl_3O + NaO = NCl + CH\ NaO_2 + H_2O + C_3H_4Cl_2$. Regarding the administration of butylchloral, Dr. Liebrich says that at first he tried an alcoholic solution but he has found that after long standing some change takes place which greatly impairs its action. He now prescribes it combined with glycerine—you will perhaps remember that in a paper I read to you three sessions ago on this substance I advocated the use of glycerine as a vehicle for its administration.

Chloral Hydrate maintains its position as a valuable hypnotic, the demand has become stationary, and large continental factories which were constructed for its manufacture have now arranged for the production of chloroform from this substance to a large extent; the chloroform is reported to be absolutely free from chlorine compounds. Reference to the manufacture of chloroform in this country with alcohol and methylic alcohol calls my attention to the fact that there is not any chemical test to detect the difference. Of course the resulting product is chloroform of exactly the same chemical composition ($CHCl_3$), but it is stated that the administration of the alcoholic chloroform is attended with greater safety than chloroform from methylic alcohol. How can this be? Surely it is imaginary, and if so, a large amount of money is thrown away in its use. It may be argued that in studying economy here I am treading on tender ground, and that in the administration of a substance like chloroform absolute purity is of such importance that price is no object; but surely a desire to prove what appears to be an anomaly is reasonable,—chemistry has failed hitherto.

One of the most important chemical communications of social interest during the year has been the exhaustive paper by Dr. Frankland on "Some Points in the Analysis of Potable Waters," in which he advocates what is known as the "combustion process." This paper led to one of the most important and exciting discussions which have taken place at the Chemical Society for some years. Thudichum and Kingzett have published some trials of Frankland's and Armstrong's method of combustion which show that this process can be relied on, even in its employment in elementary organic analysis, for determining the relation of nitrogen to carbon in very minute amounts of substance. They have also shown that this is an excellent method for determining the amount of nitrogen in any ammoniacal salts, as nitrate, sulphate, and chloride. In further relation to this subject Thudichum and Hake have estimated the amounts of hydrogen occluded by copper, and have shown that by passing a stream of carbonic acid gas through red hot copper which has been reduced by hydrogen, that no hydrogen is then left behind.

Professor Andrews has communicated to the Royal Society more of his elaborate researches, proving the remarkable continuity of the liquid and gaseous states of matter.

Time does not permit of my entering into the chemical investigations of commercial interest, but Newland's application of sulphate of alumina to beet-root sugar, by which the sweet principle is retained, and the application of vanadium salts in the production of pure aniline black, are worthy of note; and the year has perhaps demonstrated the success of Hargreave's process for making salt cake direct, SO_2+ air + steam over NaCl.

Mr. W. H. Hatcher, F.C.S., in experimenting on the setting points of mixtures of the fatty acids with one another and with various other fatty substances, found that they generally differed to a considerable extent from those obtained by calculation. In a communication to the Chemical Society, March 16, 1876, he called attention to some curious points about the solidification of fatty mixtures, which are at present difficult to comprehend; he suggested the application of photography to solve the mystery, and has kindly given me an opportunity to exhibit to you this evening the series of beautiful photographs of the crystalline structure of mixtures of palmitic and stearic acid which he has prepared. He will shortly announce the results of his further investigations, to which I hope to call your attention on a future occasion.

The importance of the loan exhibition at South Kensington is well worthy of our notice, its advantages from an educational point, and its historic interest considerably increasing its value. The student can see, side by side with the highly finished apparatus now used in teaching or investigation, some of the sacred relics contributed by various museums or sent from private collections, which, though rude in appearance, have been rendered immortal by being the first of their kind or having been employed by some of our grand predecessors in the investigations which we still cherish as the ground work of all our scientific knowledge. Here in a few minutes we may see the gradual steps made towards the summit of our present stand point, and how each little improvement in its day acted as the stepping stone for some other, which probably has since quite thrown a shade over the older one. If we glance for instance at the progress which has been made in the manufacture of scientific instruments, we see the great disadvantage under which our predecessors laboured, and also the enormous strides made by mechanical skill within the last twenty years. This exhibition may be regarded as a hopeful symptom, as a proof that the importance of science as a main factor in national power and prosperity is approaching nearer to recognition. Let us hope that this may become a permanent exhibition by which the nation may benefit. This leads me to a consideration of the idea so nobly advocated by the President of the British Association,—the duty of England to provide national opportunities for original research. There are many obstacles to contend with in this; for instance the government could not satisfactorily provide for the endowment of research, but they might provide laboratories for special researches, and competent directors in those laboratories. We have a good example of the feasibility of such a suggestion in the pathological laboratory of London, of which Dr. Thudichum is the director, and Mr. Kingzett and Dr. Hake are the assistants. A glance at the *Journal of the Chemical Society* for the last twelve months will show the amount of original research conducted there. Thudichum and Kingzett's various researches have greatly advanced physiological chemistry; thus besides the brain chemistry which we had the opportunity of having fully demonstrated to us last session, they have established the identity of the phosphorized matter in blood corpuscles with one of the phosphorized bodies (myelin) in brain matter. Kingzett's theory of the effect of alcohol on the brain commands considerable atttention, the question whether there exist in living brain any tissues which would nullify his hypothesis has to be demonstrated. Perhaps the examination of the brain of a subject who died under the effect of delirium tremens will help to substantiate the theory. Again, in this laboratory investigations have been conducted by Kingzett on the limited oxidation of terpenes and allied bodies, and he has studied also the atmospheric oxidation of ethers. The production of peroxide of hydrogen from ethylic ether is submitted as the genuine isolation of the radical hydroxyl. Already I have called your attention to work done by these investigators of more immediate interest to us. True, we have the science department at South Kensington, and in Professor Frankland we have another instance of the desirability of government aid,—but should not the government think well when pressure is brought to bear upon them to help science in this way. May we not look to the ancient Universities of England, and suggest that they should identify themselves more with the science of chemistry than they have done in the past and offer facilities for the chemical student such as he specially requires. The foundation, out of the enormous resources of Oxford and Cambridge, of a college where science should be the special feature of the course, and in which the chemical element should be strong, would be a proceeding fraught with very great consequences and would be beneficial to all. For on the one hand the university life would not be broken up and those links would be maintained which unite all departments of learning with one another; and on the other there can be little doubt that those ancient seats of learning would in turn derive new lustre from those on whom they set their seal and impress.

Already throughout the country, several educational centres are striving to supply the demand for scientific instruction, and unless Oxford and Cambridge wish to be entirely set aside in this competition, they ought to bestir themselves to remedy this defect in their educational course. Failing this, and if it should continue to be the case that practically only the sons of the rich can be admitted, there will be left no alternative to us but to found other colleges,—such as Owens College,—elsewhere, which will provide what we so much require and what the wants of the time demand. A start has been made in Liverpool in this matter and I trust the scheme suggested will ultimately prove successful.

In a work entitled 'British Manufacturing Industries' (edited by G. Phillips Bevan, F.G.S. London: E. Stanford), Professor Church, in noticing some of the minor chemical products of Great Britain, suggests some reflections from which the following is a quotation:—

"Although the United Kingdom maintains its pre-eminence over all other countries in the number and magnitude of its vitriol and alkali works, yet this is far from being the case with respect to factories devoted to the finer and more delicate preparations of the chemist. Here German, French, and Austrian manufacturers are ahead of our own, and still continue to make remarkable progress. If a rare and curious substance discovered by a scientific chemist and made in his laboratory painfully, grain by grain, be found useful in medicine or dyeing, or some other art, straightway the foreign manufacturing chemist makes it, not by the ounce or pound merely, but by the hundredweight or even by the ton. The success of foreign manufacturing chemists in this direction may be accounted for without difficulty. One reason is to be found in the cheapness of pure alcohol, so necessary in the preparation or purification of most of the products to which I am now referring, but I cannot help thinking that the chief reason is quite of a different sort. To foreign chemical works a sound well trained scientific chemist is attached, with a salary of £300 or £350 a year; sometimes several such chemists are employed by one manufacturer to improve old methods of manufacture and to discover new ones. According to Dr. Lunge, of the Newcastle Chemical Society, one German chemical factory has six assistant chemists (not practical managers) and one chief chemist, a distinguished man of scientific reputation to whom is given a salary approaching £2000 a year simply for investigation and original work in the laboratory, not for superintending the manufacturing operations. Two points connected with the products of these continental factories are of special interest, one being the fact that much of the crude material necessary for making some of these products is exported from England for that purpose; and another point is that the original discoveries on which some of these discoveries have been based were made in our own country."

Surely these facts are humiliating to us as Englishmen, and we should strive to remedy the evils. There is no reason why national prudence or private munificence may not supply us with schools of science from which we may obtain workers as efficient as those on the continent. Already private munificence has provided means whereby original researches may be undertaken; and our manufacturers are alive to the necessity of employing skilled labour, and to some extent government aid helps this forward by the science classes established throughout the country, so that we may certainly hope there are better times in store for the scientific reputation of England.

Gentlemen,—I feel I have already trespassed too long upon your patience; I wish my crude and imperfect remarks had been more worthy of your consideration. I have been able to tell you little that is new and nothing that is original; it is only given to the gifted few to originate ideas and to introduce innovations. But still I may hope to have completed a far from useless task if I have succeeded in interesting this meeting in one or two important chemical notices, for it is only by the accumulation of facts, and by the interchange of experiences, that we can hope to throw light upon those delicate and difficult problems in which the profession we love so well abounds. Wholly occupied, as many of us are, in the pressing work of our daily duties, too little time can frequently be devoted to the scientific and more attractive side of our profession; and yet the humblest worker in our great field of labour, diligently and conscientiously doing his daily work, may reap a rich reward—far even before wealth and honour, welcome as they are in the appreciation of our fellow men, for benefits conferred upon them.

At the conclusion of the address a lengthy discussion took place, and on the motion of the Vice-President, Mr. Woodcock, seconded by Mr. Shaw, and supported by Messrs. Fingland, Armstrong and Davies, an unanimous vote of thanks was accorded to the President for his valuable address. The President, in returning thanks, spoke of the prospects of the present session, after which the meeting closed.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION

The twenty-fourth meeting of this Association was commenced in the College of Pharmacy, Philadelphia, on Tuesday, September 12th. The meeting was called to order at half-past three o'clock in the afternoon by the President, Professor Geo:ge F. H. Markoe, of Boston. The following is an abstract of the report of the proceedings given in the New York *Druggists' Circular*, for October:—

Some business in connection with committees having been transacted, including the appointment of a committee of nine members to report upon the objects of Chemical and Pharmaceutical interest exhibited at the Philadelphia International Exposition, the President read his Address. This consisted mainly of a review of the work of the Association during the last quarter of a century and notes on the progress of pharmacy. The Address, together with the Report of the Executive Committee, giving the statistics of members elected, deceased, etc., and the Report of the Permanent Secretary, were referred to a committee to report on.

The reports of the committees being called for, the following were read by title and afterwards read in detail: Drug Market, Papers and Queries, Revision of Bye-Laws, Ebert Prize, Maximum Doses and Sign for Unusual Doses, Legislation, Adulterations and Sophistications, Liebig Memorial, Metrical Weights and Measures, Photograph Album, Complaints of Julius Fehr, and the Report on the Action of the Tennessee College of Pharmacy.

The delegates then present named each one member to act as a Committee on Nominations, to which five were added by the President.

The Executive Committee presented the names of seventy-six persons for membership, and they were duly elected.

Second Session.—Thursday Morning, Sept. 14th.

The meeting was called to order at 9·30, Vice-President F. Hoffman in the chair. The minutes were read and approved. Letters were read from the Denmark Apothecaries' Association, Swiss Apothecaries' Society, and the German Apothecaries' Society, thanking the Association for the invitation extended to their respective bodies.

Professor J. P. Remington on behalf of the Committee on Entertainment introduced Mr. S. Nagayo, Mr. H. Meiyake, Mr. S. Juranga, members of the Imperial Board of Health, Japan, and all distinguished men of science, who were received with applause, and invited to seats in the body.

The Committee on Nominations presented their Report, recommending for officers for the ensuing year:—

President.

Charles Bullock, of Philadelphia.

Vice-Presidents.

Messrs. S. A. D. Sheppard, Boston; George J. Luhn, Charleston, S.C.; J. D. Wells, Cincinnati, O.

Treasurer.

C. A. Tufts, Dover, N.H.

Permanent Secretary.

Professor J. M. Maisch, Philadelphia.

Reporter on Pharmacy.

Professor C. Lewis Diehl, Louisville, Kentucky.

Local Secretary.

Henry J. Rose, Toronto, Canada.

Executive Committee.

George W. Kennedy, Pottsville, Pa.; C. H. Dalrymple, W. H. Crawford, John Ingalls, Professor J. M. Maisch.

Committee on Drug Market.

William Saunders, London, Ontario; W. H. Wickham, Professor J. F. Judge, Professor N. G. Bartlett, Charles F. G. Meyer.

Committee on Papers and Queries.

William McIntyre, Philadelphia; Louis J. Dohme, Joseph L. Lemberger.

Business Committee.

Joseph Roberts, Baltimore, Md.; H. D. Welcome, Charles Rice.

The report of the committee was accepted, and by a vote of the Association was adopted.

By request of the Chairman, Dr. E. R. Squibb and Dr. F. Hoffman conducted the President-elect to the chair.

In accepting the position, Mr. Bullock tendered his thanks to the members for their kindness; and in a few words of welcome to their city, their college and the enjoyment of the hospitalities provided, and requested the meeting then to proceed with business.

The Treasurer's report was then read. It stated that the receipts during the past year were as follows:—

From Members	4,248·00 dols.
" Certificates	420·00
" Sale of Proceedings	64·80
Balance from 1875	1,174·11
	5,906·91
Expenses and disbursements . . .	4,181·69
Balance on hand	1,725·22

The report was accepted, and on motion referred to an auditing committee, which subsequently reported that it found the accounts of the Treasurer correct.

It was moved and adopted that the Treasurer be authorized to ask for all certificates of membership now held by persons formerly members of this Association, but who now retain them contrary to the provisions of the constitution.

The Committee on Revision of the Bye-laws presented a report recommending certain alterations in the bye-laws; one being to the effect that the committee on legislation should keep a record of, and compile for reference, the enactments of the different States regulating the practice of pharmacy and the sale of medicines; also, that it should report to each stated meeting of the Association what has been the legislation on the subject during the previous year.

The Committee on Maximum Doses and Signs for Unusual Doses reported that some progress had been made, but owing to the fact that there had not been sufficient conference with the delegates from the American Medical Association, the subject would need the further attention of a committee. On motion the committee was continued.

The Committee on Legislation reported that no great changes had occurred in this direction during the past year. In two States the law had been amended. In Baltimore the law permits the sale of patent and proprietary medicines by anyone, as also the sale of medicines put up in bottles or packages by wholesale druggists. In South Carolina the examinations were formerly conducted by the medical colleges, but now the board is constituted by four pharmaceutists and two physicians, and the receipts of the board are divided equally between the Pharmaceutical Association and the medical colleges. No other changes of note were alluded to in the report, which was then adopted.

The Report on Metrical Weights and Measures was read by Dr. F. Hoffman. The system was reported feasible. and the committee recommended that it be adopted for all wants, and that the government should fix a time after which it should be the legal standard of the country. Mr. T. S. Weigand, one of the committee, read a short note stating his reasons for signing the report; also giving other reasons why he was not in full accord with all its conclusions. On motion, both reports were directed to be published in the proceedings.

The Committee on Photographic Albums reported that the Association now had the photographs of over four hundred of its members. It recommended that the care of the albums should be entrusted to the Chairman of the committee.

Shortly afterwards an unpleasant incident occurred during the discussion of the report of a committee appointed to consider some complaints made by a member. The committee reported adversely to the complaining member, and in the course of some disputation, this person said that some remarks made by another speaker were false, whereupon it was moved and carried by 106 votes to 19 that he should be expelled from the Association, for using indecorous language.

Third Session—Afternoon.

The greater part of this sitting was taken up by the discussion of a proposed resolution offering to the American Medical Association the co-operation of the American Pharmaceutical Association, in preparing the next edition of the United States Pharmacopœia. Eventually action was deferred until the meeting next year.

Fourth Session—Evening.

The meeting was called to order at 8·30 p.m. The sitting was devoted principally to the reading of papers.

Fifth Session—Saturday Morning.

During this sitting the committee appointed to select a time and place for the next meeting reported, recommending that it be held in Toronto, Ontario, Tuesday, September 4th, 1877, at 3 o'clock p.m. The report was unanimously adopted.

Mr. Shoemaker read selections from the Report of the Committee on Drug Market. The report alluded to the changes in values, amount and character of many of the articles used in the wholesale trade. It was stated that the total imports for the fiscal year were 476,000,000 dols., while the total exports were 596,000,000 dols., leaving a balance in our favour of 120,000,000 dols. The character of many of the powdered drugs of the market was alluded to and their quality hinted at by the comparative prices at which they were sold, and the value of good crude drugs. Borax was exported to the extent of 3,000,000 pounds, California and Nevada have produced in all during the year 6,000,000. The Pacific Coast has furnished during the year 54,000 flasks of mercury, while less than that has been produced by all the other nations of the world combined. The product of opium was stated to be smaller in amount for the year than was anticipated, and it would probably advance in price still further. Many other interesting subjects were touched upon. The report concluded with a list of import of drugs for the past fiscal year. It was accepted and referred for publication.

Professor Diehl then read some extracts from his annual report on the progress of pharmacy

Some papers were also read.

Sixth Session—Afternoon.

The meeting was called to order by Vice-President S. A. D. Shepherd, at 2·45 p.m. The Committee on the President's Address, the Report of the Executive Committee, and that of the Permanent Secretary, as also of the Auditing Committee, were read and adopted. The greater part of the Session was devoted to the reading of papers.

Seventh Session.—Evening.

This being the closing session the remainder of the papers were read by title only, and after several votes of thanks had been passed, the meeting came to an end.

The following notes refer to some of the papers read at the meeting:—

Papers in Answer to Queries.

Senega Root.—In an essay on Senega Root, embracing the history of its introduction, its geographical range, and its importance as an article of commerce, Mr. J. D. Wells (the writer), stated that the name of the root is derived from an Indian tribe at one time in Western New York, and called the Senecas, who held it as a remedy against the bite of the rattlesnake. This secret was obtained by Dr. Tennant of Virginia, in 1735, and he subsequently received a reward from the State of Pennsylvania for making it known. Its geographical range is as far north as Canada, along the west slope of the Alleghany, in Indiana, Kentucky, Virginia, North Carolina, Georgia, Tennessee, Alabama, and Texas, scarcely found in Missouri, but abundant in Iowa and Minnesota, and not known to exist in the extreme western territories or on the Pacific coast. The exports are difficult to determine, but the writer was informed by a New York house that over 2000 pounds were annually exported.

After the reading of this paper, attention was called by M. W. Saunders to a so-called Senega root, of handsome appearance, which, when chewed, failed to produce the full and decided taste peculiar to *Polygala Senega*, and when made into a fluid extract gave a liquid possessing a more feeble taste, and having a decided fluorescence.

Syrup of Ferrous Iodide.—Five grams of citric acid added to the finished product of the formula of the U. S. P. for syrup of ferrous iodide are said to preserve *unchanged* the appearance of the syrup. Is this addition admissible? The experiments of Dr. Wilson H. Pile, in answer, failed to satisfy him as to the value of citric acid as a preservative for this changeable syrup, and his paper was chiefly a negative result. Discussion which followed gave more favourable results as to its tendency to protect this syrup from its proneness to change.

Paullinia Sorbilis.—In a treatise on this article, furnishing a formula for a liquid preparation of the drug, Mr. George W. Kennedy stated that in exhausting this drug he selects a menstruum containing two parts of stronger alcohol and one part each of glycerine and water, which, when mixed, give nearly the strength of dilute alcohol.

Take paullinia in moderately fine powder, 16 troy ounces.
Take stronger alcohol, 8 fluid ounces.
„ glycerine 4 fluid ounces.
„ distilled water, 4 fluid ounces.

Proceed by careful percolation to obtain twelve fluid ounces (adding above the magma, as may be necessary, dilute alcohol), which set aside, continue the percolation until exhausted, evaporate the second percolate to four fluid ounces and mix with the reserved percolate. In the hands of the writer, this method produced results entirely satisfactory.

Fluid Extract of Cotton-root bark occasionally gelatinizes on keeping. Can a modification of the process for making this fluid extract be suggested which will prevent such a change? To which principle, and to what influences is it due, and has the bark of the green root any superiority over that of the dry in the preparation of the fluid extract? Mr. J. M. Lloyd detailed many very careful experiments in the manufacture of fluid extract of cotton-root bark, both dry and fresh. He gives preference to an an alcoholic menstruum but obtained satisfactory results, in making an extract which, in his experience, *never gelatinized*, when the menstruum used was alcohol ten parts (fluid) to glycerine six parts (fluid). Numerous trials by physicians indicate plainly the *unreliability* of any preparations made from the dried cotton-bark. On the other hand, when the *fresh* bark was used, and a fluid extract made from this was tried carefully by a large number of physicians, the almost universal report was favourable, the action being to facilitate parturition, and in other cases where it was sought to re-establish suppressed menstruation, it scarcely ever failed. His conclusions, therefore, point clearly to the use of the *fresh bark only*.

Cinnamon Water.—In reply to a query whether Ceylon oil of cinnamon is used in the preparation of cinnamon water, as directed by the U. S. P., Mr. Edward C. Jones stated that the almost universal practice of pharmaceutists was to make this preparation from oil of cassia.

Scilla maritima.—The ground bulb of *Scilla maritima* when moistened with diluted alcohol and worked with the hands causes for a time an intolerable itching. In seeking to ascertain to what principle in the bulb is thi effect to be ascribed, Mr. Edward D. Chipman separated the acrid bitter principle, and also the resinoid matter from fresh and green squill, and came to the conclusion that the itching effect alluded to is due entirely to the resinoid matter.

Professor Maisch remarked that it is stated that squill root contains oxalate of lime in fine sharp crystals, and that it is thought by some that the itching is caused by the abrasion or cutting of the skin by these sharp crystals.

Commercial Phosphorus.—In answering a query as to what extent the phosphorus of commerce is contaminated with arsenic and in what proportion is it present in the various brands of phosphorus found in the American market, Mr. Louis Dohme stated that he had examined the brand of phosphorus made by an American firm, and also two samples made by an English firm, one of the samples being quite recent, the other being probably several years old. By careful examination, the details of which are given in his paper, he found that the American phosphorus gave no signs of arsenic with the most careful tests, while samples No. 2 gave ·562 per cent. and No. 3, 1·065 per cent. of metallic arsenic.

Official Aromatic Spirit.—In answer to a query as to whether it is advisable to have an officinal aromatic spirit that will represent a fine refreshing Cologne to be used in lotions and for the sick room, if so, the formula and name for the preparation, Mr. George Leis came to the conclusion that any aromatic spirit to be grateful in the sick room must be devoid of odours that are too sweet, and that a plain odour is more lasting in its usefulness for the sick room. He therefore proposes a spirit in which bergamot, cassia and lavender are the odours. In connection with its intended use in the sick room, he deemed it absolutely necessary that it should contain some ingredient which should act as a deodorizer and preventative of foul odours. This would indicate an addition of some of the well known disinfectants or deodorizers, and he thinks the addition of salicylic acid accomplishes the purpose. The formula contributed included, therefore, this acid to the extent of ten grains to the ounce of the perfume given. The name proposed was "Lotio Antiseptica Fragrans," which would, he thought, sufficiently indicate its character and uses. The best results were to be obtained by freely using it as a "Spray" in the sick room.

Parts by Weight.—The question, What advantages would result from the substitution of parts by weight for absolute quantities in the revision of the Pharmacopœia, and if any disadvantages other than those incident to change, what are they? was discussed by Professor S. P. Sharples. He objects *in toto* to the use of parts by weight, on the ground that it is neit her convenient nor practicable. He instances a few preparations which it would seem almost impossible to bring to such proportions as would make them manageable or meet the exigencies of the average apothecary. The additional objection is made to the trouble of frequent weighing of many of the fluids in use as being more tedious and not as accurate for common use as that of measuring. Considerable discussion followed this paper, but several members expressed themselves as favouring the change.

Tinctura Ferri Chloridi.—Would it be desirable to introduce liquor ferri chlor. dilut. of the same iron strength in place of the tincture? Mr. S. Bidwell concluded from his investigations that a watery solution would not be as acceptable to the medical faculty; that it would take too much trouble and time to introduce; but favours the reduction of the alcoholic strength to correspond to dilute alcohol.

Lacto-Peptin.—Mr. Emil Scheffer read a paper in answer to the question, what is lacto-peptin? He reported that taking the published formula as stated on the label, and trying the experiments suggested by the makers, they failed to prove or produce the results claimed. The digestive power of the powder proves the presence of pepsin, and as coagulated albumen is dissolved by lacto-peptin, the presence of pepsin is confirmed. Pancreatin in dilute alkaline solution, when added to a small quantity of neutral lard, will produce acidification. Pancreatin is coagulable by heat, but neither of the above results are found when lacto-peptin is tested in a suitable manner. When starch paste was used, it was not converted into sugar by lacto-peptin, which fails to prove the presence of diastase. The experiments of Mr. Scheffer he considers to prove the presence of pepsin, sugar, lactic acid, hydrochloric acid, starch, cellular tissue, mucus and fat, but *no pancreatin or diastase*, and that it is inferior in digestive strength to the saccharated pepsins of the market.

Wine of Tar, by Charles A. Heinitsh, who said a formula which had proved very satisfactory, and most easily prepared was to take eight ounces of tar, and add it to three pints of beer, which after twenty-four hours may be separated for use. Several other formulæ were given; but where *wine* is desired, one and one-half troy ounces of tar are triturated with one-half troy ounce carbonate of magnesia and one pint of sherry wine, and afterwards filtered.

Emulsions.—In reply to a query how much acacia is needed to emulsify perfectly the fixed or volatile oils and balsams, Mr. E. Gregory gave several detailed processes of manipulation, as laid down in the various works that come under notice of pharmaceutists. His judgment is that three parts of acacia are needed to readily emulsify volatile and fixed oils and balsams, and that mucilage which is kept already made is not so good as that made freshly for the purpose. The process of manipulation preferred is that in which powdered acacia, one part, is mixed with two parts oil, and water one and one-half parts afterwards added at once. Numerous other experiments were given; but this in his hands had proved most rapid, the whitest, the oil globules most readily divided, and the emulsion to be longest retained in intimate mixture without separation.

Medicated Wafers.—In an essay on wafers for the administration of powders, including mode of manufacture, working formula, and samples of product, Mr. G. A. Zwick said that to manufacture the wafers it was necessary to have a fine quality of wheaten flour as a first indispensable. This is mixed with water to a cream, strained and poured on hot polished steel plates which have a suitable concavity on one plate, with corresponding projection on another plate to match. The wafer is then baked, and afterwards cut to the appropriate size by a suitable steel cutter made like a gun-wad cutter. The imported wafer has a superiority in thinness, tenacity, and appearance, which it is believed to be due mainly to the Hungarian flour used abroad.

Cacao Butter.—In an investigation having for its object to ascertain the best way of detecting adulteration in oleum theobromæ, Mr. Gustavus Ramsperger prepared cacao butter by expression, by ether and by bisulphide of carbon, as a standard and for the application of tests. The specific gravity of the three samples, though made from the same cacao butter, was not uniform; therefore, the sp. gr. cannot be considered a test. Pure cacao butter is soluble quickly in two parts of ether at the ordinary temperature, forming at first a clear solution, but after a while it sometimes separates into two layers. Ether was found to be the best test of pure cacao butter, as neither will small portions of tallow, wax, paraffin, if in combination, give a clear solution in two parts of ether. Ox-marrow is not thus affected, but gives the clear solution as does cacao butter. Of twelve commercial samples tested, nine were pure; the other three were not much adulterated.

American Vesicating Insects.—In answer to questions, what species of insects are found in America which could be used for vesicating purposes? whether any of them are to be had in sufficient quantities to become an article of commerce? and how they compare in strength with the *Cantharis vesicatoria*, and other species, found in commerce? Mr. Saunders gave an interesting reply, stating the several varieties of vesicatorial insects that he had secured, and illustrating the insects as cabinet specimens, and also presenting a steel plate in illustration of them for inserting in the next volume of Proceedings.

Santonin has been seen in the market in thick prisms, very different in appearance from the usual flat crystals. To ascertain whether this is due to crystallization from a different liquid than that generally used, Mr. O. Eberbach operated with alcohol, dilute alcohol, water, benzole, rectified fusel oil and ordinary fusel oil, and finally concludes that the differences in the form of crystals are due mainly to the quantities of santonin operated upon, and the conditions under which the crystallization takes place. The crystals obtained from fusel oil bears some resemblance to the form in question.

Volunteer Papers.

Phosphorus as a Remedial Agent.—Dr. Edward R. Squibb commenced his paper with very full accounts of the reputed therapeutic properties of phosphorus as stated by various authors. Both sides of the question were fully drawn from, and the comments of the writer were mainly as the character of the formulæ for its administration. He does not advocate, but rather rejects, the idea of giving it in the form of pills or in volatile liquids, and maintains that a fixed solvent, such as some of the oils, is the most appropriate. His own preference was for cod liver oil as a vehicle, and his careful experiments are detailed, giving full particulars of the mode of treatment by which it is freed from air during the process. The preparation does not keep well in quantity, nor should it be kept long. The solution exhibited was stated to contain 1 per cent. of phosphorus. Pills may be made from this oil, and some were exhibited, and their formula was described. In these pills there can be no possible separation of phosphorus in solid form.

Ammoniacal Glycyrrhizin.—Mr. Henry N. Rittenhouse follows the details of Mr. Roussin's paper published in the *Pharmaceutical Journal*, July 17, 1875, with the exception of the final solutions in alcohol and precipitation with ether, which add unnecessarily to the expense. Attention is called to the excellence of this preparation for masking the taste of quinia either in powder, pill, or solution. Ammoniacal glycyrrhizin is sixteen times as strong as liquorice root, and one hundred times sweeter than sugar.

Notes on Pancreatin, Diastase and Ptyalin.—Mr. Emil Scheffer finds that his assertion at Boston last year, that pancreatin in presence of acidulated pepsin is destroyed, is confirmed by subsequent experiments. As diastase is found in malt in a neutral state, and both pancreatin and ptyalin are secreted in a neutral or alkaline state, it is to be pre-supposed that these are the natural conditions under which they act. Hydrochloric acid impedes the action of diastase upon starch, and destroys it. The experiments detailed by the writer with this acid prove conclusively that the presence of a small quantity of the acid so far destroys diastase that starch is not changed into sugar. Pepsin converts diastase into peptone, and in an acidulated solution of pepsin, diastase cannot convert starch into sugar. Freshly secreted saliva alters starch paste into sugar, but when a minute quantity of acidulated pepsin is added no such change occurs. Other concurring experiments led the writer to a firm conviction that in the presence of acidulated pepsin all albuminoids are converted into peptone.

Pycnanthemum linifolium.—Mr. Charles Mohr says that this plant is used in Alabama for debilitated and impaired conditions of the digestive organs by the negroes of that section. In attempting a chemical examination the author obtained an acid which by all the tests given appears to be identical with caffeotannic acid. Besides this acid were found a volatile oil, a caoutchouc-like resin, chlorophyll, a bitter resin, colouring matter, gum and sugar. The writer gives also a very complete botanical description of the plant itself.

Michigan Opium.—Mr. Joseph P. Remington having recently received some of this article took the trouble to examine it. Its physical properties pointed to a product like extract of lettuce, and on fully examining it no morphia whatever was found.

Ergotin.—Mr. Chas. L. Mitchell, stated some of the physiological and chemical reasons which led him to deviate from the published formulæ in making an active, solid extract to represent the medicinal virtues of this drug

The product of the following formula yields a result in *every way* satisfactory:—

Ergot, in fine powder . . .	8 troy ounces.
Acetic Acid	2 fluid drachms.
Alcohol	4 fluid ounces.

Moisten the ergot with a mixture of the acid and 8 fluid ounces of water; let it stand twenty-four hours; pack in percolator, and exhaust with water; evaporate to 4 fluid ounces, add the alcohol, let it stand several hours, filter and evaporate to an extract. Result, about 480 grains; 1 grain is equal to 8 grains of ergot.

Adulteration of Milk and Testing for its Purity.—Mr. S. P. Sharples, without claiming originality, gives the following process as entirely satisfactory. The specific gravity being first determined, five grammes are weighed out in a flat platinum dish, and dried by water-bath for one and a-half hour at a temperature of 212° F.; then by an air-bath at 220° F. for one-half hour; when weight will be constant. The weight of the dish and contents deducted from the weight of the dish and the milk together, gives the total weight of solids. The dish is then treated with benzine for one-half hour, and the operation being carefully repeated twice, it is dried for half an hour, till the weight is constant. The weight of the dish and contents deducted from the last previous weight gives the weight of the fatty matters. The dish is now heated to ignition, its contents are converted into ash, and the weight of this is ascertained. These determinations are all that is necessary to settle the question of the purity of the milk. If sugar is required to be determined this may be accomplished by a test solution of copper tartrate of such strength that 20 c.c. of the solution =0·67 gramme of milk sugar. The above examinations give the weight of *milk solids*, the weight of *milk solids not fat*, the difference between these weights of *the fat*, the weight of *ash*, and that of the sugar. The addition of the weights of fat, sugar and ash, deducting these from the weight of the milk solids, gives the weight of casein and albumen.

Parliamentary and Law Proceedings.

Supposed Poisoning by Infants' Cordial.

On Monday last, October 16th, Mr. Malcolm, Leeds Borough Coroner, held an inquest respecting the death of a child, five weeks old, named Alice Pinder. The child's mother stated that it had been suffering from diarrhœa, and on the previous Friday she sent a neighbour for some "Meconio," or infants' cordial, which she had been in the habit of giving to her other children. She was supplied with what she supposed to be "Meconio," in a spoon, and gave the child a few drops of it. The child slept for several hours afterwards, but awoke screaming and in convulsions. Mr. Smith, surgeon, saw the child in the evening, and prescribed castor oil and milk, but it died about seven o'clock the following morning. Mr. Smith made a *post-mortem* examination of the body, and found the venous circulation of the brain much loaded. Although he detected no trace of poison in the stomach, yet he was of opinion that death was the result of vegetable poisoning. The castor oil or milk would have the effect of absorbing or passing off the poison. In the then state of the child's health the poison would be more likely to take effect. He knew that "Meconio" was very frequently administered to children in that neighbourhood. He had not analysed the liquid, part of which had been given to the child. An empty bottle was produced (but not that from which the liquid had been taken), bearing a label marked "Meconio—infant cordial." Mrs. Wade was examined, and stated that a friend of her husband's at Northowram, having written for a bottle of "Meconio," she got one. That bottle was wrapped up as it had come from the chemist's, when Mrs. Pinder sent for some "Meconio." Her husband tore off as much of the wrapper as enabled him to take out the cork, and poured out a teaspoonful of the liquid. He could not have seen what was on the bottle. The bottle was recorked, and sent to the friend at Northowram. The jury returned a verdict to the effect that the child was accidentally poisoned, and recommended that the bottle supposed to contain "Meconio" should be looked after, and its contents analysed for the benefit of the public. The Coroner said that he had already given instructions that the person at Northowram to whom the battle was sent should be communicated with.—*Leeds Mercury.*

The Singular Death of a Chemist and Druggist and his Son.

The adjourned inquest respecting the death of Mr. Edward Clarkson Pearson and his son (see before, p. 325) was held at Bradford on Monday last.

Mr. F. M. Rimmington reported that he had made a toxicological examination of the stomach and other organs. The stomach was free from any signs of irritant poison. It contained about two or three drachms of a thick fluid of chocolate red colour, having but little smell, and consisting entirely of amorphous unorganized matter, but free from all remains of food. Neither was there any blood present. He had made a chemical examination of this matter, and found it free from any metallic or irritant poison, and also from any narcotic or vegetable poison. He had also made analyses of the stomach itself, and also of the liver and the kidney, without finding any trace of any poisonous substance. The jury concurred with the Coroner, and a verdict of "Accidental death" was returned in regard to the death of the boy. —*Leeds Mercury.*

Obituary.

JOHN PALMER TYLEE.

Another old friend of the Pharmaceutical Society has passed away in Mr. John Palmer Tylee, Pharmaceutical Chemist, of Bridge Street, Bath, who died at an advanced age on the 10th inst. In 1841 the first meeting of the chemists and druggists of Bath in support of the newly formed Pharmaceutical Society of Great Britain was held in Mr. Tylee's house, and he was elected local secretary, the duties of which office he discharged so well for twenty years, that when he resigned a suitable testimonial was presented to him by the Bath members. At the time of the visit of the British Pharmaceutical Conference to Bath, in 1864, Mr. Tylee was President of the Bath Chemists and Druggists' Association. A local newspaper says of him:—"As one of the founders of the Bath Microscopical Society, and ever an active and valuable member, Mr. Tylee will long be remembered for his generous disposition and constant willingness to help forward all younger students. A man of keen perception and marked sagacity, he was diffident to a fault, and through taking little share in public life, his loss in this respect will be less regarded. The genuine character of the man, and the singular simplicity of his life, will embalm his memory among all who knew him."

Notice has also been received of the deaths of the following:—

On the 21st of September, 1876, Mr. George Lent, Chemist and Druggist, Rotherham. Aged 38 years.

On the 24th of September, 1876, Mr. Charles John Cann, Chemist and Druggist, of Alma Terrace, Hammersmith. Aged 26 years. Mr. Cann had been an associate of the Pharmaceutical Society since 1869.

On the 26th of Sept., 1876, Mr. George Nicol, Pharmaceutical Chemist, of Wick. Aged 76 years. Mr. Nicol had been a member of the Pharmaceutical Society since 1852.

On the 29th of September, 1876, Mr. Geo. Peter Ogilvie, Chemist and Druggist, of Arbroath. Aged 57 years.

On the 7th of Oct., 1876, Mr. Edward Clarkson Pearson, Chemist and Druggist, of Bradford. Aged 39 years.

Correspondence.

THE LATE NORWICH CHEMISTS' ASSOCIATION.

Sir,—It is my unpleasant duty to inform you that after an existence of six years the Norwich Chemists' Association has entirely failed. This unfortunate circumstance, is due, not to any want of a suitable room provided with appliances for chemical research, the nucleus of a museum and library, with excellent charts for botanical study, or from lack of means, or from the absence of willing and efficient teachers, but after a thorough and careful canvass of the assistants and apprentices of the city it was found that only seven were willing to enrol their names as students in the course of classes for the ensuing session—twenty-two having joined the previous year. This is much to be regretted as Norwich from its central position affords numerous facilities to the student.

The members of the Committee have been informed from time to time by those who have in previous sessions attended the classes that their present knowledge has been mainly acquired under the auspices of this Association. It is now too late to point out to Norwich students that the instruction here proffered would have been in most cases sufficient to enable them to pass the requisite examinations of the Society. It is worthy of remark that the fall of the Norwich Chemists' Association is simultaneous with the opening of a fashionable skating rink.

OCTAVIUS CORDER.

THE ABSENT FACTOR.

Sir,—With the whole of your remarks in the Journal of September 30th, I to a certain extent agree, but those with which you conclude I, from experience, heartily endorse, viz.: "But for this result (the attention of pharmacists bring given to the dispensing of prescriptions, etc.) an important factor is at present much wanting,—the prescriptions. As soon as these are forthcoming there is little doubt that they will command the attention of pharmacists."

This is perfectly true, and I believe will be the opinion of numerous chemists and druggists in country towns all over the kingdom.

In this town, the medical men, seven or eight in number, as a rule, make up their own medicines and we do not see half-a-dozen prescriptions in the course of the year. Those from strangers too are comparatively rare, therefore if we depended upon prescriptions for a living, we should have been dead long ago, instead of struggling for an honest existence, as we are at the present time.

THE "NEW" EXCIPIENT FOR PILL MASS.

Sir,—In the January number of the *Pharmaceutical Journal* for 1870, there is a note by Mr. S. B. Turney of Plymouth, of which the following is a summary:—

"*Excipient for Pills.*

Pulv. Tragacanth.	ʒij
Glycerini	ʒvj

Mix in mortar and keep in covered jar. In the course of a few hours this becomes a firm tenacious mass. 24 grains of quinine require 10 grains. ʒj iodide of potassium 6 grains only. ♏ 24 creasote, grains 36 pulv. glyc. decort. require 6 grains.

"A softer kind made with

Tragacanth	ʒij
Glycerine	ʒj

is useful, and when added to a refractory mass renders it generally manageable."

At that time, 1870, I made some according to this latter form, and have still a little left, of which I enclose a sample. It has become darker in colour, but in other respects is perfect.

ALFRED P. BAKER.

33, *Norfolk Terrace, W.*

Sir,—In reference to Mr. Welborn's letter headed "A New Pill Excipient" in last week's Journal, I would suggest that however much he may be disappointed to find he is not the original inventor of a glycerine and tragacanth excipient, such is certainly the case. His formula, however, differs from the one I have been accustomed to use in the possession of two ingredients, which, I venture to think, are equally unnecessary, and one of which I consider, notwithstanding his statements to the contrary, must be an objectionable addition to any excipient intended for general use. I refer to the water and oil of pimento.

I was present at the Conference during the reading of his paper, and could not help wondering—and, indeed, to the present moment remain in doubt—as to whether or not Mr. Welborn intended the ingredients to be incorporated by the means of heat; but certainly I see no reason why he should jump to the conclusion that Mr. Greenish, in referring to the fact that a similar mixture of tragacanth and glycerine had been in use for some time in London, necessarily implied that those two articles were merely used in a state of simple admixture, without the application of heat.

It is a pity to have to disabuse Mr. Welborn's mind in respect to "the pleasing and peculiar formations" into which he gives us poor Londoners credit for getting our pill masses, but if he will try the following formula I think he will find it in all respects equal, and in some superior, to his own:—

℞ Pulv. Tragacanth	ʒj
Glycerini	fl. ʒvi

Mix and apply heat by means of a water-bath till the mixture is converted into a thick jelly.

The product, on cooling, is a very stiff jelly, and may be kept for months—and, I believe, for years—in an ordinary covered pot.

When necessary a small quantity of glycerine can be added at the time of dispensing, the proportion of course depending on the nature of the ingredients in the formula under manipulation.

The above possesses all the good qualities claimed on behalf of Mr. Welborn's "New Excipient" without the presence of the oil of pimento, to which Mr. Greenish so naturally took exception.

Whilst recommending this excipient for use in those instances in which the choice is left to the dispenser, or where (as we do occasionally find) the one prescribed lacks the powers attributed to it by a too confiding physician, I think we should be careful in making too liberal a use of any such preparation in preparing the Pharmacopœia masses, for by the employment of such substitutions we shall either greatly increase the proportion of active ingredients in any given weight of the mass, or shall experience some difficulty in persuading customers that their pills are of the same actual strength as the larger—and, indeed, correctly dispensed—ones to which they have been accustomed.

Indeed, as regards any improved excipient for the Pharmacopœia pill masses, we cannot do better than leave the subject in the hands of the esteemed editor of the Pharmacopœia, who, I feel sure, will be only too pleased when opportunity offers to adopt any suggestion calculated to render more complete and valuable the work in which he takes so much interest, and of which, notwithstanding some few imperfections, he has just cause for pride.

PHARMACEUTICAL APPARATUS.

BY OCTAVIUS CORDER.

It has been frequently urged upon the Council of the Pharmaceutical Society, to provide at Bloomsbury Square a set of apparatus suitable for the use of retail establishments for the making all such pharmaceutical preparations as may reasonably be expected by a chemist of the present day. Whether it is the duty of the Council to act the part of an educating body, either for students or mature pharmacists, I leave for the present (although I have a very decided opinion on the subject), my object on the present occasion being to assist those who may be in the same difficulty which I have felt. Having no set of apparatus to guide me I should have been glad of information. I therefore send a short description of what I have found to answer my purpose, with a drawing of the apparatus.

A is a copper boiler holding about 12 gallons, fixed in a wrought iron jacket and heated by a ring gas-burner. I used copper for the boiler, because being made thinner than iron the water is brought to a boil much more rapidly; it does not foul so soon, and is altogether better adapted for the purpose. I chose gas as a heating power, not that it was so cheap as coal, but from its being clean, free from smoke, and at once lighted, lowered, or put out, as occasion may require.

The boiler is supplied with water direct from the main by merely turning on the tap, B. The boiler is provided with steam gauge, C, which blows off at 5 lb. pressure; also, with a water gauge, D, and with a suitable arrangement for blowing out the boiler whenever it becomes foul by deposit of lime, etc. H is a galvanized iron tank, provided with a tin worm, so that all waste steam may be condensed as distilled water; those who are accustomed to use distilled water for all dispensing purposes, making tinctures, infusions, decoctions, indeed all pharmaceutical preparations, will fully appreciate this part of the arrangement. The whole of the pans, etc., being copper tinned all the condensed steam is available as distilled water. The pan, E, holds 16 gallons, and is adapted for decoctions, etc.; its evaporating power is about 2 gallons per hour. The pan, F, holds 6 gallons, and being fitted with a suitable head and worm is used for all the distilled medicated waters, such as dill, cinnamon, peppermint, etc., also for recovering the spirit from ext. colocynth and such like preparations. It distils about 1 gallon per hour. G, is one of Doulton and Watts' make, fitted with an earthenware still (holding about 3 gallons) with head and worm of the same material, fixed in an oval jacket. This is only used for sp. ammon. arom., for which purpose it is well adapted; being the furthest from the boiler the steam power is less, and there is but little risk of the luting being displaced, especially if the carbonate of ammonia is added at several times in small quantities.

The amount of gas used is about 50 feet per hour, costing somewhat less than 3*d.*, but by saving the condensed steam sufficient distilled water will be obtained to more than pay the heating. If the full steam of the boiler is turned into the worm, H, about 4 gallons of water per hour are obtained. Two gallons of sp. ammon. aromat. may be run over during the day in conjunction with other preparations. The whole of the work, as far as the boiler, gas burner, pans and pipe fittings, were made for me by Messrs. Pontifex and Wood, Farringdon Works, Shoe Lane, who have not only paid every attention to what I required, but have also executed it in a substantial and most satisfactory manner. I would add, that it is well to cover the top of the boiler, and the sides of the pans and pipes, with felt, which effectually prevents a considerable loss of heat by radiation.

Norwich.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 310.)

COLEUS AROMATICUS.—*Local name*, OWA.

Although this name is in general use it is not properly applied to the plant under notice, it is the name of *Ptychotis Ajowan.* The leaves, which are broad, ovate, crenated, and very thick, are about three inches long, and thickly studded with hairs; those on the upper surface are principally jointed and tapering, with a few simple ones surmounted by a globular, transparent, brilliant gland like a minute dewdrop. On the under surface the glandular hairs are much the most numerous and give rise to a frosted appearance. The epidermis is provided with numerous simple stomata. The venation is reticulate and remarkably prominent on the under surface of the leaf. A few oil globules are met with in the parenchyma, but the aroma is chiefly situated in the glandular hairs. The taste of the leaf is at first pleasantly aromatic, afterwards very pungent; the odour is agreeable and refreshing. In Bombay the Owa is found in almost every garden; it is often used with success in colic and dyspepsia, and is mixed with articles of food by the natives and with drinks by Europeans. I have never heard of its producing any intoxicating effect; if it ever does, it must be when taken in much larger quantity than is usual.

ZINGIBER MACROSTACHYUM.—*Local name*, NEESUN.

A plant resembling ginger, but larger. Stem and under surface of leaves pubescent, spikes several, with long peduncles. Flowers yellowish white, middle lobe of lip marked with diverging purple lines. Fruit obvate, pubescent, red, about ½ inch long. Rhizome 1—2 inches in diameter when fresh-jointed, compressed, with numerous radicles, each joint furnished with a bud. Epidermis scaly, light brown. Cut surface of the fresh root a rich golden yellow. Odour powerful, like a mixture of camphor and turmeric; taste hot and camphoraceous. Under the microscope the epidermis is seen to be formed of many layers of compressed and obliterated cells. The parenchyma consists of large polyhedral cells; those in the cortical portion of the root are nearly free from starch, but those in the central portion are filled with large ovoid starch granules. In all parts of the rhizome large cells full of a golden yellow essential oil abound. The vascular system resembles that of turmeric. Neesun is common in the Konkon and is a popular remedy in diarrhœa and colic.

CASSIA TORA.—*Local name*, TAKLA.

This is a common annual weed in cultivated ground. Leaflets 3 pair, obovate, obtuse, glabrous, the terminal pair being much the largest, all folding up closely at night. Flowers axillary, generally in pairs, dull yellow. Legumes about 6 inches long, narrow, quadrangular, about ⅛ of an inch in diameter, containing numerous elongated seeds. The whole plant has a fetid smell. In good soil it attains a height of about three feet. The leaves are mucilaginous and have a nauseous taste, they are very generally used as a remedy for the so-called Indian ringworm, and as a poultice to boils, etc. They are also purgative.

CRATÆVA RELIGIOSA.—*Local name*, VAIVARNA.

A small tree, with 3-foliolate leaves on long petioles, leaflets lanceolate acuminate, thin, smooth, upper surface dark green, under of a lighter colour, about eight inches long and three broad. Green bark of young shoots and petioles of leaves marked with small white prominent specks. The bruised leaves have a disagreeable smell something like Hellebore; they are slightly bitter and very pungent, causing a tingling sensation in the tongue; not aromatic. In Bombay the bruised leaves are used as a remedy for swelling of the feet and burning of the soles. They are popularly considered to be efficacious in such cases.

VERNONIA ANTHELMINTICA.—*Local name*, KALEE JEEREE.

The seeds and their properties are sufficiently and correctly described in the Pharmacopœia of India. They contain no alkaloids or glucoside. The active principle appears to be a resin.

PSORALIA CORYLIFOLIA.—*Local name*, BAWACHI.

The seeds are well described in Moodeen Sheeriff's Appendix to the Pharmacopœia of India. The oil expressed from them has been a good deal used in Bombay as an alterative in leprosy, and, it is said, with very favourable results. The seeds contain no alkaloid or glucoside, but a large quantity of oil and resin.

MORINDA CITRIFOLIA.—*Local name*. AAL or BARTUNDIE.

M. TOMENTOSA.—*Local name*, ASA.

The first is distinguished by its large oval oblong shining leaves, and the second by the young branches and leaves being tomentose. Both have white flowers with a long infundibuliform corolla, and in both the berries are fused into an oblong fleshy fruit. That of *M. citrofolia* is the largest, being often more than three inches in length. It is pale green, smooth, and when fully ripe fetid beyond description. In the pulp are imbedded a number of black seeds, somewhat like apple pips. The leaves are used as a healing application to wounds and ulcers. They are very bitter, and are said to be tonic and febrifuge.

TRICHOSANTHES CUCUMERINA.—*Local name,* JAUGLI PUDWAL.

Leaves broadly cordate, generally seven-lobed, serrated, fetid; tendrils three-cleft; flowers like those of the cultivated snake gourd; fruit 3—6 inches long, ovate, pointed at both ends, greenish white, marked with broken longitudinal lines of darker green; seeds large, from 20—30, surrounded by a thin fetid, bitter, watery pulp. The natives consider the fruit to be antiperiodic. It abounds in the Konkon, and matures in September and October. This plant is noticed in the Pharmacopœia of India under the name of *T. cordata,* and the root is said to be used in Bengal as a tonic.

(*To be continued.*)

OCCURRANCE OF A SUBSTANCE RESEMBLING COLCHICINE IN BEER.

In a recent report on an examination of Melbourne ales undertaken on behalf of the colonial government,* the analysts stated that in some ales they had met with a crystalline substance resembling crystals of picrotoxin and likely to be mistaken for it, but which a chemical and physiological examination had shown not to be picrotoxin, either modified or unmodified, but a saccharine substance having some relation to the formation of fusel oil. In a paper in the *Archiv der Pharmacie,*† Herr Dannenberg, an apothecary in Fulda, has since stated that he has found in beer a substance resembling closely another substance alleged to be used as an adulterant,—colchicine.

Being employed professionally to examine a sample of beer that was suspected to contain colchicine, and was the subject of legal proceedings, Herr Dannenberg sought directly for that alkaloid, and he obtained a body that in its solubility and in its behaviour towards several reagents showed the greatest similarity with it. Six litres of the beer were evaporated in a water-bath to about one third, taking the precaution, at the commencement, to make the hot liquor alkaline with sodium carbonate, and then faintly acid with tartaric acid. The cooled dark brown liquid was precipitated with basic lead acetate, and the lead removed with sodium phosphate. The then very light wine-yellow filtrate being strongly acid was again treated with sodium carbonate and tartaric acid, and evaporated to the consistence of an ordinary extract. This extract was carefully rubbed up with about three times its volume of absolute alcohol, when the portion which remained undissolved aggregated together in lumps. As soon as this took place the mixture was allowed to settle, and the clear brown liquor poured off, and concentrated by distillation and evaporation; the lumps were then treated with a fresh quantity of absolute alcohol, and this operation was repeated four times. The alcoholic extract thus obtained was completely freed from alcohol in a water-bath, and after cooling formed an almost pulverizable mass, which in aqueous solution had an acid reaction. Ether dissolved out from this too much extractive to be suitable for testing with reagents. It was, therefore, shaken with chloroform, when a thin layer of colourless extract was obtained that upon evaporation left only a very small residue. The remainder of the alcoholic extract was then dissolved in water sufficient to make a thin liquid, and this was shaken successively with three equal volumes of chloroform, carefully freed from alcohol. After distilling off the chloroform the residue was dried as thoroughly as possible in a water-bath, when it was left as a thin, light-brown, glutinous coating on the side of the dish. This was dissolved in water, and—as its passage into ether from an acid aqueous solution is an essential character of colchicine,—the distinct, though not strong, acid reaction of the solution was noted. The solution was first shaken with three times its volume of ether, and then three times more with five to six times its volume. The united ethereal solutions gave a coating to the dish, similar to, though weaker than, that from the chloroform solution. This substance had a bitter taste, and no crystallization could be detected in it with a glass.

The ethereal residue was used for testing with different reagents, a solution of pure colchicine being used at the same time for comparative experiments. The behaviour of tannin, solution of iodine, platinic chloride, gold chloride and phosphomolybdic acid, was exactly the same with both. Flückiger's test with potassio-hydrargyric iodide behaved similarly in Professor Otto's hands, but was not tried by the author. Nitric acid dissolved the substance with a dirty yellow colour, but an addition of strong sulphuric acid to this, instead of producing a blue colour, as is the case with colchicine, gave a red-violet colour. The production of this reaction, however, seems to be dependent upon some at present unknown conditions, as it only took place in two out of five experiments. Strong nitric acid (sp. gr. 1·48) also dissolved the extract with a beautiful violet colour, instead of the blue or blue-violet of colchicine, and the colour is produced even by contact with the vapour of the acid. This colour reaction took place, but with much greater intensity, in the aqueous solution that had been shaken with ether, which if colchicine had been present, might be supposed still to contain some, as colchicine is very incompletely taken up by ether. Consequently it was only in the red coloration with nitric acid that the substance in question differed from colchicine. Soluble in water and alcohol, and passing from an acid aqueous solution into chloroform and ether, less readily into the latter, in its behaviour towards the other reagents mentioned it might pass for colchicine.

The author is not at present prepared to say what this substance is, or whether the only reaction noticed at present in which it differs from colchicine is dependent upon some other constituent of the beer. With respect to the latter point, however, he states that he has repeatedly seen the same red-violet colour produced upon treating with nitric acid colchicine that has been in contact with fleshy substances.

The above communication has been succeeded by

* See *Pharm. Journ.* [3], vol. vi., p. 50.

† *Archiv der Pharmacie* [3], vol. viii., p. 411.

another from Herr Van Geldern,* a Dutch military apothecary, who states that being engaged in 1874 in the examination of some beers he found a substance which in many respects presented a similarity to colchicine. The substance was yellow, and dissolved with a yellow colour partially in water and entirely in ether. The aqueous solution gave a precipitate with tannin and solution of iodine; the dried substance was coloured an intense yellow by concentrated sulphuric acid and a moderate, but not a fine, red by concentrated nitric acid. The last liquid, diluted with water, became light yellow, and orange-red with excess of potash solution. Chlorine water added to the aqueous solution gave a precipitate which dissolved with an orange-yellow colour in ammonia. Herr Van Geldern therefore came to the conclusion that colchicine was present in the beer. But while experimenting afterwards upon some samples of hops, some of them collected by himself, he obtained from them a yellow substance which also gave the above colchicine reaction, except that no precipitate was produced by solution of iodine or tannin. But when some mucilage, which is a never failing constituent in beer, was added, all the reactions were obtained. The reaction with nitric acid, however, was not always the same, sometimes a magnificent red-violet colour was produced and sometimes the colour was not bright.

In an experiment upon two dogs, one of which was injected with colchicine and the other with the substance obtained from hops, the latter was found to be non-poisonous.

THE USE OF METRICAL WEIGHTS IN PRESCRIPTIONS.†

BY PROFESSOR JOHN M. MAISCH.

The desirability of uniform values of the weights and measures in use among civilized nations, and the admirable simplicity of the French or metrical system, are so apparent that this standard is now not merely legalized, but has been adopted, and is actually used, by a large majority of the nations of Continental Europe. The inconveniences attending such a change are more due to the alteration of values than to the introduction of the system with which, through the Arabic numeration, every one is familiar, and the practical application of which we have in our monetary system. The intimate acquaintance with the latter must doubtless facilitate the comparison of values, the multiples and divisions of which are based upon the same system of decimal numeration. While the general introduction of the metrical system in the United States must be regarded merely as a question of time, it cannot be denied that considerable progress towards this end would have been made, if, in accordance with a resolution passed by the National Convention of 1870, for revising the Pharmacopœia, the Committee of Revision had "abandoned in the Pharmacopœia, measures of capacity, and expressed the quantities in all formulas, both in weights and in parts by weight." Coupled with the direction, "to include some part of the metrical system in the list of officinal weights and measures," the parts by weight could scarcely have been expressed otherwise than upon the basis of the metrical weight.

The different value of the *grain*‡ as formerly used occasioned many difficulties in adapting formulas and doses to the weights of other countries; and for similar reasons the use of local values in measures and weights has long since been abandoned in all physical sciences, in favour of the metrical system. Medicine and pharmacy only lagged behind until a few years ago, when it was adopted also in the two branches named, by nearly all civilized nations, except those speaking the English tongue, and the labour of translating the values contained in formulas and prescriptions is now almost exclusively confined to the systems of the troy weight, and the English and American apothecaries' measures, as arraigned against the metrical weight.

It may be remarked in this place that the Pharmacopœias of Continental Europe and the prescriptions of physicians in those countries express all quantities by weight only, whether the material directed be solid or liquid. The greater exactness of gravimetric over volumetric measurement needs scarcely any argument, if the variation in volume under the influence of temperature is considered, and the difficulty of exact measurement in glass vessels of large diameter is taken into account. Moreover, weighing is more convenient, and those who have accustomed themselves to this method will only reluctantly change it for measuring again, if compelled to do so.

From long custom, physicians are apt to over-estimate the difficulties of writing prescriptions for liquid medicines by weights instead of measures. Medicines can be given in absolutely definite doses only, if divided by the apothecary; but their division by him is impracticable in case liquids are employed, and the familiar tea-, dessert- and table-spoons are then resorted to for dividing the medicines at the bedside. How widely these approximate measures differ from each other, and to what extent the difference is increased by the manner of measuring with them, is well known. The apportioning of doses of liquid medicine would, therefore, offer no greater difficulty as long as these convenient and handy, but variable, measures must be employed in the sick-room.

Of the officinal liquid preparations which are prescribed for internal use, the alkaline solutions (of soda, potassa and ammonia), the diluted acids, and the solutions of some salts (ammonium acetate, potassium citrate, etc.), do not differ materially in bulk from an equal weight of distilled water, this difference being less, particularly for the quantities representing their medicinal doses, than the variations of the popular approximate measures by which liquid medicines are taken. Tinctures and fluid extracts vary to a great extent in density, not only from water, but likewise among themselves. The apportioning of their doses by weight, however, would be an easy matter if the resolution of the National Convention above referred to had been carried out; for a given weight of the preparation would then represent a definite weight of the drug, and the proportion of the weight of the drug to that of the preparation would, for tinctures, most likely be 1 : 5 or 1 : 10, the standard generally adopted in Europe. Our present tinctures made with alcohol and diluted alcohol in the proportion of two troyounces to the pint, are very nearly of the strength 1 : 6½ and 1 : 7 respectively; and those containing three troyounces to the pint, 1 : 4¼ and 1 : 5. Tinctura opii is in the proportion of 1 : 11½, and tinctura opii camphorata, 1 : 250 (for opium). It will be observed that the changes necessary in the officinal formulas to bring them in harmony with the metrical system are by no means as great and revolutionary as is sometimes supposed, particularly if the necessary, or at least desirable, change in the alcoholic strength of the menstruum is taken into consideration.

A uniform standard of strength for fluid extracts would most likely be the proportion of 1:2; or, to give it in the metrical system, 5:10; for the proportion 1:1 is unattainable in all cases where sugar or much glycerin is requisite for preservation; and it appears to be desirable to adhere to an adopted standard, also, for those in the

* *Archiv der Pharmacie* [3] vol. ix., p. 32.

† From the *American Journal of Pharmacy* for October.

‡ The variation from our troy grains ranged in different countries between —11 and +46 per cent.

preparation of which alcohol or stronger alcohol is exclusively employed.

Of the remaining liquid medicines, the doses by weight can be as easily acquired as by minims or fluidrachms; but for those who have already become conversant with the measures now in use in the United States, the following observations will offer all requisite facilities for converting them into weights. Ether, having the specific gravity ·750, occupies precisely the same volume as $1\frac{1}{3}$ time its weight of water, and the difference in the volume of stronger ether (specific gravity ·720) is considerably within the limits of variation of the approximate measures; or, in other words, three parts by weight of ether occupy the same space as four parts by weight of water. The relation of the weight of spiritus ætheris compositus (specific gravity ·815) and spiritus ætheris nitrosi (specific gravity ·837) to volume is very nearly as 4:5, that is to say, four parts by weight of the preparations named occupy (a little less than) the same space occupied by five parts of water.

Glycerin (specific gravity 1·25) has a proportion of weight to volume as 5:4; syrups (specific gravity 1·317) nearly as 4:3; chloroform (specific gravity 1·48) nearly as 3:2, *i.e.*, $1\frac{1}{4}$ part by weight of glycerin, $1\frac{1}{3}$ part of syrup, and $1\frac{1}{2}$ part of chloroform, occupy, approximately, the same volume as 1 part of water.

If the relative density of the officinal liquids is not lost sight of, it will be seen that there is no great obstacle in the way of prescribing by metrical weights even the preparations of our present Pharmacopœia, except in the cases of fluid extracts, which vary so considerably that no reliable rule can be given for their relative proportion of weight to volume. But, with this exception, the task is comparatively easy, if it is remembered that for all practical purposes one gram equals 15 grains—that two tablespoonfuls, *i.e.*, 1 fluidounce, of water weigh 455·69 troy grains, or (within less than 8 grains) precisely the same as 30 grams (468 grains). Fifteen grams of water, or its equivalent in bulk of other liquids, is, therefore, to be taken as equal to the tablespoonful; 7·5 to 8 grams of water, or its equivalent, to the dessert-spoonful; and 3·7 to 4 grams to the teaspoonful.

Applying these values to the heavier and lighter liquids, it will be seen that—

$15 \times \frac{3}{4} = 11{\cdot}25$ grams ether.
$15 \times \frac{5}{4} = 18{\cdot}75$ grams glycerin.
$15 \times \frac{3}{2} = 22{\cdot}50$ grams chloroform.
$15 \times \frac{4}{5} = 12$ grams spir. æther. comp. (or nitr.).
$15 \times \frac{4}{3} = 20$ grams syrup,

are, in measure, equal to about half a fluidounce, and that the deviation from this measure is in each case considerably less than the difference in the amounts obtained by scant and full measurement with the same tablespoon, or between different patterns of that useful domestic utensil.

The average doses of these liquids, expressed in metrical weights, are, therefore—

Ether	11·25 : 8 = 1·40	grams	or	$\frac{1}{2}$	teaspoonful.
Spr. æth. comp., and					
Spr. æth. nitr.,	12 : 4 = 3·00	„	or	1	„
Chloroform,	22·50 : 8 = 2·80	„	or	$\frac{1}{2}$	„
Glycerin,	18·75 : 4 = 4·70	„	or	1	„
Syrups (some),	20 : 4 = 5	„	or	1	„

For the conversion of grain weights of solids into grams, close approximations to the correct weight, within the fraction of $\frac{1}{34}$, are obtained by dividing the number of grains by 15. The error resulting from this rule is best appreciated by comparing the results obtained with the larger weights, thus:—

	Correct weight.	Difference. Grams.	Difference. Grains.
grs. lx give $\frac{60}{15} = 4{\cdot}00$	3·887	0·113	1·7436
℥i „ $\frac{480}{15} = 32{\cdot}00$	31·100	0·90	13·89

The actual difference obtained by the above rule amounts, therefore, to rather less than a plus of $1\frac{3}{4}$ grain for the drachm, and 14 grains for the troy ounce.

A few examples may yet be added to show the insignificance of this difference for smaller weights; thus we obtain for—

	Actual weight.	Difference. Gram.		Difference. Grain,
grs. x, $\frac{10}{15} = 0{\cdot}66$	0·648	0·012	less than	$\frac{1}{6}$
grs. viii, $\frac{8}{15} = 0{\cdot}53$	0·518	0·012	„	$\frac{1}{5}$
grs. iii, $\frac{3}{15} = 0{\cdot}20$	0·194	0·006	„	$\frac{1}{10}$
grs. ii, $\frac{2}{15} = 0{\cdot}13$	0·129	0·001	nearly	$\frac{1}{65}$
grs. i, $\frac{1}{15} = 0{\cdot}066$	0·065	0·001	„	$\frac{1}{65}$

In prescribing by metrical weights, the amounts should in all cases be expressed in grams and decimal fractions of grams, and with Arabic numerals, in which case no signs or abbreviations are required; a few examples of prescriptions, written in the usual manner, with their (practical) equivalents in metrical weights, will readily explain this, and show the greater clearness of the latter method, and the less liability to error from indifferently made signs and Roman numerals.

It is the writer's opinion that physicians could very materially promote the introduction of the metrical weights, since by writing their prescriptions in the manner indicated, they would at the same time compel apothecaries to procure a suitable set of weights, which would save them the trouble of calculating the grams into grains and troy ounces; such a movement would be a great step toward carrying out the resolution of the Convention of 1870, and toward harmonizing the strength of the various pharmaceutical preparations with those of other Pharmacopœias, or at least bringing them into a simpler relation.

* Representing $7\frac{1}{2}$ grains of digitalis; menstruum diluted alcohol.

THE CONSTITUENTS OF BALSAM OF TOLU.*

It has long been a disputed point whether balsam of Tolu contains only cinnamic acid, or a mixture of this with benzoic acid. The presence of the latter had been denied by Frémy,† and although Deville afterwards obtained benzoic acid from the balsam, yet, according to Kopp, this did not pre-exist therein, but was produced during the process of extraction. The latest researches of Carles‡ likewise seem to prove the absence of benzoic acid.

The question has been again taken up by E. Busse, who attributes the conflicting results to the fact that the various investigators employed methods which caused chemical changes in the pre-existing constituents. He employed the method pursued by Kraut in his examination of balsam of Peru, by which such decompositions are avoided as much as possible.

One kilogramme of strongly resinified balsam of Tolu was dissolved in 2 litres (about 68 fl. ℥) of ether, the solution filtered from the trifling residue, and shaken for some time with 2 litres of soda solution, containing 100 gm. anhydrous soda. The decanted ether was repeatedly washed with fresh soda solution, and finally with water, until all alkalinity had disappeared. The clear ethereal liquid was deprived of its ether by distillation in the water-bath, when it left behind 85 gm. of a neutral liquid, which was subjected to fractional distillation. During this process three separate portions distilled over, part at near 200°, another at 250°—300°, and most at over 320° C., from which latter separated, on standing, a crystalline mass, exhibiting, after purification, the melting point of cinnamic acid. In order to remove this product, which had probably been formed by the action of heat and water, the several distillates were once more dissolved in ether, deprived of acid by shaking with dilute soda solution, washed, and after removal of the ether, dehydrated with calcium chloride. Each product was then again rectified and immediately analysed.

The first distillation yielded figures which led to no certain formula. But the reaction seemed to indicate that it consisted of impure benzyl alcohol.

The second distillate, which boiled at 300° C., yielded the formula $C_{14}H_{12}O_2$, corresponding to benzoate of benzylic ether, and after treatment with potassa, and addition of sulphuric acid, yielded an acid, having the melting point 121° C., and proving to be undoubtedly *benzoic acid.*

The third distillate, boiling at over 320°, yielded the formula $C_{16}H_{14}O_2$ (cinnamate of benzylic ether), and yielded an acid, melting at 133° C., which was therefore *cinnamic acid.*

These results prove that balsam of Tolu contains the same constituents as balsam of Peru, but in smaller quantities and in different proportions—cinnamic acid predominating in the former, in the latter benzoic acid.

The alkaline solution was deprived of resin and divided into two portions, one of which was treated with milk of lime, and the resulting calcium salt, after re-crystallization, decomposed. It yielded cinnamic acid. The liquid filtered from the difficultly soluble calcium cinnamate yielded another salt, the acid of which was found to be benzoic acid. The other portion was dissolved in alcohol and converted by hydrochloric acid gas into the corresponding ethylic ethers.

Balsam of Tolu therefore contains cinnamic and benzoic acids, neutral benzoate and cinnamate of benzylic ether, and a peculiar resin, which, however, requires further investigation.

PRELIMINARY NOTE ON LITMUS.*

BY HOWARD W. MITCHELL.

Wartha† has separated four organic bodies from litmus. The first is obtained by treating commercial litmus with alcohol of about 90 per cent., filtering cold, and boiling the clear tincture; whereupon indigo is precipitated as a fine powder, according to the author. The second body is obtained by evaporating the violet-red mother-liquor; it is a beautiful red, or, from many varieties, green, fluorescent substance, indifferent to acids. The litmus residue left after the above treatment with alcohol, and which is insoluble in that fluid, is digested with distilled water for twenty-four hours, after which the deep-coloured solution is evaporated to dryness on the water-bath, the residuary extract treated several times with absolute alcohol containing a little glacial acetic acid and again evaporated, until it forms a brown powdery mass. This brown powder is now extracted with absolute alcohol and acetic acid, whereby a large quantity of a scarlet-red body is dissolved, which resembles orceine and becomes purple-red, in place of blue, with ammonia. The portion of the brown powder insoluble in the acidified absolute alcohol consists of the litmus colouring matter in a state of great purity—so pure, in fact, that by means of it the carbonated alkaline earths contained in spring waters may be titrated with as great delicacy as by the use of cochineal tincture, which is far from being the case with crude litmus.

To get this perfectly pure, it is first washed with absolute alcohol, then dissolved in a small quantity of water and thrown into a large excess of alcohol, the flocculent purple precipitate collected and again thoroughly washed with alcohol.

I have repeated Wartha's experiments as here stated upon some samples of litmus obtained from Bullock and Crenshaw, of Philadelphia, and said to have come from Pettitt, Aimee, and Co., Paris, France. My observations confirm his results in every particular, save as regards the indigo. No deposit of indigo was obtained upon boiling the alcoholic tincture, not even after repeated ebullitions, with intervals of rest and cooling.

The fluorescent body which he mentions is violet or purple, as I have obtained it, and gives a solution in alcohol of a similar colour, which shows a beautiful green fluorescence with sunlight, even when very dilute, and with the spectroscope gives a very characteristic absorption band in the green, together with an almost total absorption of the violet end of the spectrum.

It is soluble in water, amylic alcohol, and common ether to some extent, extremely soluble in alcohol, but seems to be wholly insoluble in bisulphide of carbon, chloroform, petroleum-naphtha, and oil of turpentine, imparting neither colour nor fluorescent property to those liquids.

The solutions in amylic alcohol and in ether both exhibit a beautiful fluorescence, but the ethereal solution shows the absorption band in the green only very faintly, even when the solution is thoroughly saturated. The solubility of the substance in both of these liquids is probably due to the trace of common alcohol, which they both contain, as found commercially. The body which resembles orceine shows a very faint fluorescence and in alcoholic solution gives a spectrum in which the absorption is characteristic, and quite distinct from that of the last. It is slightly soluble in water, very soluble in alcohol, but seems to be insoluble in ether, chloroform, bisulphide of carbon, and petroleum-naphtha.

The pure colouring matter proper of litmus is insoluble in alcohol, ether, chloroform, bisulphide of carbon, and petroleum-naphtha, both in the cold and upon boiling; it is very soluble in water, and its aqueous solution yields

* From the *American Chemist*. Read before the American Chemical Society, June, 1876.

† 'Ueber den Lakmusfarbstoff. v. Wartha,' *Ber. Chem. Ges. Berlin*, 9, 217.

an absorption spectrum differing from that of each of the preceding substances.

This substance turns blue with ammonia, and seems more like the azolitmine of Kane than either of the other substances, but I obtained no ammonia from it by heating with sodic or calcic hydrates, that is, sufficient to show its presence by odour or by reaction upon reddened litmus paper.

It yields in alkaline solution a beautiful violet lake with alumina, one of a pale violet colour with stannous acetate, and deep blue lakes with calcium and barium salts.

The residue left, after extracting litmus with alcohol and then with water, is soluble to the extent of 8 per cent. in dilute hydrochloric acid, and the portion dissolved in this liquid consists of calcic and magnesic carbonates, free from colouring matter, in the proportions of about 90 per cent. and 10 per cent. of the carbonates respectively. The residue, insoluble in dilute hydrochloric acid, consists mostly of fine sand, but yields some colouring matter to strong ammonic hydrate, and forms a solution of a blue colour, with a precipitate, red and gelatinous, somewhat like alumina, upon supersaturation with an acid.

About 25 grs. of the pure colouring matter, 15 grs. of the body like orceine, and 10 grs. of the fluorescent body, were obtained per ounce of litmus.

Diagrams of the absorption spectra yielded by these several substances I reserve for a second paper.

NOTE ON THE DECOMPOSITION OF A SOLUTION OF IODIDE OF POTASSIUM BY LIGHT.*

BY M. BATTANDIER.

It has often been observed that a solution of iodide of potassium turns yellow under the influence of sunlight, and after a time contains free iodine. According to Vidau† this decomposition is due to light alone and the atmosphere takes no part in the phenomenon. In seeking to verify this statement the author has arrived at a different conclusion.

A ten per cent. solution of pure iodide of potassium was divided into three portions, and exposed (1) to sunlight in the open air, (2) to sunlight in a vacuum, and (3) to the air in the shade. Decomposition took place in No. 1 only. The liquid first turned yellow; then at the end of the third day it gave up to chloroform a small quantity of iodine which gradually augmented. The experiments were repeated three times, being continued during a fortnight each time and always with the same result.

These experiments appeared to demonstrate that the intervention of air is necessary to the decomposition. To verify this the same solution was exposed (1) to air and sunlight; (2) to air and sunlight after boiling; (3) to air and sunlight after passing through it a current of pure carbonic acid; (4) to air and light, with a little chloride of barium; (5) to air and light with a little caustic potash; (6) to sunlight and in confined air deprived of carbonic acid by lime; (7) to sunlight and in carbonic acid deprived of air.

In experiments, 4, 5, and 6, no appreciable decomposition took place. In experiment 7, on the contrary, it was quite energetic, so that in two hours the solution was already sensibly yellow, and it gradually darkened. In experiment 3, the decomposition was a little less energetic; and still less pronounced in experiments 1 and 2.

From these experiments the author concludes that sunlight and acids present in the atmosphere, and especially carbonic acid, are the principal agents of the decomposition, which results probably from the setting free of a little hydriodic acid.

Vidau found the decomposition to take place in the presence of an excess of caustic potash; this the author would attribute to the action of ozone. He has noticed that his altered solutions possessed marked decolorizing properties, a peculiarity that he has also met with in the iodide decomposed by ozone and in a liquid obtained by saturating a solution of potash with iodine.

SURFACE BIOLOGY.*

BY ALFRED RUSSEL WALLACE, F.R.G.S., F.L.S.

(*Continued from page* 334.)

The Philippine Islands seem to have the peculiarity of developing metallic colours. We find there at least three species of *Euplœa*† not closely related, and all of more intense metallic lustre than their allies in other islands. Here also we have one of the large yellow *Ornithopteræ* (*O. magellanus*), whose hind wings glow with an intense opaline lustre not found in any other species of the entire group; and an *Adolias*‡ which is larger and of more brilliant metallic colouring than any other species in the archipelago. In these islands also we find the extensive and wonderful genus of weevils (*Pachyrhynchus*), which in their brilliant metallic colouring surpass any thing found in the whole eastern hemisphere, if not in the whole world.

In the Andaman Islands in the Bay of Bengal there are a considerable number of peculiar species of butterflies differing slightly from those on the continent, and generally in the direction of paler or more conspicuous colouring. Thus two species of *Papilio* which on the continent have the tails black, in their Andaman representatives have them either red or white-tipped.§ Another species|| is richly blue-banded where its allies are black while three species of distinct genera of Nymphalidæ¶ all differ from their allies on the continent in being of excessively pale colours as well as of somewhat larger size.

In Madagascar we have the very large and singularly white-spotted *Papilio antenor*, while species of three other genera** are very white or conspicuous compared with their continental allies.

Passing to the West-Indian Islands and Central America (which latter country has formed a group of islands in very recent times) we have similar indications. One of the largest of the Papilios inhabits Jamaica,†† while another, the largest of its group, is found in Mexico.‡‡ Cuba has two of the same genus whose colours are of surpassing brilliancy;§§ while the fine genus *Clothilda*—confined to the Antilles and Central America—is remarkable for its rich and showy colouring.

Persons who are not acquainted with the important structural differences that distinguish these various genera of butterflies can hardly realize the importance and the significance of such facts as I have now detailed. It may be well, therefore, to illustrate them by supposing parallel cases to occur among the Mammalia. We might have, for example, in Africa, the gnus, the elands, and the buffaloes, all coloured and marked like zebras, stripe for stripe over the whole body exactly corresponding. So the hares, marmots, and squirrels of Europe might be all red with black feet, while the corresponding species of Central Asia were all yellow with black heads. In North America we might have raccoons, squirrels, and opossums, in parti-coloured livery of white and black, so as exactly to resemble the skunk of the same country; while in South America they might be black with a yellow throat patch, so as to resemble with equal closeness the tayra of the Brazilian forests. Were such resemblances to occur in any thing like the number and with the wonderful accuracy of imitation met with among the Lepidoptera, they would certainly attract universal attention among naturalists, and would lead to the exhaustive study of the influence of local causes in producing such startling results.

* Presidental Address delivered to the Biological Section of the British Association, at Glasgow, on Sept. 6, 1876.

† *Euplœa hewitsonii, E. diocletiana, E. lætifica.*

‡ *Adolias calliphorus.*

§ *Papilio rhodifer* (near *P. doubledayi*) and *Papilio charicles* (near *P. memnon*). || *Papilio mayo.*

¶ *Euplœa andamanensis, Cethosia biblis, Cyrestis cocles.*

** *Danais nossima, Melanitis massoura, Diadema dexithea.* †† *Papilio homerus.*

‡‡ *P. daunus.* §§ *P. gundlachianus, P. villiersi*

One somewhat similar case does indeed occur among the Mammalia, two singular African animals, the Aard-wolf (*Proteles*) and the hyæna-dog (*Lycaon*), both strikingly resembling hyænas in their general form as well as in their spotted markings. Belonging as they all do to the Carnivora, though to three distinct families, it seems quite an analogous case to those we have imagined; but as the Aard-wolf and the hyæna-dog are both weak animals compared with the hyæna, the resemblance may be useful, and in that case would come under the head of mimicry. This seems the more probable because, as a rule, the colours of the Mammalia are protective, and are too little varied to allow of the influence of local causes producing any well-marked effects.

When we come to birds, however, the case is different; for although they do not exhibit such distinct marks of the influence of locality as do butterflies—probably because the causes which determine colour are in their case more complex—yet there are distinct indications of some effect of the kind, and we must devote some little time to their consideration.

One of the most curious cases is that of the parrots of the West-Indian Islands and Central America, several of which have white heads or foreheads, occurring in the two distinct genera, while none of the more numerous parrots of South America are so coloured. In the small island of Dominica we have a very large and richly-coloured parrot (*Chrysotis augusta*) corresponding to the large and richly-coloured *Papilio homerus* of Jamaica.

The Andaman Islands are equally remarkable, at least six of the peculiar birds differing from their continental allies in being much lighter, and sometimes with a large quantity of pure white in the plumage, exactly corresponding to what occurs among the butterflies.

In the Philippines this is not so marked a feature; yet we have here:—the only known white-breasted kingcrow (*Dicrurus mirabilis*); the newly discovered *Eurylæmus Steerii*, wholly white beneath; three species of *Diceum*, all white beneath; several species of *Parus*, largely white-spotted; while many of the pigeons have light ashy tints. The birds generally, however, have rich dark colours, similar to those which prevail among the butterflies.

In Celebes we have a swallow-shrike and a peculiar small crow allied to the jackdaw, whiter than any of their allies in the surrounding islands; but otherwise the colours of the birds call for no special remark.

In Timor and Flores we have white-headed pigeons, and a long-tailed flycatcher almost entirely white.

In the small Lord Howe's Island we have the recently extinct white rail (*Notornis alba*), remarkably contrasting with its allies in the larger islands of New Zealand.

We cannot, however, lay any stress on isolated examples of white colour, since these occur in most of the great continents; but where we find a series of species of distinct genera all differing from their continental allies in a whiter coloration, as in the Andaman Islands and the West Indies, and, among butterflies, in the smaller Mollaccas, the Andamans, and Madagascar, we cannot avoid the conclusion that in these insular localities some general cause is at work.

There are other cases, however, in which local influences seem to favour the production or preservation of intense crimson or a very dark coloration. Thus in the Moluccas and New Guinea alone we have bright red parrots belonging to two distinct families, and which therefore most probably have been independently produced or preserved by some common cause. Here, too, and in Australia we have black parrots and pigeons; and it is a most curious and suggestive fact that in another insular subregion—that of Madagascar and the Mascarene Islands—these same colours reappear in the same two groups.

Some very curious physiological facts bearing upon the presence or absence of white colours in the higher animals have lately been adduced by Dr. Ogle. It has been found that a coloured or dark pigment in the olfactory region of the nostrils is essential to perfect smell, and this pigment is rarely deficient except when the whole animal is pure white. In these cases the creature is almost without smell or taste. This, Dr. Ogle believes, explains the curious case of the pigs in Virginia adduced by Mr. Darwin, white pigs being killed by a poisonous root which does not affect black pigs. Mr. Darwin imputed this to a constitutional difference accompanying the dark colour, which rendered what was poisonous to the white-coloured animals quite innocuous to the black. Dr. Ogle, however, observes that there is no proof that the black pigs eat the root, and he believes the more probable explanation to be that it is distasteful to them; while the white pigs, being deficient in smell and taste, eat it and are killed. Analogous facts occur in several distinct families. White sheep are killed in the Tarentio by eating *Hypericum crispum*, while black sheep escape; white rhinoceroses are said to perish from eating *Euphorbia candelabrum*; and white horses are said to suffer from poisonous food where coloured ones escape. Now it is very improbable that a constitutional immunity from poisoning by so many distinct plants should, in the case of such widely different animals, be always correlated with the same difference of colour; but the facts are readily understood if the senses of smell and taste are dependent on the presence of a pigment which is deficient in wholly white animals. The explanation has, however, been carried a step further, by experiments showing that the absorption of odours by dead matter, such as clothing, is greatly affected by colour, black being the most powerful absorbent; then blue, red, yellow, and lastly white. We have here a physical cause for the sense-inferiority of totally white animals which may account for their rarity in nature: for few, if any, wild animals are wholly white; the head, the face, or at least the muzzle or the nose, are generally black; the ears and eyes are also often black; and there is reason to believe that dark pigment is essential to good hearing, as it certainly is to perfect vision. We can therefore understand why white cats with blue eyes are so often deaf, a pecularity we notice more readily than their deficiency of smell or taste.

If, then, the prevalence of white coloration is generally accompanied with some deficiency in the acuteness of the most important senses, this colour becomes doubly dangerous; for it not only renders its possessor more conspicuous to its enemies, but at the same time makes it less ready in detecting the presence of danger. Hence, perhaps the reason why white appears more frequently in islands, where competition is less severe and enemies less numerous and varied. Hence, also, a reason why *albinoism*, although freely occurring in captivity, never maintains itself in a wild state, while *melanism* does. The peculiarity of some islands in having all its inhabitants of dusky colours (as the Galapagos) may also perhaps be explained on the same principles, for poisonous fruits or seeds may there abound which weed out all white or light-coloured varieties, owing to their deficiency of smell and taste. We can hardly believe, however, that this would apply to white-coloured butterflies; and this may be a reason why the effect of an insular habitat is more marked in these insects than in birds or mammals. But though inapplicable to the lower animals, this curious relation of sense-acuteness with colours may have had some influence on the development of the higher human races. If light tints of the skin were generally accompanied by some deficiency in the senses of smell, hearing and vision, the white could never compete with the darker races so long as man was in a very low or savage condition, and wholly dependent for existence on the acuteness of his senses. But as the mental faculties become more fully developed and more important to his welfare than mere sense-acuteness, the lighter tints of skin and hair and eyes would cease to be disadvantageous whenever they were accompanied by superior brain power. Such variations would then be preserved; and thus may have arisen the

Xanthochroic race of mankind, in which we find a high development of intellect accompanied by a slight deficiency in the acuteness of the senses as compared with the darker forms.

I have now to ask your attention to a few remarks on the peculiar relations of plants and insects as exhibited in islands.

Ever since Mr. Darwin showed the immense importance of insects in the fertilization of flowers great attention has been paid to the subject, and the relation of these two very different classes of natural objects has been found to be more universal and more complex than could have been anticipated. Whole genera and families of plants have been so modified at first to attract, and then to be fertilized by, certain groups of insects; and this special adaptation seems in many cases to have determined the more or less wide range of the plants in question. It is also known that some species of plants can be fertilized only by particular species of insects; and the absence of these from any locality would necessarily prevent the continued existence of the plant in that area. Here, I believe, will be found the clue to much of the peculiarity of the floras of oceanic islands, since the methods by which these have been stocked with plants and insects will be often quite different. Many seeds are, no doubt, carried by oceanic currents, others probably by aquatic birds. Mr. H. N. Moseley informs me that the albatrosses, gulls, puffins, tropic birds, and many others nest inland, often amidst dense vegetation, and he believes they often carry seeds, attached to their feathers, from island to island for great distances. In the tropics they often nest on the mountains far inland, and may thus aid in the distribution even of mountain-plants. Insects, on the other hand, are mostly conveyed by aerial currents, especially by violent gales; and it may thus often happen that totally unrelated plants and insects may be brought together, in which case the former must often perish for want of suitable insects to fertilize them. This will, I think, account for the strangely fragmentary nature of these insular floras, and the great differences that often exist between those which are situated in the same ocean, as well as for the preponderance of certain orders and genera. In Mr. Pickering's valuable work on the 'Geographical Distribution of Animals and Plants,' he gives a list of no less than sixty-six natural orders of plants *unexpectedly* absent from Tahiti, or which occur in many of the surrounding lands, some being abundant in other islands—as the Labiatæ at the Sandwich Islands. In these latter islands the flora is much richer, yet a large number of families which abound in other parts of Polynesia are totally wanting. Now much of the poverty and exceptional distribution of the plants of these islands is probably due to the great scarcity of flower-frequenting insects. Lepidoptera and Hymenoptera are exceedingly scarce in the eastern islands of the Pacific, and it is almost certain that many plants which require these insects for their fertilization have been thereby prevented from establishing themselves. In the western islands, such as the Fijis, several species of butterflies occur in tolerable abundance, and no doubt some flower-haunting Hymenoptera accompany them; and in these islands the flora appears to be much more varied, and especially to be characterized by a much greater variety of showy flowers, as may be seen by examining the plates of Dr. Seemann's 'Flora Vitiensis.'

Darwin and Pickering both speak of the great preponderance of ferns at Tahiti; and Mr. Moseley, who spent several days in the interior of the island, informs me that "at an elevation of from 2000 to 3000 feet the dense vegetation is composed almost entirely of ferns. A tree fern (*Alsophila tahitensis*) forms a sort of forest to the exclusion of almost every other tree, and, with huge plants of two other ferns (*Angiopteris evecta* and *Aspelenium nidus*), forms the main mass of the vegetation." And he adds, "I have nowhere seen ferns in so great proportionate abundance." This unusual proportion of ferns is a general feature of insular as compared with continental floras; but it has, I believe, been generally attributed to favourable conditions, especially to equable climate and perennial moisture. In this respect, however, Tahiti can hardly differ greatly from many other islands, which yet have no such vast preponderance of ferns. This is a question that cannot be decided by mere lists of species, since it is probable that in Tahiti they are less numerous than in some other islands where they form a far less conspicuous feature in the vegetation. The island most comparable with Tahiti in that respect is Juan Fernandez. Mr. Moseley writes to me:—"In a general view of any wide stretch of the densely clothed mountainous surface of the island, the ferns, both tree ferns and the unstemmed forms, are seen at once to compose a very large proportion of the mass of foliage." As to the insects of Juan Fernandez, Mr. Edwyn C. Reed, who made two visits and spent several weeks there, has kindly furnished me with some exact information. Of butterflies there is only one (*Pyrameis carie*), and that rare—a Chilian species, and probably an accidental straggler. Four species of moths of moderate size were observed (all Chilian), and a few larvæ and pupæ. Of bees there were none, except one very minute species (allied to *Chilicola*), and of other Hymenoptera a single specimen of *Ophion luteus* (a cosmopolitan ichneumon). About twenty species of flies were observed, and these formed the most prominent feature of the entomology of the island.

Now, as far as we know, this extreme entomological poverty agrees closely with that of Tahiti; and there are probably no other portions of the globe equally favoured in soil and climate, and with an equally luxuriant vegetation, where insect-life is so scantily developed. It is curious, therefore, to find that these two islands also agree in the wonderful predominance of ferns over the flowering plants—in individuals even more than in species; and there is no difficulty in connecting the two facts. The excessive minuteness and great abundance of fern-spores cause them to be far more easily distributed by winds than the seeds of flowering plants, and they are thus always ready to occupy any vacant places in suitable localities, and to compete with the less vigorous flowering plants. But where insects are so scarce, all plants which require insect-fertilization, whether constantly to enable them to produce seed at all, or occasionally to keep up their constitutional vigour by crossing, must be at a great disadvantage; and thus the scanty flora which oceanic islands must always possess, peopled as they usually are by waifs and strays from other lands, is rendered still more scanty by the weeding out of all such as depend largely on insect-fertilization for their full development. It seems probable, therefore, that the preponderance of ferns in islands (considered in mass of individuals rather than in number of species) is largely due to the absence of competing phænogamous plants, and that this is in great part due to the scarcity of insects. In other oceanic islands, such as New Zealand and the Galapagos, where ferns, although tolerably abundant, form no such predominant feature in the vegetation, but where the scarcity of flower-haunting insects is almost equally marked, we find a great preponderance of small, green, or otherwise inconspicuous flowers, indicating that only such plants have been enabled to flourish there as are independent of insect-fertilization. In the Galapagos (which are perhaps even more deficient in flying insects than Juan Fernandez) this is so striking a feature that Mr. Darwin speaks of the vegetation as consisting in great part of "wretched-looking weeds," and states that "it was some time before he discovered that almost every plant was in flower at the time of his visit." He also says that he "did not see one beautiful flower" in the islands. It appears, however, that Compositæ, Leguminosæ, Rubiaceæ, and Solanaceæ form a large proportion of the flowering plants; and as these are orders which usually require insect-fertilization, we must suppose, either that they have become modified so as to be self-fertilized, or that they are fertilized by the visits of the minute Diptera and Hymenoptera, which are the only insects recorded from these islands.

In Juan Fernandez, on the other hand, there is no such total deficiency of showy flowers. I am informed by Mr. Moseley that a variety of the Magnoliaceous winter-bark abounds and has showy white flowers, and that a Bignoniaceous shrub with abundance of dark blue flowers was also plentiful; while a white-flowered Liliaceous plant formed large patches on the hill-sides. Besides these there were two species of woody Compositæ with conspicuous heads of yellow blossoms, and a species of white-flowered myrtle also abundant; so that, on the whole, flowers formed a rather conspicuous feature in the aspect of the vegetation of Juan Fernandez.

But this fact—which at first sight seems entirely at variance with the view we are upholding of the important relation between the distribution of insects and plants—is well explained by the existence of two species of humming-birds in Juan Fernandez, which, in their visits to these large and showy flowers, fertilize them as effectually as bees, moths, or butterflies. Mr. Moseley informs me that "these humming-birds are *extraordinarily abundant*, every tree or bush having one or two darting about it." He also observed that "nearly all the specimens killed had the feathers round the base of the bill and front of the head clogged and coloured yellow with pollen." Here, then, we have the clue to the perpetuation of large and showy flowers in Juan Fernandez; while the total absence of humming-birds in the Galapagos may explain why no such large-flowered plants have been able to establish themselves in those equatorial islands.

This leads to the observation that many other groups of birds also, no doubt, aid in the fertilization of flowers. I have often observed the beaks and faces of the brush-tongued lories of the Moluccas covered with pollen; and Mr. Moseley noted the same fact in a species of *Artamus*, or swallow-shrike, shot at Cape York, showing that this genus also frequents flowers and aids in their fertilization. In the Australian region we have the immense group of the Meliphagidæ, which all frequent flowers; and as these range over all the islands of the Pacific, their presence will account for a certain proportion of showy flowers being found there, such as the scarlet *Metrosideros*, one of the few conspicuous flowers in Tahiti. In the Sandwich Islands, too, there are forests of *Metrosideros*; and Mr. Charles Pickering writes me, that they are visited by honey-sucking birds, one of which is captured by sweetened bird-lime, against which it thrusts its extensile tongue. I am also informed that a considerable number of flowers are occasionally fertilized by humming-birds in North America; so that there can, I think, be little doubt that birds play a much more important part in this respect than has hitherto been imagined. It is not improbable that in Tropical America, where the humming-bird family is so enormously developed, many flowers will be found to be expressly adapted to fertilization by them, just as so many in our own country are specially adapted to the visits of certain families or genera of insects.

It must also be remembered, as Mr. Moseley has suggested to me, that a flower which had acquired a brilliant colour to attract insects might, on transference to another country, and becoming so modified as to be capable of self-fertilization, retain the coloured petals for an indefinite period. Such is probably the explanation of the *Pelargonium* of Tristan d'Acunha, which forms masses of bright colour near the shore during the flowering season; while most of the other plants of the island have colourless flowers in accordance with the almost total absence of winged insects. The presence of many large and showy flowers among the indigenous flora of St. Helena must be an example of a similar persistence. Mr. Melliss indeed states it to be "a remarkable peculiarity that the indigenous flowers are, with very slight exceptions, all perfectly colourless;" but although this may apply to the general aspect of the remains of the indigenous flora, it is evidently not the case as regards the *species*, since the interesting plates of Mr. Melliss's volume show that about one-third of the indigenous flowering plants have more or less coloured or conspicuous flowers, while several of them are exceedingly showy and beautiful. Among these are a *Lobelia*, three *Wahlenbergias*, several *Compositæ*, and especially the handsome red flowers of the now almost extinct forest-trees, the ebony and redwood (species of *Melhania*, Byttneriaceæ). We have every reason to believe, however, that when St. Helena was covered with luxuriant forests, and especially at that remote period when it was much more extensive than it is now, it must have supported a certain number of indigenous birds and insects, which would have aided in the fertilization of these gaily-coloured flowers. The researches of Dr. Hermann Müller have shown us by what minute modifications of structure or of function many flowers are adapted for partial insect- and self-fertilization in various degrees; so that we have no difficulty in understanding how, as the insects diminished and finally disappeared, self-fertilization may have become the rule, while the large and showy corollas remain to tell us plainly of a once different state of things.

(To be continued.)

COUNTER PRESCRIBING.

The following remarks appeared under the above heading in the editorial columns of the *Medical Press and Circular* this week:—

"It is, moreover, as we remarked on a previous occasion, only fair to consider, when talking of the chemist usurping the office of medical adviser, how many there are in our profession who trespass upon the province of the chemist and druggist. One of our medical contemporaries thinks there is far more work to be done by pharmacists whenever they will give their undivided energy and attention to the duty of preparing remedies for public use on the prescription of medical men. But to this very considerate remark the *Pharmaceutical Journal* justly retorts that 'an important factor is at present much wanting—the prescriptions.' The fact is, that the medical men who prescribe form but a very small portion of the profession, and we are sorry to say that a great number not only make up their own medicines, but sell drugs and other things indiscriminately, and carry on a trade little different from that of an ordinary chemist. Besides, the prescriptions are most wanting just in those neighbourhoods where the practice of counter-prescribing is most rife. It is not the fashionable chemist who does much prescribing business, but the chemist in the back street. The former is well supplied with prescriptions, and sells to the surrounding gentry a large amount of aërated waters, scents, and other fancy articles. The latter makes up nice cough mixtures for Mrs. Brown's only child, or liniments for her husband's sprained ankle. It stands to reason if every member of the profession were to write prescriptions, chemists could have little or no further motive for prescribing themselves, inasmuch as they would know that they must eventually make up the prescriptions of their customers. Until this is the case we cannot expect that counter-prescribing, much as it is to be deprecated, will be entirely given up, and until this is the case we are not justified in throwing all the blame upon the chemists. But the abolition of counter-prescribing would be productive of much good. As we said months ago, 'if every member of the profession tried to confine his practice to prescribing, and every chemist to dispensing only, there is reason to believe that the good intentions of the chemist will have to yield to a strong pressure from without.' This difficulty could only be got over by the general public being better educated than they are at present with respect to the respective claims of the pharmaceutical and the medical profession upon their confidence in the hour of illness."

The Pharmaceutical Journal.

SATURDAY, OCTOBER 28, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PROFESSOR HUXLEY ON EDUCATION.

ACCORDING to the dictum of the wise preacher, "To everything there is a season," and this saying represents briefly the spirit of a large part of an admirable address on educational subjects, which was delivered by Professor HUXLEY, at Baltimore, on the occasion of the opening of the John Hopkins University last month. In then expressing his views as to the amount of elementary knowledge students should possess before they enter a university, and especially its medical school, Professor HUXLEY said many things that are of interest to pharmacists, and one at least that is strictly pertinent to youths entering the chemists and druggists' business. For although in the technical education of the latter the shop should for the greater part, if not wholly, take the place of the lecture room of the University, the conditions which obtain in each are to a considerable extent similar.

Professor HUXLEY is of opinion that the time and opportunities of the University should not be wasted in conferring such elementary instruction as can be obtained elsewhere. He considers that a boy of fifteen or sixteen should already have undergone an elementary education that will enable him, among other things, to read and write his own language with ease and accuracy; to have a general acquaintance with the history of his own country and with the laws of social existence; to have acquired the rudiments of the physical and physiological sciences and a fair knowledge of elementary arithmetic and geometry. Then the work of the university,—or the pharmaceutical preceptor in shop or school,—would only be to develop, intensify and specialize the instruction in certain departments of knowledge already obtained in the elementary school. Professor HUXLEY complains that at present young men come to the medical schools,—and the same may be said of the pharmacy—without a conception of even the elements of physical science, learning there for the first time that there are such sciences as physics, chemistry and physiology. He argues that there would not be the slightest difficulty in giving sound elementary instruction in these subjects in the ordinary schools; or, in other words, that the student might come provided with as much knowledge of these several sciences as he ordinarily picks up in the first year of his attendance at the medical school.

All this applies strictly to the case of a lad who seeks to become a pupil in the art and mystery of pharmacy. It is very satisfactory to know that there has been a great advance in the recognition of the importance of this principle by pharmacists during the last few years, and that the passing of the Preliminary or an equivalent examination is now so generally made a test—to a certain extent—of a lad's fitness before he is bound. But there are many exceptions to this rule, and it is to be regretted that it is still possible to say of a city like Norwich—as is said by a correspondent on another page—that a large proportion of the apprentices have not yet passed the Preliminary examination, whilst some of them have little prospect of ever doing so. Of course, it is unsatisfactory that there should be so much difficulty in obtaining as apprentices youths who are fairly educated, but this is due to the present inferiority of middle class education in this country. It must be more unsatisfactory still for a pharmacist to waste time and trouble in doing the work of an elementary school master.

One other subject alluded to by Professor HUXLEY may be mentioned here. It may be claimed as one of the results of thirty-five years' effort by the Pharmaceutical Society, that the position of pharmacy as an art requiring special study is now much more distinctly recognized than formerly. For instance, early in the present year, on the recommendation of its board of examiners the Royal College of Physicians felt themselves justified in calling the attention of medical schools to the fact that candidates for its licence present themselves for the pass examination very imperfectly prepared, as a rule, on the subject of chemistry in its application to pharmacy, and intimated that it would be imperatively necessary in future for the candidates to present themselves as well prepared on the subject of chemistry applied to pharmacy, pathology and toxicology, as on other subjects of the examination. In the neighbourhood of Apothecaries' Hall also there have been manifested some indications of a similar spirit. But we are of opinion that so far there has been only a partial recognition of the necessities of the position. As Professor HUXLEY points out, in about four years a young man fresh from school has to acquaint himself with medicine, surgery, obstetrics, therapeutics, pathology, hygiene, as well as with the anatomy and physiology of the human body, and his knowledge should be of such a character that it can be relied upon in any emergency and always ready for practical application. Under these circumstances Professor HUXLEY would lighten the medical curriculum by cutting out of it everything which is unessential. And as his opinion as to some of the things that are unessential may assist in the more rapid maturation of the healthy state of opinion on the respective sphere of the medical man and the pharmacist we here quote a passage:—

"Undoubtedly the doctor should know the common poisonous plants of his own country when he sees them, but that knowledge may be obtained by a few hours devoted to the examination of specimens of such plants, and the desirableness of such knowledge is no justification, to my mind, for spending three months over the study of systematic botany. Again, materia medica, so far as it is a knowledge of drugs, is the business of the druggist. In all other callings the necessity of the division of labour is fully recognized, and it is absurd to require of the medical man that he should not avail himself of the special knowledge of those whose business it is to deal in the drugs which he uses. It is all very well that the physician should know that castor oil comes from a plant, and castoreum from an animal, and how they are to be prepared, but for all practical purposes of his profession that knowledge is not of one whit more value, has no more relevancy, than the knowledge of how the steel of his scalpel is made."

From the foregoing, therefore, we think it may be inferred that in Professor HUXLEY's opinion, the "season" for obtaining an elementary education is whilst at an elementary school, and that the "season" for obtaining pharmaceutical training is not whilst struggling with the multifarious subjects of a medical curriculum.

THE NORTH BRITISH BRANCH.

WE wish to call attention to the fact that amongst the official announcements will be found the details as to the classes for pharmaceutical students which commence to meet next week in connection with the North British Branch of the Pharmaceutical Society. It will be seen that this session there is a day and an evening series of classes. The former include a course of Lectures on Chemistry, by Dr. STEVENSON MACADAM, and Demonstrations on Practical Chemistry; also a course of Lectures on Materia Medica by Dr. F. W. MOINET. The Evening Classes include a class in Practical Chemistry conducted by Mr. WILLIAM J. MACADAM, a course of lectures on Materia Medica by Dr. WILLIAM CRAIG, and a course of lectures on Botany by Mr. JOHN SADLER. A special arrangement exists respecting the fees to be paid by pharmaceutical students in the above classes, the particulars of which will be found in the announcement referred to. Besides these, those students who prefer to attend the University courses can do so by entering for the classes on Materia Medica, by Sir ROBERT CHRISTISON; and on Elementary, Practical and Analytical Chemistry by Professor CRUM BROWN. For these courses the students matriculate, and in addition pay the full fee for each course.

A CRACE-CALVERT SCHOLARSHIP.

THE sum of £700 has been presented to OWENS College, Manchester, by Mrs. CRACE-CALVERT for the foundation of a Scholarship in Chemistry, of the annual value of £25, in memory of her late husband, Dr. CRACE-CALVERT, F.R.S. The scholarship will be competed for by members of the evening classes.

PRIZE IN INDUSTRIAL HYGIENE.

IT is announced that an offer has been made by Mr. BENJAMIN SHAW, and accepted by the Council of the Society of Arts, to provide a medal of the value of £20 every fifth year to be awarded "for any "discovery, invention, or newly devised method for "obviating or materially diminishing any risk to life, "limb or health, incidental to any industrial occupa- "tion, and not previously capable of being so ob- "viated or diminished by any known and practically "available means." The first award will be made in May, 1877, and persons desirous of competing should communicate with the Secretary of the Society of Arts before the 31st of March next.

AN EXTRAORDINARY CINCHONA BARK.

IN the report of Mr. VAN GORKOM to the Dutch Government upon the progress of the Dutch Cinchona Plantations in Java during the second quarter of the present year mention is made of a number of excellent seed-bearing trees of *Cinchona Calisaya Ladgeriana*. During the chemical examination of some specimens of bark from these plants one was met with that yielded 13·25 per cent. of quinine, or equal to 17·86 per cent. of quinine sulphate.

THE END OF THE CINCHONA EXPERIMENT IN ST. HELENA.

THE attempt to acclimatize the Cinchona in the island of St. Helena, which if we may judge from reports previously published in this Journal has been but a half-hearted affair from the commencement, has now been abandoned. A correspondent of the *Gardeners' Chronicle*, writing under the date of September 24, says, "The Cinchona plantation is deserted, the last labourer being taken off; more's the pity!"

THE LORD ADVOCATE ON "PATENT MEDICINES."

IN a letter addressed to Dr. J. M. CROMBIE, quoted in the *British Medical Journal*, the Lord Advocate who is now a candidate to represent the Universities of Glasgow and Aberdeen in Parliament, states that if returned he would cheerfully use his influence towards the suppression of the sale of quack medicines, professing himself to be well aware of the dangers to which the public are exposed from this cause. He would prefer a remedy by which patents should still be granted to inventors of truly useful and wholesome medicines; but he would support the total abolition of such patents if their existence could not be safely continued without affording protection to quack medicines. Apparently the Lord Advocate has to begin with the A, B, C, of the subject, and learn that the connection between most so-called "patent medicines" and patents is analogous to the *lucus à non lucendo* etymology.

A PHARMACEUTICAL BADGE.

AMONGST the business before the American Pharmaceutical Association at its recent meeting in Philadelphia was the report of a Committee to which had been entrusted the designing of a badge to be worn by the members. The design adopted consists of a "trilobed leaf, upon which is impressed a mortar and a Liebig's condenser, the latter bearing upon the cooler the inscription, 'AM. PHAR. ASS'N.'" Copies of the badge, finished in nickel-plated silver were supplied to the officers and the members of the committees at work during the meeting, and others were obtainable by ordinary members at 50 cents. each.

THE RESEARCH FUND OF THE CHEMICAL SOCIETY.

IT is stated by the *Medical Press and Circular* that the Goldsmiths' Company has voted a sum of £1000 to the Chemical Society to aid in the formation of the fund to be devoted to the promotion of original research in the science of chemistry, to which £1000 had been previously promised by Dr. LONGSTAFF.

DEATH OF M. STE.-CLAIRE DEVILLE.

WE regret to have to report the death of the eminent French chemist, M. CHARLES SAINTE-CLAIRE DEVILLE.

THE USE OF METHYLATED SPIRIT.

IN reference to the subject of the recent Memorial of the Council of the Pharmaceutical Society, the Board of Inland Revenue has issued a General Order, dated October 19, stating that "in addition to Soap and Compound Camphor Liniments as the only medicines in the composition of which methylated spirit was allowed by General Order of 24th July last, the Board now also consents to the use of such spirit in Aconite and Belladonna Liniments," and the respective officers are ordered to inform the chemists in their several stations accordingly.

THE NEXT EVENING MEETING.

AN Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, November 1, when a paper entitled "Suggestions for an Improved Method of Making Mistura Guaiaci and Similar Mixtures," will be read by Mr. GREENISH. The chair will be taken at 8·30 precisely.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

October 18th., 1876.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor and Umney.

Messrs Buchanan and Kinninmont were also present as a Deputation from the Board in Edinburgh.

Dr. Greenhow attended on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven Candidates were examined. *Two* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Helmore, William Holloway ...Stratford-on-Avon.
Kidd, William Champley ..... Malton.
Smith, George ....Sunderland.
Squire, Alfred Herbert ....London.
Turner, William Spencer.........Hingham.

MINOR EXAMINATION.

Twenty Candidates were examined. *Nine* failed. The following *eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Briggs, William Henry ....Wakefield.
Cooley, Walter Bromley ....Wolverhampton.
Day, John ....London.
Jones, Thomas ....Seacombe.
Lewis, David........................Merthyr.
Lincolne, William..................Ely.
Rundle, Charles .... St. Blazey.
Short, George William...........Swindon.
Thomas, Henry James......... .Llandilo.
Weston, Matthew Frank.........Bury.
Williams, James ....St. Clears.

October 19th, 1876.

Present—Mr. Savage, Vice-President, Messrs. Allchin Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall and Taylor.

MAJOR EXAMINATION.

Six candidates were examined. *One* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Bibbings, John Henry............Exeter.
Campbell, Henry ....Hammersmith.
Ferguson, William Harry ......London.
Keeling, Charles James ....Stafford.
Skinner, Kenneth Geo. Walrond Christchurch.

MINOR EXAMINATION.

Twenty candidates were examined. *Thirteen* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Griffith, Charles ....Weston-super Mare.
Heaton, George.....................Farnworth.
Hill, Francis ....Horncastle.
Holding, John ....London.
Littlewood, John Oscroft ....Sutton-in-Ashfield.
Nicholson, Richard ....Darlington.
Smale, Charles ....Totnes.

October 20th, 1876.

Present—Mr. Williams, president; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor and Umney.

MINOR EXAMINATION.

Twenty candidates were examined. *Thirteen* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists :—

Beken, Alfred Edward ....Canterbury.
Blackadar, Henry William......Portsea.
Bomford, Alfred Charles.........Oxford.
Glover, William Kensit ....Aberdeen.
Parkinson, Charles ....Preston.
Richards, Philip ....Bury St. Edmunds.
Trood, Richard.....................Bath.

MODIFIED EXAMINATION.

Five candidates were examined. *Two* failed. The following *three* passed, and were declared qualified to be registered as Chemists and Druggists :—

Clark, Cornelius .. ..Calne.
Hunn, Benjamin ....Henley-on-Thames.
Sutton, William Denny ....Norwich.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination :—

Certificate of the University of London.

Cox, John Goodwin .. ..Bridport.

Certificates of the University of Oxford.

Bartlett, Arthur Henry ....Newport, I. of W.
Collett, William James ....Nantwich.
Palmer, Harvey .... Wingham.

Certificates of the University of Cambridge.

Barugh, Edwin.......................York.
Cox, Webster ....Liverpool.
Roberts, Henry William.........Folkestone.
Rye, Frank ....Northampton.

Certificate of the University of Durham.

Graham, Andrew Ward ....Brighton.

Certificate of the Society of Apothecaries of London.

Slipper, Joseph Octavius.........London.

Certificate of the Apothecaries' Hall of Ireland.

Shine, Alfred ....London.

Certificates of the College of Preceptors.

Bosher, Alexander ....London.
Harrison, Robert ....Stockton-on-Tees.
Rigden, George.......................Folkestone.

GENERAL MEETING—BENEVOLENT FUND.

ELECTION OF ANNUITANTS.

A General Meeting of the Members, Associates in Business, and Associates of the Pharmaceutical Society, and of the Subscribers and Donors to the Benevolent Fund was held at the house of the Society, 17, Bloomsbury Square, on Wednesday, October 25th, at twelve o'clock, for the Election of Four Annuitants.

Mr. John Williams, President, in the chair.

The notice convening the meeting was read.

Scrutineers were appointed, who examined the voting papers, and brought up the following report :—

Scrutineers' Report.

We the undersigned Scrutineers, appointed at the twelfth election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us and report the following result :—

—	Votes Polled at Previous Elections.	Votes Polled at Election, 1876.	Total.
1. Atherton William	822	3065	3887
2. Brunton, Sophia............	....	3390	3390
3. Collins, Annie............ ..	1162	2503	3665
4. Naftel, Thomas Pradon...	817	2675	3492
5. Nichols, James	....	1048	1048
6. Trumper, Susan	257	1165	1422

4423 voting papers were received of which number 85 were informal, and were disallowed.

John Williams, *Chairman.*
Alex. Bottle.
John Robbins.
Edward Whaley.
Charles E. Turner.
J. P. Parkes.
S. C. Betty.
Thomas Greenish.
G. W. Sandford.

October 25, 1876.

The President announced that one of the candidates, Thomas Pradon Naftel, had died last week and he therefore declared the following four duly elected Annuitants:

William Atherton.
Sophia Bruton.
Annie Collins.
Susan Trumper.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The Eighth Annual Meeting of the members of this Association took place at their rooms, 37, Blackfriars Street, on Thurday evening, October 12th. Mr. Mumbray in the chair. The following gentlemen were elected associates :—Messrs. J. Haddock, J. Whittaker, H. C. Major, T. W. Dean, E. Foden, C. E. Lister, J. R. Atkinson, R. Wolstenholme, F. Bradbury, J. H. Beard, Arnfield, Skinner, Blaymile, F. P. Wood, C. Challinor, Linscott, Williams, and Morris.

The Secretary (Mr. F. Baden Benger) then read the Report of the Council, and, in the absence of Mr. G. S. Woolley, the Treasurer's statement.

In the report the Council expressed its trust that from the record of the work done during the past year it would be sufficiently evident to those who look with stedfast faith to the higher scientific education of pharmacists as the surest and best safeguard of our interests, that the Association continued to merit cordial support. During the past session five papers had been read at the ordinary monthly meetings. The courses of lectures on chemistry, pharmacy and materia medica, and botany had been well attended, and the report of the lecturer, Mr. Louis Siebold, had been presented at the end of the session when the prizes were distributed. (This report, the names of the prize takers, and the questions in the examination were published in the *Pharmaceutical Journal* of June 10, 1876.) The Council reported that the Association had been again indebted to the Council of the Pharmaceutical Society for its liberality in augmenting the fees in these classes by the sum of £25. It was gratifying to observe the increasing number of entries in the school, and the hope might now be reasonably entertained that the Manchester School of Pharmacy would eventually be self-supporting. Such a condition was, in the opinion of the Council, the only satisfactory one, and its attainment would be the best evidence that the executive of the Association had been right in asking, and the Pharmaceutical Council wise, as well as generous, in promptly rendering, assistance during the establishment of the School. The following courses of lectures will be delivered by Mr. Louis Siebold during the present session:—Chemistry, including the elements of physics, thirty lectures, fully illustrated by experiments, on Friday evenings, from 7·30 to 9 o'clock, commencing on October 6th. Fee 30*s.* Materia medica and pharmacy, twenty-five lectures, on Tuesday evenings, from 7·30 to 8·45, commencing October 10th. Fee 25*s.* Analytical chemistry, twenty lectures, on Tuesday evenings, from 8·45 to 9·45, commencing October 10th. Fee 20*s.* Composition Fee, admitting the student to all three courses, £3 5*s.* Students attending these courses must be Associates of the Manchester Chemists' Association. The subscription, 2*s.* 6*d.*, may be paid with the fees. A course of lectures on botany, by Mr. Leo H. Grindon, will be commenced early after Christmas. It is intended to hold the ordinary winter meetings of members and associates in the Memorial Hall, Albert Square, and to provide tea. It is hoped that this course will ensure a larger attendance, and afford better opportunities for friendly intercourse amongst members and associates. Due notice of these will be issued by the secretary. The income of the Association derived from annual subscriptions has slightly diminished this year, and the treasurer's report shows that the balance due to him at the last annual meeting has increased. Under these circumstances the Council see no alternative but to reduce the expenditure, and they propose to effect this by giving up one of the rooms at Blackfriars Street. The Council are more willing to adopt this course, as neither the classes nor the winter meetings will in future be held in that building, and one room will afford all the accommodation required. The Council regret to state that the very small number of students who use the reading room in the evening does not warrant it in continuing to incur the expense of nightly attendance, etc. Students may obtain the keys at any time by applying to the Secretary as heretofore; the valuable reference library, specimens, etc., will always therefore be at the command of those connected with the Association. Since the formation of this Association in 1868, 568 members and associates have been connected with it—many of these being assistants. Most of the leading members of the trade in the district have subscribed regularly.

The Treasurer in Account with the Manchester Chemists and Druggists' Association.

On the motion of the Chairman, seconded by Mr. J. I. Slack, the reports were adopted.

Mr. Siebold, in reply to the Chairman, said that he was very pleased with the attendance at his three courses of lectures just commenced. Already sixty entries had been made—viz., chemistry 23, materia medica and pharmacy 21, analytical chemistry 16. This was a larger number than last year, and did not include the botanical students whose course would not commence till after Christmas.

The Secretary announced that Messrs. Bostock and Waterhouse had expressed a wish to retire from the Council, as they were unable to devote the time and attention to the business of the Association which they considered to be the duty of its officers. Messrs. Fisher and Slack had consented to fill the vacancies thus caused, and Mr. Hermann Woolley had kindly allowed himself to be nominated as joint honorary secretary.

The following names were then read as proposed officers for the ensuing session, and these gentlemen were unanimously elected:—President, Mr. W. Scott Brown; Vice-Presidents, Mr. J. T. Slugg, F.R.A.S., Mr. W. Wilkinson; Treasurer, Mr. George S. Woolley; Hon. Secretaries, Mr. F. Baden Benger, F.C.S., Mr. Hermann Woolley; other members of Council, Messrs. Barnaby, Blain, Botham, Fisher, Hargraves, Hughes, Kay, Mumbray, Payne, Robinson, and Slack.

The usual vote of thanks to the retiring officers, and to the Chairman, brought the meeting to a close.

HULL CHEMISTS' ASSOCIATION.

The chemical class in connection with the above Association began the winter session on Wednesday evening last, October 18th, at the New Laboratory, Royal Chambers, Scale Lane, under the superintendance of Mr. Jas. Baynes, Junr.

Mr. C. B. Bill, the President of the Association, occupied the chair, and called upon Mr. H. T. Parson to read the inaugural address.

THE ADDRESS.

"Most of you are aware of my former connection with this Society—I mean, that of lecturer for three consecutive winter sessions, which naturally extended my sympathy with the students; and my presence in your midst again this evening shows that I am still interested in your studies, so, though my address will be brief, I wish at the outset for us to feel quite at home with each other.

"In the first place I have to congratulate the committee upon having a laboratory for your use, and I must offer you my gratulations upon the greater advantages you will consequently enjoy, which, if you make the best of, must substantially accrue to your benefit; for after all though theory is necessary and very well in itself, if not supplemented by practical example, it often falls unheeded on our ears, and a little while after the lesson passes from the mind, perhaps altogether. I rejoice to think there is such a laboratory in this town, and I think your thanks are due to Mr. Baynes for throwing it open to you. And when I say this, I intend that kind of thanks which is most acceptable to all teachers—persevering industry and an unlimited amount of diligence and attention to the lectures.

"You will meet together week by week, I suppose, for the study of chemistry, and you must try to feel interested in it, your success depending very much upon the amount of pleasure you have in your work. Chemistry is a science that is gaining ground every day, in fact making rapid strides. What is now known of the properties of matter has been discovered by men in each successive generation who have spent years in such inquiries. This knowledge has not been gained by sitting down and waiting for the turn of the tide, but by perseverance and hard toil, joined of course to a pure love for the work. In chemistry the minute particles of matter are investigated, and the manner in which atoms of one kind affect atoms of another kind of matter when they are intimately mixed—producing changes;—and it is these which are to be your chief study, and from which you will find that your greatest difficulties will come. The importance of a knowledge of chemistry is daily visible. Take for example the manufacture of iron—of all uninteresting things, nothing can be more so than a lump of iron ore (to a person unacquainted with it). But let it be subjected to the operations of the blast furnace and the metal appears. Think of the multitudinous uses to which it is applied; even the ancient wooden walls of old England have had to give place to iron; and from the mighty engine to the delicate needle how indispensable has it become. But it cannot be extracted from the iron ores, nor applied to any one object without the aid of chemical action. Seeing the importance of our subject, I have now to urge you to its pursuit. Like others who have studied before you, you will find it dry and uninteresting at first; but never mind that; persevere, and as you become more familiar with your task, it will transform itself into a pleasure and even a pastime. But there must be a great deal of careful reading and honest work if you mean to succeed, and when I talk of succeeding I don't mean merely filling your head with just sufficient facts to enable you to pass the necessary examinations—aim higher than that—at the attainment of information of every kind which will help in after life to tide you over the daily difficulties of our craft. A little learning is a dangerous thing; therefore, seek to know all you can, and make it your full determination to be thorough in everything, that you may sustain the credit of the order of pharmacists. Now let me remind you of the facilities you have in the town of Hull, such as only two or three others in the kingdom possess. The principal houses of business are closed at 7 p.m., and surely it is not too much to suggest that you devote one hour at least each evening to study; you may vary your subjects if you choose, the examiners give you that privilege by requiring a knowledge of five or six, so you cannot complain of sameness. And these lectures will help you considerably if you really wish to learn; and you must remember that they are opportunities for acquiring knowledge which, a few years ago, were not attainable anywhere in the country. I trust, therefore, you will be regular in your attendance, and at the end of the session I may hear that you have made considerable progress. Of course all cannot get prizes, but you can all try for them, and for encouragement to those of you who do not feel as if you were brilliant in any contest, just remember that in the old fable it was the tortoise that won the race though the hare could run so fast. Patient earnest plodding goes further and fares better than uneven bursts of study. I would also impress upon you that mental work cannot be replaced by anything in the world beside; all extraneous assistance can only be accessory to your own exertions.

'O! listen not to that enchantress, ease,
With seeming smile; her palatable cup
By standing grows insipid; and beware
The bottom, for there's poison in the lees....
Think we that man, with vigorous power endowed,
And room to stretch, was destined to sit still?'

"I cannot very well help saying a few words on the political prospects of the trade. Perhaps I am wrong in doing so in an address to students, if so, pardon me. Lord Hartington, some few weeks ago, expressed an opinion to the effect, that he regretted men were not trained to be politicians just as they are for any other profession; so I think his idea will bear me out in trying to impress you with the notion, that as soon as ever you begin your studies you ought to have sufficient interest in the trade you are to all appearance to follow for the rest of your life, to study its political economy as well.

"The *Pharmaceutical Journal* has informed us, that it is probable some of the chemists at Nottingham may be prosecuted by the Medical Defence Association for prescribing over the counter. I cannot but think much more good might be effected if medical men would approach us in a conciliatory manner. There certainly will have to be a radical change in this country when every trivial case that we are asked about is taken to a doctor. Surely, from the number of years that the populace have been accustomed to apply to their "druggist" for simple remedies, they will take it hard to be compelled to make a trifling headache into a formidable doctor's bill.

"Many would rather suffer. But, seriously they cannot think of asking us to cease prescribing in these minor cases without offering to meet us by ceasing to dispense. I dare say in this, as in other cases, the innocent will suffer for the guilty. I believe there are some who overstep the boundary and take upon themselves much greater responsibilities than they are justified in doing. Fair play is a jewel everywhere, and I should like to see medical men have their due. We cannot but admire those who spend their lives in trying to alleviate human suffering. We want them to continue their daily duties among the sick and afflicted, but we think it right that the public should have the liberty of asking whom they please for homely remedies. I am sure the proceedings of the Council as recently reported will be satisfactory to the members of the Society. I sometimes wish the members of the Council were more interested in country trade; also that it was customary for them to express their views on current topics before election, that we might judge how far their views corresponded with our own before giving them our countenance and support. Of course in our trade, as in every other, there are subjects upon which an endless variety of opinion is held, and there is nothing easier than to vote for a man who thinks in direct opposition to oneself, under the present system. I think it is the duty of the Society from time to time to see that our trade is protected from the attacks of outsiders. If this had been always the case I think we should not have grocers selling patent medicines at list prices, as some are doing in this town. All medicines ought to be retailed by chemists. Certainly if we are not keenly alive to our own interests we shall soon have to turn either to the profession of surgeon or to the grocery trade, for there will be nothing left of the old business. During the past year a Trade Protection Society has been established and promises to be of much service,—we wish it all possible success. In putting these things before you, I do not wish to present a gloomy view of your future prospects, but I want you to feel that the interests of the trade are already yours. The Pharmaceutical Society is and will be, whatever each member makes it, and I trust you will be useful members of it. Do not rest with being associates; rise to the full dignity of your privileges. We live in an age in which there is no room for standing still, we must either go forward or lag behind. It behoves me then to impress upon you the necessity of making the best use of time,

'That every thought and every deed
May hold within itself the seed
Of future good and future meed.'

I do hope you will not rest satisfied without learning something every day. It is very nice to have a pretty little array of works on chemistry, botany, materia medica and the like, to show your acquaintance, but they will be of little use unless their contents are fixed in the storehouse of your memory. Don't be afraid of packing too closely there—there's plenty of room yet.

"And now, gentlemen, in conclusion, I leave you to your studies. Shall these opportunities be of service to you? Shall Mr. Baynes work for and with you for results worth having? These are questions which you must answer—not in words merely but in deeds—to which both hand and brain must contribute earnestly and heartily.

'No desponding, no repining,
Leisure must by toil be bought.
Never yet was good accomplished
Without hand and thought.'"

At the conclusion, the President said that it afforded him very great pleasure to propose a most cordial vote of thanks to Mr. Parson for his address to the students, and exhorted them to be punctual in attendance and attentive to the instruction offered them. The motion was seconded by Mr. J. F. Smith, and supported by Messrs. Stoakes and Baynes, and carried unanimously.

LEEDS CHEMISTS' ASSOCIATION.

The session for 1876-77 of this Association was inaugurated on Wednesday evening, October the 18th, by a tea at the Assembly Room, Queen's Hotel, when close upon seventy of the gentlemen connected with pharmacy in Leeds spent a very agreeable evening together.

One new member and six associates were added to the ranks of the Association, and in addition to the addresses reported below, the proceedings were enlivened by a few choice songs kindly rendered by two gentlemen, the friends of a member.

In the course of a brief address, the President, Mr. E. Yewdall (who also occupied the chair), referred to the danger under which pharmacists are placed by the stringent provisions of the "Sale of Food and Drugs Act," illustrating his remarks by reference to the reports of cases which have come before the courts during the past year. Urging the claims of the Association to the support of the trade, he showed in what manner it endeavoured to promote the interests of the members and associates. He then reviewed the events of the past year more immediately affecting the chemists and druggists' business, and drew attention to the Chemists and Druggists' Trade Association, suggesting that the vexed question of prescribing by chemists might be far more easily settled at a meeting of representatives from that Association, the Medical Defence Association, and the Pharmaceutical Society. Referring to Sir William Frazer's notice of motion to amend the "Sale of Poisons Act," he remarked that absence of any knowledge whether the proposed amendment would be beneficial to the interests of chemists or place more restrictions upon the sale of poisons was a good reason why this "Trade Association" should have their support, and had the pleasure to inform them that Mr. Haydon, the secretary, had come over from Birmingham to attend that meeting, and would now lay the objects of that Association before them.

Mr. Haydon then proceeded to trace the origin, history, and objects of the Chemists and Druggists' Trade Association, an account of which has already appeared in this Journal. In the course of his remarks, Mr. Haydon said that on the 29th of last month the Association took possession of permanent offices at No. 23, Burlington Chambers, New Street, Birmingham, and that at the present time there were some 1450 members. Two of the objects of the Association, namely, the amendment of the Pharmacy Act and the exemption of all registered chemists and druggists from serving on juries could not, of course, be attempted until the Association was thoroughly organized. To accomplish them Parliament must necessarily be appealed to, and to approach the lower house until some pressure could be brought to bear on its members would be suicidal policy. Therefore, these very desirable objects must remain in abeyance *pro tem.* Meantime the best means of ultimately bringing about these desiderata would be constantly before the committee and officials, so that when the time was ripe action might be speedy and effectual. With regard to the defence of the members from vexatious and unjust prosecutions under the Adulteration and Medical Acts, and the defence of the trade from encroachments by unauthorized dealers in drugs, the Association was now able and willing to immediately carry out this portion of its programme, and any case that may reach it, for prosecution or defence, would receive the careful consideration of the solicitor and secretary. On the 6th of last month information had been received from Nottingham that a recently formed branch of the Medical Defence Association had instructed a detective to obtain the opinion of some of the local chemists respecting an imaginary cold. This functionary did so, and in several instances was successful in obtaining medicine and advice. For these misdeeds, the informant added, "summonses were imminent." The following day he (Mr. Haydon) proceeded to Nottingham and thoroughly investigated these so-called "cases." As a result, he would say, that should the summonses be served the solicitor of the Association would be in readiness. If the law did not allow chemists to give a mixture for a simple cold in the head, or a gargle for a sore throat, unless these remedies were written in the form of a prescription duly signed by a medical practitioner, then it was quite time the law should be repealed, and one more in accordance with the custom of the age and the opinion and wishes of the public take the place of such antiquated rubbish. The subject of co-operative trading had been brought before the Birmingham Conference in a very able paper by Mr. Hampson, of London, a member of the Pharmaceutical Council, and, after discussion, a resolution had been passed, urging upon the Pharmaceutical Society the necessity of testing the legality of co-operative traders selling and dispensing poisons. This resolution was duly forwarded to the Pharmaceutical Society, and the Council referred it to the Law and Parliamentary Committee for consideration. On the 6th inst., a letter had been received from the Secretary of the Pharmaceutical Society, inviting the Chemists and Druggists' Trade Association to appoint a deputation to meet the Law and Parliamentary Committee of the Council in order that the whole case may be fairly explained. The argument that the Association would be antagonistic to the elder Society had been freely used. Such was not the case; on the other hand, it would aid and assist the Society by every means in its power. Already more than half of the members of the Pharmaceutical Council were members of the Association. The county of York would be divided into 15 districts; Leeds would be the head quarters and place of election for one of these districts, which would return two members to the General Committee.

A long and animated discussion, taken part in by Messrs. F. Reynolds, Milestone, Iredale, Stead, Ward, and Clapham, followed the delivery of Mr. Haydon's address, and ultimately the following resolution, proposed by Mr. Ward, and seconded by Mr. Clapham, was passed *nem. con.*:—"That this meeting learns with satisfaction that such a trade association of chemists and druggists as that described by Mr. Haydon is formed for defending the rights of the trade, and pledges itself to support the Association to the utmost of its ability."

Mr. Brown, one of the delegates from the Leeds Chemists' Association to the meeting of the British Pharmaceutical Conference, recently held at Glasgow, next gave a short *résumé* of that meeting and its accessories. After pointing out the objects of the Conference, and the advantages of its holding its meeting yearly in the same town, and at a time contiguous to that of the British Association, he said he thought the value of the report as embodied in the 'Year Book of Pharmacy,' ought of itself to be sufficient to induce all who took an interest in pharmacy to become members. It was the first time he had attended one of its meetings, but with the many pleasant memories of his visit—the pleasure of meeting so many gentlemen of similar tastes and engaged in similar pursuits, over the breakfast table each morning; the courtesy, hospitality, and evident pleasure exhibited by the Scottish chemists in entertaining their Southern friends; the excursion down the Clyde, and other social enjoyment, combined with the intellectual entertainment of the Conference itself, still crowding upon his mind, he indulged the hope of attending many others in the future. Referring to the papers read, he thought they had been so well reported and so ably criticized elsewhere, that anything he could say about them would be superfluous. The President's address had been condemned as being too cautious, but he thought that great allowances should be made to a man holding the public position which the Professor did in handling subjects of such delicacy. He had been struck with the ability and critical acumen displayed by some of the younger members of the Conference, and believed there would be no lack of talent in the "coming men" of pharmacy. The method adopted of reading the papers seriatim had a rather narcotic effect; he would prefer their being discussed as read, when probably the discussion might be more largely entered into.

Votes of thanks to the Chairman (proposed by Mr. Richard Reynolds) and to the gentlemen who contributed the music were carried by acclamation.

Parliamentary and Law Proceedings.

Infringement of the Pharmacy Act.

The Pharmaceutical Society of Great Britain v. *Statham.*

In the Bloomsbury County Court, before George Lake Russell, Esq., the Judge, on Friday, October 20th, Henry G. Statham, of 15, Broadley Terrace, Blandford Square, was sued by the Council of the Pharmaceutical Society of Great Britain for a penalty of £5, incurred by the defendant "in selling or keeping an open shop for the retailing, dispensing, or compounding poisons or a poison contrary to the provisions of the Pharmacy Act, 1868 (31 & 32 Vic. cap. 121)."

Mr. Flux appeared for the plaintiffs, and the defendant appeared in person.

Mr. Flux, in opening the case, said that the defendant was sued under the 15th clause of the Act of Parliament for illegally trading as a chemist and druggist. He had a witness present who could prove the sale by the defendant of the poison; he had also Professor Redwood present who would prove that the mixture so sold contained prussic acid; but he believed that the defendant was prepared to admit that he sold the poison, and if so his Honour's time could be saved.

The Judge (to the defendant): Do you admit having sold this poison?

Defendant: Yes. I dispensed the prescription for my employer.

Mr. Flux: But do you admit that you were the person who sold the poison.

Defendant: Yes, for my employer.

Mr. Flux: I understand, your Honour, that the defendant will contend that the business had passed out of his hands at the time of the sale complained of; as to that I can offer evidence to show that defendant is the owner of the business.

The Judge: You will have to prove it.

Mr. Ward was then called and examined by Mr. Flux: On the 10th July last he went to the defendant's shop, 15, Broadley Terrace, Blandford Square, and saw the defendant who dispensed a prescription for him, one of the ingredients of which was prussic acid. The defendant appeared to have control of the shop. There was no other person but an old man present, whom he (witness) concluded to be acting under defendant's orders, as he entered the prescription in a book under defendant's direction. He (witness) held conversation with the defendant, and was informed by him to the purport that he had bought the business because he saw that it was going cheap, and thought it was a chance for making a good profit. He was not a qualified chemist and druggist but had intended to qualify. He (witness) had seen the landlord of the premises, who informed him that the defendant was the tenant of the house, and showed him a counterpart of a lease by him to the defendant executed by the defendant, it was dated in June last, and subsequently he had served a notice upon defendant requiring him to produce the lease in court.

Mr. Flux called on the defendant to produce to the court "a certain indenture of lease of the premises No. 15, Broadley Terrace, Blandford Square, in the County of Middlesex, granted by Thomas Claxston, Esq., to the defendant."

Defendant: I never had it in my possession. Mr. Bull would not take the business unless he got the lease, and the lease was brought to me and I signed my name to it, and that's all I know about it.

Mr. Flux: You admit that you did execute a counterpart of the lease.

Defendant: Yes.

The Judge: There is a *primâ facie* case, Mr. Flux. (To defendant) Do you wish to ask the witness any questions?

Defendant: No, only whether I did not warn him of the dangerous character of the medicine.

The Judge: That does not matter. You sold the poison, and this Act which was passed for the protection of the public very properly provides a penalty in such cases. I will hear what you have to say in defence.

Defendant: Well, I sold this business to Dr. Carter in January last and he has since sold it to Mr. Bull. Dr. Carter is a duly qualified medical practitioner, and I dispensed this prescription as Dr. Carter's assistant. I am still managing the business, and am paid a salary and have apartments on the premises.

The Judge: Can you prove this?

Defendant: I have proved it. I have stated the facts on my oath.

The Judge: You must prove the transfer; what you have stated is not sufficient. I have no doubt that you are the owner of the business and that you have offended against the law. This Act must be construed with great strictness, because its provisions are for the benefit of all of us, and we should never be safe from poisoning if any one was allowed to deal in poisons. Judgment for the plaintiffs with costs.

Mr. Flux then drew the attention of the learned judge to the provisions of the Acts of Parliament regulating the disposal of the penalties, and providing that the party which should prevail should recover the full costs of suit or other proceedings, and asked an expression of his Honour's opinion as to whether or not the words "full costs" meant anything more than the ordinary party and party costs according to the county court scale. He added that the plaintiffs had to stand in peril of costs, and in cases such as the one before the court, where a defendant occasioned great trouble regarding services and other matters, the party and party costs were far from indemnity.

The Judge said: I consider that, having regard to the provisions of the statute, I may make an order for solicitor and client costs, to be taxed by the officer of the court, and I do so accordingly.

BOOKS, PAMPHLETS, ETC., RECEIVED.

EPITOME OF SKIN DISEASES, WITH FORMULÆ FOR STUDENTS AND PRACTITIONERS. By TILBURY FOX, M.D., F.R.C.P., etc., and F. C. FOX, B.A., M.R.C.S. London: H. RENSHAW, 1876. From the Publisher.

Notes and Queries.

[526]. SULPHUR HAIR RESTORER.—I would feel obliged if any correspondent would kindly furnish me with a recipe for the above preparation.—PEN GWYN.

[527]. SURFEIT WATER.—"Ignoramus" asks for a recipe for Surfeit Water.

ARTIFICIAL IVORY.—Two parts of caoutchouc are dissolved in thirty-six parts of chloroform, and the solution is saturated with pure gaseous ammonia. The chloroform is then distilled off at a temperature of 85° C. The residue is mixed with phosphate of lime or carbonate of zinc, pressed into moulds and dried. When phosphate of lime is used the product possesses to a considerable degree the nature and composition of ivory.—T. G., in *L'Union Pharmaceutique.*

CHLORAL PLASTER.—Dr. Solari, of Marseilles, recommends this plaster as an excellent application in cases of neuralgia and certain nervous pains arising from exposure to cold. The plaster is easily prepared by powdering the chloral over a common pitch plaster—one to two scruples of chloral for every four square inches of the plaster. Care is taken not to incorporate the chloral with the pitch. It is applied for twenty-four to forty-eight hours; when removed, the skin is found covered by a number of small vesicles; these are opened and the part then covered with a cerate dressing. Generally speaking, it will be found that the pain has disappeared before the vesicles heal. Dr. Solari states that numerous cases of lumbago, intercostal, and other forms of neuralgia, etc., have been rapidly cured by this simple method.—*Medical Examiner*, from the *Paris Med.*

SPONTANEOUS DEVELOPMENT OF HEAT IN RECENTLY POWDERED MYRRH.—Mr. E. N. Butt, of Curzon Street, writes—"One evening, a short time ago, I had a quantity of large picked gum myrrh powdered and sifted through a moderately fine sieve, for the purpose of preparing some tincture. Circumstances prevented my using it when powdered, and it was left till the following morning on the paper on which it was sifted, when it was found to have formed a hard and solid lump, requiring several sharp blows to break it in pieces. It was again powdered, which was easily accomplished, and placed in a paper bag. Some twenty minutes afterwards, on proceeding to use it, I was surprised to find the bag warm, and also to find the heat rapidly increasing, so much so that I placed a thermometer in it, when the mercury quickly rose from 62° F. to 108° F., at which it remained stationary. On turning out the myrrh into the vessel in which I was going to make the tincture I found it had assumed a pasty condition, and on using my hand to remove it the heat in the lower portion of the bag was so great that I could scarcely bear it, and doubtless had I plunged the thermometer deeper into the mass should have found the temperature much higher than that above mentioned. I should be glad to know if any one else has observed the same occurrence, or can assign any reason for the rapid development of heat, other than the rapid oxidation of the oleoresin when freshly exposed to the air."

INDELIBLE INK FOR PRINTING COTTON AND LINEN FABRICS INTENDED FOR CHLORINE BLEACHING.—One part of coal-tar is to be mixed with one part of benzene and one-tenth part of lamp-black. The mixture can be made thinner or thicker by using more or less benzol.—*Chem. Centr.*, 1875, 576.

XANTHIUM SPINOSUM.—A single specimen of this plant was found near to, and within the walls of Chester last year, but this year it has not been seen in the same place. The field had had a coating of manure, ashes, etc., and it is probable that the plant was brought to the spot with the rubbish. —F.S.

Obituary.

Notice has been received of the death of the following:—

On October 14th, 1876, at his residence, Garden Cottage, Chelmsford, Thomas Fardon, Chemist and Druggist, late of Maidstone, aged 65 years.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication but as a guarantee of good faith.*

"THE ABSENT FACTOR."

Sir,—Mr. W. T. Martin, of Lewes, complains in your last number that there are seven or eight medical men in his town who dispense their own medicines, and that he does not see half a dozen prescriptions, save from strangers, in the course of a year. The passage in Professor Redwood's address at Glasgow affecting such a case tells plainly on Mr. Martin's, and I wish Mr. M. were so busy dispensing that he had no time for complaint. But what claim have we on the medical profession for prescriptions? We have come into existence comparatively recently, and long after the appointment of a legally qualified staff of dispensers, the apothecaries, a staff in which most medical men are enrolled. I certainly think that there are reasons why we can and do dispense medicines rather better than most professional men. Yet there are surgeries better conducted than many so-called dispensing establishments. If a man chooses to fit himself for dispensing, and open shop convenient to the patients of medical men, this can be no reason why people should in many instances incur additional expense by procuring their medicines from the chemist. If the doctor finds that the shallow pockets of the majority of his patients are equal only to his fees and a slight additional charge for medicine, it is not to be expected that he will sacrifice the former, either to save some extra care and cost in dispensing or in the exercise of charity to his neighbour, the chemist. The fact, in many instances, is, that he cannot do so. The next step would be advice and prescriptions gratis; and there is difficulty in medical men drawing a line between those who can afford to pay the chemist and those who cannot, to say nothing of the consideration of medical men parting with prescriptions and so parting with a repetition of opportunities for consultations that they are impressed may be as much to their patients' good as to their own. We must not shut our eyes to these things in our thirst for an influx of dispensing business. We have been steadily fitting ourselves to hold with credit the "fourth estate" in medicine, and the possession of that estate will no doubt grow and be assured as time progresses, not by constraint, but by the good will, confidence, and convenience alike of medical men and the public.

After thirty years of dispensing, both in the surgery and for the most part at the retail counter, I am of opinion that pressure on the medical profession, beyond what our ability and method in business offer, must tend only to subvert our aim and to induce an increase of those legal restraints that many chemists find to be already irksome.

Leeds. EDWARD BROWN.

RELUCTANCE TO LEARN.

Sir,—It is with regret, yet not surprise, that I read particulars of the collapse of the Norwich Chemists' Association; and I have no doubt the perusal of Mr. Corder's letter will awaken some sympathy for the members of the committee in their disappointment, after their strenuous efforts to keep alive an association which appeared to be in a thriving condition for some time back. It is strange, yet true, that an immense number of aspirants to this so-called profession show considerable aversion to any studious training, and still more is it notorious that there is much disinclination for social intercourse with their fellows. I know several towns where there is great antipathy between the pharmaciens established there, and a sort of inherited dislike amongst the assistants for any association, whether private or in connection with the business. The amount of jealousy and party feeling exhibited by both masters and their employees throughout the country is almost incredible, and I believe exists more in our association than in any other. Now, why should this be? We have lately had many advocates for a state of harmony between doctors and druggists, but "charity begins at home," and if a more fraternal spirit was displayed by the latter individually, and more good feeling by their assistants, such a condition of things would be the best stepping-stone for the attainment of such a desirable end. The capital of Norfolk, however, is not singular in its educational failures, for in Edinburgh and elsewhere, many fruitless attempts have been made to organize classes, debates, meetings and the like. Similarly, in this large town, notwithstanding many facilities for acquiring knowledge, various obstacles are thrown in the way of taking advantage of them, and all may be traced to indifference. For instance, in no fewer than seven institutions science classes have been advertised, lectures appointed, etc., yet it is with the utmost difficulty that any students can be got to enrol their names in many of the subjects (which are nearly related to pharmacy), and that in a town with about seventy chemists' shops, and nearly twice the population of Norwich. I entered my name for several, but owing to lack of numbers, no class could be carried on. I tried several schools successively, but with equally unsatisfactory results; in some cases I was the only applicant. I particularly desired to attend a course of instruction in human physiology and laws of health, and after a good deal of trouble we managed to get eight persons to join said class at one of these places, but nine students were required to ensure delivery of the lectures and continuation of the class throughout the session, in order to make it remunerative to the teacher, yet we have failed to obtain any one to complete the requisite number. No amount of persuasion will induce strangers to come, consequently the whole affair falls to the ground, and we are doomed to disappointment. It is rather discouraging to those who are willing to increase their knowledge. Few embryo pharmacists care to study any branch of education not required in the "Minor;" attention to extraneous subjects they think a waste of time. This is a fatal mistake, however, for, apart from the fact that the study of this interesting subject is calculated to improve the mind, enlarge the conceptions, and develop the power of observation, a knowledge of physiology is of great benefit to druggists, who ought to know something about the structure of the animal frame and the various uses of the several functions.

It is, therefore, a source of regret that, in this enlightened age, inclination for mental advancement, and even desire for erudition, should be at such a low ebb.

Newcastle-on-Tyne, JAMES B. L. MACKAY.
October 24, 1876.

NORWICH CHEMISTS' ASSOCIATION.

Sir,—I think one sentence in Mr. Corder's letter on this subject, in your last week's issue, requires some notice, as it conveys what I consider to be a false impression.

Mr. Corder remarks that the decay of the Norwich Chemists' Association is cotemporaneous with the opening of a fashionable skating rink. This is quite true, but the remark implies that the two facts have some connection, and this I think is not strictly true.

The two circumstances are cotemporaneous, but they have no other connection.

As a student who has been connected with the Association nearly five years out of the six of its existence, I attribute its decay to the new regulations concerning the age of Minor candidates.

All or nearly all the apprentices who were in the trade before the new regulations came into force have since left Norwich, or passed their examination; but it is worthy of note that a session or two just after that time was the most prosperous, as regards the number of students, of any that the Association has experienced since the charm of novelty wore off.

The younger apprentices, on whom the Association depends for its chief support, have but few of them passed the Preliminary examination, and those that have passed think, I need not say how wrongly, that the four or five years which must elapse before they are admitted to the Minor are much more than they need to prepare for it. The general cry is, "There's plenty of time, what's the use of sweating (!) yet."

I think that these considerations prove, at least presumptively, that the new regulations have produced an effect the reverse of what was expected by Norwich pharmacists: they have discouraged study among the younger apprentices, and to them, I think, the decay of the Association must be attributed.

It is perhaps hardly necessary to add that I do not lay the blame on the regulations but on the shortsightedness of the students, and perhaps I may be allowed to state that it is still the custom of Norwich chemists to take as apprentices lads who have not only not passed the Preliminary, but who in some cases have little chance of doing so.

WALTER G. PIPER.

M. P. S.—Several formulæ for Bow's Liniment have been published during the present year. See vol. vi., pp. 678, 638, 658.

X.—The Science Primer on Chemistry, published by Macmillan.

"Devonia."—A paper bearing upon the subject of your question will be read at the next Evening meeting, and published in the *Pharmaceutical Journal* next week.

"Spes" and T. McKay.—It is illegal for any person whose name is not on the Register of Chemists and Druggists to sell or to keep an open shop for the retailing, compounding, or dispensing of poisons under the Pharmacy Act, 1868.

C. H. Snell.—A satisfactory mixture may be prepared by mixing the one drachm of nitrite of amyl with two drachms of rectified spirit, then adding gradually with constant trituration in a mortar, four drachms of mucilage, and finally the water. Five minims being probably a large dose of nitrite of amyl it would be more safe to attach a "shake the bottle" label.

Pharmacist G.—We think you should follow the intention of the prescriber and add the acid to the chlorate.

"Theta."—(1) *Bryonia dioica*; (2) Probably the leaf of some species of *Ranunculus*; (3) *Galium cruciatum*; (4) *Artemisia vulgare*: (5) Impossible to say from such a scrap; (6) Leaf of *Solanum Dulcamara*.

"Country Student."—(1) The fruit of *Cuminum Cyminum*; (2) A mixture of the fruits of *Carum Carvi, Cuminum Cyminum*, and *Fœniculum dulce*: (3) The fruit of *Conium maculatum*; (4) *Alchemilla arvensis*.

COMMUNICATIONS, LETTERS, ETC., have been received from Mr. Gostling, Mr. Benger, Mr. Brooks, Mr. Clift, Mr. Bore, Mr. J. B. L. Mackay, Mr. Wilkes, "Captene," C. B., T. S.

SUGGESTIONS FOR AN IMPROVED METHOD OF MAKING MISTURA GUAIACI AND OTHER SIMILAR MIXTURES.

BY THOMAS GREENISH, F.C.S.

A few days ago I was asked the best mode of preparing the following mixture :—

℞	Resinæ Copaibæ	ʒiss.
	Spirit. Vini Rect.	ʒii.
	Mucilaginis	ʒj
	Aquæ ad	℥vj. Misce.

When I undertook to mix it I scarcely appreciated the difficulties I afterwards met with. To rub the resin up with the spirit and then add the mucilage first suggested itself, but that method did not prove satisfactory. After several experiments, I found that by rubbing the resin of copaiba with sugar of milk, then adding the spirit, and continuing the trituration, a homogeneous mixture was made. Powdered gum arabic was next added and the trituration continued, then gradually the water. This method succeeded perfectly, the resin of copaiba remained suspended, and an elegant mixture was the result. The formula would necessarily be slightly altered and stand thus :—

℞	Resinæ Copaibæ	ʒiss.
	Sacch. Lactis	ʒiij.
	Spirit. Vini Rect	ʒiij.
	Pulv. Acaciæ	ʒv.
	Aquæ ad	℥vj. Misce

The only addition to the prescription would be 3 drachms of sugar of milk, and 1 drachm of rectified spirit.

Where resinous substances are prescribed so as to be given in a mixture, this mode of manipulation will prove very expeditious and satisfactory. It occupies scarcely more time to make the mixture than to read this paper.

It occurred to me that probably the same method of manipulation would improve a mixture, considered a valuable, but which is not an elegant preparation, I mean Mistura Guaiaci. I followed the same course of procedure as in the copaiba mixture, and to my mind succeeded in improving this preparation. The resin of guaiacum is dissolved and retained in the form of an emulsion. Following the directions in the original formula, there is always more or less of deposit which requires to be shaken up before the pouring out of each dose.

In making up a prescription much is left to the dispenser with regard to the details of mixing, so as to carry out faithfully the intentions of the prescriber, but in an officinal formula, like that of mistura guaiaci, I can only suggest this, as I think, a better method of making the Pharmacopœia preparation, and we have been invited in this room to make suggestions for the improvement of officinal formulæ. In both these cases the solution seems to be perfect and the deposit scarcely appreciable, or of such a character as not to require the bottle to be shaken before each dose.

The formula for Mist. Guaiaci would then stand thus:—

Take of

Guaiacum Resin in powder	½ ounce.
Sugar of Milk	½ ounce.
Gum Acacia in powder	½ ounce.
Rectified Spirit	5 fluid drachms.
Cinnamon Water	to one pint.

Further experiments would be desirable to determine the best proportions of powdered gum and spirit, my present object being mainly to direct attention to that method of mixing which I have just suggested.

That the session should be opened by a paper from the dispensing counter will, I hope, be taken as an indication that subjects of a practical character will, equally with those of more scientific interest, meet with acceptance. If the habit of observation were cultivated, and the laboratory-book had its counterpart in the note-book of the dispensing counter, our evening meetings would never want a subject of general interest, in the discussion of which the younger members could take their share.

[*The Discussion on this paper is printed at p.* 381].

COMPARATIVE EXAMINATION OF THE MORE IMPORTANT COMMERCIAL VARIETIES OF GALBANUM AND AMMONIACUM GUMS.*

I. GALBANUM.

BY EDWARD HIRSCHSOHN.

1. *Historical.*—As is the case with most of the older drugs we are by no means exactly acquainted with the history of galbanum, for very diverse and sometimes directly contradictory views have been set forth by different investigators. Thus Martiny says† that galbanum is a very ancient drug which is frequently mentioned in the writings of Hippocrates; it is thought even that it was known to Moses (Ex. xxx. 34). It is the χαλβάνη of Theophrastus (ix. 7) and of Dioscorides (lib. iii. c. 97); the latter states that it came from Syria, where it was obtained from an indigenous *Ferula*, and that it was sometimes adulterated with ammoniacum. According to Dioscorides the plant was also called μετώπιον, a name that was given besides to an ointment containing galbanum. It is further mentioned by Pliny (xii. 25, 26; xxiv. 5), who speaks of its adulteration with sagapenum, and by Lucan, Celsus, Cælius Aurelianus, and others. Flückiger‡ thinks that the "chalbane" of the ancients cannot be satisfactorily identified with galbanum.

Botanical Origin.—Our knowledge respecting the mother-plant of galbanum is still very imperfect, for from the short and little characteristic descriptions, and the various appellations used by the botanists of the middle ages—C. Bauhinus, Lobelius, Parkinson, Tabernæmontanus, etc.—it is difficult, according to Borszczow,§ to understand exactly what their *plantæ galbaniferæ* actually were. Paul Hermann|| figures an umbellifer indigenous at the Cape of Good Hope, the milky juice of which was very similar to galbanum; this plant Linnæus named *Bubon Galbanum* and considered to be the true mother plant of the gum resin. But according to Don the juice of this

|| 'Paradisus Batavus,' p. 163.

plant possesses neither the smell nor the taste of galbanum, hence he did not adopt it as the true mother plant, but on the contrary, the *Galbanum officinale* described by him in 1829 from seeds found in galbanum.*

Lindley† would not adopt this derivation; he considered that it could not be proved that the fruit found by Don actually originated with the galbanum yielding plant, and thought it had been accidentally introduced. In 1838 MacNeill remitted to Lindley specimens of a plant which he had collected at Durrod, in the province of Chorassan, Persia, and had indicated as a second kind of ammoniacum. On the branches of this plant, which Lindley named *Opoidia galbanifera*,‡ hung pieces of a pale yellow gum resin, which Lindley considered to be galbanum, but which Pereira,§ to whom he sent some of the gum resin, declared to be not true galbanum, but a gum resin standing between asafœtida, ammoniacum and galbanum.

At present it is generally accepted that the mother plant of galbanum is the same as that collected by Aucher-Eloy and Kotschy, and described in 1844 by Boissier‖ as *Ferula erubescens*, and afterwards by Borszczow as two scarcely differing species, *Ferula gummosa* and *F. rubricaulis*.¶ This plant was again met with by Dr. Buhse** in 1850 and by Drs. Bunge and Bienert during the expedition to Chorassan. The specimens collected by Buhse and Bunge agreed, according to Borszczow,†† very well with *Ferula erubescens*, Boiss.; the depressions on the under surfaces having one very wide vitta, filled with yellowish oil and not 2—3 narrow irregular ones, as stated by Boissier; the commissure has no vittæ and is channelled. According to Dr. Buhse‡‡ the stem of the plant at its base is more than an inch thick, full of pith and round. The radical leaves are 1½ to 2 feet long and 6 inches wide; the upper cauline leaves are much smaller. All the leaves are quadripinnate and the pinnæ are egg-shaped, very small, and 5- to 7-lobed. The flowers are yellow, hermaphrodite, or, in the lateral umbels, male through abortion; they occur in compound umbels, the incised bracts of which fall off early or are entirely wanting.

The plant, according to Borszczow, is distributed here and there throughout the entire northern province of Persia; in southern Persia it was found by Kotschy in the Kuh-Baena mountains. Buhse says it occurs throughout the entire province of Elbrus-Kette from the south-east to the south-west corners of the Caspian Sea, and indeed that it is found only in this and the Demarend regions; in the latter, however, very abundantly, and reaching an elevation of 4000 to 8000 feet in the mountains. It also grows in quantity on the precipices of Alvend, near Hamadan; and according to Borszczow it is found on the margin of the great central Persian salt-waste. Professor v. Bunge has observed the plant in the mountains near Scabsivar, between Gurgen and Chaf, westward of Herat, and in the upper desert, westward of Chaf.

The entire distribution, so far as at present known, of this galbanum plant, which according to Borszczow appears to be exclusively indigenous to Persian soil, lies between 36° and 32° north latitude, and 66° and 79° longitude.

Dr. Buhse states that in some Persian provinces this plant is called "khassuch" by the inhabitants. Borszczow found another umbellifer smelling strongly of galbanum, almost a metre high, in a salt loamy waste which lies north of Fort Peroffsky (Ak-Betschet) to Syr-Darja, and runs along near the rivers Ssary-Sau and Tschu; it also occurred in larger quantities some three miles further east, in a sunny, arid, and nearly barren tract. The inhabitants called this plant "schair," which in the Kirgish dialect indicates resin also. Borszczow did not observe any spontaneous exudation of gum-resin, but an incision yielded a viscous, aromatic, bitter, milky juice, smelling strongly of galbanum. Borszczow described this plant as *Ferula Schair*.*

3. *Collection.*—Concerning the collection also of galbanum, our knowledge is still very imperfect. According to Dr. Buhse,† the galbanum exudes spontaneously from the lower parts of the stalk and at the base of the leaves. Geoffrey affirmed,‡ without giving his authority, that an incision is made in the stalk about three fingers' breadth above the root, from whence the galbanum issues in drops, which become dry and sufficiently hard for collection in a few hours. According to Landerer it is obtained by making an incision in the plant, under which a mussel shell is placed. At any rate the product appears to differ very much with the locality, the plant, or the time of the year. It will be seen from the author's notes that most kinds of galbanum contain fragments of roots, for which reason he is almost induced to affirm that most of the galbanum appearing in commerce is obtained by an incision of the root and collection of the exuded juice, which would explain the frequent occurrence of fragments of roots in the commercial gum resin.

4. *Commercial Varieties.*—According to Martiny the Levant and Persian galbanums are distinct.

a. Levant Galbanum.

(i) Galbanum in granis seu in lacrymis s. amygdaloidis.— Granular or almond shaped resin.— Fragments varying in size from that of a pea to that of a nut, irregular or roundish, not or only slightly adhering, transparent, dull or shining, whitish, partly with a greenish or brownish yellow to a reddish lustre. These have a waxy or harder consistence, and at the fracture appear to have a smooth or uneven shiny wax-like yellow or white surface, sometimes showing white or yellow specks. Martiny says that this gum is also met with in light spongy, almost frothy, non-transparent fragments. The grains soften more or less readily between the fingers, becoming pliable and sticky; but with time they become increasingly hard and friable, so that they may easily be pulverized. The smell is more or less balsamic and unpleasant; the taste is acrid, resinous and bitter. Sp. gr. 1·213.

Triturated with water galbanum forms an emul-

sion, in which Berg* says are to be observed under the microscope numerous very small resinous globules, in molecular motion, and filled with a volatile oil.

(ii) Galbanum in massis s. in placentis s. in panibus.—Mother resin, in masses, cakes, or bread.—Irregular, greenish, yellowish, light or dark brown masses, which consist of or contain agglutinated tears. It encloses fragments of stem, leaf stalks and even fruit.† In consistence this kind differs much from the former, being ordinarily softer; it is either opaque or transparent, with a dull waxlike to a dark resinous lustre. The smell is usually stronger than that of the seed galbanum.

Guibourt distinguishes two sorts of galbanum, soft and dry—"*galbanum mou et sec*"—both of which are said to occur in tears and masses.‡ His "*galbanum mou*" appears not to differ from the ordinary fresh Levant variety. Its principal character is its soft and adhesive quality. In this sort Guibourt never found any fruit. Concerning his "*galbanum sec*" he says: "Like the former it is found in masses and in tears, but it is much drier, and its tears which are neither sticky nor glossy do not unite in a mass. Externally the tears are yellow, internally whitish and often opaque, and they are discriminated from those of ammoniacum by their slight consistence and their uneven fracture. The "*galbanum sec*" contains stray fragments of stalk and the fruit of an umbelliferous plant.

b. Persian Galbanum.—Galbanum Persicum.

This kind was spoken of by Spielmann§ and Murray|| as a fluid galbanum coming from Persia, of the consistence of turpentine and varying in its odour. Nemnich¶ mentions the Persian galbanum, also East Indian, and observes that it scarcely ever appears in commerce in cakes, but contained in casks and chests, as well as hollowed portions of trees. It is inferior to the Levant galbanum, always soft, and mostly contaminated with portions of stalks.

Martiny** examined two kinds of Persian galbanum, which he described nearly as follows:—One sort consists of fragments partly run together, partly squeezed together, having a semi-transparent or opaque yellowish white or brownish appearance. Internally this galbanum appears as a soft, turpentiny, shining, very oily mass, of a yellow brown colour. It smells very strongly and disagreeably of turpentine and galbanum, and its burning acrid turpentiny taste recalls that of castoreum. The second sort, which he had obtained through a Leipzig commercial house was, according to him, a light brown, almost transparent, shining mass, contaminated only with soft yellowish fragments of stalk of very loose structure, and having a consistence which resembled closely that of turpentine. It smelt like galbanum, not offensively but agreeably, and even with somewhat of fennel-like odour. The taste was balsamic and warm. Ludewig†† described the Persian galbanum as a mass much contaminated with stalk fragments, running together at ordinary temperatures, brownish-red in colour, with white veins, never passing into green. The smell he speaks of as quite different from that of the Levant, being more disagreeably penetrating, and often resembling that of asafœtida, the taste as disagreeably acrid and bitter. Goebel gives a similar description.

Respecting the commercial route of galbanum, Wiggers is of opinion that the Levant sort is imported from Central Africa through Trieste and Marseilles, whilst that officinal in the British Pharmacopœia may be imported into London from Bombay. The Persian galbanum comes, according to Ludewig, from Astrachan and Orenburg; but, according to Goebel,* it comes chiefly from Astrachan through Nischni-Nowgorod. Goebel† saw in Astrachan large quantities packed in skins, besides being sewn up in mats, each pack weighing from 50 to 80 pounds. According to him it is only sold in large quantities, the dealer, however, occasionally opening a pack to judge of the quality of the article. The seller in Astrachan, who is simply a commission agent, knows as little as the buyer about the quality of the unopened parcel. Only when the transaction is complete is the package opened and the galbanum weighed. The price was at that time (1838) very low, 7 to 8 silver copecks per pound.

(*To be continued.*

THE QUININE-FLOWER.‡

BY J. DABNEY PALMER, M.D.

The quinine-flower is an annual from twelve to eighteen inches high, has an erect green stem, linear leaves of about one-half to one inch in length, and small white flowers. The root consists of numerous slender fibres.

It is a native of Florida, and is found most abundantly in flat pine woods, in a moderately dry soil, making its appearance in March or April, and flowering from July to September. The specimens furnished me were gathered three or four miles south of Monticello, in Jefferson county. In the lower portions of the county it is very abundant, and is successfully employed by those living in its vicinity for the cure of different types of malarious fever, the whole plant being used, either in the form of decoction or extract, and given *ad libitum*, or until the patient feels the effects of quinine in his head. It is a curious fact that persons brought under the influence of this remedy experience similar sensations—such as tension or fulness in the head, ringing in the ears or partial deafness—as when under the influence of quinia, and hence its name. Its reputation as an antiperiodic was established during the late civil war, when, owing to the scarcity of quinine, every opportunity was offered for testing the relative value of various substitutes.

The quinine-flower is intensely and permanently bitter, yielding its properties to water and alcohol. A saturated tincture in doses of one teaspoonful every two hours was found sufficient to break the paroxysm of intermittent fever. Larger quantities, however, may be given in obstinate cases, or in the remittent form of the disease.

To the foregoing the following remarks are added by the Editor of the *American Journal of Pharmacy*:—

* 'Pharm. Waarenkunde,' 4th edition, p. 546.

† This kind, enclosing fragments of stalks, fruit, etc., is not at the present time met with in commerce, all the commercial varieties from the Levant containing root fragments exclusively.

‡ From the *American Journal of Pharmacy* for October.

At our request Dr. Palmer has sent us some of the flowering plants referred to in the preceding paper. The plants are found to belong to the natural order of Gentianaceæ, and to the sub-order Gentianeæ, having the corolla lobes twisted (contorted) in the bud; the distinct style being deciduous, it must be placed into the section to which *Erythræa* and *Sabbatia* belong. Its botanical characters agree with those of the last-named genus, and more particularly with the group which has the white or purplish flowers scattered on alternate peduncles, and the corolla five-parted.

On comparing it with the American species in the College herbarium of Dan. B. Smith, it was found to correspond with a specimen of *Sabbatia Elliottii*, Steud., which is marked *ex herbar. Chapmani.* This plant is described in Chapman's 'Flora of the Southern United States' as follows:—

"Stem low, terete, paniculately much branched from near the base, the branches diffuse; leaves small, sessile, the lowest obovate, the upper linear; lobes of the corolla three to four times as long as the short filiform calyx-lobes. (*S. paniculata*, Ell.) Open pine barrens, Florida to South Carolina. Aug. and Sept.—Stems ½ to 1½ feet high. Leaves 3 to 6 lines long. Corolla 8 to 10 lines wide."

In both the herbarium specimen and the plants sent by Dr. Palmer, the calyx lobes are more prominent than might be supposed from the description given, but they are evidently described as *short*, in comparison with the much longer calyx lobes of *Sabbatia stellaris, gracilis* and allied species, in which they are about equal in length to the corolla, while in the species under consideration they are about one-third the length. The lowest leaves are obovate, those a little higher on the stem oblanceolate with an acute point, and become rapidly narrowed to a linear shape. The stems of the plants recently received are from 20 to 24 inches high, and consequently rather exceed the height as given by Chapman.

The herb has at first an herbaceous taste which gradually develops into a pure and persistent bitter, free from astringency.

The popular name *quinine-flower* appears to be confined to a small locality, probably to only a portion of Florida; at least, I have not been able to find it in any of the floras or popular botanical works of the United States. Porcher's 'Resources of the Southern Fields and Forests,' p. 556, however, mentions *Gentiana quinqueflora* under the names of *Indian quinine* and *Ague weed*—and states that "this and the *G. saponaria* are esteemed fully equal to the imported gentian; in large doses they are said to be laxative; Dr. E. P. Wood, of Wisconsin, has given this plant with success in intermittent fever." He also gives a detailed account of the medicinal properties of *Sabbatia angularis*, the American centaury, and states that *S. stellaris* and *S. gracilis* possess properties similar to the former.

This genus of North American plants is closely allied to *Erythræa*, of which several species (*E. chilensis, E. centaurium, E. linarifolia*, etc.) are still employed in different countries as tonics, and sometimes as antiperiodics; but we do not remember that effects resembling quininism have been ascribed to any of those plants, such as Dr. Palmer states are experienced from the quinine-flower of Florida.

DETECTION OF THE MINERAL ACIDS BY MEANS OF COLCHICINE.*

BY F. A. FLUCKIGER.

Mohr has observed that under certain conditions the behaviour of inorganic acids differs totally from that of the organic acids; this difference may be utilized for their discovery in presence of organic acids, for example, in vinegar or lemon juice.

Potassium sulphocyanate in a dilute solution of ferric acetate causes no change, but if there be the smallest trace of hydrochloric, nitric, or sulphuric acid present, the blood-red colour of ferric sulphocyanate is at once apparent: this, however, quickly vanishes on the addition of an acetate or oxalate; but in this case phosphoric acid acts like the organic acids in preventing the formation of ferric sulphocyanate. Another of Mohr's methods depends on the fact that iodine is precipitated from a solution of potassium iodide if a ferric salt with an inorganic acid radicle be added. Ferric acetate causes no precipitation in a solution of potassium iodide, but if the smallest trace of an inorganic acid be present the iodine is immediately precipitated.

But there is a case the reverse of this, in which the inorganic retards and the organic acid hastens the reaction. A solution of pure ferrous sulphate mixed with a saturated solution of gallic acid produces no change if the air be excluded, but acetates immediately produce in it a violet colour.

Still more remarkable effects are produced by colchicine. Some colchicine was extracted from a few grams of the seeds by means of alcohol and water, the yellowish solution was diluted till the colour was scarcely perceptible.

With concentrated sulphuric or nitric acid it gave a very distinct yellow, and on adding a drop of hydrochloric acid to this solution a bluish-violet was produced.

If some colchicine solution with a drop of nitric acid is strongly concentrated and then a fragment of sodium acetate added, an orange colour is produced.

If to a portion acidulated with sulphuric acid, a mixture of iodide of potassium and iodide of mercury in the proportion of 50 to 13·5 is added, a precipitate is formed; by means of this solution it was easy to detect ½ a per cent. of sulphuric acid in vinegar.

THE AILANTHUS GLANDULOSA IN DYSENTERY.*

BY J DUDGEON, M.D., ETC., PEKIN.

The *Ailanthus* is a very common tree in North China, growing readily and rapidly, and attaining a considerable height. The Chinese note two varieties, the fragrant and the fetid. Two synonyms for the latter tree are given—"Tiger's eye," from the resemblance of the facets, when the branches fall off from the main stem, to that animal's eye; and "Great eye varnish," from which circumstance the French name "Vernis du japon" may be derived. The Chinese name has no connection with the word *ailanto*, which is supposed in Europe to be its native name in China and India, and is thought to mean "tree of the gods." It is intensely bitter and astringent, of a lukewarm taste, free from poison, and emits a disagreeable smell, from which latter circumstances its Chinese name is derived. The Chinese medical works recommend it a an antidote against sulphur, arsenic, and gold-poisoning. It is said, also, to possess anthelmintic properties, and to be used in demonology against the supposed transfer of disease from a corpse. It is also useful in diarrhœa, prolapsus ani, and leucorrhœa. It is frequently prescribed alone; at other times in conjunction with other remedies, particularly *Radix hedysari* and the fruit of *Terminalia chebula*, favourite remedies in diarrhœa and dysentry, which increase its efficacy. It is strongly recommended in all cases of hæmorrhage, from whatever cause or locality. It is used, too, in gonorrhœa and spermatorrhœa, and, in short, in fluxes in general. The part used is the inner white bark of the root and stem of the non-fragrant species. Whether taken in infusion or in pill, it is invariably prescribed to be taken on an empty stomach, in

* Reprinted from the *Medical Times and Gazette* for October 28, 1876.

congee or with milk or soft boiled rice. In the most severe cases it is taken in conjunction with *Castus amarus* and vinegar. I refrain from adding a number of the standard prescriptions against dysentery in which the *ailanthus* plays an important part, the mode of preparation and administration and the dose being of the simplest description.

This remedy has been used in a few cases with marked success by my colleague M. Dugat, of the French Legation. It has been submitted lately to the Paris Academy for a report of its virtues. It has been brought under the attention of the French surgeons in the navy in Eastern waters, and those who have tried it have reported favourably regarding it. From its strongly astringent character, combined with rice and milk diet and rest, which are, strictly enjoined, it cannot fail, I think to do good. The rest and regimen, although important measures, do not altogether account for the results obtained. M. Dugat has published five cases in the *Chinese Customs' Half-Yearly Report* (April to September, 1875), in which marked benefit resulted.

I have personally had no experience of the effects of this remedy. Diarrhœa and dysentery are very common in North China during the summer months, arising out of errors in diet, certain habits of the people, and sudden atmospheric changes. The Chinese consume large quantities of cucumbers and the various species of the melon tribe, and unripe, raw, or salted vegetables of all sorts. They distinguish a red and a white dysentery, according to the character of the discharge; there is almost no constitutional disturbance, tenesmus and frequent stools being the chief characteristics. In the great majority of the cases I have found a full dose of castor oil and laudanum by the mouth, with an occasional enema of rice-water and laudanum, followed by one or two compound ipecac powders, all that was necessary. I have come across a large number of almost intractable cases of what is know all over China, and greatly dreaded, as opium dysentery—a severe form of this affection occurring in confirmed opium-smokers, with greatly debilitated constitutions, and caused sometimes by the deprivation of the drug, and at other times without any obvious cause during the continuance of the habit. A very large mortality from deprivation occurs amongst the criminal class in Chinese prisons. In such cases opium loses its customary astringent power; and so great is this astringency at ordinary times that the confirmed smoker may not have more than two evacuations in the month, and then only by external, artificial means.

SURFACE BIOLOGY.*

BY ALFRED RUSSEL WALLACE, F.R.G.S., F.L.S.

(*Continued from page* 358.)

Another interesting fact in connection with this subject is the presence of arborescent forms of Compositæ in so many of the remotest oceanic islands. They occur in the Galapagos, in Juan Fernandez, in St. Helena, in the Sandwich Islands, and in New Zealand; but they are not directly related to each other, representatives of totally different tribes of this extensive order becoming aborescent in each group of islands. The immense range and almost universal distribution of the Compositæ is due to the combination of a great facility of distribution (by their seeds) with a great attractiveness to insects, and the capacity of being fertilized by a variety of species of all orders, and especially by flies and small beetles. Thus they would be among the earliest of flowering plants to establish themselves on oceanic islands; but where insects of all kinds were very scarce it would be an advantage to gain increased size and longevity, so that fertilization at an interval of several years might suffice for the continuance of the species. The arborescent form would combine with increased longevity the advantage of increased size in the struggle for existence with ferns and other early colonists; and these advantages have led to its being independently produced in so many distant localities, whose chief feature in common is their remoteness from continents and the extreme poverty of their insect life.

As the sweet odours of flowers are known to act in combination with their colours as an attraction to insects, it might be anticipated that where colour was deficient scent would be so also. On applying to my friend Dr. Hooker for information as to New Zealand plants, he informed me that this was certainly the case, and that the New Zealand flora is, speaking generally, as strikingly deficient in sweet odours as in conspicuous colours. Whether this peculiarity occurs in other islands, I have not been able to obtain information; but we may certainly expect it to be so in such a marked instance as that of the Galapagos flora.

Another question which here comes before us is the origin and meaning of the odoriferous glands of leaves. Dr. Hooker informed me that not only are New Zealand plants deficient in scented flowers, but equally so in scented leaves. This led me to think that perhaps such leaves were in some way an additional attraction to insects —though it is not easy to understand how this could be, except by adding a general attraction to the special attraction of the flowers, or by supporting the larvæ which, as perfect insects, aid in fertilization. Mr. Darwin, however, informs me that he considers that leaf-glands bearing essential oils are a protection against the attacks of insects where these abound, and would thus not be required in countries where insects were very scarce. But it seems opposed to this view that highly aromatic plants are characteristic of deserts all over the world, and in such places insects are not abundant. Mr. Stainton informs me that the aromatic Labiatæ enjoy no immunity from insect attacks. The bitter leaves of the cherry-laurel are often eaten by the larvæ of moths that abound on our fruit-trees; while in the Tropics the leaves of the orange tribe are favourites with a large number of lepidopterous larvæ; and our northern firs and pines, although abounding in a highly aromatic resin are very subject to the attacks of beetles. My friend Dr. Richard Spruce —who while travelling in South America allowed nothing connected with plant-life to escape his observation—informs me that trees whose leaves have aromatic and often resinous secretions in immersed glands abound in the plains of tropical America, and that such are in great part, if not wholly, free from the attacks of leaf-eating ants, except where the secretion is only slightly bitter, as in the orange tribe, orange-trees being sometimes entirely denuded of their leaves in a single night. Aromatic plants abound in the Andes up to about 13,000 feet, as well as in the plains, but hardly more so than in Central and Southern Europe. They are perhaps more plentiful in the dry mountainous parts of Southern Europe; and as neither here nor in the Andes do leaf-eating ants exist, Dr. Spruce infers that, although in the hot American forests where such ants swarm the oil-bearing glands serve as a protection, yet they were not originally acquired for that purpose. Near the limits of perpetual snow on the Andes such plants as occur are not, so far as Dr. Spruce has observed, aromatic; and as plants in such situations can hardly depend on insect visits for their fertilization, the fact is comparable with that of the flora of New Zealand, and would seem to imply some relation between the two phenomena, though what it exactly is cannot yet be determined.

I trust I have now been able to show you that there are a number of curious problems lying as it were on the outskirts of biological inquiry which well merit attention, and which may lead to valuable results. But these problems are, as you see, for the most part connected

* Presidental Address delivered to the Biological Section of the British Association, at Glasgow, on Sept. 6, 1876.

with questions of locality, and require full and accurate knowledge of the productions of a number of small islands and other limited areas, and the means of comparing them the one with the other. To make such comparisons, however, is now quite impossible. No museum contains any fair representations of the productions of these localities; and such specimens as do exist, being scattered through the general collection, are almost useless for this special purpose. If, then, we are to make any progress in this inquiry, it is absolutely essential that some collectors should begin to arrange their cabinets primarily on a geographical basis, keeping together the productions of every island or group of islands, and of such divisions of each continent as are found to possess any special or characteristic fauna or flora. We shall then be sure to detect many unsuspected relations between the animals and plants of certain localities, and we shall become much better acquainted with those complex reactions between the vegetable and animal kingdoms, and between the organic world and the inorganic, which have almost certainly played an important part in determining many of the most conspicuous features of living things.

Rise and Progress of Modern Views as to the Antiquity and Origin of Man.

I now come to a branch of our subject which I would gladly have avoided touching on; but as the higher powers of this Association have decreed that I should preside over the Anthropological Department, it seems proper that I should devote some portion of my address to matters more immediately connected with the special study to which that Department is devoted.

As my own knowledge of and interest in Anthropology is confined to the great outlines rather than to the special details of the science, I propose to give a very brief and general sketch of the modern doctrine as to the Antiquity and Origin of Man, and to suggest certain points of difficulty which have not, I think, yet received sufficient attention.

Many now present remember the time (for it is little more than twenty years ago) when the antiquity of man, as now understood, was universally discredited. Not only theologians, but even geologists, then taught us that man belonged altogether to the existing state of things; that the extinct animals of the Tertiary period had finally disappeared, and that the earth's surface had assumed its present condition before the human race first came into existence. So prepossessed were even scientific men with this idea—which yet rested on purely negative evidence and could not be supported by any arguments of scientific value—that numerous facts which had been presented at intervals for half a century, all tending to prove the existence of man at very remote epochs, were silently ignored; and, more than this, the detailed statements of three distinct and careful observers confirming each other were rejected by a great scientific society as too improbable for publication, only because they proved (if they were true) the coexistence of man with extinct animals.*

But this state of belief in opposition to facts could not long continue. In 1859 a few of our most eminent geologists examined for themselves into the alleged occurrence of flint implements in the gravels of the north of France, which had been made public fourteen years before, and found them strictly correct. The caverns of Devonshire were about the same time carefully examined by equally eminent observers, and were found fully to bear out the statements of those who had published their results eighteen years before. Flint implements began to be found in all suitable localities in the south of England, when carefully searched for, often in gravels of equal antiquity with those of France. Caverns giving evidence of human occupation at various remote periods were explored in Belgium and the south of France—lake-dwellings were examined in Switzerland—refuse-heaps in Denmark—and thus a whole series of remains have been discovered carrying back the history of mankind from the earliest historic periods to a long distant past. The antiquity of the races thus discovered can only be generally determined by the successively earlier and earlier stages through which we can trace them. As we go back metals soon disappear, and we find only tools and weapons of stone and of bone. The stone weapons get ruder and ruder; pottery, and then the bone implements, cease to occur; and in the earliest stages we find only chipped flints of rude design, though still of unmistakably human workmanship. In like manner domestic animals disappear as we go backward; and though the dog seems to have been the earliest, it is doubtful whether the makers of the ruder flint implements of the gravels possessed even this. Still more important as a measure of time are the changes of the earth's surface, of the distribution of animals, and of climate which have occurred during the human period. At a comparatively recent epoch in the record of prehistoric times we find that the Baltic was far salter than it is now and produced abundance of oysters, and that Denmark was covered with pine forests inhabited by Capercailzies, such as now only occur further north in Norway. A little earlier we find that reindeer were common even in the south of France; and still earlier this animal was accompanied by the mammoth and woolly rhinoceros, by the arctic glutton, and by huge bears and lions of extinct species. The presence of such animals implies a change of climate; and both in the caves and gravels we find proofs of a much colder climate than now prevails in Western Europe. Still more remarkable are the changes of the earth's surface which have been effected during man's occupation of it. Many extensive valleys in England and France are believed by the best observers to have been deepened at least a hundred feet; caverns now far out of the reach of any stream must for a long succession of years have had streams flowing through them, at least in times of floods; and this often implies that vast masses of solid rock have since been worn away. In Sardinia land has risen at least 300 feet since men lived there who made pottery and probably used fishing-nets;* while in Kent's Cavern remains of man are found buried beneath two separate beds of stalagmite, each having a distinct texture, and each covering a deposit of cave-earth having well-marked differential characters, while each contains a distinct assemblage of extinct animals.

Such, briefly, are the results of the evidence that has been rapidly accumulating for about fifteen years as to the antiquity of man; and it has been confirmed by so many discoveries of a like nature in all parts of the globe, and especially by the comparison of the tools and weapons of prehistoric man with those of modern savages (so that the use of even the rudest flint-implements has become quite intelligible), that we can hardly wonder at the vast revolution effected in public opinion. Not only is the belief in man's vast and still unknown antiquity universal among men of science, but it is hardly disputed by any well-informed theologian; and the present generation of science-students must, we should think, be somewhat puzzled to understand what there was in the earliest discoveries that should have aroused such general opposition and been met with such universal incredulity.

(*To be continued.*)

* In 1854 (?) a communication from the Torquay Natural History Society confirming previous accounts by Mr. Godwin Austen, Mr. Vivian, and the Rev. Mr. M'Enery, that worked flints occurred in Kent's Hole with remains of extinct species, was rejected as too improbable for publication.

INSTITUTE OF PROFESSIONAL CHEMISTS.

SOME months ago we gave an account of the steps that were taken with the object of establishing an organization which should control that class of chemists who apply themselves to technical matters under the designation of consulting and analytical chemists. For some years past there has been a growing sense of the want of some authoritative formal qualification of those engaged in such pursuits no less for the protection of the public against pretenders, than for the sake of providing for the interests of competent practitioners, and it is strange that the attempt to carry out some practical arrangement of the kind had not been made before. As we pointed out at the time, this is a matter which interests all persons engaged in retail trades now that the official analyst has become a public institution and the interests of the trader are liable to be seriously prejudiced if the duties of that office are not properly performed.

Naturally the attempt to carry out a project of this kind is surrounded by many difficulties, and we are by no means surprised to find that the idea first entertained of attaining this desirable end through the medium of the Chemical Society has not been found practicable. Every facility, however, was afforded by the Council of that Society for the consideration of the project, and a committee was appointed to confer with the gentlemen deputed to act on behalf of the chemists who were desirous of becoming enrolled in some body that could satisfactorily confer on its members the required stamp of qualification. Plans of procedure were suggested on both sides and discussed, but the main result arrived at was the conviction that, although the objects aimed at were approved of on all hands, there were grave objections to all of the plans for attaining them through the medium of the Chemical Society. In the first place, the legality of any alteration in the fellowship of the Society was more than doubtful, and it became a question whether the bulk of the fellows might not object to the establishment of a class of "practising fellows," on the ground that it would place them at a disadvantage as occupying an apparently inferior position.

It is at least satisfactory, however, to find that the idea of organization of a particular class of chemists was warmly sympathized with by the council and officers of the Chemical Society, and that many whose avocations lead them in other directions than the practical application of the science were willing to devote their time and energies to the consideration of plans for benefiting their fellows in other spheres of action.

A notice has recently been issued that the adjourned general meeting of the Chemical Profession is to meet at two o'clock on Saturday, the 4th November, at the Rooms of the Chemical Society, to reconsider the subject of organization. Subsequent to the reading of a report of the proceedings of the Committee appointed last June, it is expected that a motion will be made to the effect that the contemplated organization should be effected independently of the Chemical Society, and a definite proposal will be made in reference to the mode in which that should be done.

It is proposed in the first place that the new body shall be styled "The Institute of Professional Chemists of Great Britain and Ireland." The objects of the organization are to be the general advancement of Chemistry in its applications to the arts, manufactures, agriculture, and public health; secondly, to ensure that persons adopting the profession of consulting chemists or acting as analytical chemists for reward are qualified by study and training for the proper and competent discharge of the duties they undertake.

Persons desirous of membership are to give evidence of the possession of one or more of certain qualifications before being balloted for; among these it is stipulated that they shall have passed through a course of study, extending over three years, of theoretical and analytical chemistry and physics under recognized teachers, and that they shall have been subsequently engaged for three years either as assistant to some member of the Institute or some chemist of repute, or have been for the same period in the position of chemist in a chemical factory. Also that they shall have published some original research on a chemical subject of sufficient interest in the opinion of the Board. For anyone who proposes to devote himself to the pursuit of technical or professional chemistry there is nothing in these regulations which would not be undertaken almost as a matter of course, and no objection can well be urged against making the curriculum indicated a necessary one for the acquirement of membership. But the project goes further, and with a wise liberality makes provision for cases in which persons may not have commenced life with the intention of practising as professional chemists, but have by various circumstances been induced to do so at a period too late to enter upon the prescribed course of training. It is quite conceivable that persons in this position might be fully competent to act as professional chemists and that they would be entitled to recognition upon producing evidence of their fitness to become members of the Institute.

To meet such cases it is proposed that in the event of any person producing to the Council evidence of having been trained and occupied in other ways than those above specified, such that the Council considers equivalent to fulfilling the above-mentioned conditions, he shall be eligible to become a member of the Institute. It is further proposed that in cases where no such evidence can be produced candidates for membership must undergo an examination to be conducted by a Committee of the Council or such other members of the Institute as may be appointed by the Council.

In addition to these provisions for ensuring the qualification of members it is proposed that the Institute, through its Council, shall have the power of controlling the action of its members in the exercise of their professional duties. For this purpose the Council is to have the power of expelling members in cases where ten or more members of the Institute shall demand it. In such cases the Council is to inquire into the matter complained of and to seek explanations from the person charged so as to ascertain whether there be sufficient ground for expulsion before proceeding to that step.

The management of the affairs of the Institute are to be vested in the hands of a Council with a President and two Vice-Presidents (one of whom is to be the retiring president of the previous year), a Treasurer and two Secretaries, who are to be *ex officio* members of the Council. All the officers of the institute are to be elected annually, but to be eligible for re-election, with the exception of the President, who is not to be eligible for re-election for more than two successive years. One third of the Council is to retire each year and not to be eligible for re-election until the following year.

The proposed entrance fee to the Institute is to be five guineas for those persons who join during the first three months of the existence of the Institute, the annual subscription is to be two guineas a year and the fee for examination is to be ten guineas.

It is further proposed that at the meeting on Saturday the first Council of the Institute is to be elected and empowered to elect the requisite officers from their number as well as to take the various steps necessary for the formation of the Institute and the election of members.

THE USE OF METHYLATED SPIRIT.

We think ourselves justified in pointing out, what we were unable to state when referring to this subject last week, that the Commissioners of the Board of Inland Revenue in communicating to the President their decision to waive any further objection to the use of methylated spirit in the preparation of aconite and belladonna liniment (see p. 379), state that they do so "in deference to the wishes of the Council of the Pharmaceutical Society of Great Britain."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, November 1st, 1876.

MR. JOHN WILLIAMS, PRESIDENT.

MR WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present.—Messrs. Atherton, Betty, Bottle, Cracknell, Frazer, Greenish, Hampson, Hanbury, Hills, Owen, Rimmington, Robbins, Sandford, Schacht, Shaw, and Stacey.

The minutes of the previous meeting were read and confirmed.

The Threatened Prosecutions at Nottingham.

Mr. Atherton said it would probably be interesting to the Council to know that the threatened medical prosecutions at Nottingham, mentioned last month, had been abandoned. He believed that there had been a revulsion of feeling on the part of the higher class of the medical profession, and that there need be no fear of further interference with chemists and druggists in their ordinary business.

Mr. Greenish said that observation only applied to Nottingham, of course.

Mr. Shaw remarked that in Manchester several persons had been prosecuted and fined, but they had been notoriously carrying on business of an improper character.

Mr. Hampson said the cases at Manchester were of a totally different character to those at Nottingham, and came under a different Act of Parliament. They really related to quack doctors of a particular class, practising openly without any qualification.

The President said it must be quite understood that the Council had no desire to support improper practices, but simply to protect respectable men who were unfairly attacked in the prosecution of their ordinary business.

The Board of Examiners.

It was moved by Mr. Sandford and seconded by Mr. Greenish—

"That as the Board of Examiners for the ensuing year must be appointed at the next meeting of the Council, it is desirable that any Member of Council desirous of nominating any Pharmaceutical Chemist as an Examiner should send the name of such person to the Secretary before the 23rd instant. That the Secretary be instructed to communicate with any persons whose names may be suggested as suitable persons for Examiners, asking if they will accept office if elected."

Mr. Bottle suggested that it would be well if the Council would elect Examiners in special subjects. Experience had shown that certain gentlemen examined in chemistry, others in botany, and so on, and it seemed to him that instead of electing the Board *en masse* and somewhat at random with regard to their special qualifications, it would be well to classify the Examiners. Otherwise, if the Council made any considerable changes in the Board, there might be a little difficulty in arranging the work.

The President remarked that the theory was that every Examiner was capable of examining in all the subjects. Practically it was known that some men were specially fitted to examine in particular subjects, but that was a matter of arrangement for the Board.

Mr. Bottle said the impression he had received from a conversation with Dr. Fowler, one of the Examiners of the Apothecaries Company, was that the system pursued at Apothecaries' Hall of each Examiner taking the different subjects in rotation was not satisfactory.

The President said the Board of Examiners did in practice allot certain subjects to certain members, but that was hardly a matter which they as a Council could consider.

Mr. GREENISH had always thought it would be an advantage if occasional changes were made in the *personnel* of the Examining Board, and he found that this opinion was also set forth in the 'Science Papers' of the late Mr. Hanbury. It was not that he was dissatisfied with any particular Examiner, but he thought it would be for the general benefit of the Board that occasional changes should take place.

Mr. SCHACHT said it was not by any means easy to get a really good Examiner, and gentlemen who were properly qualified could not always spare the time. It was not therefore desirable to push the system of change too far, and it seemed to him that the great object aimed at, namely, to prevent the Examiners getting into a groove and thus aiding the designs of crammers, would be met by following the system in use at the Apothecaries' Hall, and by letting each Examiner take the various subjects in rotation.

Mr. CRACKNELL thought the arrangement suggested by Mr. Schacht was almost impossible. He could see much in its favour, but it would be attended with a very great deal of inconvenience if it were attempted to carry it out. He did not think the Examiners as a rule worked in such grooves that any evil resulted. He believed the work would be best done by allowing the Board to apportion it according to its discretion.

Mr. GREENISH desired to repeat the suggestion he made in August last when it met with very little support, that the Examiners should be requested to furnish information as to the subject or subjects in which the majority of the candidates who failed were deficient. He found that the Examining Body of the Royal College of Physicians drew attention to the fact that their candidates were many of them ill prepared, as a rule, in the subject of chemistry and its application to pharmacy. This showed that such information could be furnished, and he thought it would be very useful if the Examiners would report once or twice a year, in what subject the deficiency mainly arose.

The PRESIDENT said the materials for such information existed in the books of the Board of Examiners. It was only a question of the trouble of preparing and the policy of publishing it.

Mr. GREENISH thought the statistics would be valuable if published.

Mr. CRACKNELL said his experience led him to believe that there would be very little difference between the different subjects.

The PRESIDENT remarked that from his short experience he should be inclined to agree with Mr. Cracknell. It must also be remembered that when a man failed hopelessly in more than one subject he was not tested in the remainder, so that the numbers would not represent a percentage. He thought the views of the Board of Examiners should be ascertained before any such step was taken.

The resolution was then passed unanimously.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society:—

Bibbings, John Henry.
Campbell, Henry.
Ferguson, William Harry.
Helmore, William Holloway.
Keeling, Charles James.
Kidd, William Champley.
Skinner, Kenneth George Walrond.
Smith, George.
Squire, Alfred Herbert.
Turner, William Spencer.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

Bibbings, John Henry............Newton Abbot.
Keeling, Charles James ....Congreve.

ASSOCIATES.

The following having passed their respective examinations and having severally paid (as Apprentices or Students) or tendered the subscription for the current year, were elected "Associates" of the Society:—

Minor.

Beken, Alfred Edward ....Canterbury.
Briggs, William Henry ....Wakefield.
Cooke, Edmund Herbert.........Northampton.
Cooper, John......................Newcastle-under-Lyne.
Day, John ....London.
Glover, William Kensit ....Aberdeen.
Heaton, George....................Farnworth.
Holding, John ....London.
Lewis, David........................Merthyr.
Littlewood, John Oscroft ......Sutton-in-Ashfield.
Parkinson, Charles ....Preston.
Richards, Philip ....Bury St. Edmunds.
Robinson, Thomas Dexter ......Bedford.
Rundle, Charles .... St. Blazey.
Short, George William...........Swindon.
Smale, Charles ....Totnes.
Thomas, Henry James......... ..Llandilo.
Weston, Matthew Frank..........Bury.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination, and tendered their subscriptions for the current year were elected "Apprentices or Students" of the Society:—

Lowe, Moses Howl ....Great Barr.
Squire, Frederick John Cripps Plymouth.

Two persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was read and adopted, and various accounts ordered to be paid.

BENEVOLENT FUND.

This Committee had met twice during the month. The following grants were recommended:—

£10 to the widow of a registered chemist and druggist with 5 children.

£10 to the widow of a registered chemist and druggist, having no means of support and in ill health.

£15 to the widow of a chemist and druggist, to assist in the education of her two girls; applicant having had two former grants of £10 each for the same purpose.

£15 to the widow of a registered chemist and druggist and formerly a member of the Society. Applicant has seven children, of whom five are wholly dependent upon her.

£10 to a registered chemist and druggist, aged 64, formerly in business, but latterly has acted as an assistant, and unable to continue in the business from deafness.

£10 to a registered chemist and druggist, aged 51, formerly in business, but now confined to his bed from spinal paralysis. Four previous grants of similar amounts had been made.

£10 towards the education of the orphan children of a deceased member. £20 had been granted about twelve months ago.

£10 to the widow of a candidate for an annuity who died a few days before the recent election.

The report and recommendations of the Committee were received and adopted.

Mr. HILLS remarked that it would no doubt be satisfactory to the Council to have noticed that at the recent election of annuitants very much less canvassing than usual had been adopted.

Library, Museum, and Laboratory.

The report of this Committee included the following information. Professor Attfield had reported 45 entries in the laboratory, being the average number in the month of October since 1868.

The attendance in the library since July 11th had been day, highest 25; lowest 0; evening, highest 16; lowest 0. The circulation of books had been 238 in London; 70 to the country, 32 places.

The following books had been reported as missing:—

Barber's 'Pocket Companion to the Pharmacopœia,' 4th edition.

Haselden's 'Notes on the Pharmacopœia,' 1864.

Heaton's 'Experimental Chemistry,' 1872.

'Pharmaceutical Journal, O. S.,' Vol. i., 1841-2.

Phillip's 'Elements of Metallurgy,' 1874.

'Journal of the Chemical Society,' Vol. x.

'British Pharmacopœia,' 1867.

The following books were recommended to be purchased for the library:—

Dragendorff's 'Die gerichtlich-chemische Ermittelung von Giften,' 2e Auflage.

Dragendorff's 'Beiträge zur gerichtlichen Chemie einzelner organischer Gifte.'

Fischer's 'Synopsis Astragalorum Tragacantharum.'

Les Œuvres d'Ambroise Paré.

The Curator had reported that the attendance in the museum had been on an average in August, 3, September, 6.

The inorganic portion of the Chemical Catalogue was reported to be in the hands of the printer.

The Committee had discussed the conditions of eligibility for competition for the sessional prizes, but did not recommend any alteration in the present system. The Committee also was of opinion that the attendance of the Jacob Bell scholars should be reported monthly.

Mr. Greenish said he did not wish to re-open a subject which had been settled by the Committee, but perhaps some members of the Council were not aware of the question which had been brought forward with regard to sessional prizes. At present, at the end of *each* course of five months, a bronze medal was offered for competition, for which students who had attended more than one course were ineligible to compete. It was his wish that the silver medal, awarded at the end of the session, should be competed for by students of that session only, and not by students who had also attended a previous session.

The President said the Committee had considered this question, and had not recommended any alteration.

Mr. Sandford remarked that the Committee appeared to think that any alteration of the conditions would look like discouraging proficiency. To say that a man who had attended a previous course should not obtain a silver medal was like saying that the school only brought men up to a certain standard, as far as they could get in one session, and no farther.

Mr. Bottle added that some students commenced their studies at the end of one session and went on in the next.

Mr. Hampson thought if the arrangement for the bronze medal were the right one, that with regard to the silver one must be wrong. It seemed to him simply as a matter of fair play that this question was brought forward. If the prize were a sessional prize there was a very strong case for a revision of the regulations.

Mr. Frazer had had no knowledge of this question until the present moment, but he entirely sympathized with the sentiments Mr. Hampson had expressed. In the Scotch universities the seniors were never allowed to compete with the juniors. He saw no objection to extra prizes for work done being offered separately, but that was a different matter.

Mr. Hampson remarked that this rule already existed in the laboratory.

Mr. Greenish said that he simply wished that the silver medal should be competed for by students of the one session only in which it was awarded.

The President agreed with the decision of the Committee that it would be unwise to make any alteration at present in the prize regulations. They had been altered so frequently lately that people hardly knew what they really were. It was also a question whether it would be right for the Council to take any step to discourage the higher amount of knowledge which it was really its desire to encourage. It would be very hard to say that a man should not obtain a prize because he happened to have attended a course of lectures elsewhere, perhaps in his youth.

Mr. Greenish said it only applied to the courses of lectures delivered by Professor Redwood and Professor Bentley.

Mr. Schacht asked if the silver medal was open to competition by those only who had attended for ten months, or could it be competed for by those who had attended for five months only?

Mr. Sandford said that any student who had attended during the course of the session might compete for the silver medal.

Mr. Schacht thought in that case it would be unwise to make the change suggested. If a five months' man were allowed to compete, he could not see why a twenty months' man should be excluded. A man might be well educated elsewhere and then come in for five months and take the medal.

Mr. Robbins observed that Mr. Greenish's plan would prevent a man who studied five months in one year and five months in another from competing. The Committee thought that would be a great injustice, and it would be discouraging higher education.

Mr. Sandford said he believed the same system obtained in other institutions, as for instance at King's College. There a second year's man might go in and compete for the prizes.

Mr. Hanbury said they were very particular in the Medical Schools that a second year's man should not compete with the first year's men.

Mr. Bottle thought that even where it was strictly permissible, there was a strong feeling against such a thing being done.

Mr. Hanbury said he was hardly prepared to give a decided opinion on the question, but it seemed to him that there were two matters which were liable to be confounded. Prizes must be offered with two views, one for real excellence, and the other for relative excellence. There was a great injustice in admitting a second year's man to compete with a first year's for a prize which was really only relative. If on the other hand, like the Pereira Medal, the prize was regarded as a token of proficiency, the regulation ought not to be altered. The inevitable injustice of men trained elsewhere coming in and carrying off the prizes could not be prevented.

Mr. Greenish asked the Council to be consistent in this matter. The system he advocated in regard to the lecture classes already obtained in the laboratory.

Mr. Hampson said that the matter might be referred back to the Committee for reconsideration.

Mr. Schacht suggested that if this were done the whole question of prize regulations might be considered. It might be that in order to be consistent the regulations affecting the laboratory should be altered.

The President remarked with reference to the last sentence in the report of the Committee that it had been reported that certain of the Jacob Bell scholars had not attended the laboratory regularly. It was the opinion of the Committee that the gentlemen elected to these scholarships were bound to avail themselves of the instruction provided, or otherwise they were keeping out others who would do so.

Mr. Rimmington asked why they did not attend.

The President said he was not prepared to say at present. But he thought it well that a report of the attendance should be presented.

The report of the Committee was then received and adopted.

It was moved by Mr. Greenish, seconded by Mr. Hampson, and carried unanimously—

"That the subject of the prizes for Botany, Materia Medica, and Chemistry classes be reconsidered by the Library, Museum, and Laboratory Committee."

House.

The report of this Committee stated that the work done in the house during the vacation had been inspected and found to be satisfactory, and the payment of the tradesmen's bills was recommended accordingly.

The report was adopted.

North British Branch.

The Secretary read a letter he had received asking the permission of the Council to use the rooms of the Society in Edinburgh for the delivery of a course of lectures on Botany and Materia Medica, especially adapted for pharmaceutical students.

A resolution was unanimously passed, granting the use of the room for this purpose.

The Secretary read the report of the deputation from the Board of Examiners in Scotland to the Board of Examiners in London.

Law and Parliamentary.

The report of this Committee stated that it had received a deputation from the Chemists and Druggists' Trade Association, and had explained to the members thereof why the Council had not considered it advisable to prosecute co-operative stores for the sale of poisons.

Application of Penalties Recovered under the Pharmacy Act.

The following communication had been received from the Treasury with reference to the application of fines recovered for infringements of the Pharmacy Act, 1868.

"Treasury Chambers,
"12th October, 1876.

"Sir,—In reply to your letter of the 4th inst., preferring a request on behalf of the Pharmaceutical Society of Great Britain, that the penalties recovered by the Society may be applied to meet the cost of prosecutions instituted under the Pharmacy Acts of 1852 and 1868, I am directed by the Lords Commissioners of Her Majesty's Treasury to state that my Lords do not consider there is sufficient reason for acceding to your request.

"The Act has provided that the fines shall be paid as the Commissioners of the Treasury shall direct, and my Lords request that the amount now in your hands may be paid to Mr. T. E. Kebbel, Receiver of Fines, 2, St. Martin's Place, W.C., to be by him carried to the Consolidated Fund, as has been done with all other fines hitherto received under the Act.

"I am, Sir, your obedient servant,
"William Law.

"Elias Bremridge, Esq.,
"Registrar to the Pharmaceutical Society of Great
"Britain, 17, Bloomsbury Square, W.C."

This communication was in reply to the following letter which had been sent to Her Majesty's Treasury in compliancewith a resolution passed at the last meeting of the Council.

[Copy.]

"October 4th, 1876.

"To the Lords Commissioners of Her
Majesty's Treasury.

"My Lords,—As Registrar appointed under the provisions of the Pharmacy Act, 1852, and of the Pharmacy Act, 1868, I beg to bring under the notice of your Lordships the provisions set forth in sections 12 and 14 of the Pharmacy Act, 1852, and section 15 of the Pharmacy Act, 1868.

"Section 14 of the Act 1852 is as follows:—

"'All and every sums and sum of money which shall arise from any conviction and recovery of penalties for offences incurred under this Act, shall be paid as the Commissioners of Her Majesty's Treasury shall direct.'

"In carrying out the provisions of the above-mentioned Acts, in the interest and for the protection of the public, it has been found necessary to institute proceedings for the recovery of the penalties therein provided. Several such penalties have been recovered and are now in the hands of this Society. I am, therefore, requested by the Council to apply to your Lordships for instruction as to the appropriation of such penalties. I would draw the attention of your Lordships to the fact that, there is no provision in the Pharmacy Acts, 1852 and 1868, to meet the expenses of prosecutions under those Acts, and the Society has been, and still continues to be, put to considerable expense in the recovery of penalties, and otherwise in regard to offenders, largely in excess of the sums recovered from the defendants, and I have to ask that your Lordships may therefore be pleased to direct that the penalties may be applied towards the reimbursement of such expenses.

"I have the honour to be,
"My Lords,
"Your Lordships' obedient servant,
"(Signed) Elias Bremridge.

"*Registrar under the Pharmacy Act*, 1852 *and* 1868."

The Committee recommended that a deputation, consisting of the President, Mr. Sandford, Mr. Hills, the Secretary and the Solicitor, be requested to wait on the Commissioners of Her Majesty's Treasury, with a view to obtain a more favourable decision.

Use of Methylated Spirit.

The President stated, that in reply to the memorial to the Commissioners of the Board of Inland Revenue (see before p. 292), he had received the following communication:—

"October 2, 1876.

"Sir,—The Commissioners of Inland Revenue having had under careful consideration your letter of the 16th August last, I am desired to acquaint you, in reply, that in deference to the wishes of the Council of the Pharmaceutical Society of Great Britain, the Commissioners now consent to raise no objection on the part of the Revenue to the use of methylated spirit in the preparation of aconite and belladonna liniments. The requisite instructions have been issued to the local officers of the Revenue, as you will perceive on reference to the 4th paragraph of the enclosed general order, which has just been issued by the Commissioners.

"I am, Sir,
"Your obedient servant,
"Adam Young."
"*Secretary.*

"John Williams, Esq."

Letters were also read from the Society's solicitor, narrating the progress made in the various cases which had been placed in his hands.

After some conversation the report of the Committee was received and adopted.

Report of Examinations in October, 1876.

ENGLAND AND WALES.

	Candidates. Examined.	Passed.	Failed.
Major	13	10	3
Minor	60	25	35
Modified	5	3	2
Total	78	38	40

SCOTLAND.

	Candidates. Examined.	Passed.	Failed.
Minor	21	10	11
Modified	3	2	1
Total	24	12	12

Preliminary Examination.

Fourteen certificates received in lieu of the Society's examination:—

1 University of London.
3 „ „ Oxford.
4 „ „ Cambridge.
1 „ „ Durham.
1 Society of Apothecaries, London.
1 Apothecaries' Hall of Ireland.
3 College of Preceptors.

Candidates. Examined.	Passed.	Failed.
235	115	120

The following letter had been laid before the Board:—

"College of Preceptors, 42, Queen Square,
"London, W.C.,
"20th October, 1876.

"Dear Sir,—I beg to forward a few remarks made by the Examiner in relation to the recent Preliminary Examination, and am, Dear Sir,

"Yours faithfully,
"C. R. Hodgson, *Secretary.*

"E. Bremridge, Esq.

"*Latin.*—The Latin translation was generally moderate. I did not notice any candidate's work as being first-rate. The grammar was generally pretty good, and in some few cases thoroughly well done.

"*Arithmetic.*—In arithmetic, too many failed in calculating the value of a given weight at a given price. But few could answer the questions on the metric system properly.

"*Grammar.*—The English grammar was on the whole satisfactory and much better than the English composition. The Spelling was generally correct."

PHARMACEUTICAL MEETING.

Wednesday, November 1, 1876.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting were read and confirmed.

The following donations to the Library, Museum, and Herbarium, were announced, and the thanks of the Society were awarded to the donors:—

Library.—'Calendar of University College, London, 1876–7,' from the College; 'Zur quantitativen Bestimmung des Veratrins und Physostigmins,' von E. Masing, from Professor Dragendorff; 'Classification de 250 Fécules,' from M. Bernardin (Author); 'Étude Comparative du Galbanum et de la Gomme Ammoniaque suivie de quelques considérations sur l'Opoponax et le Sagapénum, par E. Hirschsohn,' from Dr. J. Morel (Translator); 'Aanteekeningen op het systematisch-en pharmacognostisch-Botanische gedeelte der Pharmacopoea Neerlandica,' door C. A. J. A. Oudemans, M.D., and Sundry Parliamentary Reports, volumes and numbers of periodicals, etc., out of the library of the late Daniel Hanbury, from Mr. Thomas Hanbury; 'Chemistry, General, Medical, and Pharmaceutical, by J. Attfield, Ph.D., Seventh (United States) Edition,' from Mr. H. C. Lea (Publisher).

Museum.—Fine Specimens of Crystallized Palmitic Acid, from Price's Patent Candle Co.; Specimens of the Chemical Principles extracted from Ergot, from Professor Dragendorff; Specimen of a New Variety of Benzoin, from Mr. Morson; Single Camomile flowers, from Mr. C. B. Allen; Flower of Tea, from Mr. T. B. Groves; Resin of *Terminalia angustifolia*, from the India Museum; Fruits of *Xanthoxylon fraxineum*, specimens of Dolomite, Chebulic Myrobalans, from Mr. Geo. Smith, Sunderland; Seeds of *Amomum xanthioides*, from Mr. C. Hanbury; Specimens of Nepaul, Benares, Patna, and Malwa Opium, from Mr. Morson; Specimens illustrating Fluorescence, from Mr. W. G. Lettsom.

Herbarium.—Specimen of *Primula farinosa* and other rare plants, from Mr. Geo. Smith.

The Chairman drew special attention to one of the donations to the Library viz., the seventh edition of Professor Attfield's 'Chemistry,' published by Mr. Henry C. Lea, of Philadelphia, who had presented it to the library. It was a new edition, especially adapted to American pharmacy. It was worthy of remark, and most gratifying, that every Professor of the Society up to the present time—Pereira, Fownes, Thomson, Redwood, Bentley and Attfield—had been the author of some work on his particular branch of science allied to pharmacy which had been accepted as a standard authority upon the subject.

The Centennial Exhibition at Philadelphia.

The Chairman said that there was present a gentleman who had recently returned from the United States, where he had been acting as one of Her Majesty's Commissioners to represent Great Britain at the great International Exhibition held in Philadelphia; he referred to Professor Archer, of Edinburgh. He would ask Professor Archer to kindly give the meeting some information respecting the way in which pharmacy was represented at that exhibition.

Professor Archer after stating that he was wholly unprepared for the task which he had been called upon to perform at only two hours' notice, said:—With respect to the very great exhibition at Philadelphia which will close in a few days, there are very many points from which we may look at it with great satisfaction, and there are none from which I at least can look at it with anything but satisfaction. I allude entirely to the management of that very great affair, the most magnificent exhibition the world has ever yet seen, and which I do not hesitate to say is the best managed exhibition that has ever been held. As a Commissioner there I had very arduous duties to perform which almost prevented the possibility of a minute examination into the general details of an exhibition which covered nearly 300 acres of ground, 70 of which were under a roof. But there was one thing which certainly did strike me very much indeed, viz., the wonderful perfection to which the pharmaceutical and chemical branches were carried. Had I merely seen them in the exhibition I might probably have been a little suspicious that good specimens had been collected together from any available source and displayed there, because I have known such things done; but I had the good fortune on one occasion especially to be present when the College of Pharmacy of Philadelphia, which represents the State of Pennsylvania, gave away its degrees, and I then saw a sight which I certainly shall never forget. The meeting was held in what is called the Academy of Music, a large theatre, quite equal in size to anything we have in London, having seats for between 5000 and 6000 people, and I think there were fully that number present. A more crowded theatre I never saw in my life, and as I had the honour of a seat on the stage with the Professors, I had a good opportunity of seeing, not only the immense crowd before me, but the intense interest that it took in the proceedings, viz., the distribution of degrees to over 100 graduates in pharmacy. As I sat there many thoughts occurred to me, one of the most prominent being the memory of having talked over with the great mind whom we all look upon as the founder of the Pharmaceutical Society of Great Britain, Jacob Bell, his views as to the elevation of the profession to which he belonged; and I remembered that I, with him, had thought that if this great Society could be established and carry out its objects as they are being carried out now, that would be the culminating point of our hopes. I now think that both he and I, and all who were associated with us then were in error. We did not see as far as we ought to have seen; we did not see that there was something still beyond all that, and the scene I saw in Philadelphia teaches me that we have to look to something far beyond it. Instead of the Pharmaceutical Society of Great Britain it must be some day or other the Pharmaceutical College or University of Great Britain, and degrees and honours must be given, and the whole thing must be made to assume a much more elevated aspect. Such is the case in Philadelphia. There I saw these thousands of ladies and gentlemen filling the largest theatre in that immense city of 800,000 inhabitants, all taking intense interest in the event of the evening, the distribution of prizes to those who had succeeded in passing their examination and gaining honours. There was a curious feature connected with this, showing that this enthusiasm was not the mere effervescence of the moment. Along the front of the stage, just behind the footlights, were piled more bouquets of flowers than, I will venture to say, you could find any day in Covent Garden Market, parcels of books, and boxes, containing, no doubt, something very nice, all nicely tied up with ribbons and labelled; these had been sent by those who took an interest in the proceedings as a sort of kindly mark of the delight felt by the donors at the success of the students. Now I think there is in all this something that we ought to aim at. All these things showed the young men that there was a wide interest felt in their welfare, which interest would accompany them through life provided they did as well in the future as they had done in the past. The speeches made by the Professors were such as I am sure all here would have been delighted to listen to, and none could have listened without advantage. I certainly came away with a strong feeling of respect for the position which pharmacy occupies in the United States, and I think most of you will agree with me that there is something in what I have said which ought to stimulate us to aim at even greater things than have been yet accomplished. With respect to the Great Exhibition itself, the chemical and pharmaceutical displays that were made, I do not feel that I have sufficient data before me to waste your time by attempting to detail them. All I can say is, that there was such a display as I had never seen before; a perfect grandeur of chemical art in every possible direction. But it was not altogether American. German chemists were pre-eminent in the Exhibition and the display made by them was beyond anything ever before witnessed. Pharmacy itself has certainly made very great progress in America, though in rather different ways to which it has here. It has its own peculiar materia medica to deal with, and it has to cope with the notions of practitioners, altogether different from the views of our own practitioners in these matters. It is a very important subject to look into, but all that I can say upon the subject is, that there is very much for us to learn, and perhaps for them also. When we come to compare notes it is possible that they may throw aside much of their materia medica, and we may adopt some of those which they retain. I wish it were in my power to go more into the matter, but I had not time to prepare.

The PRESIDENT proposed a vote of thanks to Professor Archer for the kind manner in which he had responded to his request, which was carried unanimously.

The CHAIRMAN said the next business was the reading of a paper entitled—

SUGGESTION FOR AN IMPROVED METHOD OF MAKING MISTURA GUAIACI AND SIMILAR MIXTURES.

BY THOMAS GREENISH.

The paper is printed on p. 369, and gave rise to the following discussion:—

The PRESIDENT said this paper showed what could be done by observing at the dispensing counter the ordinary occurrences which took place, and if the younger members and assistants would remember this, they might often bring forward papers which would elicit interesting discussions. This paper showed a new application of sugar of milk in pharmacy.

Mr. GERRARD asked if Mr. Greenish had observed that different samples of resin of copaiba had different colours. He had seen some pale green and some a deep green, and some he had prepared himself was not green at all. He was somewhat suspicious that the resin prepared by distillation obtained its green colour from the copper vessels in which it was made. If that were so they ought to see that the resin was prepared in a different manner.

Mr. UMNEY said he had on many occasions seen large quantities of the resin of copaiba contaminated with copper, but that was at a time when the resin was considered to be useless, the oil distilled from it being the important remedy. But since Dr. Wilkes's communication in the *Lancet* about eighteen months or two years ago, showing the value of the resin, there had been a demand for it, and he thought that manufacturers now distilled the oil in stills either tinned inside or made of lead or earthenware.

Mr. HODGKINSON said that the resin prepared in copper vessels was perfectly useless for pharmaceutical purposes. It should not be in the slightest degree green. Until recently, however, it had been regarded as a worthless residuum which every conscientious dealer had thrown away.

Professor REDWOOD said that the resin of copaiba consisted of resin acids which would combine with the oxide of copper. It appeared to him, therefore, that the use of a leaden still would be equally objectionable although the contamination might not be so apparent. He should recommend an earthenware or an iron still.

Mr. UMNEY said he had used both lead and tinned copper, to the latter of which he gave preference. He had not tested the resin to see whether it was contaminated with lead, but he could quite believe that it would be when a leaden still was used. He had distilled considerable quantities, and generally preferred to operate upon the particular kind of balsam known in the market as Para Copaiba. This would sometimes yield as much as 60 per cent. of volatile oil, whereas the other kind, (Marahnam Balsam,) usually preferred by druggists, would only yield 30 to 40 per cent. The essential oil came over very readily with the vapour of water.

Mr. GERRARD said when Dr. Wilkes first proposed using resin of copaiba he had the honour of preparing several mixtures for him with the object of finding what was the best way to dispense it, and they concluded at the time that a compound powder of almonds formed the most excellent emulsifying agent for the purpose.*

* See *Pharm. Journ.* [3], vol. iv., p. 63.

Mr. MARTINDALE, referring to the mixture of guaiacum prepared by Mr. Greenish, wished to know whether it had been prepared with the ordinary powder or with freshly powdered guaiacum. That made with a freshly powdered guaiacum generally showed a dirty dull white colour, but if prepared with old powder it was of a dark green.

Mr. CLEAVER thought that if there were lime salts present in the sugar of milk, a soluble compound would be probably formed with the acids present, and therefore, probably if the guiacum resin were older it would not be attacked so easily.

Mr. HOLMES asked if Mr. Greenish had tried more than one specimen of copaiba resin, because it was well known that copaiba was obtained from different trees, and that the balsam met with in commerce varied very much in consistence and appearance, and possibly might also in chemical properties.

Mr. GREENISH, in answer to Mr. Gerrard, said he had never noticed the green colour in the resin of copaiba. He always used pure resin, and he was sorry Mr. Gerrard, when he noticed this green colour, had not made a note of it, and brought it forward in a short paper. With regard to the guaiacum mixture he always took a mass of resin, broke a piece of it, and powdered it at the time. The green colour was a question of time. The principle involved which he had wished to bring forward, was this:—If the resin were put into a mortar and rubbed down with the spirit alone, it stuck to the sides of the mortar, but if sugar of milk were previously added to the powdered resin, and then the spirit, the resin could be rubbed into a minute state of division, and the whole would form a homogeneous mixture, to which the powdered gum could be added, without adhesion to the mortar, and afterwards, on the addition of water, the emulsion was obtained.

Mr. HODGKINSON asked if any gentlemen present could say whether the green colour was due to oxidation or to the action of the solar rays.

Professor REDWOOD was not aware that the exact nature of the change which took place had ever clearly been ascertained, but there were several substances which promoted that change; a piece of freshly cut potato, for instance, was used as a test, and gum arabic produced a similar change. He should be disposed to ascribe the colour present in the mixture Mr. Greenish had produced to a great extent to the action of the gum upon the resin. The resin of guaiacum, however, when exposed simply to air for a great length of time, acquired a green colour on the surface, and no doubt there were specimens in the museum showing the action, but it was much more speedily developed by contact with certain organic and other substances. He had not any experience in the preparation of mistura guaiaci, but he had heard years ago the late Mr. Ince indicate as an improvement in the way of making it, the use of unpowdered resin on account of its more readily emulsifying than the resin after it had been kept in powder for any length of time. Guaiacum as met with in commerce consisted of resinous matter and extractive matter, both of which underwent change on exposure, and would be more likely to do so when kept in powder. Whether this change affected the emulsifying properties he could not say, and should be glad to learn from any gentlemen present what their experience had been.

Mr. ROBBINS said it had been fully recognized that the change in the colour of guaiacum was due to oxidation, in fact it was used as a chemical test to distinguish ozone from antozone. It was the most delicate test known for detecting spots of blood on articles of dress, or anything of that kind. Peroxide of hydrogen did not oxidize guaiacum, but the smallest trace of blood immediately converted the peroxide of hydrogen, which was considered to be in the state of antozone, into the form of ozone, and the guaiacum immediately produced a deep blue colour. It had been used extensively as a test in this way by Dr. Day, of Geelong.

Professor ATTFIELD said the whole subject of the changes which took place in these resins and gum resins both before, during, and after mixture with certain liquids to form emulsions, required investigation. Some thirteen years ago the question of emulsions, and what they were, was introduced into the list of subjects for research issued by the British Pharmaceutical Conference. In 1864 Mr. Proctor read a paper on emulsions, and undertook further to work on the subject, provided he received from his brother pharmacists some contributions resulting from their observations of emulsions. Mr. Proctor had recently told him that he had not been much encouraged to carry on the work, and, as a matter of fact, had not done much at it; he rather feared that he had given it up altogether. There was room for a very extended series of researches on this subject. It was very desirable that practical pharmacists should bring the result of their experience to these meetings from time to time as to the best mode of making this, that, or the other emulsion; but in addition to such work, a research was needed into the nature of emulsions generally. The qualifications for such a research should obviously be competent chemical, physical, and botanical knowledge—in fact, it was just the subject which any well-educated man who had passed the Major examination might take up. They wanted all the emulsions, natural as well as artificial, brought within the range of science. In other words, what was required was a knowledge of the laws which governed matter; then the youngest pharmacist, once getting hold of the principles regulating the formation of emulsions would be able to make any and every emulsion, whether or not previously known, without a failure and without loss of time.

Mr. GREENISH said the mixture of guaiacum when first made showed no green colour, but it was developed in a short time. The colour became green more rapidly when powdered guaiacum was used. In every instance he should recommend a piece of lump guaiacum to be employed. He could not answer the question of Mr. Holmes as to the kind of resin of copaiba he had employed. He had only one specimen which was very pure.

Mr. UMNEY asked if Mr. Greenish used the drop guaiacum or the mass. There were two kinds known in the market, the drop being about the size of a small walnut and exceedingly pure, and the lump which was variable in purity.

Mr. GREENISH said he used one large piece, but it was very clear and bright.

Mr. HODGKINSON thought that if the tears had run into a block together Mr. Greenish probably would not know the difference between one and the other.

Mr. BLAND had observed that the change in the colour of powdered guaiacum proceeded much more slowly in the absence of solar light, and if the powder were kept in the dark it would remain a considerable time without undergoing any change. He could also corroborate what was said by the last speaker about block guaiacum. He had some in masses which appeared quite as pure as the ordinary tears. It broke up into small fragments with a conchoidal fracture and a transparent appearance which indicated purity.

Professor BENTLEY said they must naturally expect as a general rule that tear guaiacum would be purer than the ordinary guaiacum in mass, because it was simply the natural exudation, or one which came after incisions, and so far as he had seen, the tears were generally unmixed with any foreign substances, although not invariably so. There was no reason at all, as Mr. Hodgkinson had said, why there might not be lump guaiacum almost free from extraneous matter, but considering the very rough manner in which it was usually prepared, it would naturally happen that in most cases, pieces of bark, earth, and other impurities would be found mixed with it, although he had seen guaiacum in mass almost free from impurity. It was quite true that an agglomeration of tears might take place, but still they were never so perfectly fused together as the ordinary mass which was prepared by heat. Till lately guaiacum was generally believed to be derived from one plant only, namely *Guaiacum officinale*, but it was now known, through the investigations of their lamented friend, Mr. Hanbury, that *Guaiacum sanctum* also yielded some of the commercial guaiacum.

Mr. HALL had noticed some years ago, when more engaged in dispensing than at present, that powdered guaiacum showed a more decided change of colour in the direction in which it was exposed to the light than in any other. The same thing might be observed in the case of Pulv. Rhei. It was probable, therefore, that the actinic rays had something to do with the change.

The PRESIDENT proposed a vote of thanks to Mr. Greenish, which was carried unanimously.

PLASTERS.

Mr. MARTINDALE next drew attention to and described several varieties of plaster prepared by an American firm. They included cantharides plaster on cloth, which had been proved to act well as a vesicant, and only required oiling before application; mustard plaster, spread on cloth, made with a basis of so adhesive a character, that it left none of the mustard adhering to the skin when the plaster was removed; surgeon's adhesive plaster, very flexible and apparently a great improvement on that at present in use; this was termed india-rubber plaster, and had a strong aromatic smell, and the slight oxidation of some aromatic principles yielding peroxide of hydrogen; it possibly might act as an antiseptic. There were also porous plasters and belladonna plasters.

Mr. GREENISH inquired the reason of the dark colour of the mustard plaster.

Mr. MARTINDALE thought it was due to the basis by which it was made to adhere to the cloth. It was made with black mustard seed, and the basis was of the same composition as the surgeon's adhesive plaster, a mixture of india rubber and frankincense, or something of that kind.

Mr. UMNEY said he imagined from the odour that instead of using chloroform, petroleum had been used for the solution of the india rubber.

Mr. GREENISH said the black mustard seed had only a black skin, and, therefore, there must be something besides this to account for the colour of the plaster.

Mr. GERRARD said he had prepared a great deal of plaster and it appeared to him that there was something which gave this plaster a dark appearance; if the makers retained all the oil in the mustard that might account for it, but if the oil were extracted there must be something more than mustard present. He had on a previous occasion remarked on the superiority of india rubber to gutta percha for such purposes and believed that one part of caoutchouc dissolved in benzol was equal to ten parts of gutta percha dissolved in chloroform for the purposes of adhesion of mustard to paper or any other material, and it rendered it far more flexible and better adapted for the purpose intended.

Mr. GREENISH said it was very necessary in introducing mustard plasters to be sure there was nothing besides mustard in them, because other substances might be injurious.

Mr. MARTINDALE said he found on immersing this plaster in warm water that it immediately evolved a strong odour of essential oil of mustard. The colour he had no doubt was due to the basis with which it was made to adhere.

Mr. HOLMES next called attention to sundry articles he had placed on the table. The first was a specimen of benzoin which had a different odour to that generally met with, being more like that of tolu, and it was more translucent than usual, and contained very few tears. He had no information as to its botanical source, but it yielded a beautifully white benzoic acid by sublimation, the proportion being, he was informed, about 10 per cent. Whether or not it was obtained from the *Styrax Benzoin* he could not say. Mr. Hanbury had described in the 'Pharmacographia' two or three kinds of benzoin, but this variety was not mentioned. It was said to come from Zanzibar, but he doubted if that were its real origin. He had tested it for cinnamic acid, but it did not contain any. There was also a beautiful specimen of olibanum resin, showing the peculiar papery bark of the tree on its undersurface. It was the variety called by the natives Lubân Matti, derived from *Boswellia Frereana*, Birdw. It was distinguished from other varieties of olibanum by a peculiar whitish efflorescence on its surface and stratified opaque white layers in its interior. There were also two specimens of palmitic acid beautifully crystallized, presented by Price's Patent Candle Company; the one represented the commercial article, usually known under the name of palm stearine, and the other was nearly pure palmitic acid. There were also some interesting specimens representing the chemical principles obtained from ergot by Professor Dragendorff, as referred to in the Journal for June, 1876; a sample of single chamomile flowers collected in Cornwall by a former student of the Society; and several solutions illustrating the phenomenon of fluorescence, presented by Mr. Lettsom. These solutions included æsculin, lately shown to be identical with the fluorescent principle of *Gelsemium sempervirens*, and formerly called gelseminic acid; fraxin; aqueous infusion of lignum nephriticum; eosin, weak solution; eosin, strong solution; tincture of the seeds of *Peganum Harmala*; fluorescin; sodium salt of dichloranthracene, and æsculetin.

Professor BENTLEY remarked in reference to the so-called Zanzibar benzoin that it was doubtless only indirectly derived from that port, the only varieties at present known being from Sumatra and Siam. The present specimen appeared most nearly to resemble the variety termed by Pereira, translucent Siamese benzoin, and which he obtained from Dr. Royle, who conjectured its botanical source to be *Styrax Finlaysonianum*. He had not, however, had an opportunity at present of comparing the specimens. The great peculiarity of the specimen now exhibited was the translucency of the white tears, for as a general rule, these were opaque, and the dark substance between them transparent. The amount of benzoic acid obtained from this benzoin being only 10 per cent. it could not be regarded as a very fine variety, for the quantity usually obtained from the best kinds varied from 12 to 20 per cent. Professor Bentley said that it was generally stated that the dark portions of benzoin yielded the most benzoic acid, and if this be correct, the large amount of white translucent matter would account for the comparatively small proportion of benzoic acid in this specimen. Professor Bentley said that much still remained to be done in reference to the botanical source of the varieties of benzoin, that of Sumatra benzoin having been clearly traced to *Styrax Benzoin*, but the plant yielding the best variety of benzoin now known, namely Siam benzoin, had not been botanically determined. It was highly probable, judging from the varying appearances of the varieties of benzoin, that they were derived from different plants.

The CHAIRMAN said it was now well known as a chemical fact that the benzoic acid obtained from gum benzoin was always a mixture of benzoic acid and cinnamic acid, and that pure benzoic acid could only be obtained by decomposing hippuric acid. He would now draw attention to some specimens of opium presented by Mr. Morson, and also to a series of tubes containing solutions illustrating the phenomena of fluorescence.

Professor BENTLEY remarked that galbanum might be made to form a beautiful fluorescent solution, and he believed he could distinguish it from some of the allied gum resins by this character. Thus by taking a piece of galbanum and putting it in water for an hour or two, the water would not in itself exhibit any marked fluorescence, but on the addition of a drop of ammonia a beautiful blue fluorescence was at once observable; and this fluorescent appearance was again destroyed by the addition of an acid. Asafœtida would also cause a similar fluorescence, but not to the same extent; and with ammoniacum it was scarcely observable. This fluorescence was due to the presence of umbelliferone in the gum resins.

The CHAIRMAN then declared the meeting adjourned until Wednesday, December 6.

EXAMINATIONS IN EDINBURGH.

October 24th and 25th, 1876.

Present—Messrs. Ainslie, Borland, Buchanan, Kemp, Kinninmont, and Young.

Professor Maclagan attended on behalf of the Privy Council.

MINOR EXAMINATION.

October 24th.

Twelve candidates were examined. *Six* failed. The following *six* passed, and were declared qualified to be registered as Chemists and Druggists :—

Beveridge, William .... Edinburgh.
Blaine, Thomas James Stewart Hawick.
Croskell, William Joseph......... Liverpool.
Ferriday, Edwin Jos. Pitchford Oakengates.
Goodchild, Thomas Archibald Belfast.
Halhead, John Armstead ...... Kirkby Lonsdale.

October 25th.

Nine Candidates were examined. *Five* failed. The following *four* passed, and were declared qualified to be registered as Chemists and Druggists :—

Mann, Edwin .... Atherstone.
Munro, Hugh .... Hampton Wick.
Rowe, Sampson.................. Redruth.
Watson, Lund .... York.

MODIFIED EXAMINATION.

October 25th.

Three candidates were examined. *One* failed. The following *two* passed and were declared qualified to be registered as Chemists and Druggists :—

Beech, Thomas .... Birmingham.
Hume, Robert .... Birmingham.

Provincial Transactions.

HALIFAX AND DISTRICT CHEMISTS AND DRUGGISTS' ASSOCIATION.

This Association held its annual meeting at the Old Cock Hotel, Halifax, on Oct. 12, 1876, Mr. Robert Brook, President, in the chair. The following gentlemen, the nominations of a previous committee meeting, were elected officers of the Association for the coming year.

President, Mr. R. Brook; Vice-Presidents, Messrs. Dyer and Jessop; Treasurer, Mr. Councillor Brierley; Hon. Sec., Mr. B. Shaw; Committee, Messrs. Slott, Hebden, Farr, Swires and Blade; Librarian, Mr. Brook

Having expressed his thanks for the honour of reelection, the President delivered the following address, which was warmly received, and the meeting, having heard the Annual Report from the Honorary Secretary, decided that both should be printed and circulated.

THE PRESIDENT'S ADDRESS.

I had the honour last year of addressing a few remarks to you on the policy that should govern our prices in dispensing prescriptions, and I wish this evening to place before you a few practical reasons for the necessity of upholding and strengthening the early closing movement. When we consider how the business of shopkeepers is carried on, one is apt to come to the conclusion that a great amount of profitless expenditure both of time and money is swallowed up in the process. And although we profess to be a practical people, and on no account given to sentimental nonsense, yet many naturally arrive at the conclusion that much of this time and money might be saved, and an incalculable amount of good effected by the curtailment of the hours of business. It is a very practical question to ask what is there to prevent this reduction. The assumption I take it to be is this.

We have our shutters taken down at the earliest moment we are likely to secure custom, and they are put up again as soon as the chances for the day and night are over and gone. Here and there an enthusiast may let his gas flare through his windows out of share hilarity of spirits, or an eccentric individual out of mere opposition, or some solitary being may plead like the Apothecary of Mantua that his poverty and not his will compels; but as a rule I take it for granted that shopkeepers would be very glad to leave their counters at an earlier hour if they could so without any corresponding diminution of profits. Well, can this twofold result be obtained? What is wanted is just that amount of courage necessary to enable the experiment to be made. There are only two parties in the transaction, the customer on the one side, and the tradesman on the other. Restrict the amount of time within which the two may be brought into contact and it must follow that the one will find opportunity to sell that which the other wishes to buy. There would be less waste of time, but there would be no less custom.

This view of the subject which seems so self-evident is not yet fully comprehended by the retail tradesman; nevertheless it is very desirable to settle the question on a voluntary basis, rather than by legislative action. What is required is a little more public spirit on the part of shopkeepers, coupled with a more enlightened sense of duty on the part of the public, who have the power of making the most obstinate soon tire if he could not turn a profitable penny after eight o'clock.

In placing these considerations in the foreground, I do not wish to lose sight of what our Association has done in the matter. A dozen years ago no arrangement amongst chemists for closing existed in this town. It might be some thought nine o'clock quite late enough, or were perfectly satisfied with the contents of the till, or perhaps nature rebelled in the form of weariness both of mind and body. It might be some would let the hands slowly take their course round the dial-plate once more and nurse the idea that druggists specially were required and expected to keep open till the very last moment. But one of the first and best acts of this Association was to change all this and arrange for a plan of early and systematic closing. This was brought to a successful conclusion, and I think we have all of us benefited by the change both mentally and physically. Nay more, I say, if this Association had done nothing else than this, it would have deserved the gratitude not only of the present but also of the future generation of druggists.

If this is the case you may naturally ask, why am I bringing it under your notice this evening. For this reason, I fear there is a tendency to relax our efforts to keep well abreast of the early closing movement, and to let slip the many benefits that we have received from it, and I want therefore to stir you up to a lively remembrance of what we stand committed to. Our position as tradesmen with our superior education and responsibilities eminently fit us for taking the lead in this matter; do not then let us commit the folly of lagging behind. Bear in mind the tendency of the age is against us. For some time past we have been threatened with legislation on the subject, and much as I object to too much meddling in trade by Parliament, I should not regret to see a compulsory closing Act, so valuable would be the benefits we should receive from it.

In presiding over the meetings of our Association I have often thought that a good deal of time was wasted and a want of clearness and decision evinced in discussing the various subjects brought under its notice, owing to extraneous matter being introduced not bearing directly on the question at issue. I think a change for the better is desirable, and I would therefore suggest that the official business on the notice paper be taken first, and in discussing the various items all extraneous matter be avoided as much as possible. If this be done we shall find that we have a clearer and distinct idea as to what we are aiming at; it will be a great deal easier to comprehend and chronicle the proceedings by the Honorary Secretary, and will most certainly have a tendency to prevent us getting into—what has some seldom times occurred—a state of muddle and confusion.

One of the most remarkable circumstances in connection with pharmacy during the year, has been the formation of a Trade Defence Association with head quarters at Birmingham. An organization of this kind—one in which we should have confidence, and might look up to for guidance and advice—has been a long-felt want to most outside the charmed circle of the Pharmaceutical Council. I commend it to your favourable consideration and hope that by a large increase of members and subscriptions to the Defence Fund, it may become unto us as a parent society strong in attack and powerful in defence of trade rights and interests. And I think we can very well afford to treat with indifference the sneers of the Journal, the soreness of some members of the Council, and the comments made by some London chemists. These gentlemen no doubt fully understand the nature and business of a druggist's establishment in town, but are just as ignorant of the nature of those that are carried on in the provinces. And this is just the point where the Council has failed. I give them all the credit that is their due for the educational and scientific successes they have achieved, but with regard to trade matters they either cannot or will not perceive the difference between town and country experience in pharmacy.

And whilst commending the new Association to your consideration, let me not forget to remind you of the claims our own elder Association has upon your attention and support. Probably no one now present can call to mind any period within the last twenty-five years when a more pressing claim could have been put forth. We do not know for certain what is looming in the future, but we do know this, that we are threatened with troubles and trials in all directions. The Inland Revenue authorities have given us a hint that their officers are going to look sharp after us in the matter of quinine wine; they are harrassing us with regard to methylated preparations for outward use and liquid extract of meat in a most absurd manner. We are to be visited by the inspectors under the Food and Drug Adulteration Act, which after being so long a dead letter in the town is now to be enforced. The Medical Defence Association tells us plainly they will prosecute, when they can get hold of a case, for counter prescribing, under the Apothecaries' Act, which said Act specially contains a clause exempting chemists *from* prosecution. More still, barristers tell us that the poisons in the second schedule of the Pharmacy Act ought to be registered, which if enforced will prove a most serious affair to the trade. And to crown all and make our cup of misery full to overflowing, we are threatened with another Poison Bill next session. I say then, there never was a time when we should so call in our reserve forces and putting shoulder to shoulder, closing in our ranks, present a bold front on behalf of trade interests. For we must remember this, however conscientiously we may desire to do what is right and honest, we never know what is in store for us. And whether it be the decision of a superior or a county court judge, the vagaries of county or borough magistrates, or worse still, the remarks of coroners, and the absurdities and contradictions of analysts; nearly all seem ignorant or strongly biassed against our trade. Notice too with what eagerness a doctor, when he thinks he has a case against us either with regard to the sale of poison or counter-prescribing, rushes into print and thinks to crush us at once. And the press is in no way backward in following up the attack, and leaders soon appear, nearly always displaying any amount of prejudice and ignorance, and in some paltry cases exemplifying the couplet of the poet,

"The ocean into tempest tossed
To waft a feather, or to drown a fly."

The Annual Report, 1875–6.

The report for the seventh year of this society's life stated that the number of meetings during the year, including the annual dinner, had been eight, there having been two extraordinary meetings in the months of June and July. The average attendance had been 7·75. The number of members remained the same. Changes had however occurred. The year now closing had been an expensive one for the members, two calls having been made upon their voluntary liberality in aid of the finances of the Association, besides others from without and related to the business its members pursue. With ordinary care there was no likelihood of similar demands during the new year. The balance in hand twelve months ago had been spent in providing the annual dinner, to which the Association invited several medical gentlemen. The gathering of the members was good, and the kindly feeling between the guests and their entertainers was very agreeably manifest. Two matters had taken up much of the time of the monthly meetings. The first was the rise and establishment of a small but excellent scientific library. A handsome sum remained in hand after the disposal of the effects of the recent Halifax Chemists' Assistants and Apprentices' Association. These moneys the representatives of that association, Messrs. Illingworth and Rhodes, desired to spend in standard works on the sciences and arts immediately connected with the business and practice of pharmacy. They proposed to hand over such books to the care of the Halifax Chemists' Association to be held by them in trust for the use of its own members, and young men engaged by chemists in the town and district from time to time. This offer was received with much favour, and the list of books submitted was most carefully considered by a committee. Its suggestions were approved by the next meeting, and then passed on for the consideration of the young men's representatives. On receiving their reply, a smaller committee had an interview with them, and the arrangements were completed. The books had been for some time in the hands of the President, who had kindly acted as librarian *pro tem*. The works were the best treatises on the subjects in the English language, and more than sufficient as to number and variety to admit of ample preparation for the dreaded examinations being obtained by their study, without necessarily attending lectures or laboratory, or undergoing the degradation of being "coached." A small herbarium of medicinal plants and one of Messrs. Southall's materia medica cabinets were handed over with the books into the librarian's care. One of the members, Mr. B. Wood, had also kindly added a set of the *Pharmaceutical Journal*. The second principal subject of the year was the demand for and formation of a Trade Defence Association. As soon as the project was broached, the Association, considering such a body would meet a real and pressing want, expressed its approval and promised co-operation, and ultimately Messrs. Dyer and Jessop, Vice-Presidents, were selected as delegates to the preliminary conference, which met in Birmingham. Some ten guineas had been forwarded from members of the Halifax Association as subscriptions and donations in aid of the new body. In reference to closing hours and Sunday trade, it was to be regretted that in many cases the agreement to put shutters up at 7 p.m. had fallen through. Final closing at 8 p.m. was still general, and Sunday business was not only unsought, but undesired.

During the year the meetings had been very much meetings of the same faces. But few visitors from the less regularly attending members had shared the cares, or added to the interest. The average attendance had been as good, if not better than in some years, and good feeling had been preserved unimpaired.

Arrangements were afterwards made for the annual dinner, and guests were selected for invitation. The meeting passed this resolution unanimously:—"This Association recognizes the peculiar appropriateness and value of the gift of books, herbarium, and cabinet, constituting the scientific library, and tenders to Messrs. Illingworth and Rhodes, the representatives of the late Chemists' Assistants and Apprentices' Association, its hearty thanks for having disposed of the balance at their command in such a permanent and useful manner. The Association also hereby undertakes to exercise all needful care in respect of the circulation and keeping of the above-named property." The prospect for the coming session is stated to be clear and good.

HULL CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held on Thursday, October 26, at the Cross Keys Hotel, the President in the chair.

The ordinary business having been gone through, the Secretary read the report of the committee, from which we gather that the year just ended has not been quite so sensational as the preceding one; still matters of great importance have occurred affecting the interests of the trade generally. One of the most important was the conference held at Birmingham in July, when the Trade Defence Association was formed, which gives promise of being of very great advantage to the trade. Three gentlemen attended from this Association, and rendered practical service there. The treasurer's balance sheet showed a small balance in hand.

An alteration in one of the rules was proposed by the President, by which a solicitor is elected at the annual meeting.

A ballot was then taken for the office bearers for the ensuing year, when Mr. C. B. Bell was re-elected President; Mr. W. Staning, Vice-President; Mr. B. M. Stoakes, Secretary and Treasurer; Messrs. Myers, Earle, Oldham, and W. Hammond, the Committee; and Dr. A. K. Rollitt, Solicitor.

Votes of thanks were cordially passed to the past officers and the auditors for the services they had rendered.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The first meeting of the above Association for the present session was held at 17, Bloomsbury Square, on Thursday evening, October 26th, Professor Attfield, President, in the chair. There were present thirty members and four visitors.

The Secretary, Dr. Senier, read the minutes of the previous meeting, which included a report of the work of the last session. The number of members had been seventy-nine. There had been eighteen meetings, with an average attendance of eighteen members. Besides the President's address (already reported in the *Pharmaceutical Journal*, 3rd series, p. 279), twenty-five papers had been read and discussed as follows:—

"Life Germs," by Mr. Chas. J. Boorne; "Infusions," by Mr. H. G. Greenish; "Pharmaceutical Zoology, Pt. I." by Mr. Charles Shapley; "The Botanical Relationships of some Thalamifloral Orders and their Pharmaceutic and Economic Products," by Mr. Arthur Hunt; "John Dalton," by Mr. Thos. Slater, jun.; "Reminiscences of Session, 1871-2,' by Mr. R. W. Houghton; "Notes upon the Properties and Uses of Magnoliaceæ, Sarraceniaceæ and some other Allied Natural Orders," by Mr. Arthur Hunt; "Cortex Winteranus," by the late Daniel Hanbury, F.R.S.; "The Composition of Pilula Hydrargyri, B.P." by Mr. Harold Senier; "Notes upon some Branches of Physical Science," by Mr. Ernest Cardwell; "Notes upon Hydriodate of Quinia," by Mr. Arthur Hunt; "Albuminous Urine," by Mr. R. W. Houghton; "Ultimate Organic Analysis," by Mr. Sydney Plowman; "Vegetable Nutrition," by Mr. W. A. H. Naylor; "Pharmaceutical Zoology, Part II.," by Mr. Chas. Shapley; "Glycerine," by Mr. A. J. G. Lowe; "Spectrum Analysis," by Dr. Senier; "Ferns," by Mr. E. B. Walton; "Ext. Nucis Vomicæ a Cumulative," by Mr. R. W. Houghton; "Guarana," by Mr. W. A. H. Naylor; "Absorption Spectra," by Mr. Chas. J. Boorne; "Note on the Solar Spectrum," by Mr. Henry Campbell; "Voltaic Electricity," by Mr. Chas. H. Hutchinson; "The Production of Aniline and its Derivatives," by Mr. Edwin Richardson; "Polarization of Light," by Mr. Chas. H. Hutchinson.

The President then addressed the meeting. He read the objects of the Association from the prospectus, and reminded the members that the papers expected of them were not original memoirs, such as would be acceptable to the Chemical or Pharmaceutical Societies, but essays on the work of the older chemists, physicists and botanists, experimental confirmation of results published from time to time in the various journals of chemistry and pharmacy, and discussions on subjects and observations drawn from their past daily experience in the shop, the dispensing counter, and the reading-room. The papers of last session the titles of which they had just heard, had been very creditable to the authors, and to the management of the Association, and, he was informed would shortly be in a form in which they might be consulted by members. In order to perform the duties of an educated pharmacist it was necessary that something should be learned besides chemistry, botany, materia medica, and dispensing. Professor Attfield did not believe that any student came to the school of which he was a teacher, for the simple purpose of passing the examinations of the Pharmaceutical Society. If a teacher chose he could so rapidly prepare his students that they would be able to pass examinations in about half the time devoted to study in the Society's school. He need hardly say, however, that facts so hurriedly acquired were as quickly lost, and left behind them a weakened rather than an educated mind. He thought that the students of the Society's school knew all that, and came to their studies with a sincere desire for lasting knowledge. He trusted they would accomplish their desire, but further would endeavour to give their gems of knowledge the golden setting of a well-cultured mind. In doing this no aid was more valuable than the preparation—by each member—of papers and essays for the meetings of the Students' Association, and the intelligent comprehension and discussion of the communications of other members. The Professor then drew attention to the duties of an educated pharmacist to his calling and to the public, as well as to himself and his household, reminding his audience that in the time to come as now and in the past, Councillors, Educators, Examiners, and other leaders would be wanted and that those students who took the broadest, widest, and soundest view of their present position would best be able to guide pharmacy in the future. In conclusion he earnestly advised every student to avail himself of the advantages of this Association and to contribute as much as possible to its papers and discussions.

The election of officers being next in order the President appointed Mr. W. F. Gadd and Mr. S. Eliott a committee to examine the voting papers.

While this examination was being made Professor Attfield introduced the subject of the necessity now being felt for competent sanitary advisers who might be consulted in cases of defective ventilation and drainage. He thought that those pharmaceutical chemists who had passed the Major examinations were fully capable of acting as such advisers.

An interesting discussion followed in which Messrs. Plowman, Hutchison, Atkins, Elliot, and Naylor took part.

The report of the Committee on elections was then read and the following gentlemen declared to be the officers and committee for the session of 1876—77.

Vice-presidents; Mr. Harold Senier, Mr. Henry Campbell: Committee; Mr. Chas. H. Hutchinson, Mr. Jas. C. Shenstone, Mr. John F. Savory, Mr. Edwin Richardson: Secretary and Treasurer, Mr. J. Howden Hugill, 17, Bloomsbury Square, W.C.

A vote of thanks to the retiring officers was acknowledged by Mr. W. A. H. Naylor, after which the papers for its next meeting were announced and a vote of thanks to the President brought the meeting to a close.

Parliamentary and Law Proceedings.

Suicide of a Chemist and Druggist.

On Tuesday last Mr. Donaldson held an inquiry at Lower Clapton, respecting the death of Mr. William Lambert Kibble, aged 50 years, who had up to five years ago, carried on business as a chemist and druggist, at 34, Tavistock Place, Tavistock Square. From some unforeseen circumstances he failed, and shortly after Mr. Edwards, of Clans House, Seven Sisters Road, Tottenham, placed him in charge of his shop, 4, Portland Place North, Lower Clapton. In September last Mr. Edwards advertised for another assistant, whom he engaged. He then informed the deceased what he had done, which seemed to prey much upon his mind, An agreement was then arranged between the deceased and witness that the deceased should pay the person engaged a month's salary and witness would keep him on. He was then having £120 per annum.

Sarah Elizabeth Taylor, who attended upon the deceased daily with his meals, stated that at 5 o'clock on Friday last he said to her that he was going to the devil, as he had no money. On her arriving at the shop the following morning she could not gain admission, and, thinking something was wrong, sent to the police-station, when Inspector Taylor, accompanied by a constable, came and broke open the door. The deceased was found lying partly dressed in bed. He was dead, and on the dressing-table were a glass and a bottle labelled "Poison."

Dr. Aveling, on making a *post mortem* examination, found enough prussic acid of Scheele's strength to kill fifty people.

The jury returned a verdict of "Suicide while in a state of unsound mind."—*Times.*

Reviews.

The Dispenser's Chart (An Abstract from the "British Pharmacopœia" of 1867), showing at a glance the Formulæ of Preparations in constant use by the general practitioner,—quickly and readily made,—other Preparations requiring length of time or percolation, see the above work. London: H. K. Lewis, 136, Gower Street.

This double-crown sheet contains a jumble of formulæ composed principally of dog Latin of the worst kind and English, of which a specimen is given above, where certain preparations are given eyes to "see the above work." The Latin may be exemplified by the following:—"Tinctura Opii Ammoniata; ℞ Opium, 100 gr.; Croci., Ac. Benz., of each 180 gr.; Anisi Ol., ʒj.; Liq. Ammon. Fort., ℥iv.; Sp. Rect., ℥xvj. 1 in 96;" and "Tinctura Lobelia Œtherea; ℞ Lobelia, ℥iiss.; Sp. Œtheris, vj., 1 in 8." Some of the groups of preparations have special headings with notes on their general preparation, as under the head of Unguenta we have "Ointments to be made by the heat of a Water Bath." It is somewhat curious to note, that not one half the ointments mentioned are ordered to be heated at all in the British Pharmacopœia. The spirits are headed "Spirita." The sugar and water are directed to be boiled together in making simple syrup.

Many preparations are inserted which are never used, such as Conf. Terebinthinæ, and Tinct. Cocci, whilst others in constant use, such as Liquor Ammoniæ, are not to be found. We think that with the uncertainty of finding what we wanted in this chart, it would be a saving of time to refer to the Pharmacopœia at once, especially when we find that the compiler stated that "5 minims of either Liq. Soda Arsen., Liq. Arsenic., or Liq. Arsenic. Hydrochl. contain $\frac{1}{24}$ grain of arsenic." Tabulated formulæ such as are in the Pharmacopœia, are much more easily referred to than those running line into line as in this chart. To assist the memory, the compiler might have used a little more ingenuity, and have composed a few more rhymes of the formulæ like the following:—

"Asafœtida, Galbanum, Myrrh,
Treacle by weight, and give it a stir."

His work might then have possessed about as much merit as a Comic Sermon on the Mount, which it at present lacks.

Notes and Queries.

[528]. CRIMSON MARKING INKS.—*O. K.* is desirous of obtaining a good recipe for Crimson Marking Ink.

[518]. COCKROACHES.—The following methods of destroying cockroaches are quoted from *The Garden*:—

Arsenic.—Mix some arsenic with honey, and lay it on scraps of paper about the floor for them to eat. If arsenic be mixed with boiled potatoes, and laid about in the same way, it will answer the same purpose.

Bracken.—Another remedy is said to be to procure some bracken, *Pteris aquilina*, or common fern, plentiful on commons, and put it down about the house at night. The black beetles will eat it ravenously and soon die, and their relatives will pick their bones. It is commonly used in the north of England.

Honey.—Mix some honey and water together. Two teaspoonfuls of honey will be ample for half a common basinful of water; put the basin on the floor at night, half filled with the mixture, and place three or four small sticks, about half-an-inch wide, to rest on the edge of the basin for the cockroaches to walk upon. They will fall into the liquid and get drowned. Some tumbler-glasses half filled with the mixture, and sunk to the rim in pits in the tan or soil, make excellent traps for them. Porter and brown sugar is said to be equally efficacious.

Oatmeal.—Bait them well with oatmeal for three or four successive nights, or until such time as they feed greedily on it; then mix some arsenic with the meal for one night, repeating the process from time to time if necessary. Mr. Wilson states that if a bowl be wrapped round with a wet cloth they will get into the bowl, from which they cannot escape.

Phosphorus.—A very simple and effectual remedy is given in the *Revue Horticole*, communicated by M. Loury, chief propagator at the Jardin Fleuriste, Paris. It is as follows:—Dissolve the heads of a couple of boxes of common phosphorus matches (not *Safety* matches) in a pint and a half of water; then mix with it about one lb. of flour, and add about half lb. of sugar, of which these insects are very fond. The mixture may then be distributed in various parts of the house overnight on pieces of board, slates, etc., and when examined in the morning, numbers of dead cockroaches will be found close to wherever the poison has been laid.

The remedies given for crickets are equally effective in the case of cockroaches.

Obituary.

Notice has been received of the Deaths of the following:—

On the 22nd of October, 1876, suddenly, at 37, George Street, Edinburgh, Mr. Evan Thomas, Chemist and Druggist, aged 37 years. Mr. Thomas had been upwards of twelve years principal assistant to Messrs. James Robertson and Co., Pharmaceutical Chemists, 35, George Street, Edinburgh.

On the 24th of October, 1876, Mr. Henry Robert Maynard, Pharmaceutical Chemist, Brandon, Suffolk. Aged 52 years. Mr. Maynard had been a Member of the Pharmaceutical Society since 1848.

On the 25th of October, 1876, Mr. Jonathan Briggs Fletcher, Chemist and Druggist, Hampstead. Aged 47 years.

On the 31st of October, 1876, Mr. John Lomas Pimlott, Chemist and Druggist, Leek, Staffordshire. Aged 35 years.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication but as a guarantee of good faith.*

The Norwich Chemists' Association.—De Mortuis Nil Nisi Bonum.

Sir,—To the mutual honour of teachers and students will you allow me to record that on my son leaving Norwich a few months since, the members of the chemical class of the above association presented to him, as their teacher for a portion of two sessions, twelve volumes of valuable scientific works?

W. Symons, F.C.S.

Barnstaple.

Dangerous Green Fire.

Sir,—In the Journal of the 14th October, there are some tables for coloured fires, by Kern. I have mixed a number of the different numbers of these tables, and I find the greens of the higher numbers to be dangerous. I mixed 5 oz. of the No. 6 green (having previously found that it suited us best), and I may say that we should have mixed much more if we had not been short of Pulv. Pot. Chlor. It was put in a bottle and then bunged up. About ten minutes after I heard a hissing sound, and found that it proceeded from between the bung and the neck of the bottle containing the No. 6 green fire. I seized the bottle and ran with it into the middle of the back-yard and laid it on the ground. I had no sooner done so than out flew the bung with a slight report, and a jet of visible vapour issued from the mouth of the bottle with such a velocity that the jet was almost a straight line for some feet; the bottle then broke from the heat generated, and the mixture now having a free access of air took fire. I may add that another person and I felt the effects of breathing the medley of gases which were generated (whilst we were opening the door to run out with the bottle) all the evening, nitric oxide and chlorine being preponderant.

Last year I added a small quantity of chlorate of potassium to some green fire containing nitrate of barium for the purpose of making it burn better, and I found that nitric oxide was copiously evolved after some days, but the mixture never took fire. I used dry Bar. Nit.

Wm. West.

Bradford.

Toughened Glass.

Sir,—A few days ago I supplied myself with some cylindrical two ounce toughened glass measures, with an idea that I should perhaps lessen my too many breakages.

This evening whilst using one simply for measuring cold water from my shop filter, it suddenly went to pieces, breaking into minute crystalline fragments, which were strewn about the floor in every direction.

My object in writing is to deter others from purchasing these measures, as, although this accident did no harm, it might have been otherwise, had it contained a corrosive acid or other strong preparation.

I find that one of the measures left is beginning to shed small pieces from the edges of the thickened bottoms.

I should also mention that the glasses had been standing on the shelf in my shop, the temperature of which at the time was 58° F., and that the filter had been filled up in the early part of the morning, so that there could not have been any very great lowering of the temperature of the glass.

Country Member.

W. W.—*Humulus lupulus.*

G. W. S. Highmoor.—(1) *Valeriana officinalis;* (2) *Veratrum album;* (3) *Helleborus niger.*

C. B.—(1) Page's 'Advanced Text-Book of Geology,' published by Blackwood. (2) See an article on 'Preparations of Coca,' by Shuttleworth, before, vol. v., 483. (3) Squire gives the following formula for Syrupus Ferri Hypophosphitis:—"Sulphate of Iron, 1; Carbonate of Soda, 1⅓; Hypophosphorous Acid, 6; Dilute Phosphoric Acid, 1; Sugar, 12; Distilled Water, a sufficiency. Dissolve the sulphate and carbonate in separate portions of water, mix the solutions, collect the precipitate, wash it, and dissolve it in the acids, and then add the sugar to form a syrup. Dose, 1 drachm.

W. W Leete is thanked for his communication. The liniment of chloral hydrate and camphor has, however, been already referred to on several occasions in this Journal, and a paper on the nature of the union that takes place will be found on p. 89 of the present volume.

"*Kappa.*"—Apply to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields.

E. J. Clark.—Candidates for the appointment of Dispenser in Her Majesty's Naval Hospitals, must "possess certificates of either the Major or the Minor qualifications of the Pharmaceutical Society of Great Britain," and must make a written application to the Director-General of the Medical Department of the Navy. Information respecting pay, etc., will be found in the Order in Council on the subject, printed in vol. iii. of the present series of this Journal, and in the Calendar of the Pharmaceutical Society.

"*Captene.*"—(1) For the pyrogallic acid hair dye, see *Pharm. Journ.* [3], vol. iv., p. 747. (2) For the hyposulphite of sodium and acetate of lead, etc., see vol. i., p. 78. (3) No. (4) The active principle is slowly decomposed by caustic fixed alkalies in the cold.

"*Inquirer.*"—A formula for Pepsine Wine was given on p. 20 of the present volume.

J. B. L.—See a paper on the composition of sea-water in various parts of the world, by G. Forchhammer, printed in the *Philosophical Transactions* for 1865. Answers to the other questions will be forwarded.

S. P.—See before, p. 314; also a letter in the preceding column.

Communications, Letters, etc., have been received from Mr. Watson, Mr. Wilkinson, Mr. Redford, Mr. Paul, R. H., S. P.

A GLYCEROLE OF NITRATE OF BISMUTH.

BY BALMANNO SQUIRE, M.B. LOND.,

Surgeon to the British Hospital for Diseases of the Skin.

A note I contributed to the *Pharmaceutical Journal* on glycerole of subacetate of lead, this summer, has been followed by the adoption of that preparation as a remedy, not only in skin diseases (particularly in chronic eczema, the purpose for which I had designed it), but also quite as much in uterine diseases. I am encouraged, therefore, to propose now a soluble preparation of nitrate of bismuth, if such a proposition is not too absurd to be listened to.

The value of bismuth as an application in a great variety of skin diseases is well known, but its use in this direction, and indeed as I may say for every purpose for which bismuth has yet been employed as a remedy, has always been much crippled by the difficulties that have always hitherto existed in the way of obtaining a solution of bismuth.

There is of course the liquor bismuthi et ammoniæ citratis of the Pharmacopœia, but it is a matter of doubt whether this double salt presents the properties, as a local application, of a simple salt of bismuth. It is of course merely as a local application that bismuth is employed in medicine, that is to say as a local application to the stomach in cases of painful digestion or of waterbrash and its use in skin affections, in gonorrhœa, and so forth, is equally of the character of a topical application.

The difficulty, or rather the impossibility, of making an aqueous solution of nitrate of bismuth, otherwise than in the presence of a large excess of nitric acid (an agent which renders that solution perfectly useless for any purpose for which bismuth is serviceable), arises from two causes, the one the feeble basic properties of teroxide of bismuth, and the other the basic properties of water,—the water robbing the nitrate of bismuth of the greater portion of its nitric acid, and so precipitating nearly all of the bismuth in the form of the so-called trisnitrate.

It occurred to me, accordingly, that by the employment of glycerine as a solvent in place of water, both of these drawbacks might be circumvented, if only it should prove that nitrate of bismuth should be capable of solution in glycerine. I find that it is freely soluble in glycerine and that it dissolves without decomposition. As I think there is likely to be a large demand for this solution I think it necessary to communicate this fact to the pharmaceutical body through their Journal. For example, I applied to one of the first pharmaceutical chemists of this city for a solution of nitrate of bismuth in glycerine and I was told, firstly, that the salt would certainly not dissolve in glycerine, so that he could not supply me with such a solution, and in the next place he told me that the nitrate was not kept by any chemist because there was no demand for it.

Now I think that henceforward the nitrate should be kept by every chemist in the kingdom. I will explain why I think so. In the first place its solution in glycerine will prove without doubt the most valuable means of applying the remedy to any external surface, and in the next place it will serve equally as a means of administering bismuth internally, or if it be desired that an aqueous solution should be so administered even that may be done. For on diluting freely the glycerole with water, the presence of glycerine, as I find, serves to delay the precipitation of the bismuth by water. So that for quite half an hour, at the least, no turbidity whatever takes place provided the water used be cold water. It seems to me, moreover, that the presence of glycerine absolutely prevents, even after the lapse of several hours, the precipitation of more than a small proportion of the contained nitrate; insomuch that I have reason to believe that a merely moderate dilution of the glycerole might leave a permanently clear solution, but I have not as yet made quantitative experiments on this head.

We accordingly have henceforward at our command a preparation which has for long been a desideratum, and one the contrivance of which has baffled the efforts of the compilers of our Pharmacopœia, and indeed the efforts of every one who has devoted attention to the point.

I was assured on all hands that if I ever should succeed in getting by any means a solution of nitrate of bismuth, I should find that I had before me a very irritating application instead of what I desired, that is to say, a bland astringent. But I have sucked my glycerole; I have even rubbed it into my tongue, and I find it to be merely what I had designed it to be, and that is a bland and mild astringent. It is obvious that a soluble preparation of a drug is a much more efficient and certain mode of employing it than an insoluble one, and that a simpler preparation of the article is likely to prove a more active and serviceable mode of administering it than any more complicated preparation of it. I accordingly lay the results of my investigation before the pharmaceutical body in the confidence that they will soon develop its capabilities in a very considerable degree.

As an application to the throat, the larynx, the vagina, the uterus and the urethra, as well as to the skin, and no less as an internal remedy, I believe the preparation of glycerole of nitrate of bismuth will be found to open out a new field of therapeutics.

Since writing the above, I find the glycerole of nitrate of bismuth to be a somewhat more stimulant application, in cases of eczema, than a glycerole of the subacetate of lead of corresponding strength.

On the other hand, I find by sucking the actual crystals of the nitrate of bismuth, that the salt is in no degree a caustic, and not more acid to the taste than crystals of citric acid.

COMPARATIVE EXAMINATION OF THE MORE IMPORTANT COMMERCIAL VARIETIES OF GALBANUM AND AMMONIACUM GUMS.

I. GALBANUM.

BY EDWARD HIRSCHSOHN.

(*Continued from page* 371.)

5. *Chemical Composition.*—The first examination of galbanum appears to have been made by Carthäuser,* and his results gave for its composition a resin, a gum-like substance and a volatile oil. In 1812, Pelletier† analysed a galbanum; the sort is not stated. Fiddechow‡ also analysed an un-

* Pelletier, in 'Bull. de Pharmacie,' vol. iv., p. 97.
† 'Bull. de Pharmacie,' vol. iv., p. 99.
‡ 'Berlin Jahrbuch f. d. Pharm.' (1816), p. 250.

described kind. In 1816, Caspar Neumann* examined a galbanum in massis; Meissner, in 1817, a galbanum in granis; and Vigier,† in 1869, another undescribed sort. The results of these examinations are set forth in the following table:—

	Undescribed Kinds.			In massis.	In granis.
	Pelletier.	Fiddechow.	Vigier.	Neumann.	Meissner.
Resin	66·86	67·3	65·80	59·4	65·8
Gum	19·28	23·6	21·50	18·7	22·6
Tragacanth substance	...	...	...	...	1·8
Volatile Oil	...	5·7	6·75	4·7	3·4
Volatile Oil and Loss	7·52	...	...	...	...
Malate of Lime	traces.	...	...	...	...
Malic Acid	...	...	0·20	...	...
Extractive	...	3·5	...	...	0·2
Residue	7·52	4·8	5·75	12·5	2·8
Moisture	...	...		...	2·0

The resin, according to the general description of the above authors, is of a dark yellow brown colour, transparent, friable, with a shining fracture, and tasteless. It is soluble in ether and alcohol, scarcely so in almond oil, and insoluble, according to Berzelius,‡ in turpentine oil even when hot. It is dissolved by alkaline solutions. The melting point of the resin Pelletier found to be 50° C., but Vigier 60° C. According to Mössmer§ the resin dissolves in milk of lime and can be precipitated from such solution by hydrochloric acid. The resin so precipitated, he states, dissolves completely in ordinary but not in absolute ether; alkalies dissolve it imperfectly and also carbon bisulphide. All attempts to crystallize it, or to prepare from it crystalline nitrated or brominated compounds failed. Mössmer found the composition of the resin, as stated by Johnston,‖ to correspond with the formula, $C_{26}H_{38}O_5$.

Pelletier made the observation that when galbanum is heated to 120—130° C. a blue oil distils over, and Fiddechow obtained thus 8·33 per cent. of blue oil.

Sommer¶ observed that by heating the gum resin, as well as the pure resin, besides the blue oil umbelliferone is formed, of which he obtained 0·8 per cent. He also obtained umbelliferone by treatment with concentrated sulphuric acid. According to Hlasiwetz and Grabousky** the stronger the heating the greater is the yield of umbelliferone.

By melting the resin with caustic potash Hlasiwetz and Barth†† obtained, besides oxalic acid and a small quantity of fat acids, about 6 per cent. of resorcin.

According to Schwanert,‡‡ when boiled with nitric acid galbanum yields camphresinic acid.

** Ibid., vol. cxxxix., p. 99.
†† Ibid., cxxx., p. 354.
‡‡ Ibid., vol. cxxviii., p. 123.

The gum is described as being perfectly similar to gum arabic.

Mössmer obtained the volatile oil (about 7 per cent.) by distillation with the vapour of water;* it had a balsamic galbanum odour, and by another rectification with water was prepared perfectly colourless and fairly refractive. Rectified over calcium chloride, a platinum wire being placed in the retort, it showed a constant boiling point of 160° C., and distilled over almost without residue at that temperature. Analysis gave results corresponding with the formula $C_{10}H_{16}$. The specific gravity of the oil at 9° C. was 0·8842. It rotated the plane of polarized light to the right, the specific rotatory power being 0·1857. By treatment with dried hydrochloric acid gas it was coloured reddish to purple red, and eventually lost its transparency. After a time, in the cold, a hydrochloric acid compound separated out, which crystallized from alcohol; it had a strong cajuput-like smell and resembled the substances obtained from oil of turpentine and other isomerous hydrocarbons. By nitric acid the oil was darkened, but no crystals separated in three months. Vigier,† on the other hand, obtained microscopic crystals by treatment with nitric acid. Other observers agree pretty closely with Mössmer. Fiddechow‡ states that the oil has a specific gravity of 0·876 at 15° R.; according to Berzelius its specific gravity is 0·92 and its colour a faint yellow.

6. *Description of Samples Examined by the Author.*—Before proceeding to give the results of his comparative examination the author gives the following description of the various specimens he had at his disposal collected from various sources.

(*a*) Persian Galbanum.

(1) Galbanum persicum, obtained through Apothecary Osse, Astrachan. A homogeneous turpentine-like mass, with numerous stalk fragments and little fruit; it has a penetrating garlic-like odour of galbanum.

(2) Galbanum persicum, obtained through Apothecary Langel, Kasan. A soft turpentine-like mass, mixed with dark tears of varying sizes, having a waxy glossiness; also with fragments of stalk, fruits, and stones. Its smell recalls that of turpentine and galbanum.

(3) Galbanum persicum, about twenty years old, from the collection of the Dorpat Pharmaceutical Institute. Large hard lumps, varying from a light wax-yellow colour to a dark cherry red. Fracture tough. The galbanum is mixed with fragments of stalk and small stones. Smell similar to No. 2, but more pungent.

(4) Galbanum persicum. Old and badly preserved. Like No. 3, but darker in colour.

(*b*) Levant Galbanum.

(5) Galbanum in granis, from the collection of the Pharmaceutical Institute, Dorpat. Tears varying in size from linseed to that of a hazel nut, roundish, reddish, or brownish-yellow, transparent, with a yellowish fracture and waxy lustre, the tears softening between the fingers, and having a weak smell. Mixed with some small fragments of root, pieces of stalk and fruit.

(6) Galbanum in granis, from a Dorpat pharmacy,

* Ibid., vol. cxix., p. 259.
† 'Gommes Resines des Ombellifères,' p. 76.
‡ 'Berl. Jahr. d. Pharm.' (1816), p. 236.

at present in the collection of the Pharmaceutical Institute. Similar to No. 5, more symmetrically roundish, yellow, some tears softening and some not between the fingers, and having a very weak smell. Rubbing the tears between the fingers causes some of them to give off a decided odour of olibanum, while others emit an odour of sagapenum or of opoponax. It is a mixture of olibanum, sagapenum, opoponax and galbanum.

(7) Galbanum in granis, from the collection of the Pharmaceutical Institute, Dorpat. Similar to No. 5, the tears agglutinated together and shining. It contains fragments of stalk and fruit.

(8) Galbanum in granis, obtained from Hamburg in 1873. Tears varying from the size of a pea to that of a walnut, irregularly formed, white to amber yellow, opaque, with here and there semi-translucent pieces, white to yellowish at the fracture, readily softening between the figures, and having a strong smell of galbanum. Mixed with slices of root.

(9) Galbanum in granis (ordinary kind), obtained from Hamburg in 1873. Like No. 8, but darker coloured. No white tears, yellowish green. Mixed with fragments of roots and stones.

(10) Galbanum in massis, Hamburg, 1873. Irregular soft masses, formed of different sized bluish, greenish and yellowish translucent tears, large slices of root, and stones. Smells strongly of galbanum. Nos. 8, 9, and 10, have, since the opening of the Suez Canal, again come into commerce from India by this route.

(11) Galbanum in massis, from a Dorpat pharmacy. Irregular, hard, homogeneous, greenish brown coloured masses permeated by white veins (slices of root); fracture with a waxy lustre, greenish semi-translucent, soft, with yellow friable spots.

(12) Galbanum in massis, obtained from Nischni-Nowgorod through the Russian Drug Company (1873). Large adherent masses, formed of bluish and greenish almost translucent tears and numerous large slices of root. In the interior of the large pieces are masses having the consistence of turpentine and a strong smell.

(13) Galbanum in granis. Sent to St. Petersburg from Trieste as a sample (1873). Pieces 1½ inches in diameter, containing slices of root, which are agglutinated together by yellowish, internally milk-white, opaque or slightly transparent tears, mixed with a little black substance that softens between the fingers.

(14) Galbanum, sold in London in 1840, supplied by Mr. Hanbury. Like No. 11, but without white veins.

(15) Galbanum imported into London in 1850 and sent by Mr. Hanbury to the Dorpat Pharmaceutical Institute. Rather soft colophonium coloured dusty pieces, mixed with fruit and fragments of stalk. Similar to the Persian galbanum in smell, and probably, as shown by further investigation, wrongly named, and to be considered a Persian variety.

(16) Galbanum imported into London (1872) through Horner and Co., supplied by Mr. Hanbury. Irregularly formed pieces, formed of transparent greenish or opaque milk-white tears, which contain slices of root up to 1¼ inches in diameter.

(17) Galbanum, purchased in Paris by Mr. Hanbury (1849). Similar to No. 15, somewhat harder. Probably, as shown by further investigation, wrongly named, and to be considered a Persian variety.

(18) Galbanum in lacrymis. Reached Mr. Hanbury through Dr. Mohr of Coblentz (1851). Like No. 5.

(19) Galbanum from the Lens collection, obtained by Mr. Hanbury. Pieces of a red-brown myrrh colour, rather brittle, and with a weak smell; mixed with tolerably thick very porous stalk fragments.

(20) Galbanum in massis, from the Lucae collection, imported into London from Bombay. This and the next three numbers were supplied to the Dorpat Pharmaceutical Institute by the present possessor of the Lucae collection, Dr. Witte Rostock. Similar to No. 11, but more shining, permeated by root fragments.

(21) Galbanum (persicum ?), from the Lucae collection. Homogeneous, amber coloured, almost transparent pieces, having a weak smell and mixed with slices of root.

(22) Galbanum artificiale, from the Lucae collection. Homogeneous, amber yellow, non-transparent tears, the size of a nut, softening between the fingers, and then giving off a strong odour of olibanum.

(23) Galbanum in granis, from the Lucae collection. Non-transparent, reddish-yellow, dusty, tolerably symmetrical tears, not readily softening between the fingers, and having a weak smell of galbanum.

(*c*) Galbanum depuratum.

(24) Galbanum depuratum, 20 years old, from the collection in the Dorpat Pharmaceutical Institute; prepared from Persian galbanum. Dark, almost black, masses, internally still soft, and smelling of turpentine and galbanum.

THE DETECTION AND QUANTITATIVE DETERMINATION OF FREE SULPHURIC AND HYDROCHLORIC ACIDS IN VINEGAR, LIME AND LEMON JUICES, AND SIMILAR LIQUIDS.*

BY OTTO HEHNER.

Although a large number of methods for the detection and determination of free mineral acids in vinegar have been proposed, yet there is none, as far as I am aware, which could be considered to fulfil all the requirements expected from such a method. These requirements are, first, that a simple quantitative test should at once answer the question, whether a given sample of vinegar contains free mineral acids or not, so that, the result being negative, no quantitative determination need be resorted to; second, that the method for determining the amount of free mineral acid present should be exact within a few hundredths of a percentage; and third, that no substance or re-agent should be required which is not within reach of every chemist, and which is not to be found in the laboratory of any public analyst.

The older qualitative tests, as proposed by Normandy, Muspratt, and other chemists, were mostly based upon the charring action of sulphuric acid upon paper or other organic substances. Thus we read, "Sulphuric acid may be detected by writing with a quill upon white paper and drying it strongly before the fire, when the paper will become charred," but, fortunately, the author adds, "if the quantity of sulphuric acid exceeds two per cent." (Muspratt.) Another writer recommends that a drop of the suspected vinegar should be placed upon paper and dried before the fire, when a black stain will be produced, and a third, to heat a solution of cane sugar nearly to boiling, and then to add a small quantity of the liquid containing the sulphuric acid, when the charring of the sugar will at once point out the presence of mineral acid. These absurd and worse than useless methods

* From the *Analyst*.

seem to have been in general use, as they are to be found in most books dealing with the subject, which were written fifteen or twenty years ago.

But, besides the above methods, there are several worthy of attention. Thus it is directed to evaporate a measured quantity of the vinegar on the water-bath and to extract the syrupy liquid with spirits of wine, when the sulphates will be left in the residue on account of their insolubility in alcohol, while the sulphuric acid will be found in the alcoholic solution. But I have not unfrequently found an appreciable quantity of sulphate to pass into solution, even where no trace of free sulphuric acid could be present.

Another plan is to determine the total amount of sulphuric acid, both free and combined, gravometrically by means of chloride of barium, and to evaporate and incinerate another portion of the vinegar, thus driving off the free sulphuric acid, and to determine in the residue left the amount of the combined sulphuric acid, the difference between the two determinations being calculated as free sulphuric acid. This method, however, is quite incapable of giving accurate results, as free sulphuric acid so pertinaciously clings to the ash, that even with the acid of carbonate of ammonium it cannot be completely got rid of without some loss by volatilization of the sulphate of soda invariably present. In addition, it will be seen, this method requires two tedious gravimetrical estimations, in order to find out whether free sulphuric acid is present or not, and as even in the purest vinegar, which has never been contaminated with free mineral acid, the results before and after incineration are never exactly identical, it cannot be relied upon when small quantities of sulphuric acid are to be determined.

Mr. Thresh, in a late volume of the *Pharmaceutical Journal*, described a method similar in principle. He estimates the amount of chlorine before and after incineration of the vinegar, the difference being equivalent to the quantity of sulphuric acid added; but although this method is capable of giving more accurate results than the method just described, yet the same objection applies to it, namely, that two quantitative determinations are needed to obtain a qualitative result.

There have lately been published two other methods; one based upon the solubility of oxalate of lime in mineral acids, it being insoluble in acetic acid; and the other upon the change of colour which methylaniline violet undergoes, on the addition of mineral acids, it being unaffected by vegetable acids. Both these methods, however, are nearly useless; the former, because the solubility of the oxalate of lime depends upon a great variety of circumstances; and the latter because the quantity of mineral acid usually present in proportion to the acetic acid is by far too small to allow of a direct accurate determination. Both methods may however be useful, if the quantity of mineral acid present is very large.

As vinegar consists, except in the case of its being distilled, not merely of acetic acid and water, but always contains potash and soda salts of organic acids, as the tartrate or acetate, and chloride of sodium, it is obvious that sulphuric or hydrochloric acids, if added in small quantity, can no longer be considered to exist as such in vinegar, but that they decompose an equivalent quantity of acetate or tartrate. Whenever there is any undecomposed acetate or tartrate present in vinegar, no trace of any mineral acid can be present in the free state. As the organic salts of the alkalies are converted by incineration into the corresponding carbonates, it can safely be asserted that whenever the ash of a vinegar exhibits an alkaline re-action, free mineral acid cannot be present in the vinegar. Mineral acid may have been added, but it then has become neutralized by the decomposition of the acetates or tartrates. We have thus the simplest possible qualitative test for free mineral acids in vinegar.

But whenever the ash is neutral, free mineral acid is most likely present. The quantity of this may be ascertained with the utmost accuracy by following the same principle. If we add to a measured quantity of the suspected vinegar, a known and exactly measured volume of decinormal soda solution, somewhat more than would be necessary to neutralize the total amount of free mineral acid present, evaporate and incinerate, the alkalinity of the ash gives the measure of the quantity of the free sulphuric or hydrochloric acid. Supposing we add 20 c.c. of standard alkali to a vinegar, and find after incineration, by titration with standard acid, an alkalinity corresponding only to 5 c.c., then 15 c.c. of the soda solution have been neutralized by the mineral acid in the vinegar.

As the point of neutralization can be far easier ascertained, litmus being used as an indicator, by titrating from red to blue, than from blue to red, and as the latter plan offers several other advantages, it is advisable to operate as follows:—A measured quantity, say 50 c.c. of the vinegar to be examined, is mixed with 25 c.c. of decinormal soda solution (capable of neutralizing 0·200 per cent. of SO_3). The liquid is evaporated on the water-bath in a platinum basin, the residue is dried to prevent spirting in the air, or on the sand-bath at about 110°C, and is then carefully incinerated at the lowest possible temperature. The ash need not be burned white. 25 c.c. of a decinormal sulphuric acid solution, corresponding exactly to the soda solution, are now added to the ash, the liquid is heated to expel all carbonic acid, and is then filtered into a small beaker. The filter is washed with hot water, tincture of litmus is added to the filtrate, the acidity of which is ascertained by means of the decinormal soda solution. The volume of soda necessary for neutralization directly gives the proportion of free mineral acid present in the vinegar, 100 cc. of the standard solution, corresponding to 0·49 grammes of H_2SO_4.

It may happen, when more than 0·200 per cent. of free mineral acid is present, that the 25 c.c. of decinormal solution added to the vinegar are insufficient to neutralize all free mineral acid: in that case 25 c.c. of decinormal soda would be required to neutralize the filtrate. A fresh experiment, with the addition of a larger quantity of soda solution, say 35 or 40 c.c. to the vinegar, must then be made.

An error of 1 c.c. of decinormal soda solution, would cause with 50 c.c. of vinegar an error only in the amount of free mineral acid of 0·0098 per cent., calculated as H_2SO_4, but practically results of far greater accuracy can be obtained, as the following experiments show. I will remark, that they are taken without selection, but were made with scrupulous care.

A vinegar was prepared by diluting pure acetic acid, to a strength of 5·475 per cent. and by adding about one per cent. of cane-sugar. to represent the organic residue present in all non-distilled vinegar. To four portions of this liquid as much decinormal sulphuric acid was added, as corresponded to 0·2, 0·1, 0·05, and 0·025 per cent. respectively, and which I will call, I., II., III., IV. To 50 c.c. of I., I added 30; to 50 c.c. of II. III. and IV. each, 25 c.c. of decinormal soda solution. The liquids were evaporated in a platinum basin, and incinerated at the lowest possible temperature, the basin not being allowed to become heated to redness.

To the carbonaceous residue in I. 31 c.c. of deci. H_2SO_4 were added, the liquid was boiled and filtered; the filtrate needed 25·07 c.c. of deci. soda for neutralization, equal to 0·10028 gram SO_3 or 0·20056 per cent., instead of 0·2000 per cent. Error, + 0·00056 per cent.

To ash II., 25 cc. of deci. acid were added; the filtrate required 12·79 cc. of deci. soda, equal to 0·05116 gram SO_3, or 0·1022 per cent., instead of 0·100. Error, + 0·0022 per cent.

Ash III., was likewise treated with 25 cc. of deci. acid, the filtrate requiring for neutralization 6·30 c.c. of acid, corresponding to 0·0252 gram SO_3, or 0·0504 per cent. instead of 0·0500 per cent. Error, 0·0004 per cent.

To ash IV., 25 c.c. of deci. acid were added; 3·8 c.c. of deci. soda were required for neutralization, corresponding to 0·0152 gram. SO_3, or 0·0304 per cent., instead of 0·0250 per cent. Error, +0·0054 per cent.

It will be seen that in no case is the error greater than 0·054 per cent., and this only when the total quantity of free sulphuric acid present was as small as 0·025 per cent.

As vinegar mostly contains some chloride of sodium, which would be converted by the action of free sulphuric acid into free hydrochloric acid, and sulphate of soda, and as hydrochloric acid might be directly used as an adulterant, a similar series of experiments as that described above was undertaken, the vinegar being admixed with hydrochloric acid to the extent of 0·2, 0·1, 0·05, and 0·025 per cent. To 50 cc. of each of these adulterated vinegars, 25 cc. of decinormal soda solution was added, and the quantities determined as in the previous series. The following are the results:—

I. Used 24·14 cc. of deci. soda, equal to 0·08814 gram HCl, or 0·1763 per cent. instead of 0·200 per cent. Error, +0·0237 per cent.

II. Used 1403 cc. of deci. soda, equal to 0·0512 gram HCl, or 0·1040 per cent., instead of 0·100 per cent. Error, +0·0040 per cent.

III. Required 7·93 cc. of deci. soda equal to 0·02894 gram HCl, or 0·05789 per cent., instead of 0·050. Error, +0·0079 per cent.

IV. Used 5·63 cc. of deci. soda solution, corresponding to 0·0205 gram HCl, or 0·0410 per cent., instead of 0·025. Error, 0·016 per cent.

Thus it is shown, that although the error of estimation in the case of free hydrochloric acid is greater than with free sulphuric acid, the results are still highly favourable and accurate, the difference between theory and experiment not exceeding 0·02 per cent. The experiments quoted show that the amount of free mineral acids may be determined with far greater accuracy alkalimetrically than by any other method.

The same method may be applied to lime and lemon juices, wherein I have repeatedly come across large quantities of sulphuric acid.

With a view to establish the correctness of the conclusion that an alkaline reaction of the ash of the vinegar is the best proof of its freedom from uncombined mineral acid, the following experiments were undertaken. They may, perhaps, appear somewhat superfluous, but I quote them, as again demonstrating the extreme accuracy of the method.

A pure distilled vinegar was mixed with a solution of acetate of soda, and it was found that 100 c.c. were capable of saturating 0·1065 gram SO_3, corresponding to 26·62 c.c. of decinormal sulphuric acid.

To 50 c.c. of this artificial vinegar, 12·5 c.c. of decinormal sulphuric acid were added; the liquid was evaporated and the residue was charred at a low temperature. The ash was all but neutral, but slightly alkaline, showing the absence, as was expected, of free sulphuric acid in the vinegar. The alkalinity of the ash was found to be equivalent to 0·0085 gram of SO_3. Theoretically there ought to have been an alkalinity corresponding to 0·0065 gram of SO_3.

To 50 c.c. of the same vinegar 6·25 c.c. decinormal sulphuric acid were added. The alkalinity of the ash corresponded to 0·0643 per cent. of SO_3, instead of 0·0565 per cent.

To another 50 c.c. of the same solution, 3·13 c.c. of decinormal acid were added. The alkalinity of the ash corresponded to 0·0776 per cent. of SO_3, theoretically 0·081 per cent.

The final conclusion to be drawn from these results is obvious. The alkalinity of an ash is diminished in exact proportion to the amount of mineral acid added to the vinegar; alkaline reaction is the surest and safest criterion that free mineral acid is absent from the vinegar.

MEGARRHIZA CALIFORNICA, Torrey*.

BY JOHN P. HEANEY, PH.G., SAN FRANCISCO.

This plant, better known by the synonyms of the "big or giant root" and "manroot," is a herbaceous, climbing and succulent vine, growing abundantly throughout the State. It is closely allied to the echinocystis of the Eastern States, and also to a new species called *Marah muricatus*, or California balsam apple, which has been described by Dr. Kellogg in the proceedings of the California Academy of Natural Sciences (vol. i.). It is found both in dry sandy and rich soil. In the former it grows in bushy tufts about two feet high and four or more wide, being evidently somewhat stunted; but in rich soil, when well shaded, its annual stem climbs thirty to forty feet over trees and acquires its largest growth. It flowers in March and April.

The most remarkable feature of this plant is its gigantic root, which is perennial, tubero-fusiform, externally of a yellowish-grey colour, and rugose; within white, succulent and fleshy, of a nauseous odour, which is lost in a great measure by drying, and of a bitter, acrid and disagreeable taste, which leaves a feeling of acridity in the fauces. The Indians are said to use this root as a drastic purge in dropsy. It has also been used by domestic practitioners, in the form of decoction, both as a laxative and cathartic with good results. On drying, the root lost from 70 to 75 per cent. in weight. The dried root is externally of a yellowish-brown colour and longitudinally wrinkled; internally of a white colour, becoming somewhat darker by age, concentrically striated, light, brittle and readily pulverizable, yielding a whitish powder.

A preliminary examination made with the aqueous, alcoholic and ethereal extracts of the fresh root led to the following conclusions, namely: That the root contained a bitter principle soluble in water and alcohol, but more readily in the latter; also a resinous, fatty matter and an organic acid, probably of a fatty nature, which was soluble in and extracted both by alcohol and ether. The probable presence of gum and pectin was likewise indicated, as well as the absence of albumen, sugar and volatile oil.

Examination of the Dried Root.—A quantity of the powdered dried root was first treated with ether until thoroughly exhausted by this menstruum, in order to remove the fatty and resinous matter. The ethereal tincture had a lemon-yellow colour, and left, on evaporation, a yellowish-brown residue, which possessed the characteristic odour of the root, a slight bitter taste, was brittle, and had an acid reaction.

To determine the nature of the free acid, the residue was treated with a weak solution of sodic carbonate and filtered from the insoluble portion. To the filtrate a sufficient quantity of tartaric acid was added, when whitish oily globules were observed on the surface of the liquid. These had an acid reaction, possessed a disagreeable odour, and gave to paper a stain unaffected by heat; the author names it megarrhizic acid. The portion insoluble in sodic carbonate was treated with a solution of caustic potash in order to effect the saponification of the fatty matter, and the insoluble resinous substance was removed by a filter, washed, dried and reserved to be examined subsequently. To the solution of soap obtained was added a sufficient quantity of tartaric acid to decompose it. Ether was now added, and the mixture agitated. After a few hours the supernatant ethereal liquid was removed and allowed to evaporate spontaneously, when it was found to possess properties characteristic of fatty acid bodies. The insoluble resinous substance obtained before was first boiled with water, then thrown on a filter, well washed and dried. It was afterwards

* From the *American Journal of Pharmacy*. Abstract from an Inaugural Essay presented to the California College of Pharmacy.

dissolved in ether, and the solution decolorized by animal charcoal. The filtrate was evaporated, the residue, redissolved in alcohol and then allowed to evaporate spontaneously, when it left a deposit, exhibiting under the microscope a rhomboidal crystalline structure; it is evidently a resin. This *megarrhizitin* is soluble in alcohol and ether, and is unaffected by alkalies and solution of cupric sulphate.

The root previously exhausted by ether was next treated with alcohol (sp. gr. 0·835), until deprived of its bitter taste. The tincture was evaporated to a small bulk, then thrown into water to remove traces of fat or resin, and afterwards filtered. The liquid was heated to expel the spirit. To the resulting aqueous fluid was added a concentrated solution of tannic acid. A bulky gelatinous precipitate was obtained. This, being removed by a filter, was well washed and dried. It was now dissolved in alcohol (95 per cent.), the tannin thrown down by plumbic subacetate, the excess of lead removed by H_2S, and the liquid filtered and evaporated. The residue well washed with ether yielded the bitter principle pure. This process was adopted from that of Dr. Waltz, as mentioned in his analysis of colocynth.

To the principle thus obtained, the name of *megarrhizin* is given. It is of a brownish colour, somewhat transparent, brittle and friable, yielding a yellowish-brown powder. It is fusible below 100° C., inflammable, more soluble in alcohol than in water, both solutions being intensely bitter. It is insoluble in ether. The following reactions, with reagents, were obtained: H_2SO_4, dissolved it slowly with the production of first a bright red and afterwards a brown colour; HCl gave a faint violet colour; HNO_3, a yellow dull colour. An aqueous solution of it produced with ferric chloride a deep colour, but no precipitate; with plumbic acetate and subacetate, mercuric chloride, solution of iodine, potassa or its carbonate, or argentic nitrate, no change; with tannic acid, a bulky, gelatinous precipitate, and with bromine water, a white, insoluble precipitate. Boiled with baryta water, decomposition ensued; treated with dilute H_2SO_4 or HCl, no change was observed in the cold, but upon boiling, immediately decomposition took place, yielding glucose and an insoluble substance, which may be called *megarrhizioretin*.

This *megarrhizioretin* when washed and dried possesses a dark-brown colour, a resinous appearance, and is somewhat brittle. Alcohol dissolves it, but ether is only a partial solvent of it, leaving an insoluble portion behind. It is, therefore, a complex body.

The ashes showed, on analysis, the presence of magnesia, lime, iron, potassa, soda, chlorine, sulphuric and phosphoric acids, also a silicious residue.

It will be seen from the foregoing that megarrhizin belongs to that class of substances known as glucosides, to which belong also colocynthin and bryonin, and that it agrees with these two in many of their chemical and physical properties. But megarrhizin differs from colocynthin in the fact that colocynthein, the insoluble resinous substance obtained from the boiling of it with diluted acids, is soluble in ether, while megarrhizioretin is but partially soluble in that liquid, thereby agreeing with bryoretin. But it differs from bryonin principally in the behaviour to sulphuric acid, which dissolves megarrhizin, yielding a brown colour; while bryonin produces with it a blue colour. Therefore, it was concluded to be a distinct principle.

Physiological Investigation.—A sample of an extract prepared from an alcoholic tincture, and also some of the bitter principle, were sent to a physician in this city to be examined physiologically, and the following note received:—

"Your note, with samples of the alcoholic extract and bitter principle of *Megarrhiza Californica*, for the purpose of ascertaining their physiological action on the animal organism, has been received. I would state that the extract in large doses is a powerful irritant, causing gastro-enteritis and death. It produces griping pains in the stomach, nausea, vomiting and profuse diarrhœa, violent strangury, with other symptoms of renal and vesical irritation. Given in a quarter to half grain doses, the extract is a drastic hydragogue cathartic, causing nausea, sometimes vomiting, griping pains and copious watery stools. In smaller doses, frequently repeated, it is a diuretic and laxative. Notwithstanding its activity, I should deem it a safe and convenient purgative, and should consider it useful in all cases where it is desirable to produce an energetic influence on the bowels, to obtain large evacuations. Its hydragogue properties must prove beneficial in dropsies. It also augments the urinary discharges. In intestinal inflammations it should not be used. The above is the result of a series of experiments made upon myself and others. Its toxicological action on a dog was undertaken, but proved a failure in so far as it caused emesis. Five grain doses of the bitter principle were repeated every fifteen to thirty minutes, until thirty grains were administered. However, purging and frequent desire to urinate followed, but, otherwise, the animal showed no symptoms of disturbance. The following day, I again administered five grains of bitter principle, which was also ejected. Finding that nothing would be retained in the stomach (not even food), the animal was killed for examination, which was conducted immediately after its death. The chief morbid appearance observed was a patch of redness in the mucous membrane of the stomach near its cardiac orifice. The intestines were found to be slightly inflamed, as also the bladder, which was nearly empty. There was also a marked congestion of the kidneys."

THE MANUFACTURE OF MILK SUGAR IN SWITZERLAND.

BY A. SAUTER.

In a communication to the *Schweizerische Wochenschrift für Pharmacie* for the 20th of October, the author gives an account of a visit to Marbach, in the canton of Luzern, Switzerland, where a half-a-dozen refiners are said to make a handsome income from the manufacture of milk sugar.

The raw material used for the recrystallization comes from the neighbouring Alps, in the cantons of Luzern, Bern, Schwyz, etc.; a considerable quantity is supplied also by Gruyères. It is the so-called "Schottensand" or "Zuckersand," the French "déchet de lait," obtained by simple evaporation of the whey after cheese-making. Notwithstanding a continual rise in the price, consequent upon the demand and the increased cost of labour and fuel, the manufacture continually expands, and now amounts to 1800 to 2000 cwts. yearly, corresponding to a gross value of about 300,000 francs, certainly a handsome sum for a small mountain village with but few inhabitants.

The manufacture is only carried on in the higher mountains, because there the material can no longer be used profitably for the fattening of swine, which are found chiefly in the valleys, and the wood required for the evaporating process is cheaper in the highlands.

The crude material is sent to the manufacturer, or refiner, in sacks containing one to two hundredweights. It is washed in copper vessels, and dissolved to saturation at the boiling temperature over a fire, and the yellow brown liquor, after straining, is allowed to stand in copper-lined tubs or long troughs to crystallize. The sugar crystals form in clusters on immersed chips of wood, and these are the most pure and therefore of rather greater commercial value than the milk sugar in plates which is deposited on the sides of the vessels.

In ten to fourteen days the process of crystallization has ended, and the milk sugar has finished growing ("*ausgewachsen*"). The crystals are then washed with cold water, afterwards dried in a cauldron over a fire, and packed in casks holding four to five hundredweights.

As the "Schottensand" can only be obtained in the summer, the recrystallization is not carried on in the winter, hence a popular saying that the milk sugar does not "grow" in the winter. The entire manipulation is carried on in a very primitive manner, it being a matter of astonishment to find a specific gravity instrument in any place. The author is of opinion that with a more rational method of working a whiter and finer quality sugar could be produced.

SURFACE BIOLOGY.*

BY ALFRED RUSSEL WALLACE, F.R.G.S., F.L.S.

(*Concluded from page* 374.)

But the question of the mere "Antiquity of Man" almost sank into insignificance at a very early period of the inquiry, in comparison with the far more momentous and more exciting problem of the development of man from some lower animal form, which the theories of Mr. Darwin and of Mr. Herbert Spencer soon showed to be inseparably bound up with it. This has been, and to some extent still is, the subject of fierce conflict; but the controversy as to the fact of such development is now almost at an end, since one of the most talented representatives of Catholic theology, and an anatomist of high standing—Professor Mivart—fully adopts it as regards physical structure, reserving his opposition for those parts of the theory which would deduce man's whole intellectual and moral nature from the same source and by a similar mode of development.

Never, perhaps, in the whole history of science or philosophy has so great a revolution in thought and opinion been effected as in the twelve years from 1859 to 1871, the respective dates of publication of Mr. Darwin's 'Origin of Species' and 'Descent of Man.' Up to the commencement of this period the belief in the independent creation or origin of the species of animals and plants, and the very recent appearance of man upon the earth, were, practically, universal. Long before the end of it these two beliefs had utterly disappeared, not only in the scientific world, but almost equally so among the literary and educated classes generally. The belief in the independent origin of man held its ground somewhat longer; but the publication of Mr. Darwin's great work gave even that its death-blow, for hardly any one capable of judging of the evidence now doubts the derivative nature of man's bodily structure as a whole, although many believe that his mind, and even some of his physical characteristics, may be due to the action of other forces than have acted in the case of the lower animals.

We need hardly be surprised, under these circumstances, if there has been a tendency among men of science to pass from one extreme to the other, from a profession (so few years ago) of total ignorance as to the mode of origin of all living things, to a claim to almost complete knowledge of the whole progress of the universe, from the first speck of living protoplasm up to the highest development of the human intellect. Yet this is really what we have seen in the last sixteen years. Formerly difficulties were exaggerated, and it was asserted that we had not sufficient knowledge to venture on any generalizations on the subject. Now difficulties are set aside, and it is held that our theories are so well established and so far-reaching, that they explain and comprehend all nature. It is not long ago (as I have already reminded you) since *facts* were contemptuously ignored, because they favoured our now popular views; at the present day it seems to me that facts which oppose them hardly receive due consideration. And as opposition is the best incentive to progress, and it is not well even for the best theories to have it all their own way, I propose to direct your attention to a few such facts, and to the conclusions that seem fairly deducible from them.

It is a curious circumstance that notwithstanding the attention that has been directed to the subject in every part of the world, and the numerous excavations connected with railways and mines which have offered such facilities for geological discovery, no advance whatever has been made for a considerable number of years in detecting the time or mode of man's origin. The Palæolithic flint weapons first discovered in the north of France more than thirty years ago are still the oldest undisputed proofs of man's existence; and amid the countless relics of a former world that have been brought to light, no evidence of any one of the links that must have connected man with the lower animals has yet appeared.

It is, indeed, well known that negative evidence in geology is of very slender value; and this is, no doubt, generally the case. The circumstances here are, however, peculiar, for many converging lines of evidence show that, on the theory of development by the same laws which have determined the development of the lower animals, man must be immensely older than any traces of him yet discovered. As this is a point of great interest we must devote a few moments to its consideration.

1. The most important difference between man and such of the lower animals as most nearly approach him is undoubtedly in the bulk and development of his brain, as indicated by the form and capacity of the cranium. We should therefore anticipate that these earliest races, who were contemporary with the extinct animals and used rude stone weapons, would show a marked deficiency in this respect. Yet the oldest known crania (those of the Engis and Cro-Magnon caves) show no marks of degradation. The former does not present so low a type as that of most existing savages, but is (to use the words of Professor Huxley) "a fair average human skull, which might have belonged to a philosopher, or might have contained the thoughtless brains of a savage." The latter are still more remarkable, being unusually large and well formed. Dr. Pruner-Bey states that they surpass the average of modern European skulls in capacity, while their symmetrical form, without any trace of prognathism, compares favourably not only with those of the foremost savage races, but with many nations of modern times.

One or two other crania of much lower type, but of less antiquity than this, have been discovered; but they in no way invalidate the conclusion which so highly developed a form at so early a period implies, viz., that we have as yet made a hardly perceptible step towards the discovery of any earlier stage in the development of man.

2. This conclusion is supported and enforced by the nature of many of the works of art found even in the oldest cave-dwellings. The flints are of the old chipped type, but they are formed into a large variety of tools and weapons—such as scrapers, awls, hammers, saws, lances, etc., implying a variety of purposes for which these were used, and a corresponding degree of mental activity and civilization. Numerous articles of bone have also been found, including well-formed needles, implying that skins were sewn together, and perhaps even textile material woven into cloth. Still more important are the numerous carvings and drawings representing a variety of animals, including horses, reindeer, and even a mammoth, executed with considerable skill on bone, reindeer horns, and mammoth-tusks. These, taken together, indicate a state of civilization much higher than that of the lowest of our modern savages, while it is quite compatible with a considerable degree of mental advancement, and leads us to believe that the crania of Engis and Cro-Magnon are not exceptional, but fairly represent the characters of the race. If we further remember that these people lived in Europe under the unfavourable

* Presidental Address delivered to the Biological Section of the British Association, at Glasgow, on Sept. 6, 1876.

conditions of a sub-Artic climate, we shall be inclined to agree with Dr. Daniel Wilson, that it is far easier to produce evidences of deterioration than of progress in instituting a comparison between the contemporaries of the mammoth and later prehistoric races of Europe or savage nations of modern times.*

3. Yet another important line of evidence as to the extreme antiquity of the human type has been brought prominently forward by Professor Mivart.† He shows, by a careful comparison of all parts of the structure of the body, that man is related not to any one, but almost equally to many of the existing apes—to the orang, the chimpanzee, the gorilla, and even to the gibbons—in a variety of ways; and these relations and differences are so numerous and so diverse that, on the theory of evolution, the ancestral form which ultimately developed into man must have diverged from the common stock whence all these various forms and their extinct allies originated. But so far back as the Miocene deposits of Europe we find the remains of apes allied to these various forms, and especially to the gibbons; so that in all probability the special line of variation which led us to man branched off at a still earlier period. And these early forms, being the initation of a far higher type, and having to develop by natural selection into so specialized and altogether distinct a creature as man, must have risen at a very early period into the position of a dominant race, and spread in dense waves of population over all suitable portions of the great continent—for this, on Mr. Darwin's hypothesis, is essential to rapid developmental progress through the agency of natural selection.

Under these circumstances we might certainly expect to find some relics of these earlier forms of man along with those of animals which were presumably less abundant. Negative evidence of this kind is not very weighty, but still it has some value. It has been suggested that as apes are mostly tropical, and anthropoid apes are now confined almost exclusively to the vicinity of the equator, we should expect the ancestral forms also to have inhabited these same localities—West Africa and the Malay Islands. But this objection is hardly valid, because existing anthropoid apes are wholly dependent on a perennial supply of easily accessible fruits, which is only found near the equator, while not only had the south of Europe an almost tropical climate in Miocene times, but we must suppose even the earliest ancestors of man to have been terrestrial and omnivorous, since it must have taken ages of slow modification to have produced the perfectly erect form, the short arms, and the wholly non-prehensile foot, which so strongly differentiate man from the arboreal apes.

The conclusion which I think we must arrive at is that if man has been developed from a common ancestor with all existing apes, *and by no other agencies than such as have affected their development*, then he must have existed, in something approaching his present form, during the tertiary period—and not merely existed, but predominated in numbers, wherever suitable conditions prevailed. If then, continued researches in all parts of Europe and Asia fail to bring to light any proofs of his presence, it will be at least a presumption that he came into existence at a much later date, and by a much more rapid process of development. In that case it will be a fair argument, that, just as he is in his mental and moral nature, his capacities and aspirations, so infinitely raised above the brutes, so his origin is due, in part, to distinct and higher agencies than such as have affected their development.

There is yet another line of inquiry bearing upon this subject to which I wish to call your attention. It is a somewhat curious fact that, while all modern writers admit the great antiquity of man, most of them maintain the very recent development of his intellect, and will hardly contemplate the possibility of men equal in mental capacity to ourselves having existed in prehistoric times. This question is generally assumed to be settled by such relics as have been preserved of the manufactures of the older races showing a lower and lower state of the arts, by the successive disappearance in early times of iron, bronze, and pottery, and by the ruder forms of the older flint implements. The weakness of this argument has been well shown by Mr. Albert Mott in his very original but little known presidential address to the Literary and Philosophical Society of Liverpool in 1873. He maintains that "our most distant glimpses of the past are still of a world peopled as now with men both civilized and savage," and "that we have often entirely misread the past by supposing that the outward signs of civilization must always be the same, and must be such as are found among ourselves." In support of this view he adduces a variety of striking facts and ingenious arguments, a few of which I will briefly summarize.

On one of the most remote islands of the Pacific—Easter Island—2000 miles from South America, 2000 from the Marquesas, and more than 1000 from the Gambier Islands, are found hundreds of gigantic stone images, now mostly in ruins, often thirty or forty feet high, while some seem to have been much larger, the crowns on their heads cut out of a red stone being sometimes ten feet in diameter, while even the head and neck of one is said to have been twenty feet high.* These once stood erect on extensive stone platforms; yet the island has only an area of about thirty square miles, or considerably less than Jersey. Now as one of the smallest images eight feet high weighs four tons, the largest must weigh over a hundred tons, if not much more; and the existence of such vast works implies a large population, abundance of food, and an established government. Yet how could these coexist in a mere speck of land wholly cut off from the rest of the world? Mr. Mott maintains that this necessarily implies the power of regular communication with larger islands or a continent, the arts of navigation, and a civilization much higher than now exists in any part of the Pacific. Very similar remains in other islands scattered widely over the Pacific add weight to this argument.

The next example is that of the ancient mounds and earthworks of the North American continent, the bearing of which is even more significant. Over the greater part of the extensive Mississippi valley four well-marked classes of these earthworks occur. Some are camps, or works of defence, situated on bluffs, promontories, or isolated hills; others are vast enclosures in the plains and lowlands, often of geometric forms, and having attached to them roadways or avenues often miles in length; a third are mounds corresponding to our tumuli, often seventy to ninety feet high, and some of them covering acres of ground; while a fourth group consists of representations of various animals modelled in relief on a gigantic scale, and occurring chiefly in an area somewhat to the north-west of the other classes, in the plains of Wisconsin.

The first class—the camps or fortified enclosures—resemble in general features the ancient camps of our own islands, but far surpass them in extent. Fort Hill, in Ohio, is surrounded by a wall and ditch a mile and a half in length, part of the way cut through solid rock. Artificial reservoirs for water were made within it, while at one extremity, on a more elevated point, a keep is constructed with its separate defences and water-reservoirs. Another, called Clark's Work, in the Scioto valley, which seems to have been a fortified town, encloses an area of 127 acres, the embankments measuring three miles in length, and containing not less than three million cubic feet of earth. This area encloses numerous sacrificial mounds and symmetrical earthworks, in which many interesting relics and works of art have been found.

The second class—the sacred enclosures—may be com-

* 'Prehistoric Man,' 3rd ed., vol. i., p. 117.

† 'Man and Apes,' pp. 171–193.

* *Journ. of Roy. Geog. Soc.*, 1870, pp. 177, 178.

pared for extent and arrangement with Avebury or Carnack, but are in some respects even more remarkable. One of these at Newark, Ohio, covers an area of several miles with its connected groups of circles, octagons, squares, ellipses, and avenues on a grand scale, and formed by embankments from twenty to thirty feet in height. Other similar works occur in different parts of Ohio; and by accurate survey it is found not only that the circles are true, though some of them are one third of a mile in diameter, but that other figures are truly square, each side being over 1000 feet long, and, what is still more important, the dimensions of some of these geometrical figures, in different parts of the country and seventy miles apart, are identical. Now this proves the use, by the builders of these works, of some standard measures of length, while the accuracy of the squares, circles, and, in a less degree, of the octagonal figures shows a considerable knowledge of rudimentary geometry and some means of measuring angles. The difficulty of drawing such figures on a large scale is much greater than any one would imagine who has not tried it, and the accuracy of these is far beyond what is necessary to satisfy the eye. We must therefore impute to these people the wish to make these figures as accurate as possible; and this wish is a greater proof of habitual skill and intellectual advancement than even the ability to draw such figures. If, then, we take into account this ability and this love of geometric truth, and further consider the dense population and civil organization implied by the construction of such extensive systematic works, we must allow that these ancient people had reached the earlier stages of a civilization of which no traces existed among the savage tribes who alone occupied the country when first visited by Europeans.

The animal mounds are of comparatively less importance for our present purpose, as they imply a somewhat lower grade of advancement; but the sepulchral and sacrificial mounds exist in vast numbers, and their partial exploration has yielded a quantity of articles and works of art which throw some further light on the peculiarities of this mysterious people. Most of these mounds contain a large concave hearth or basin of burnt clay, of perfectly symmetrical form, on which are found deposited more or less abundant relics, all bearing traces of the action of fire. We are therefore only acquainted with such articles as are practically fire-proof, or have accidentally escaped combustion. These consist of bone and copper implements and ornaments, disks, and tubes—pearl, shell, and silver beads, more or less injured by the fire—ornaments cut in mica, ornamental pottery, and numbers of elaborate carvings in stone, mostly forming pipes for smoking. The metallic articles are all formed by hammering, but the execution is very good; plates of mica are found cut into scrolls and circles; the pottery, of which very few remains have been found, is far superior to that of any of the Indian tribes, since Dr. Wilson is of opinion that it must have been formed on a wheel, as it is often of uniform thickness throughout (sometimes not more than one sixth of an inch), polished, and ornamented with scrolls and figures of birds and flowers in delicate relief. But the most instructive objects are the sculptured stone pipes, representing not only various easily recognizable animals, but also human heads, so well executed that they appear to be portraits. Among the animals, not only are such native forms as the panther, bear, otter, wolf, beaver, raccoon, heron, crow, turtle, frog, rattlesnake, and many others well represented, but also the manatee, which perhaps then ascended the Mississippi as it now does the Amazon, and the toucan, which could hardly have been obtained nearer than Mexico. The sculptured heads are especially remarkable, because they present to us the features of an intellectual and civilized people. The nose in some is perfectly straight, and neither prominent nor dilated; the mouth is small, and the lips thin; the chin and upper lip are short, contrasting with the ponderous jaw of the modern Indian, while the cheek-bones present no marked prominence. Other examples have the nose somewhat projecting at the apex in a manner quite unlike the features of any American indigenes; and although there are some which show a much coarser face, it very difficult to see in any of them that close resemblance to the Indian type which these sculptures have been said to exhibit. The few authentic crania from the mounds present corresponding features, being far more symmetrical and better developed in the frontal region than those of any American tribes, although somewhat resembling them in the occipital outline;* while one was described by its discoverer (Mr. W. Marshall Anderson) as a "beautiful skull worthy of a Greek."

The antiquity of this remarkable race may perhaps not be very great as compared with the prehistoric man of Europe, although the opinion of some writers on the subject seems affected by that "parsimony of time" on which the late Sir Charles Lyell so often dilated. The mounds are all overgrown with dense forest, and one of the large trees was estimated to be eight hundred years old, while other observers consider the forest growth to indicate an age of at least 1000 years. But it is well known that it requires several generations of trees to pass away before the growth on a deserted clearing comes to correspond with that of the surrounding virgin forest, while this forest, once established, may go on growing for an unknown number of thousands of years. The 800 or 1000 years' estimate from the growth of existing vegetation is a minimum which has no bearing whatever on the actual age of these mounds; and we might almost as well attempt to determine the time of the glacial epoch from the age of the pines or oaks which now grow on the moraines.

The important thing for us, however, is that when North America was first settled by Europeans, the Indian tribes inhabiting it had no knowledge or tradition of any preceding race of higher civilization than themselves. Yet we find that such a race existed; that they must have been populous and have lived under some established government; while there are signs that they practised agriculture largely, as, indeed, they must have done to have supported a population capable of executing such gigantic works in such vast profusion; for it is stated that the mounds and earthworks of various kinds in the state of Ohio alone amount to between eleven and twelve thousand. In their habits, customs, religion, and arts they differed strikingly from all the Indian tribes; while their love of art and of geometic forms, and their capacity for executing the latter upon so gigantic a scale, render it probable that they were a really civilized people, although the form their civilization took may have been very different from that of later people subject to very different influences, and the inheritors of a longer series of ancestral civilizations. We have here, at all events, a striking example of the transition, over an extensive country, from comparative civilization to comparative barbarism, the former left to tradition and having hardly any trace of influence on the latter.

As Mr. Mott well remarks:—Nothing can be more striking than the fact that Easter Islands and North America both gave the same testimony as to the origin of the savage life found in them, although in all circumstances and surroundings the two cases are so different. If no stone monuments had been constructed in Easter Island, or mounds, containing a few relics saved from fire, in the United States, we might never have suspected the existence of these ancient peoples. He argues, therefore, that it is very easy for the records of an ancient nation's life entirely to perish or to be hidden from observation. Even the arts of Nineveh and Babylon were unknown only a generation ago, and we have only just discovered the facts about the mound-builders of North America.

But other parts of the American continent exhibit

* Wilson's 'Prehistoric Man,' 3rd ed., vol. ii., p. 123.

parallel phenomena. Recent investigations show that in Mexico, Central America, and Peru the existing race of Indians has been preceded by a distinct and more civilized race. This is proved by the sculptures of the ruined cities of Central America, by the more ancient terra-cottas and paintings of Mexico, and by the oldest portrait-pottery of Peru. All alike show markedly non-Indian features, while they often closely resemble modern European types. Ancient crania, too, have been found in all these countries, presenting very different characters from those of any of the modern indigenous races of America.*

There is one other striking example of a higher being succeeded by a lower degree of knowledge, which is in danger of being forgotten because it has been made the foundation of theories which seem wild and fantastic, and are probably in great part erroneous. I allude to the Great Pyramid of Egypt, whose form, dimensions, structure, and uses have recently been the subject of elaborate works by Professor Piazzi Smyth. Now the admitted facts about this pyramid are so interesting and so apposite to the subject we are considering, that I beg to recall them to your attention. Most of you are aware that this pyramid has been carefully explored and measured by successive Egyptologists, and that the dimensions have lately become capable of more accurate determination, owing to the discovery of some of the original casing-stones and the clearing away of the earth from the corners of the foundation showing the sockets in which the corner-stones fitted. Professor Smyth devoted many months of work with the best instruments in order to fix the dimensions and angles of all accessible parts of the structure; and he has carefully determined these by a comparison of his own and all previous measures, the best of which agree pretty closely with each other. The results arrived at are:—

1. That the pyramid is truly square, the sides being equal and the angles right angles.

2. That the four sockets on which the four first stones of the corners rested are truly on the same level.

3. That the direction of the sides are accurately to the four cardinal points.

4. That the vertical height of the pyramid bears the same proportion to its circumference at the base, as the radius of a circle does to its circumference.

Now all these measures, angles, and levels are accurate, not as an ordinary surveyor or builder could make them, but to such a degree as requires the very best modern instruments and all refinements of geodetical science to discover any error at all. In addition to this we have the wonderful perfection of the workmanship in the interior of the pyramid, the passages and chambers being lined with huge blocks of stones fitted with the utmost accuracy, while every part of the building exhibits the highest structural science.

In all these respects this largest pyramid surpasses every other in Egypt. Yet it is universally admitted to be the oldest, and also the oldest historical building in the world.

Now these admitted facts about the Great Pyramid are surely remarkable, and worthy of the deepest consideration. They are facts which, in the pregnant words of the late Sir John Herschel, "according to received theories ought not to happen," and which, he tell us, should therefore be kept ever present to our minds, since "they belong to the class of facts which serve as the clue to new discoveries." According to modern theories, the higher civilization is ever a growth and an outcome from a preceding lower state; and it is inferred that this progress is visible to us throughout all history and in all the material records of human intellect. But here we have a building which marks the very dawn of history, which is the oldest authentic monument of man's genius and skill, and which, instead of being far inferior, is very much superior to all which followed it. Great men are the products of their age and country, and the designers and constructors of this wonderful monument could never have arisen among an unintellectual and half-barbarous people. So perfect a work implies many preceding less perfect works which have disappeared. It marks the culminating point of an ancient civilization, of the early stages of which we have no record whatever.

* Wilson's 'Prehistoric Man,' 3rd ed., vol. ii., pp. 125, 144.

The three cases to which I have now adverted (and there are many others) seem to require for their satisfactory interpretation a somewhat different view of human progress from that which is now generally accepted. Taken in connection with the great intellectual power of the ancient Greeks—which Mr. Galton believes to have been far above that of the average of any modern nation—and the elevation, at once intellectual and moral, displayed in the writings of Confucius, Zoroaster, and the Vedas, they point to the conclusion that, while in material progress there has been a tolerably steady advance, man's intellectual and moral development reached almost its highest level in a very remote past. The lower, the more animal, but often the more energetic types have, however, always been far the more numerous; hence such established societies as have here and there arisen under the guidance of higher minds have always been liable to be swept away by the incursions of barbarians. Thus in almost every part of the globe there may have been a long succession of partial civilizations, each in turn succeeded by a period of barbarism; and this view seems supported by the occurrence of degraded types of skull along with such "as might have belonged to a philosopher," at a time when the mammoth and the reindeer inhabited southern France.

Nor need we fear that there is not time enough for the rise and decay of so many successive civilizations as this view would imply; for the opinion is now gaining ground among geologists that palæolithic man was really preglacial, and that the great gap (marked alike by a change of physical conditions and of animal life), which in Europe always separates him from his neolithic successor, was caused by the coming on and passing away of the great ice age.

If the views now advanced are correct, many, perhaps most, of our existing savages are the successors of higher races; and their arts, often showing a wonderful similarity in distant continents, may have been derived from a common source among more civilized peoples.

I must now conclude this very imperfect sketch of a few of the offshoots from the great tree of Biological study. It will, perhaps, be thought by some that my remarks have tended to the depreciation of our science, by hinting at imperfections in our knowledge and errors in our theories where more enthusiastic students see nothing but established truths. But I trust that I may have conveyed to many of my hearers a different impression. I have endeavoured to show that, even in what are usually considered the more trivial and superficial characters presented by natural objects, a whole field of new inquiry is opened up to us by the study of distribution and local conditions. And as regards man, I have endeavoured to fix your attention on a class of facts which indicate that the course of his development has been far less direct and simple than has hitherto been supposed; and that, instead of resembling a single tide with its advancing and receding ripples, it must rather be compared to the progress from neap to spring tides, both the rise and the depression being comparatively greater as the waters of true civilization slowly advance towards the highest level they can reach.

And if we are thus led to believe that our present knowledge of nature is somewhat less complete than we have been accustomed to consider it, this is only what we might expect; for however great may have been the intellectual triumphs of the nineteenth century, we can hardly think so highly of its achievements as to imagine that, in somewhat less than twenty years, we have passed from complete ignorance to almost perfect knowledge on two such vast and complex subjects as the origin of species and the antiquity of man.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 11, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE DECOMPOSITION OF SALICYLATE OF SODA.

SINCE the important announcement of Professor KOLBE respecting the antiseptic action of salicylic acid and its capability of preventing fermentation, which was published for the first time in England in these columns scarcely two years since, quite an extensive amount of literature has been devoted to the subject. Only comparatively a small fraction of it, however, has been published in this country; for the battle of its merits and demerits has been most stoutly fought out in Germany. But it soon became evident that much of the diversity of opinion possibly had its origin in the disregard of the fact observed by KOLBE, and confirmed by KNOPP, that the antiseptic action of free salicylic acid is not shared by its salts, and that it might, for instance, be greatly diminished or even stayed by being saturated with the ammonia resulting from the decomposition of albuminous substances. It was becoming generally acknowledged that in salicylic acid a valuable addition had been made to our list of antiseptics when, in the course of the year 1875, it was stated by Dr. BUTT, that it had, as well, an almost specific action in the reduction of the temperature of the body. In this direction, also, the acid has now attained considerable reputation as a remedy in typhoid and rheumatic fever, and it is increasingly prescribed by both British and foreign physicians; but what is also notable is that the sodium salt is for certain reasons preferred by some. Bearing in mind that the antiseptic action of the acid is diminished in proportion to its saturation, this seemed to require an explanation. The question had a specially pharmaceutical aspect too, since some of the substances suggested to be used to increase the solubility of the acid would probably enter more or less into combination with it.

Professor BINZ, of Bonn, has recently suggested in a communication to the Lower Rhine Medical Society, that the explanation is to be found in the continual liberation of carbonic acid in the animal tissue, to which is due in great measure the alkalinity of the blood. The gas, evolved in an absolutely pure state, has the property of setting free the salicylic acid from sodium salicylate. This proposition Professor BINZ illustrates by the following experiment.

A solution of the salt (1 per cent.), shaken up with ether, yields to it nothing that gives a ponderable residue after evaporation. But if the same solution be treated at the ordinary temperature and under the ordinary pressure with carbonic anhydride, it will afterwards give up to ether from one-seventh to one-tenth of the salicylic acid originally in combination in the salt, and upon each repetition of the operation successive portions of the acid are set free. The salt being much more soluble in water than in ether remains in the former; but the acid being more soluble in ether than water, the conditions are reversed, and when set free (presumably by the carbonic acid), it passes into the ether from which it can be obtained upon evaporation of the ether in fine crystals.

Further, when the solution of sodium salicylate is brought into closer relations with blood by the addition of a little sodium phosphate and carbonate, and the carbonic anhydride is afterwards introduced, the salicylic acid is similarly set free, but to a less extent. An evaporating dish was coated upon the evaporation of the ether with a strong crust of salicylic acid thus set free; whilst in a comparative experiment, when the ether was simply shaken with the solution of the three salts, no residue was obtained.

Putrescible mixtures, when sufficiently diluted with water, as for instance, urine with an equal quantity of water, putrefy much less readily under access of air after an addition of 1 per cent. of sodium salicylate and carbonic anhydride, than after an addition of either alone, and this difference extends over several weeks. This was confirmed by experiments made with a mixture to which no addition had been made, one which was only treated with carbonic anhydride, a third to which only sodium salicylate was added, and a fourth treated with both sodium salicylate and carbonic anhydride.

Here also Professor BINZ is of opinion, it may be inferred, that there is a liberation of the antiseptic agent, the influence of which is eventually overcome by the ammonia gradually formed in the meanwhile.

It is apparent, therefore, that it is not admissible to describe sodium salicylate as a salt without chemical action in the organism. As Professor BINZ forcibly remarks, it cannot *à priori* be affirmed of a salt which is decomposed by carbonic anhydride that it will pass unaltered through an organism where a continual evolution of nascent carbonic anhydride is taking place.

Professor BINZ concluded his interesting communication by pointing out that in some respects salicylic acid has the greatest similarity with quinine. Like quinine it cuts short the symptoms of malarial poisoning, though somewhat less surely and lastingly, and it acts as a powerful antizymotic that can be introduced into the system in large doses. It remains for a considerable time in the system, and passes out again, at least partially, unaltered. Of course the correspondence between the two substances, as might be expected from the difference in their constitution, is not complete in all respects.

THE REPETITION OF PRESCRIPTIONS IN SAXONY.

A DECREE has recently been issued by the Minister of the Interior for Saxony, abolishing former regulations as to the repetition of physicians' prescriptions in that country, and replacing them by more inclusive rules.

With respect to medicines for internal administration, pharmacists are now forbidden to repeat, without a special order from the original prescriber or another qualified physician or surgeon, any prescription, ordering, in any dose whatever, any of the substances included in Table B (*medicamenta cautissima asservanda*) of the German Pharmacopœa. This table includes arsenic and its preparations, mercurial compounds, phosphorus, strychnine, atropine, coniine, veratrine, and to these are also now added digitalin and chloroform (whether for inhalation or internal administration). The same rule applies to the articles in Table C (*medicamenta caute servanda*) if the dose ordered exceed by one-fifth the official maximum dose. Chloral hydrate is not to be repeated when the maximum dose of 4·0 grains is exceeded; or secale cornute if the dose exceed 6 grains, or extractum secalis if the dose exceed 0·3 grains. Neither are the prescriptions of homœopathic physicians up to and inclusive of the third dilution to be repeated.

As to medicines for external use dispensers are prohibited from repeating prescriptions containing any dose whatever of an article in Table B, before referred to, with the exception of red oxide of mercury, white precipitate and veratrine; or a prescription for subcutaneous injection of a solution of a substance in Table B or Table C.

LAC AND LAC DYE.

A RECENT report on Indian trade gives a fresh illustration of the far-reaching influence that has been exercised by the wonderful discoveries of artificial dyeing materials that have been made during the past few years. The manufacture of lac-dye has been always combined with that of shellac, the dye being the colouring matter contained in the body of the insect whose resinous excretion is converted into the shellac of commerce. In the manufacture of shellac it becomes necessary to eliminate the dye, and the liquid dye is then allowed to solidify into cakes. Formerly the dye was more valuable than the shellac, but owing to the competition of aniline dyes and cochineal its price has now so declined that its manufacture is only continued because it is bound up with the preparation of shellac, the demand for which is constantly increasing. The Government therefore decided in 1874 on the remission of the duty on lac-dye, but it is thought that it is doubtful whether the trade will ever revive. The quantity exported last year was 8379 cwt. against 9902 cwt. the previous year.

On the other hand the value of the shellac exported has risen from £184,149 in 1874 to £189,564 in 1875. In Burmah and the Central Provinces measures are being taken to increase the production of lac, the only obstacle to a still further development of the trade in shellac being the scarcity of the raw material.

A CHEMISTS AND DRUGGISTS' ASSOCIATION FOR IRELAND.

MR. J. T. HOLMES, who it will be remembered took an active part in the negotiations preceding the passing of the Irish Pharmacy Act, appears now to be stirring up his brother pharmaceutical chemists in Ireland to united action to prevent any infringement of their "rights." Mr. HOLMES has issued a circular stating that as he believes that he is in a position to say that the majority of the Council of the Irish Pharmaceutical Society is averse to that Society becoming a prosecuting body he feels there is a necessity for the formation of a Pharmaceutical Defence Association. To promote this object a meeting is to be held on Monday evening next, in Molesworth Hall, Dublin.

INJURED INNOCENCE.

A NEW YORK contemporary, bearing the name of *The Druggists' Advertiser*, exhibits in its last issue a little uneditorial bashfulness at the appreciation shown by other papers in appropriating its "good things" without acknowledgment. Our contemporary, although engrossed in "labouring for the advancement of pharmaceutical knowledge," and not desiring more credit than is its due for its humble efforts, expresses a relish for a little honesty now and then, if even from an editor. As the immediate boundaries on two sides of the paragraph containing the editorial wish consist of paragraphs taken from this Journal without any acknowledgment, we are ready to admit that our contemporary in its cravings shows a keen appreciation of one of its failings at least.

M. CHARLES SAINTE-CLAIRE DEVILLE.

WE are obligingly reminded by our esteemed *confrère*, Dr. MEHU, of Paris, that M. CHARLES SAINTE-CLAIRE DEVILLE, whose death we recorded recently, was a brother of the eminent chemist who discovered anhydrous nitric acid, and who is famous for his researches on sodium and platinum. The deceased *savant* was rather a mineralogist and geologist, though he was the first to discover the amorphous form of sulphur, which he announced in 1852 in a memoir entitled "Recherches sur le Dimorphisme et les Transformations du Soufre." He was a Member of the French Academy of Sciences and Professor of Geology in the College of France.

WE learn that Messrs. T. and H. SMITH and Co., of Edinburgh, have been awarded three medals for their exhibits at the Philadelphia Exhibition of (1) Chemicals; (2) Essence of Coffee, Essence of Coffee with Chicory, and Culinary Essences; and (3) Aërated Waters.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

April 11th, 1876.

Present.—Messrs. Ainslie, Borland, Buchanan, Gilmour, Kemp, Kinninmont, and Young.

MINOR EXAMINATION.

Fourteen candidates were examined. *Six* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Brumwell, William Preston......Newcastle-on-Tyne.
Edwards, William Herbert......Kidderminster.
Glegg, John ....Edinburgh.
Greenwell, William ....Gateshead.
Gregson, James Kenyon ....Blackburn.
Irving, Peter........................Dumfries.
Lawson, William ....Glasgow.
Maddison, Thomas Harwood ...March.

MODIFIED EXAMINATION.

Four candidates were examined. *All* failed.

NOTE.—The above should have been published in the Journal in April last.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

REPORT OF THE FIRST MEETING OF EXECUTIVE COMMITTEE.

A meeting of the Executive Committee was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on Friday, October 20, 1876, at 1 p.m. Mr. S. U. Jones (Leamington), President, in the chair; Mr. Thomas Barclay (Birmingham), Vice-President.

Present—Messrs. Andrews (London), Arblaster (Birmingham), Brevitt (Wolverhampton), Churchill (Birmingham), Cross (Shrewsbury), Earle (Hull), Fairlie (Glasgow, N.B.), Greaves (Chesterfield), Greenish (London), Hampson (London), Holdsworth (Birmingham), Jervis (Sheffield), Johnson (Manchester), Laird (Dundee, N.B.), Mackenzie (Edinburgh, N.B.), Shaw (Liverpool), G. Walker (Coventry), R. Walker (Birmingham), and the Solicitor of the Association.

The minutes of the meeting of the General Committee held at Glasgow were read and confirmed.

Several letters were read by the Secretary respecting the threatened prosecution of chemists at Nottingham for counter prescribing by a local branch of the Medical Defence Association.

The Secretary reported that on the 27th of September he proceeded to Nottingham and thoroughly investigated these cases of threatened prosecution. The results were laid before the meeting.

Mr. Hampson thought if one general resolution in respect to this matter was passed it would not necessarily apply to the Nottingham cases only, but to cases in general. If they passed a cautious and wise resolution it would be of infinite service to the trade.

Mr. Churchill said they were nearly all agreed that they could not go in for wholesale prescribing, but most of them, he thought, were determined to uphold the right of prescribing in simple cases.

Mr. Mackenzie explained at considerable length the condition of chemists in Edinburgh, and stated that a great many medical men were annually sent out from the Edinburgh Universities, and they found that every Edinburgh man carried with him an inherent antipathy to dispensing his own medicines.

Mr. Fairlie said he did not think there was a town in England or Scotland so situated at Edinburgh, there were very few surgeons in the whole city who kept open shop.

Mr. Jervis said this was a subject upon which they in Sheffield felt very deeply, and it was a question on which they must protect themselves or their objects in supporting the Association would never be carried out.

Mr. Laird said he understood that chemists had a right to prescribe by usage.

Mr. Andrews said they were not there to discuss the desirability of prescribing, the broad question was really the legality or the illegality of the act.

Mr. Barclay proposed the following resolution, and thought it would recommend itself to them all because they could not carry out literally the desire of some members of the medical profession. It was a very small section of the profession who wished to carry out the view that chemists should not prescribe in any way. Of course there were some medical men who were determined to confine them to the simple compounding of medicines, but they would have the sympathy of the medical men generally if they took up such cases as ought to be defended.

Mr. Earle said he found that their branch of the Medical Defence Association was not supported by the leading medical men in the town.

It was then moved by Mr. Barclay, seconded by Mr. G. Walker, and unanimously resolved—

> "That a sub-committee, consisting of Messrs. Earle, Fairlie, Hampson, and Reynolds, together with the officers of the Association, be appointed for the purpose of considering and taking such action as they think desirable in any case submitted by its members for legal proceedings."

Moved by Mr. Barclay, seconded by Mr. Fairlie, and unanimously resolved—

> "That in any case in which a chemist and druggist is threatened with legal proceedings for recommending simple remedies when required to do so in his own shop, if he be a member and the case is such as the sub-committee appointed for this purpose approves, this Association undertakes to defend him, but at the same time disapproves of the practice of other indiscriminate prescribing."

A letter was then read by the Secretary from the Council of the Pharmaceutical Society of Great Britain referring to the resolution passed at the Chemists and Druggists' Conference held in Birmingham on July 11th last, urging upon the Pharmaceutical Society the necessity of testing the legality of co-operative traders selling and dispensing poisons. The letter contained an invitation to the Chemists and Druggists' Trade Association to appoint a deputation to meet the Law and Parliamentary Committee of the Council of the Society in order that the whole case might be fairly explained.

Mr. Hampson said he felt considerable interest in this matter, as they knew, and he was extremely anxious that this Association should do all that lay in its power to bring it to a good issue, and he maintained that they must be resolute, they should take it up as a great and important question, and he did hope they would not be content to allow this question to lie idle.

It was then moved by Mr. Fairlie, seconded by Mr. Jervis and unanimously resolved—

> "That in response to the resolution passed by the Council of the Pharmaceutical Society inviting a deputation from this Association to meet the members of the Law and Parliamentary Committee of that Council, this Committee appoints the following gentlemen to consult with them on the subject of co-operative trading in poisons:—The London Members of the Executive Committee, who are not members of the Pharmaceutical Council, together

with Messrs. Barclay, Howden, Jones, Reynolds, and the Solicitor of the Association, with powers to add to their number."

The Secretary was instructed to forward a copy of this resolution to the Secretary of the Pharmaceutical Society, and to inform him that the deputation would meet the Law and Parliamentary Committee of the Council on the day and at the hour named in his letter of invitation.

Mr. Andrews said it was a most important matter to them in London; they felt it most in large towns at present, but he believed it would be felt universally throughout the country.

Mr. Barclay strongly urged the necessity of testing in a court of law the question of the legality of co-operative trading in poisons.

The Scotch memorial and a letter containing a resolution passed at a meeting of Aberdeen chemists supporting the same were read by the Secretary.

Mr. Mackenzie said as one who had canvassed in Edinburgh he could say that it was the unanimous opinion that they should have a Scotch Board, or Executive; because of the difference in the laws of the two countries, it would save much trouble and would simplify matters.

Mr. Fairlie explained their position from a Scotch point of view. With regard to having a Scotch executive the North British Branch of the Pharmaceutical Society had no powers except those relegated to them by the Society in London and he did not ask that the Association should give the Scotch branch any larger powers. He thought the Scotch Board should have a Scotch solicitor as gentlemen there naturally knew more of Scotch law than English solicitors.

Mr. Glaisyer (the solicitor of the Association) said he was prepared to advocate the employment of a Scotch solicitor on the ground that there are gentlemen there who had a higher interest and more practice in these matters than the agent of an English solicitor.

Mr. Hampson thought it was extremely desirable that some arrangement should be made and that the request of the Scotch Memorial should be agreed to. Dealing with the Glasgow Memorial first, he moved—

"That this Committee generally approves of the proposal contained in the Memorial presented to the Association by chemists resident in Scotland at the Trade Meeting at Glasgow, asking for a separate branch of the Association for Scotland and appoints a Sub-Committee consisting of Messrs. Davison (Glasgow), Fairlie (Glasgow), Kinninmont (Glasgow), Laird (Dundee), Mackenzie (Edinburgh), Macnaught (Grenock), and Strachan (Aberdeen), to draw up a scheme which shall be submitted to the Executive Committee of this Association for approval."

This motion was seconded by Mr. Greaves and unanimously agreed to.

In reference to the Aberdeen letter it was moved by Mr. Holdsworth, seconded by Mr. Fairlie, and unanimously resolved—

"That in answer to the letter from Aberdeen the Secretary be instructed to send to Mr. Strachan a copy of the resolution adopted in reference to the Glasgow Memorial."

A correspondence was read by the Secretary respecting a case of illegal trading under the Pharmacy Act.

A full and earnest discussion took place on the matter, and on the best means of proceeding against parties who were infringing the Act.

It was then moved by Mr. Churchill, seconded by Mr. R. Walker, and unanimously resolved—

"That the deputation already appointed for the purpose of conferring with the Law and Parliamentary Committee of the Council of the Pharmaceutical Society on the question of co-operative trading, be requested to bring the question of illegal trading under the Pharmacy Act generally before it."

The Secretary explained to the Committee the scheme for organization which had been adopted at the Glasgow meetings, and it was suggested that alterations may be made in the boundaries of a district if thought desirable.

Mr. Barclay explained the system on which canvassing and the work of organization generally should proceed under the scheme.

It was moved by Mr. Earle, seconded by Mr. Cross, and unanimously resolved—

"That the President and Honorary Secretary be requested to act as a sub-committee to arrange with the Secretary as to the time and manner of canvassing the districts."

Mr. Andrews said he thought it would be advisable that a sub-committee of London members of the Committee should be formed to arrange a system for dividing the city into districts and canvassing.

It was then moved by Mr. Fairlie, seconded by Mr. Laird, and unanimously resolved—

"That Mr. Andrews and Mr. Matthews be requested to prepare a scheme for canvassing the City of London and submit it to the Executive Committee for approval."

A letter was read from a firm of chemists in Ireland, inquiring if it is intended to confine the operations of the Association to England and Scotland.

It was, after discussion, moved by Mr. Andrews, seconded by Mr. Barclay, and unanimously resolved—

"That this Association earnestly desires to co-operate with the chemists and druggists of Ireland, and should it be shown to the Executive Committee that a feeling favourable to that object prevails they will carefully consider the subject."

The following resolution was moved by Mr. Andrews, seconded by Mr. Greenish, and unanimously resolved—

"That Messrs. Barclay, Churchill, Holdsworth and Southall form a finance committee."

A vote of thanks to the President for presiding terminated the proceedings.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Thursday the 2nd inst. the members of the above association assembled to listen to a lecture on "The Starches," by Mr. J. J. Edwards.

In the absence, owing to illness, of the President and Vice-President, the chair was occupied by Mr. Thirlby. After a few preliminary observations, the chairman called upon Mr. Edwards to discuss the subject for the evening.

In complying, the lecturer, fully yet tersely, explained the chemical composition of starch; the uses it subserved in nature's economy, both in plant and in animal life, and the dependence placed upon it, in one or other of its varied forms, as a food stuff, by millions of human beings. The behaviour of starch on the microscope stage when acted upon by various reagents, including calcic chloride, chromic acid, bile, saliva, pepsin, chloral hydrate, heat, etc., was next explained and illustrated. The various theories that have been promulgated relative to the formation of starch were next described, their comparative value being carefully enunciated by the lecturer. Attention was at this stage directed to the physical portion of the subject, special value being placed upon this branch as affording to an experienced operator means of detecting foreign bodies when present in the starches used as food. The mode of determining the kind of starch under examination by noting the size of the granules, the position of the hilum, the mode of lamination, and the behaviour under polarized light. was carefully explained and illustrated by reference to slides containing specimens of starches from the yam, acorn, maize, rice, tous le mois, potato, Bermuda, St. Vincent, and Natal arrowroots. The mode of mounting starches for microscopic use was next described, particular attention being directed to the fact that for successful use with the polarizing prisms the specimens must not only be mounted in powerfully refractive media, such as canada balsam, benzol, essential oils, and the like, but must also be viewed with high powers. Finally the importance of the subject, as evinced by the operation of the Adulteration Act, and the necessity always existing in starch analysis for a careful, cautious exercise of the judgment, were imperatively insisted upon. A hearty vote of thanks to Mr. Edwards for his clear and exhaustive lectnre terminated the evening's proceedings.

Proceedings of Scientific Societies.

PARIS SOCIÉTE DE PHARMACIE.

A meeting of this Society was held on Wednesday, October 4, when the chairman, M. Coulier, announced the death of M. Gobley, one of the most eminent members, and M. Blondeau recapitulated the address he had delivered at the grave in the name of the Society.

Adulteration of Quinine Sulphate.—A note from Dr. Jaillard, Algiers, was read, describing an adulteration of quinine sulphate that had been met with in that colony, consisting of an admixture of 70 per cent. of potassium nitrate. A sample was exhibited, that had been received in Algiers. It had on it a seal and label, and was wrapped in a prospectus, all bearing the name of a respectable French house. The mixture consists of acicular interlaced silky looking crystals, resembling closely those of pure quinine sulphate. The presence of the nitre could be demonstrated by the deflagration which took place, leaving a white ash, upon placing some of the substance on the end of a knife in the flame of a lamp. The meeting requested the chairman to send the adulterated specimens to the Procureur de la République.

Xanthium spinosum.—M. Yoon described to the Society some experiments that had been made in the school at Alfort, by MM. Trasbot and Nocard, respecting the alleged prophylactic action of *Xanthium spinosum* against hydrophobia. The results had been entirely negative.

CHEMICAL SOCIETY.

November 2, 1876. Professor Abel, F.R.S., President, in the chair. After the minutes of the previous meeting had been read and the other ordinary business completed, the President announced that the Goldsmiths' Company had contributed £1000 to the recently established research fund of the Society. Mr. Lupton then read a paper on "The Oxides of Potassium," after which communications were read "On Certain Bismuth Compounds, Part III.," by M. M. P. Muir; "On Phospho- and Arseno-Cyanogen," by W. R. Hodgkinson; "A Secondary Oxidized Product formed during the Reduction of Stannic Ethide to Stannous Ethide," by W. R. Hodgkinson and G. C. Matthews; and a preliminary notice on "Pigmentum Nigrum, the Black Colouring Matter contained in Hair and Feathers," by W. R. Hodgkinson and H. C. Sorby. This black colouring matter is left on digesting the cleansed hair or feathers with dilute sulphuric acid, but is present only in very small quantity. The meeting was finally adjourned until Thursday, November 16, when papers will be read "On Barwood," by the late Dr. Anderson; "On Potassium Triiodide," by G. S. Johnson; "On the Coal Gas of the Metropolis," by J. S. D. Humpidge; and "On Calcium Sulphate," by J. B. Hannay.

Parliamentary and Law Proceedings.

POISONING BY EATING OPIUM PILLS.

On Thursday, November 2, Mr. F. Price, district coroner, held an inquest at Worsley, on the body of Martha Alice Thornley, aged one year and eight months, daughter of Thomas Thornley, stone-quarryman.

The child's mother stated that she had been in the habit of giving pills to all her children to "sleep" them. She purchased the pills from Edward Crompton, a shoemaker and farmer, who lived at the Hollins, Worsley, but did not know what were their ingredients. Crompton had never told her to be cautious in the use of the pills. On Saturday last she purchased a box of the pills from him, and, having given one to deceased and one to her twin brother, left the box, in which were 22 pills, on a chest of drawers. About one o'clock on Sunday afternoon her daughter Ellen called her attention to the fact that deceased had got the pills by standing on a chair. She saw deceased with a paper containing eleven of the pills in her hand, and another pill was lying near her on the floor. Being asked where were the pills, the child put her finger into its mouth. Witness found the pill-box empty on the drawers. Deceased afterwards had some broth, and then became very sleepy. She was taken to the surgery of Dr. Martin, at Walkden, where she died.

William Young Martin, physician and surgeon, said he found the deceased child perfectly comatose when brought to his house. The pupils of her eyes were contracted, and her skin congested—the chief symptoms of poisoning by a narcotic. He applied the usual means to restore her, but failed to give relief. The child's mother had informed him that half of one of the pills would "give the children a good night's rest," and assuming the deceased had taken ten of the pills he was decidedly of opinion that that number would be dangerous. A pharmaceutical chemist had analysed one of the pills which witness had received from Mrs. Thornley, and had stated that it contained opium. Witness considered that the sale of opium by persons ignorant of its effects to persons equally ignorant, without proper caution being given, was highly dangerous. He had doubt whatever that deceased had died from narcotic poisoning.

The jury returned a verdict that the deceased, being a child under the years of discretion, had died from the effects of poison inadvertently administered by herself. The jury recommended that the police be requested to call upon the man Crompton to inform him that they highly disapproved of his indiscriminate sale of the pills, and that they suggested he should discontinue the practice and destroy all the pills in his possession.—*Manchester Courier.*

POISONING BY CYANIDE OF POTASSIUM.

On Wednesday an inquest was held by Dr. Hardwicke, in the Farringdon Road, touching the death of Sarah Langley and her infant daughter. From the evidence it appeared that the deceased woman had herself swallowed some solution of cyanide of potassium and given some to her child, being unable to meet her husband after pawning some property without his knowledge. The husband is a silver polisher, and kept the poison in the house for the purposes of his business.

The Coroner, in summing up, observed that it was very careless to leave such dangerous poisons about, as they were great temptations to persons to make away with themselves, especially if under the influence of drink. The jury returned a verdict that Sarah Langley committed suicide while of unsound mind by taking cyanide of potassium; and that the child met her death by poison, administered by her mother, whilst of unsound mind.

Charge of Attempted Murder.

At the Hampstead Police Court on Monday Eugene Cousté, 41, mechanician, was brought before Messrs. Marshall, Faulconer, and Smith, charged on suspicion of attempting to murder his two children, Maria Cousté, aged three years, and Victor Cousté, aged two years and one month, by causing poison to be administered to them. Mr. Marshall asked prisoner, who is a Frenchman, if he understood the charge, to which he assented.—The evidence embraced the narration of circumstances attending the recent death of the children's mother.

Margaret Askew, wife of a police-constable, deposed that she lived at Hampstead, and knew the accused. He came to lodge with her in September, 1875, and was accompanied by a female who passed as his wife, and two children. The woman and the children were in perfect health when they went to witness's house. In July of this year the woman was taken ill with purging, and complained to witness very much at times of the diarrhœa. A little while afterwards she complained of sickness, and that she could not keep anything on her stomach, and of a loss of appetite. The woman also retched blood, about a pint of it a day. She suffered from the purging for about a month before the retching of blood came on. The purging was continuous, and witness sent for Dr. Prance but she did not remain long under his care. Neither prisoner nor the woman seemed quite to approve of his coming. Witness thought Dr. Prance saw the woman three times altogether. He came once before the retching, and then they sent for him when the retching of blood came. The illness continued, and the woman did not take any further steps for some time; then some one advised her to go to the hospital, and she went to the French Hospital, Lisle Street, Leicester Square. She had a card for the hospital on the 22nd of July. Witness thought she remained in the hospital the first time about a fortnight. Witness visited her during that time. Prisoner did not accompany her on the first occasion, but he did afterwards on one occasion. He had very little conversation with the woman in witness's presence—only asked her if she wished for anything. He always took a bottle of wine—a bottle of claret—with him. He did so on the occasion he accompanied witness. He spoke to the woman in French, which witness knew sufficiently to understand their conversation. He said, "I have brought you a little wine." When he gave her the bottle the cork had been taken out; he did not take the cork out in the hospital. Witness did not notice all that he used to say to his wife. Witness used to go away from the bed. He told the woman to hide the wine or put it away. She said she was allowed wine there, and prisoner said it would not be so good as what he brought her. The woman used to hide it with her clothes in a little stool by the side of the bed, and prisoner told her to mind it was not seen. They used to hide the empty bottles which they brought away. The woman left the hospital in August. After her return to witness's house she got worse, and remained an out-patient of the hospital for a fortnight. About the end of August she again became an in-patient of the hospital, and witness visited her there every week. She died on the 6th of September. The accused accompanied witness to the hospital on, she thought, three of her visits, and took wine with him on each occasion, the bottles being handed to the woman with the corks drawn as before. She appeared to witness to be getting worse and worse. Prisoner used to lean over the bed and they used to whisper. She only heard him ask her if she wished for anything. He appeared to be very kind to her. Witness felt sure that the medical people at the hospital did not know anything about this wine. Prisoner continued to reside in her house with the children. On the 2nd of October he went away, and gave her a bottle of medicine before going. Previous to that, on the 14th of September, he had given her one, which he told her was the remainder of what "Madame" had been taking before she went to the hospital. Prisoner told witness she was to give this medicine to the children to give them an appetite, and to strengthen their chests. He wished the children to have it half an hour before eating, twice a day. The children where not in good health up to that time—they were sickly. Witness said she did not think the children wanted the medicine, and prisoner said that if she did not like to give it them he would. When "Madame" went away they began to get this purging, the same as Madame had, and the little boy was taken quite off his feet. She told prisoner that she thought they had had too much, and he replied, "Excuse me, madame; but I know better than you. You have had no children. You don't understand minding them." She promised to give them some, and she did so on Sunday morning the 17th. Prisoner asked her if she had forgotten to give them the medicine, and she took the bottle into the room and gave them some. That was the only time. It was in prisoner's presence. Cousté said, "That's right; never forget to give it them." The children afterwards were purged and very fretful and did not sleep through the night. This came on in the evening when she was putting them to bed. They had not eaten much dinner, which consisted of roast beef, potatoes, and apple pudding. The next morning they were worse. She did not give them any more after that. She had seen "Madame" give it them, and they always suffered from diarrhœa afterwards. That made her reluctant to give it to the children. On the Friday morning after the Sunday witness herself was not well, and she thought as this medicine was for strengthening she would take some fasting, which she did. Again on Saturday she took some, and she was so bad during the day she could not stand up afterwards. She had seen prisoner put Peruvian bark into the bottle, but he always took it away to put the wine in. In the course of much further evidence the witness described the effects produced upon her husband by drinking half a tumblerful of what he thought was claret, which prisoner had left for her to add to the children's medicine, and which brought on violent purging in her husband. She led prisoner to believe that she continued to give the medicine to the children, which she did not during his absence from home for several days, and on his finding that the children were well he seemed surprised. At last he took them away in great haste, saying he was going with them to Paris; but she subsequently saw him and the children, the latter much altered for the worse, both bodily and mentally, in Clerkenwell. Some bottles left in her house were handed over to the police.

Superintendent O'Loghlen said that Professor Redwood, who would attend on a future occasion, had informed him that the fluid in one of these bottles contained poison.—Detective Sargeant deposed that on apprehending prisoner that morning he said the charge was a false one.—The prisoner was remanded till next week.—*Standard.*

Review.

The Quinology of the East Indian Plantations By John Eliot Howard, F.R.S., etc. Parts II. and III. London: L. Reeve and Co. 1876.

To say that the author is better qualified than any one else in this country to make authoritative statements upon all points connected with the subject of quinology, to which he has so long and ably directed his attention, is simply to express a fact that has long been recognized. The magnificent style in which the present work is got up, regardless of expense, renders it quite a work of art, while the importance of the information contained in it should lead to its finding a place in every scientific institution in the British Empire.

The present volume is a continuation of the one issued in 1869, and the pages and plates are numbered accordingly. It is divided into three sections. The first consists of information respecting the present state of the plantations in India, and is evidently intended as a completion of the volume previously issued. The second section, distinguished as Part II., contains botanical observations. Part III., which forms the third section of the present volume, comprises microscopical observations upon the bark of *Cinchona Ledgeriana*, and five Appendices presenting in detail the latest intelligence from India and Java.

From its arrangement the work must evidently be regarded rather as a complete history of the East Indian plantations since the year 1869, than as a condensed summary of the present state of our knowledge upon the subject.

The expensive character of the work renders it probable that many of our readers may be precluded from seeing much of the valuable information contained in it; we propose, therefore, to extract rather freely from its pages.

In the introduction the author points out that the "only commercially profitable investment of capital must be connected with the production of a superior description of bark, such as will continue to command a relatively high price in the market." In consequence of the quantity of inferior bark, which is yet suitable for the extraction of quinine, still imported from South America, the price obtainable for the lower qualities of East Indian bark is very low (from 5*d.* to 1*s.* 4*d.* per lb.), and does not repay the cultivator. Although the percentage of mixed alkaloids in red bark is often large, yet the quinine frequently forms but a small proportion of the whole and, there being but little demand for the other alkaloids, the bark is not one that is likely to prove a valuable speculation.

It was thought that, such being the case, it would be a saving to the Government if the mixed alkaloids were prepared in India on the plantations; but Mr. Howard states that the mixed alkaloids can be supplied by European manufacturers at half the sum which it costs to produce them in India. He then proceeds to recommend that the Indian Government should make more extended trial of cinchonidine and cinchonine (the alkaloids most abundant in red bark), which he considers have been proved, by the statistics he quotes, to be as valuable febrifuges as quinine, if given in somewhat larger doses.

The author gives *in extenso* a long and interesting letter from Mr. Charles Ledger, narrating the difficulties, dangers, and the loss of a considerable amount of money and several lives, attendant upon procuring the more valuable kinds of cinchona seed from South America. Mr. Howard emphasizes by italics, and rightly we think, the following sentence: "Surely after the success attending the seed sent by me in 1865, the government of India and that of the Netherlands should award me a sum of money commensurate with the importance and value of the service rendered." The only comment necessary upon this sentence is to state that the bark from the tree grown from Mr. Ledger's seed is now readily bought at Amsterdam by manufacturers of quinine at from seven to nine shillings a pound.

From the various chapters relating to the cultivation of the cinchona in Java we learn that the Dutch are likely to take the lead in the market for several years to come in the production of the finest and most valuable cinchona barks. This is owing partly to the fact that the climate is more favourable to the growth of the best barks, particularly of *Cinchona Ledgeriana*, and partly to the promptitude with which the resolution to grow only the best varieties was carried out, immediately the value of Ledger's seeds was discovered. At the present time there are in cultivation at Java the following kinds; *Cinchona Calisaya*, vars. *Anglica*, *Javanica*, *Hasskarliana* and *Ledgeriana* (the last variety yields from 5 to 10 per cent. of quinine and the *Anglica* from 2 to 5 per cent.); *Cinchona Pahudiana; Cinchona officinalis*, var. *angustifolia*, yielding five per cent. of quinine; *Cinchona lancifolia*; [*Cinchona caloptera; C. micrantha*, yielding a large percentage of cinchonine; and *C. succirubra*. Of these the *C. Ledgeriana* and *C. officinalis*, var. *angustifolia*, are by far the most valuable varieties. In the Java plantations the inferior varieties are being replaced by these two kinds as fast as commercial interests permit.

With regard to the species cultivated in the Indian plantations, the information supplied is very meagre when compared with that from Java; it may be gathered, however, from the body of the work, that *C. succirubra* and *C. officinalis*, with its varieties, *crispa*, *angustifolia*, *Uritusinga*, *Bonplandiana-lutea* and *Bonplandiana-colorata*, are the species chiefly under cultivation; while *C. Calisaya* (probably var. *Boliviana*) forms a smaller portion of the plantations, and *C. micrantha*, *C. Peruviana* and *C. nitida*, are cultivated only to a small extent. In fact the first importation of Calisaya bark from India, noticed by Mr. Howard, was offered for sale in London, on May 9, in the present year, and consisted of only 1000 lbs., while that of red bark, original and mossed, exported from India at the same time, was 45,000 lbs., and that of pale bark 20,000 lbs. These figures will give some idea of the relative proportion of the species at present cultivated in India.

Judging from the herbarium specimens received by Mr. Howard from Ootacamund, it would appear that the Calisaya does not thrive so well in the Indian plantations as in Java. Mr. Howard points out that the species most deserving the attention of cultivators are the following: *C. Calisaya*, var. *Ledgeriana*, of which the true plant does not appear to be cultivated, at present, in India; *C. Calisaya*, *β microcarpa*; *C. officinalis* and its varieties mentioned above; *C. Pitayensis*; *C. lancifolia*, *δ Calisaya*, Wedd. (the Calisaya of Santa Fé). The latter appears to be valuable from the fact that every shoot from a felled tree will quickly form bark of good quinine-producing quality, and hence promises a quicker return for the outlay of planting than any other species. He suggests that the Indian Government should employ the well-known collector, Mr. Cross, to procure seeds from South America.

Mr. Howard considers that *C. Pahudiana*, *C. Calisaya*, vars. *Hasskarliana*, *Javanica*, *Anglica*, and *C. caloptera* are likely to cause disappointment to cultivators.

In Ceylon the young plants of *C. officinalis* are planted so close together (4 by 4 feet) that the direct rays of the sun are excluded and the planter is enabled to dispense with the expensive process of mossing.

One chapter is devoted to the relative merits of coppicing and mossing trees, and from the statements made it appears that coppicing, which consists in cutting down the young trees about six inches from the ground, and leaving the shoots at the root, is not nearly so advantageous as mossing, many of the trees dying from excessive bleeding and the shoots not yielding marketable bark for about ten years. By the mossing process increasingly valuable bark is obtained every year. It appears from Mr. Mac Ivor's account that this operation is performed in the following manner:—The labourer proceeds to a tree eight years old (the bark separates best at this age) and makes a horizontal incision, usually about one and a half inch wide, as high up on the tree as he can reach, and then makes two vertical incisions down to the base of the tree, and seizing hold of the top of the strip thus marked out, taking care not to injure the cambium, he then pulls it off down to the root of the tree, where he cuts it off. The process is then repeated all round the trunk, leaving a space between each incision, rather broader than the strips which he has removed. He then at once proceeds to surround the trunk with moss, which is fastened round the tree with some fibre. The moss being kept constantly moist, in about three days the wound is covered over with a layer of new tissue. Each red bark tree of the above age is found to yield on the average 1¾ lb. of dried bark. In from six to twelve months the process is repeated, and the strips which were left at the first operation are now removed, so that at the end of the second operation the whole of the original bark has been removed, and future harvests must consist of "renewed" bark. The process is repeated every year, apparently without permanent detriment to the tree. It is a remarkable fact that the bark produced when the old bark has been removed is not only thicker in proportion, one year's growth being equal in thickness to two or three years' growth of the original bark, but contains a larger percentage of quinine, which increases after each operation; so that "renewed" barks fetch a much better price in the market than the original bark. The whole amount of the alkaloid is not increased, the tables showing that in proportion as the quinine is increased the cinchonidine, and in a less degree the cinchonine, are decreased in quantity, so that the total yield of alkaloid remains about the same.

With respect to these processes, Mr. Howard remarks that commercial experience has shown that mossing is the best treatment for *C. succirubra*, and that for *C. officinalis*, which grows more slowly, although mossing improves the quality of the bark, planting thick and thinning out in four or five years, may in some situations be the most feasible if not the most profitable arrangement. The bark obtained from coppiced trees abounds in colouring matter, and the bark from the smaller branches, as supplied by this plan, is comparatively barren in quinine. Indeed the only species for which coppicing appears to be suited is the Calisaya of Santa Fé.

The *C. Ledgeriana*, as being by far the richest quinine-producing bark known, deserves a few special remarks. It appears that the original seeds purchased from Mr. Ledger did not all yield the same valuable variety, and hence the Dutch chemist at Java concludes that they may have been the result of cross-fertilization. It has been found by experiment that hybrids thus formed partake in nearly equal proportions of the chemical characters of their parents, so that it has been possible to judge from the alkaloids found in the bark of what two species the plant was the offspring. It has also been shown that there is a tendency in such hybrids to revert to the type of one or other of the parent plants. Hence he concludes that if the Ledger seeds are hybrids, that it may be possible in two or three generations for this valuable form, *C. Ledgeriana*, to revert to an original type containing even 20 per cent. of quinine. For present purposes it is necessary to propagate extensively the best trees by cuttings. Singularly enough it has been found that the *C. Ledgeriana*, unlike *C. succirubra*, cannot be propagated from cuttings from the branches, but that if a tree is felled the shoots which spring from the stumps will strike readily.

It will naturally be supposed that in this bark, containing one-tenth to one-sixth of its weight of quinine the alkaloids must be visible to the eye, and such is the case. Under a lens the bark is seen to be speckled with white dots, particularly in the cellular portion just outside the liber. That these can be seen in the form of crystalline nodules in a microscopical section, and that the crystals exist in the bark and are not formed by the liquor potassæ in which the sections are soaked for a minute to remove colouring matter, is strongly insisted by the author, contrary to the opinions of Berg, and the authors of 'Pharmacographia.' He is supported in his opinion by Mr. Broughton, who says that the crystals in red bark are unmistakably those of cinchonidine.

Another fact worthy of remark is that the *C. Ledgeriana* is a trimorphic plant, having three forms, in one of which (macho form) the stamens are prominent in the throat of the corolla, the pistil being situated entirely below the anthers; in the second (hembra form) the stigmas are prominent in the throat of the corolla, the anthers being below the stigma, and in the third form the pistils and anthers are on the same level. In the first the leaves are purplish underneath, in the second, green, and in the third, green with red veins. These features are well shown in the magnificent coloured lithographs, by Fitch, at the end of the work. The masculine or feminine element does not appear to have any influence upon the production of alkaloids.

The crown barks, derived from varieties of *C. officinalis*, come next in value to the *C. Ledgeriana*, the varieties *Bonplandiana, lutea*, and *angustifolia* appearing to be the richest in quinine. All of them yield an increasing amount of quinine in the renewed bark, but the trees have the disadvantage of growing rather slowly. Altitude appears to have some influence upon their yield of quinine, the amount of alkaloids becoming less below 6500 feet, and instead of quinine, cinchonidine and quinidine are produced, as well as resin, which hinders the crystallization of the alkaloids. In *Cinchona Peruviana*, also, Mr. Broughton found that, although at 6000 feet it yielded no crystallizable quininine, at 7800, feet it yielded much beautifully crystallized sulphate of quinine almost as readily as the *C. officinalis*.

Mr. Howard evidently does not hold the theory of evolution, or at all events does not apply it to the cinchona genus. He accepts instead the views of Mr. Jordan, that every so-called species in those districts where it may be said to have its home, or in other words, is found most abundantly and luxuriantly, exists in several forms, diverging as it were from a common centre, the forms belonging to one centre being connected by intermediate links with those of another centre. He looks upon all these forms as possessing equal permanency and as indefinitely producing their like. These forms he distinguishes from accidental hybrids by their chemical characteristics, hybrids giving alkaloids representing in tolerably equal proportions both the parents, while the forms give only the alkaloid of the group to which they belong. He considers that in this very natural but difficult genus "permanence, rather than insensible variation and the gradual transformation of species, is that which meets our view." In proof of this he mentions the fact that *C. officinalis* yields bark which is not only identical in the fourth generation with that which he received from Uritusinga in 1859, "extending to the minutest characteristics of a bark which can be distinguished at sight from the other form of *C. officinalis*, but is also the same with that gathered by Pavon 100 years before." Its yield of quinine has, however, been improved by mossing.

Facts seem to show that, as in human beings, the grandson or great-grandson will strongly resemble the grandfather or great grandfather, rather than the immediate parents, so in these trees there will occasionally occur, without any apparent reason, variations in different generations marked by a subsequent return in the descendants to the original type.

It yet remains to be proved whether the method of propagating the best forms by cuttings may not lead ultimately, as it has done in the case of the potato, to diminished vitality, and consequent disease. Further experiments are also needed to show whether the bark will be indefinitely enriched in quinine by mossing, or whether there is a limit in the age of the trees beyond which it will begin to diminish.

Several interesting facts, in a botanical point of view, have been discovered in the course of experiments in the cinchona plantations. Mr. Van Gorkom, of Java, grafted two Calisayas upon two Pahudianas, and the grafts succeeded well. Upon examination of the bark it was found that the *C. Pahudianas* as well as the Calisayas, kept their alkaloids as if they had grown separately.

When bark has been stripped off the tree, the wound if exposed to the air forms new bark from the edges, if covered with moss, however, new bark is produced simultaneously from the whole of the wounded surface. In either case, the original bark surrounding the wound does not yield a diminished quantity of alkaloid. From these and other experiments taken in connection with the fact that the alkaloids have been found to be more abundant in the living cellular tissues of the bark than in the liber, Mr. Howard draws the inference that the alkaloids are formed in the cells in which they are found, and that they are probably formed at the expense of the cinchotannic acid. This opinion appears to be borne out by the fact that the leaves contain only a very small proportion of the alkaloids.

Another fact which has a bearing upon the variation from so-called types in this difficult genus is the alteration of a plant during different stages of its development; thus a tree which for six months has had the habit of *C. Uritusinga*, will suddenly begin to have shorter leaf stalks and leathery leaves and begin to look like *C. crispa*.

The latest intelligence from Java states that there are 50 to 60 trees averaging 10·91 per cent of sulphate of quinine in the bark, all blossoming and seed-bearing trees, and that the Ledgeriana trees began to blossom freely last December, so that by this time there must be a plentiful supply of excellent seed.

The latest news from India informs us that some plantations of red bark at Darjeeling are to be rooted up and tea cultivated instead. The Calisaya imported this year from India was little more than half as rich as the Ledgeriana and is probably, Mr. Howard believes, the produce of a fine sort of Bolivian Calisaya.

It is evident from the valuable information contained in this volume that the wisest policy of Indian cultivators is to follow as speedily as possible the example of the Dutch in Java, *i.e.*, to cultivate only the cinchonas yielding a large percentage of quinine and which are suitable to the climate. Those who yet cherish the hope of making quinine artificially will find a mine of valuable hints, drawn from the laboratory of nature, in this work. The only point that we regret is that the absence of a good index and the want of grouping the information makes it very difficult to find out any particular point in which the reader may be interested. The splendid plates at the end of the work will enable the cultivator to recognize without any difficulty the true *C. Ledgeriana* in its different forms as well as the other more valuable kinds of cinchona which Mr. Howard recommends to the notice of the East Indian Government.

BRILLIANT COLOURS FOR SHOW BOTTLES.—A correspondent of the *Druggists' Circular* recommends the following:—

Red Colour.

Cudbear	2 ounces.
Sulphuric Acid	2 „
Water	2 gallons.

Macerate the cudbear and the acid six or eight hours, add the water, and filter.

Purple Colour.

Cudbear	2 ounces.
Ammonia	8 „
Water	2 gallons.

SALICYLIC ACID AS INDICATOR IN ACIDIMETRY.—According to H. Weiske, a convenient quantity of salicylic acid is dissolved in distilled water, the solution filtered, and a few drops of solution of ferric chloride are added. To the intensely coloured solution a very dilute soda-solution is carefully added, until the exact point of neutralization is reached, when the liquid assumes a reddish-yellow colour. In titrating an acid, if a few cub. centim. of this solution be added, the liquid remains in the beginning colourless; but in proportion as the acid becomes gradually more and more neutralized by standard alkali solution, the violet tint increases, until just before neutralization it assumes the greatest intensity, while all colour suddenly disappears at the slightest excess of alkali. According to the author, this method permits a much more delicate titration than any other, principally because the transition from intense coloration to colourlessness is so rapid and decisive, without intermediate tints.—*New Remedies, from Zeitsch. f. anal. Chem.*

[529]. OL. VIRIDE.—Will any reader favour me with a ready formula for Ol. Viride—not the one made from the green herbs, etc.? I believe there is a way of making it for veterinary use by mixing Ol. Lini and Verdigris. It is such a one that I want.—J. S. W.

[530]. INDIA RUBBER CEMENT.—"Bicyclist" is desirous of obtaining a recipe for an India Rubber Cement suitable for fastening the india-rubber tyres on bicycle wheels.

[531]. PHOSPHORIZED COD LIVER OIL.—Can anyone oblige me with a formula for Phosphorized Cod Liver Oil?—F—x.

[*** The following appeared in the *Lancet* for June 3rd last.—ED PHARM. JOURN.]

"Take of pure unoxidized phosphorus, two grains; almond oil, two ounces. Put into a bottle, stopper it, and immerse the same in a water-bath; apply heat until the temperature of the oil is about 180°, as directed by the British Pharmacopœia in the preparation of oleum phosphoratum; shake up occasionally, and put the bottle again into the water if necessary until a perfect solution is obtained; then add about ten ounces of cod-liver oil, and again immerse in the water-bath; finally make up the measure with cod-liver oil to twenty-five ounces. One drachm so prepared will contain over one-hundredth of a grain of pure phosphorus."

THE SESSIONAL PRIZES.

Sir,—At the meeting of the Council last week a discussion took place on the advisability of altering the existing conditions of competition for the sessional prizes in the Society's school.

Being a student in the school and feeling an interest in the subject, I should like to make a few remarks thereon.

In the first place, I would ask, why alter the present regulations? No reason, as yet, has been given for altering a custom that hitherto, apparently, has worked well.

The question has been raised that it is unfair to allow a second year's man to compete with a first year's man for these prizes. I fail to see the injustice. I believe these prizes are awarded for proficiency in the various subjects taught in the school, therefore if those students who have attended the longest were ineligible to compete, it is obvious that the most efficient man may be prevented from obtaining a prize. It may with as much justice be said that a man who studied six hours daily competed unfairly against a man who worked two hours only.

There are various points that ought to be considered before an alteration is attempted. I would especially mention the relative position of the students as regards their period of studying.

Some have the whole day to work at the subjects which the students require to know; others, and by far the majority, have but two or three hours daily. It is simply natural that a person in the latter position would require a longer period of study than the former would require. In short, what the former would accomplish in ten months, the latter would only accomplish in twenty months or more.

Mr. Hanbury mentioned the fact that at medical schools second year's men were not allowed to compete against first year's man. This is so; but I fail to see the connection between the two cases; in the one, attendance is compulsory, in the other, purely voluntary. I believe even in medical schools fifth or sixth year's men are not prevented from competing with a second or third year's man.

Two or three years since, Dr. Attfield deplored the fact that students did not work in the laboratory long enough to be able to devote their time to original research. Is this not owing in some measure to the regulation prohibiting second year's students from competing for the laboratory prizes?

If there is an injustice in the present conditions, it is in the competition for the lecture bronze medals; in this case a student obtains a higher prize for an easier examination.

I would ask the opinion of the professors on this subject. I may say from experience that very few students would either take perpetual tickets, or enter for a second session if the only inducement for them to do so were taken away.

Should the Council think it advisable that a change should be made, surely some other prizes ought to be instituted to act as levers to urge on students to attain that high degree of education which the Council so much desire.

AN INTENDED SECOND YEAR'S STUDENT AT THE SQUARE.

London, Nov. 7, 1876.

DANGEROUS GREEN FIRE.

Sir,—Mr. West has done well in mentioning his experience with the formulæ he has alluded to, and his letter may be the means of averting many serious accidents, especially amongst the young and inexperienced in the trade. The percentage of sulphur, in my opinion, being most dangerous, rendering even the incorporation of the ingredients (if done in a mortar without extreme caution) not free from peril.

I have for some time made this subject a study, and now prepare colours for every purpose in which they can possibly be employed, and in most instances, excepting where the proportion of sulphur is reduced to an infinitesimally small quantity, or in others where cheapness is an object, I dispense with its use altogether. It is impossible to obtain a good green without the use of potassæ chlorat. and the preparations of baryta, but sulphur, the source of mischief, is not an absolutely necessary ingredient in producing this colour.

I shall be happy to supply (free of cost) your correspondent with a recipe that I think will please him.

J. R. P.

Newnham.

Mr. West writes again in relation to this subject that from what he has experienced in the making of coloured fires he has come to the conclusion that if fires containing a nitrate and a chlorate are placed in closed vessels in a fair quantity, they are very liable to self-combustibility (especially if in the slightest degree damp?), but if left quite open as in paper bags, etc., are comparatively safe.

THE DISPENSING OF COPAIBA RESIN.

Sir,—To dispense elegantly the mixture of copaiba resin, mentioned by Mr. Greenish in his paper of the 1st inst., the addition of sugar of milk and more spirit is, I think, unnecessary.

The following method of mixing I find satisfactory:—

Powder the resin of copaiba with about 1½ drachm of powdered gum arabic. Add the spirit and triturate till quite smooth. Add now the remainder of the powdered gum, 3½ drachms, so as to form a thick paste. Continue the trituration, and add gradually the water.

LEONARD J. READE.

3, Lower Parade, Leamington.

TOUGHENED GLASS MEASURES.

Sir,—The experience of your correspondent "A Country Member" quite coincides with my own. Reading the advertisement of "Toughened Glass," and delighted above measure at the prospect of fewer breakages, I ordered a quarter of a dozen in order to test their value; but alas! only to be "disappointed still and still deceived." Exclaiming, like the man of old, "Eureka!" I let one fall on a well carpeted board floor about two feet, to see it dashed to atoms, not merely broken but as if crushed to tiny fragments. Clearly I think Toughened Glass may be a profitable novelty for the glass manufacturer but is not yet a boon to the poor chemists.

ANOTHER (DISAPPOINTED) COUNTRY CHEMIST.

Kidderminster,
November 6, 1876.

M. P. S. (who is referred to the rule respecting anonymous communications).—We cannot advise you upon the subject.

"*Syrupus, P.B.*"—We are not aware that any site has been definitely fixed upon.

"*Compositæ.*"—*Erigeron acris.*

G. A. Redford.—Coralline is a preparation of rosolic acid, obtained by the oxidation of carbolic acid.

W. E. Paul.—"Gasaline" is one of the numerous names for petroleum spirit.

E. J. H. Thring.—We are afraid that nothing can be done to restore the colour. Why not try the plan you mention?

R. H.—Griffin's 'Chemical Testing of Wines and Spirits'; Bolley and Paul's 'Manual of Technical Analysis.'

Réa.—If made carefully in a water-bath it scarcely becomes coloured at all but retains its whiteness.

H. Clift.—Probably the brown colour was due to the liberation of bromine by some free benzoic acid present in the lard.

Mr. Wilkinson (Manchester) is thanked for his communication.

COMMUNICATIONS, LETTERS, ETC., have been received from Mr. Thresh, Mr. West, Apprentice, Viator.

"CHICLE" GUM AND MONESIA BARK.

BY JOHN R. JACKSON, A.L.S., CURATOR OF THE MUSEUMS, KEW.

So long ago as 1839 an article was published in the Paris Medical Gazette on a vegetable substance from South America, known as Monesia. This article was reprinted in the *Pharmaceutical Journal*, vol. iii. (1843–44), p. 292. It pointed out that *Monesia*, as then known, was in the form of hard thick cakes, covered with yellow paper, each weighing about 500 grammes; and in this form it was, at the date given above, a recent introduction into France. The substance consisted of an extract prepared from the bark of the tree, the botanical source of which was at that time unknown, though it was supposed to be a species of *Chrysophyllum*. It was known, however, to travellers as *goharem* or *buranhem*. The bark was described as smooth and greyish, in appearance like that of the plane tree but much thicker, showing an imbricated fracture and having a sweet taste. The extract was in colour deep brown, very friable, and when broken having the appearance of a well roasted cocoa nut, entirely soluble in water, at first sweetish to the taste, like liquorice, but afterwards becoming astringent, leaving a well marked and lasting acid taste in the mouth, which is particularly felt in the tonsils. The uses to which Monesia was put were diarrhœa, leucorrhœa, uterine hæmorrhage, inflammation of the mucous membrane, etc. Such is a brief *résumé* of what has already been published on Monesia, which will be found in detail at the reference given above as well as at pp. 125 and 187, vol. iv. (1844–45) of the *Pharmaceutical Journal*, the latter being a quotation from the 'Systema Materiæ Medicæ Vegetabilis Braziliensis.' In this the plant is referred to as the *Chrysophyllum Buranhem* of Riedel.

Quite recently the plant has been brought to notice again as the probable source of a gum or gum-resin, known as "Chicle" in New York, whence it is imported from Mexico for manufacturing purposes such as mixing with rubber for insulating telegraph cables. Some experiments have also been made with it with a view of manufacturing a paint for the bottoms of vessels, besides which an essential oil adapted for perfumery purposes can, it is said, be extracted from it. A specimen of this Chicle Gum has recently been received at the Kew Museum. In appearance it is somewhat like crude gutta percha but more friable or brittle. It is easily made plastic in warm water, but from experiments made in this country it does not seem suitable for mixing with india rubber for telegraphic purposes as it makes the rubber itself more birttle. Besides the name of Chicle the substance seems to be known in the New York Market as "Mexican Gum" and "Rubber Juice." The identification of this gum with the plant yielding Monesia is founded as yet only on the fact that the plant yielding the former is known as Zapota or Zapote and is described as a sapotaceous tree, and further that it yields a medicinal product known as Monesia. Specimens of the plant itself have not yet been received, therefore though all the circumstances indicate them to be one and the same thing it cannot be decided as a certainty until the reception of actual specimens yielding Chicle Gum.

With regard to the Buranhem or Guaranhem of Brazil, which is also known as the Imiracem, Mohica, and Cusca doce (sweet bark), it is conclusive that the plant furnishing them is the *Chrysophyllum glycyphlœum*, Cazar. (*C. Buranhem*, Riedel). It is one of the commonest trees in Brazil, and is met with even in the environs of Rio de Janeiro, where Cazareth studied it (on the Corcavado), as well as Velloso and Peckholt in Cantagallo. Both in the provinces of the north as well as in the Antilles, it is well known and employed in medicine and in veterinary practice. The bark is carried to market in fragments of from two to three millimetres thick and five to twenty centimetres in length. It is of a red or brownish colour, according to the season in which it is gathered and according to the age of the plant. When recently collected the bark is abundantly milky and has a strong astringent and sweetish taste.

Monesia, as now met with, presents under the form of transparent plates of a yellowish white colour a substance easily pulverized. When reduced to powder it has a white colour. It is soluble in alcohol and in water, but barely so in sulphuric acid. When put into water and shaken it produces a froth like soap-suds. In Brazil the preparations of the bark of this plant are used both internally and externally. It is considered an excellent astringent, applied in the same cases as the ratanhia. In Bahia, Leigipe and sundry other provinces it is the usual medicine for cases where an energetic astringent action is required. The preparations employed are—the decoction for baths and clysters; the extract for pills and to put on cataplasms, and the syrup or wine. The disorders in which this medicine is most efficacious are diarrhœa, intermittent fevers, dysentery, hæmorrhage, ulcerations of the mucosus gastro-intestinal canal, quinsy, etc.

With regard to the physiological action of Monesia, it is said that, notwithstanding its sweetish taste, it belongs strictly to the astringents and tonics. Its astringency becomes less sensible by the presence of the saccharine principle contained in the bark. On ulcers it produces a sensation of pain accompanied with great heat which lasts for hours and sometimes even for days afterwards, accompanied with a rapid formation of numerous fleshy pimples. On the fibres of the uterus it acts with the same effect as ergot of rye.

Monesine, the acrid principle, is applied in doses of 1 to 3 decigrams. The syrup has a great reputation against hæmoptisis, the extract in ulcerations of the mouth and the mucosus gastro-intestinal canal, as has already been said. Externally the extract, either with glycerine or pure, is considered very efficacious for wounded breasts, lips and arms; the powder is also used for similar purposes. With regard to the industrial applications of the bark of *Lucuma glycyphlœum* it is, on account of its astringency, used both for tanning leather and for dyeing purposes; further than this, it is said to contain a quantity of saponaceous matter which might be employed for cleaning, but which does not seem capable of development to any extent so as to make it commercially profitable.

The foregoing remarks on the products of *Lucuma glycyphlœum*, or Monesia, are abstracted from a report recently drawn up for the Brazilian Government by some of the best authorities on the subject. Although Monesia is not now used in Brazil so much as formerly it still has a reputation.

PHARMACY IN MALTA.

BY ROBERT WATSON.

Having returned from a stay of six months on the island, I thought a few words regarding the course of study required before a dispensary can be opened there would interest some of the readers of the Journal.

The course of study extends over a period of five years; the studies are conducted at the University.

First year.—Botany and Mathematics.

Second year.—Inorganic Chemistry, Zoology, and Natural Philosophy.

Third Year.—Natural Philosophy continued (an examination is held of the above studies, including English and Latin languages and Geometry).

If the student be successful he enters on the fourth year, which is devoted to Organic Chemistry.

Fifth year.—Materia Medica, and Medical Botany.

If the examination is passed at the end of the term he receives his licence to practise as an apothecary.

Any person holding the Minor or Major diploma who wished to open a dispensary in Malta would be obliged to write to the Chief Secretary of the Government to call a Medical Board, at which he would be examined in chemistry, pharmacy, and prescriptions, and would have to produce his Certificate of Registration by the Pharmaceutical Society. The fee for the licence is £1, payable at the Chief Secretary's office.

The dispensaries are owned by Maltese, except one, which is kept by Mr. Kingston, he being the only English chemist on the island. The shops have no windows, the door giving both light and entrance; it is built in the form of an arch. The fittings are very nice, principally French. There is only one counter, which is placed at the end of the shop, not touching on either side; shelves are placed all round, and to an Englishman the absence of glass cases, fancy articles, etc., is very striking, the English dispensary, which is fitted quite in home style, being the only exception. The prescriptions written by the Maltese doctors are in Italian principally; some are novel to the English dispenser. I give one, a favourite purgative—

℞ Ol. Ricini . . . . ℥j.
Ol. Amygdal. dulc. . ℥ss.
Syrup. Anthem. . . ℥ij. M. ft. Haust.

The hours of business are from 7 A.M. until 9 or 10 P.M. In the heat of the day the shops are closed for one or two hours. The prices for patents, perfumes, etc., are the same as in England. As for mixtures, etc., the Maltese cut them very fine. All the drugs are obtained from France and Sicily.

As regards the drug products, orange flower water is made in small quantities; also oil of neroli, which is very thick and dark. Almond oil is pressed, but in so small a quantity as not to be worthy of notice. Rose water is obtained from Tripoli.

THE BEHAVIOUR OF SOLUTIONS OF SOME SUBSTANCES TO POLARIZED LIGHT.*

(*Continued from p.* 192.)

BY O. HESSE.

Milk Sugar.

For milk sugar a double rotatory power has been observed. The fresh solution prepared cold, according to Dubrunfaut,† rotates $\frac{5}{3}$ times stronger to the right than one that has stood a longer time at a moderate temperature, or has been boiled. If the latter solution be left to evaporate, it does not deposit crystals, according to Dubrunfaut, before it acquires a specific gravity of 1·063. The solution then contains 21·64 per cent. of sugar, which consequently must exist in a modified form, as 85·45 parts of water at 10° C. only dissolves 14·55 parts of sugar. The modified sugar, therefore, distinguished as β, dissolves $\frac{3}{2}$ times as easily as the crystallized or α milk sugar. According to E. O. Erdmann‡ for the β modification $\alpha j = +56{\cdot}4°$.

Milk sugar deposits from its solution in water as well as from alcohol always in combination with one molecule of water; it may probably be assumed, therefore, that it exists in the respective solutions in similar combinations. The water of crystallization is not given off in the exsiccator at a temperature below 130° C. Analysis gave the following result:—

	Calculated for $C_{12}H_{22}O_{11} + H_2O$	Found I.	Found II.
H_2O ...	5·00	4·96	4·86

For the optical examination the sugar was finely powdered, dissolved in water, without heat, and the solution at once examined. It then gave:—

Ia. $p=2, l=220, \alpha=+3{\cdot}55°$, consequently $\alpha j=+80{\cdot}68°$.

IIa. $p=3, l=220, \alpha=+5{\cdot}26°$, consequently $\alpha j=79{\cdot}70°$.

After standing 52 hours—

Ib. In the same proportion as Ia., $\alpha=+2{\cdot}36°$, consequently $\alpha j=+53{\cdot}63°$.

IIb. $p=3, l=200, \alpha=+3{\cdot}19°$, consequently $\alpha j=+53{\cdot}16°$.

Solutions prepared at 60° C, and kept 5 hours at that temperature gave—

III. $p=5, l=200, \alpha=+5{\cdot}82°$, or $\alpha j=+52{\cdot}90°$.

IV. $p=12, l=200, \alpha=+12{\cdot}64°$, or $\alpha j=+52{\cdot}67°$.

The latter four solutions contained the sugar in the β modification. It is apparent that the rotatory powers of the two modifications do not stand to one another as 8:5 but 3:2; consequently in inverse proportion to the solubility of the two forms. This the author explains as follows. A freshly prepared solution of milk sugar saturated at 10° C. contains in 100 parts, 14·55 parts of sugar. In these proportions the molecules of sugar fill the given space so perfectly that any further molecules of sugar added to the solution find no more room to dissolve. By boiling, as well as by standing, there results a contraction in the building up of the molecules, so that the volume of each molecule is reduced to two-thirds of its original expansion. The solution is then only two-thirds full, so that a further one-third part of substance in the same condition may find place in it. A light ray which passes through the volume of the first form must travel a path one half longer than when it passes through the β form, and correspondingly in the first case it is more strongly affected by one-half than in the other.

According to this view the volume of the molecule would have an influence upon the rotatory power.

Within the limits of $0p$ and $12p$ the rotatory power of

* Abstract of a paper in the *Annalen der Chemie*, vol. clxxvi., p. 95.

† *Chem. Centralblatt*, 1856, 233.

‡ *Jahresbericht f. Chemie*, 1855, 671.

the β-form of milk sugar in aqueous solution at 15° C. can be calculated according to the following formula:—

$$\alpha j + 54{\cdot}54 - 0{\cdot}557\, p + 0{\cdot}05475\, p^2 - 0{\cdot}001774 p^3.$$

The α form through its instability presents difficulties to an estimation of its rotatory power. The greater p is, the greater is the lapse of time before it is all dissolved, and a trustworthy result is excluded. How much time influences the result is shown by the following:—A solution containing $p=2$ was made in the cold, but was not examined until after the lapse of half an hour, when $\alpha j = +75{\cdot}63°$ was found. With $p=3$, under the same conditions, $\alpha j = +73{\cdot}74°$ was found. Finally, a solution containing 2 p examined after two hours gave $\alpha j = +65°$.

To ascertain whether the sugar rendered anhydrous at 130° behaved in this manner, a quantity of it was taken corresponding with 3 p of hydrated sugar. Upon pouring cold water upon the sugar it caked together somewhat, evidently through the absorption of water. After standing two hours the solution gave, with $l=220$ a deviation of $+4{\cdot}18$, or $\alpha j = +63{\cdot}34$. So that it was clear that the anhydrous sugar was by contact with water restored to its former molecule, and now existed in solution like ordinary sugar.

The alkalies depress the rotatory power of milk sugar. A solution of p 3 in water containing one molecule of Na_2O gave $\alpha j = +45{\cdot}45°$, and after 24 hours, $\alpha j = +12{\cdot}57°$. Solutions of both the α and the β forms behaved similarly in this respect, so that the author concludes that only the most soluble modification of milk sugar can be contained in alkaline solution. This sugar is met with in milk in the same form.

Glucose.

Under the name glucose is understood, as is known, the crystallized grape sugar. It has been thought that the sugar actually occurring in the ripe grape, as well as the sugar which is obtained by decomposition of several organic substances, and has the same composition as crystallized grape sugar, are also identical with it. Biot has, however, stated* that the substances which are usually called glucose, or grape sugar, in respect to their optical behaviour do not quite agree with one another. The author, therefore, examined glucose of varying origin.

As a characteristic of the hitherto examined substances it is remarked that they have the composition represented by the formula $C_6H_{12}O_6 + H_2O$, and can exist in two modifications, namely, an amorphous or easily soluble form, which possesses a definitely lower rotatory power, and in a crystalline, or difficultly soluble form, in which the rotatory power is double as great as in the amorphous form. Consequently conditions are met with here similar to those occurring in milk sugar.

a. Honey Sugar.—Bees separate this sugar only in the soluble modification, according to Dubrunfaut, mixed with fruit sugar, cane sugar, and other substances. Not till after some time is this sugar converted into the other modification, the honey becoming gradually hard or crystalline. Naturally only the older crystallized honey is suited to the preparation of this kind of sugar. This was spread out between blotting paper, in order to separate the liquid portion as much as possible; then the nearly hard mass was dissolved in alcohol, the solution treated at a boiling temperature with hydrochloric acid to remove any cane sugar present, the alcohol, and at the same time the greater part of the hydrochloric acid, driven off by exposure in a flat-dish to a gentle heat, and the syrupy but still acid residue stood in a cool place to crystallize, which it did in a short time. The crystalline mass was washed with alcohol, and again spread out between blotting paper. The hard mass was then triturated with alcohol to remove yet adhering hydrochloric acid, the fine paste drained upon a filter, and treated from time to time with some stronger alcohol. After a subsequent recrystallization of the sugar from water it was perfectly free from hydrochloric acid. But as the sugar had still a slightly yellowish colour it was dissolved at a moderate temperature in a little water, and the syrupy solution treated with animal charcoal, after which the sugar separated quickly from the perfectly colourless solution in dazzling white aggregated crystals. After washing with alcohol the crystalline mass was first dried in the air between blotting paper and afterwards in the exsiccator.

Honey sugar prepared from old honey without using hydrochloric acid possessed exactly similar properties as that prepared as described. The inference drawn by the author is that the honey used contained no noticeable quantity of cane sugar, and that probably cane sugar is present in honey only under abnormal conditions.

The honey sugar thus obtained is dazzling white and forms hard warty clusters of crystals, consisting apparently of short prisms.

In the exsiccator this sugar lost no water at the ordinary temperature. But when the temperature rose to 70° C. the water of crystallization was given off except a small quantity, which finally separated at 95° C. At this temperature the sugar did not melt. The amount of water separated amounted to 9·1 per cent., the quantity required for one molecule being 9·04 per cent. At 100° and even at 110° C. the dried sugar showed no further loss. But if honey sugar be very rapidly heated it melts, and then only an unsatisfactory result is obtained relative to the amount of water of crystallization. Melted in a fine tube the author's specimen melted at 82° C. (uncorrected); Smith gives the melting point as 86° C. (corrected).

Optical experiments were made with the crystalline form (α), and the amorphous modification (β). In the former case the solution was examined immediately upon being prepared, and in the latter after twenty-four hours. If the solution were warmed it could be examined for the β-form at once. The α-form showed a rotatory power extending from $\alpha j = +91{\cdot}81°$ to $\alpha j = +91{\cdot}75°$; the β-form varied between $\alpha j = +50{\cdot}00°$ for $p=1$ and $l=220°$, to $\alpha j = +46{\cdot}34°$ for $p=12$ and $l=100$. Here also the rotatory power decreased with the increasing concentration.

The α-form is very unstable in aqueous solution showing a greater rotation at the commencement of the experiment than even at the end of the few minutes during which it lasts.

A comparative experiment was made with an acid solution, $p=3$, water containing equal to six molecules of HCl being used as a solvent. When examined directly it gave $\alpha j = +68{\cdot}50°$; after twenty-four hours $\alpha j = +47{\cdot}17°$, this latter being almost the same result as obtained with the aqueous solution.

An alcoholic solution, in which $p=3$, and the alcohol amounted to 73 per cent. gave, when examined immediately, $\alpha j = +93{\cdot}93°$; after twenty-four hours αj had sunk to $= +52{\cdot}88°$; after another twenty-four hours to $\alpha j = +49{\cdot}69°$; after this there was but a slight further decrease. Alcohol of medium strength would therefore appear to retard the change of the α-form of honey sugar into the β-modification. But if very strong alcohol is used the α-form goes into solution without altering to the β-form, whilst water separates and the sugar becomes anhydrous. The best way is to treat the sugar first with 60° to 70° alcohol, and afterwards with boiling absolute alcohol, when it forms four-sided, apparently right-angled prisms, which show no loss when heated to 110° C.; at 135° C. the crystals soften, and in a fine tube melt at 144°. When dissolved in water these crystals pass at once into the ordinary hydrated state, and after a time crystallize in that form. These crystals at 100° C. lose equal to one molecule of water. When this material was used for the optical test, for the α-form $\alpha j = +101°$; for β-modification $\alpha j = +51{\cdot}70$; being higher results than those previously mentioned.

* *Comptes Rendus*, vol. xlii., p. 351.

b. Grape Sugar.—The ripe grapes contain this sugar only in the β-modification, mixed with a larger quantity of fruit sugar, for which reason grape juice rotates a beam of polarized light to the left. But if dried and preserved for some time a portion of the fruit sugar disappears, and a deposition of the grape sugar goes on, so that not unfrequently the dried grapes become covered with a white coating of crystallized sugar. The author used only grape sugar prepared from dried grapes. These were soaked in lukewarm water, and after swelling were crushed, and the fluid portion concentrated. The syrupy residue was boiled with strong alcohol, the alcohol removed from the separated clear solution, and any tartaric acid still present removed with chalk. Upon then sufficiently concentrating the faintly acid filtrate the grape sugar very soon separated out, and was spread out between filter paper to remove adherent viscous matter. It was then twice recrystallized from water, the second solution being treated with animal charcoal, when it was obtained in beautiful aggregated crystals, resembling in external appearance honey sugar. The air-dried substance heated to 105° C. lost altogether 8·95 per cent. of H_2O (1 mol. $H_2O = 9{\cdot}04$ per cent.). The sugar melted in a fine tube at 82° C. It was rendered nearly anhydrous by 70 per cent. alcohol, and if then dissolved in boiling 97 per cent. alcohol, the anhydrous sugar crystallized out on cooling; it resembled externally the anhydrous honey sugar, and also melted at 144° C. Optically examined the hydrated sugar gave for the α-modification $aj = +94{\cdot}5°$; for the β-modification $aj = +47{\cdot}87°$; for the β-modification when the anhydride was used, $aj = +51{\cdot}78°$. The author concludes that these results show grape sugar to be identical with honey sugar.

(*To be continued.*)

THE DRUG WAREHOUSES OF THE EAST AND WEST INDIA DOCK COMPANY.

A very interesting article in the *British Trade Journal* for November is devoted to the description of the warehouse accommodation provided in London by the East and West India Dock Company, for the convenience of the merchants, brokers and buyers concerned in the foreign produce imported by the vessels using the docks. We extract from it the following paragraphs relating to the drug stores:—

"The warehouse in Billiter Street is set apart for the storage of the most valuable articles of importation, such as the finer drugs, ivory, feathers, china ware, etc. In the drug department one sees such costly articles as musk, vanilla, ambergris, and the various kinds of essential oils undergoing manipulation. Each package of musk is carefully sorted, and every individual pod subjected to close scrutiny, for Ah Sing has a peculiar knack of deftly introducing different foreign substances into the pods and closing them up again. Some mysterious compound known as 'Chinaman's Earth' is a favourite adulterant of this highly-priced natural perfume. Ambergris, a peculiar secretion of the sperm whale and the base of many scents, was not a great number of years ago accounted worthless, but as much as five guineas an ounce has since been paid for it. Essential oils occupy an important place in the drug warehouse. We noticed a large vat for the reception of cassia oil, capable of holding 206 gallons. This oil has to be turned out of its original packages and "bulked," or mixed together, buyers being chary of investing in an article which exhibits very unequal quality. . .

"In Fenchurch Street is the greatest drug store, perhaps, in the world, and here also are worked and warehoused such leading import staples as silk, tea, cigars, etc. . . . While, as already mentioned, the finer sorts of drugs find their way to Billiter Street, it is to this place that the great staples are diverted. The stowage capacity is immense. Rooms upon rooms, and cellars of vast extent, are crammed to overflowing with the medicinal produce of many climes, and the money value of the drugs here accumulated is little short of fabulous. Articles like jalap, ipecacuanha, and aloes, are stored in separate rooms, fitted with tiers of racks for the reception of the packages. Of ipecacuanha root alone the stock is valued at 6000*l.*, and it not unfrequently reaches 15,000*l.* China rhubarb is stored in a small building apart from the general drug block, as from its peculiarly penetrating and slightly nauseous smell its proximity to other drugs is not desirable. The present stock is about 850 cases, and their average value may be set down at 16*l.* a case. Every package that is received in the drug department requires "working," that is, it has to be classified, sorted, sampled, etc. The responsibility of this work falls on the experienced foreman, under whom is a staff of thirty assistants. The practice of years has made him a consummate judge, and at a glance he is almost able to appraise a parcel at its true value. In few trades are greater judgment, discrimination, and experience necessary than in the drug trade. The warehouse system is an immense advantage to the brokers in this line, for they can depend on these qualities being exercised on their behalf. The parcels entrusted to them for sale undergo manipulation in this warehouse. They are supplied from the same source with descriptive particulars for their catalogues, and practically all they have to do is to knock down the lots on the day of auction.

"The wholesale druggists muster strongly in the drug show-room at Fenchurch Street prior to the public sales, which occur every fortnight. Here they see the bulk of goods down for disposal, and at such times every nook and corner of the place is occupied with drugs. Attached to the show-room is a most complete museum, containing specimens of nearly every article in the Pharmacopœia. One could well spend a day in this department alone without exhausting all that is to be seen."

NOXIOUS VAPOURS FROM ALKALI WORKS.*

BY EDWARD DAVIES, F.C.S.

Any one who has had occasion to visit St. Helen's, Widnes, or any other centre of alkali manufacture, or who has even passed near these places in travelling, will have a lively recollection of certain odours, varying in character and intensity, but all bad, and of dense vapours which, in damp weather especially, rolled along the ground in clouds. He will also recall the features of the landscape, if we may give that name to fields without a green leaf in the hedges, trees with no more life than a clothes prop, and in the immediate vicinity of these towns, vegetation all but extinct. And as these smells and sights offend the nose and eye, the traveller will certainly feel disposed to invoke the interposition of a benevolent legislature to clear the atmosphere and restore the fair face of nature; that is, if he be in no way interested in the manufacture in question. The landed proprietors in the neighbourhood, who, perhaps, have no beneficial interest in the works, and who see trees which have graced their domains for ages struck down whilst still strong and sound at heart, whose flower gardens can no longer be a source of pride or pleasure, and who cannot at once or without a pang sever their connection with spots which their forefathers for generations have inherited, and with which historical ties have bound their name and reputation, are sure to resent the intrusion of these upstart outcomes of modern science, and to call upon them to depart or cease to be a nuisance.

* Read at a Meeting of the Liverpool Chemists' Association.

No one who has not had a practical connection with an alkali works can take a general and fair view of the subject, and if, like myself, he has ceased to have intimate relations with such works, he will form as impartial a witness as the circumstances of the case will allow.

In view of, no doubt, impending legislation on the subject we cannot, as a chemical association in the close vicinity of such works, do better than strive to attain correct views on this subject, and with this view I have brought the question on for discussion this evening.

I propose to treat it in the following manner :—

1. To describe the various vapours, noxious to animal or vegetable life, which escape from alkali works, with their effects.

2. To show how these vapours get into the atmosphere, by causes preventible and non-preventible.

3. The methods for diminishing or preventing such escape.

4. The probable effects of stringent legislation and the possibility of enforcing it.

The first part of my subject will probably be old to many here, and I must beg their indulgence whilst I speak to those who are less acquainted with substances which to others are as household words.

Sulphurous Acid Gas.—This gas, familiar to all who have burnt a sulphur match, which (by the way) is now almost a thing of the past, arises almost exclusively from the burning of sulphur, either free or combined with iron or copper. In the manufacture of sulphuric acid vast quantities of iron pyrites, FeS_2, are annually burnt, and by combination with the oxygen of the air converted into peroxide of iron and sulphur dioxide or sulphurous acid gas. In the burning of coals also, the sulphide of iron contained in all coal, and especially in the inferior qualities used in the alkali manufacture as fuel, is decomposed in like manner, yielding the same gas.

Sulphurous acid gas is a dense gas thirty-two times heavier than hydrogen and two and a quarter times heavier than air. It has a pungent smell, and when in large proportion in air produces coughing. It does not appear to be injurious to health when inhaled in small quantities and has been found useful in affections of the throat, for which, *a priori*, we should have supposed it most unsuitable. It is also a powerful disinfectant and one of the oldest known.

On vegetable life it exercises a most baneful influence, due, no doubt in part, to its direct action, but more to the formation of sulphuric acid by its oxidation in presence of moisture.

I cannot find any information with regard to the rapidity with which this oxidation takes place, but I believe that it is more rapid than is usually supposed.

Hydrochloric Acid, arising in the first process of alkali manufacture from the decomposition of salt with sulphuric acid, is a gas not so dense as SO_2, but, from its forming clouds of visible vapour by combining with the moisture in the air, is more visible. To this gas the public attribute the injury resulting from vapours from alkali works almost entirely, no doubt from the fact that before the Alkali Act manufacturers who did not make bleaching powder had no compunction about sending the gas into the atmosphere in appalling quantities, and also that the Act deals only with this gas.

This gas has no doubt a very irritating action upon the lungs, especially when concentrated, but my own experience in a works does not tend to show much injury from it.

A few months before going to an alkali works I had a severe attack of bronchitis, and I entered upon my duties in December. During a large portion of the time which I spent there (four years) I had to walk three miles to and from the works over very exposed roads, and in one or two very severe winters.

The works (it was before the Alkali Act) were rather out of repair, and such volumes of hydrochloric acid gas used to come down at times that I was driven out of the laboratory and had to take refuge on the canal bank. Yet I had no return of the disease, nor was I, from any cause due to ill health, absent one day during the four years.

The manager, a young Scotchman, who, when he came, appeared to be a certain victim to consumption, suffering from continuous cough and night sweats, gradually recovered strength and lived there for about eight years. He, when absent from the works, got thoroughly wet, caught cold, and died in a few weeks, but when I left the works his own opinion was that their influence had been beneficial. In the works I made careful inquiries as to the general health of the men, and, although I have no statistics, I found that rheumatic affections arising from exposure in the long walks to the works and alternations from heat to cold were the prevailing complaints. As to its action on plants there is no doubt that it is most destructive when in a concentrated state, but as I cannot meet with any researches on the comparative action of SO_2 and HCl I am unable to say which is the most destructive. *A priori*, I should think SO_2, not so much on account of its own specific action as on account of the H_2SO_4 which it generates. Water containing HCl on leaves as it volatilizes will take the acid with it, but H_2SO_4 concentrates as the water evaporates and is left behind.

Nitrous Fumes.—These must amount to a very considerable amount as almost all the nitrogen of the nitrate of soda (except that retained by the sulphuric acid sold away from the works) will ultimately find its way to the atmosphere in this form. These fumes consisting of $N_2O_3+N_2O_4$ are by moisture converted into nitric acid, which is well known to have a peculiar corrosive action, and also acts chemically on organic matter in a manner different to the acids named above. These gases are decidedly injurious to health, and when inhaled in quantity have been known to act as a specific poison and not merely by the local injury which they produce. As to their action on vegetable life we have no specific details, but no doubt it is injurious; against which may, perhaps, be set the manurial value of nitrates when the nitric acid is washed into the ground by rain.

Sulphuretted Hydrogen.—This gas, emanating from the vast heaps of waste which accumulate so fast as a bye-product in making soda ash, is one which calls attention to itself by its strong and offensive smell. In the concentrated state it is speedily poisonous to animal life, but in a dilute state those who have the misfortune to work much in a laboratory must hope that its poisonous action is slow. Certainly it does appear to cause headache sometimes; but except as it may gradually sap the foundation of health and imperceptibly bring on disease or a susceptibility to disease, it does not otherwise cause alarm.

To plants it does not appear injurious to anything like the extent of the gases previously named.

Chlorine.—In the manufacture of bleaching powder the production of this gas is yearly increasing. It is a heavy greenish gas and perhaps the most injurious which escapes from the works.

Its influence on man is well known to any one who has had practical experience in an alkali works, as resulting in violent irritation of the air passages, causing coughing, together with a directly poisonous action manifested by diminished action of the heart, exhaustion, and pallor of face and extremities. Alcoholic stimulants are apparently necessary for the treatment of this unpleasant affection, at least I remember having to supply large quantities when I was at a works.

On vegetable life it is no doubt equally potent as it, like nitric acid, has a chemical action on organic matter.

The only thing to be said in its favour is that it is a disinfectant and that it and H_2S, if they get mixed, neutralize one another with production of $HCl+S$.

Ammonia is the only remaining emanation from alkali works, being produced in the manufacture of caustic soda; but it cannot be considered as a noxious vapour as it neutralizes any acid with which it may mix. It sometimes intensifies the dense appearance of vapours by the formation of ammonia salts.

The second head may perhaps be best treated by taking these vapours in the same order as before.

Sulphurous Acid Gas.—I give the pre-eminence to this gas, as in the atmosphere of our alkali districts it far exceeds the hydrochloric acid. Dr. R. A. Smith, in 'Air and Rain,' gives the following figures.

	HCl	H_2SO_4
St. Helen's	1	3·48
Glasgow	1	7·82

This gas escapes from the works when it arises from the combustion of pyrites almost entirely from preventible causes. I have seen it blowing out from the kilns in consequence of insufficient draught, and in a gale an old leaden chamber will give it off from every crevice, and they are sometimes many.

The renovation of an old chamber is an expensive affair and there is a strong temptation to patch it up as long as it will hold together. Then, under the united influence of heat and acid, tunnels and pipes will leak every now and then and intermittent loss is inevitable; but its amount should be small, and as it represents money value good management will repay itself. But as regards any valuable effect to result from the checking this source of evil I fear that it will be imperceptible; for whilst we stop the leaking tap the gas from another source is escaping as by the bunghole. I allude to the SO_2 from the pyrites in the coal and slack used as fuel. In Widnes I am informed that 1,000,000 tons of coal are used in a year. These contain about 2 per cent of sulphur, but suppose, allowing for waste, etc., that 1½ per cent is converted into SO_2, this will equal 15,000 tons of sulphur or 30,000 tons of SO_2, equal to about 46,000 tons of sulphuric acid annually set free in the atmosphere. Here, in my opinion, is the true source of mischief, everything else being subordinate; and this at present is non-preventible. We may completely burn our smoke and thus prevent carbon escaping, but this has not the slightest effect in mitigating the mischief; and at present no means are known which will remove this gas from the products of combustion. To some extent lofty chimneys may afford the means of diluting the gas by sending it into the upper strata of the atmosphere, but the problem of absorbing the SO_2 without injuring the draught of the chimney is unsolved.

Another source entirely preventible is the production of SO_2 from burning waste heaps, and where this is permitted the gas, being evolved at the level of the ground, does immense mischief.

Hydrochloric acid is so completely under control from the conditions under which it is produced that, with the exception of accidental break downs, but little need escape. The condensation in most cases is within the government limit of 5 per cent., and as the inspectors have given their undivided attention to this gas, we may suppose that almost as good results are at present attained as are practicably possible. In drawing the charges there is an escape, which however is not an amount of more than a small fraction of the gas produced. Here again the difficulty of preventing leakage in the pipes which convey either the gaseous or liquid acid is great, owing to the action of heat and acid. By alternate cooling and heating, contraction and expansion loosen the joints and crack the earthenware tubes, whilst the cement does not appear to have been found which will stand the continuous action of hot acid.

The adoption of Hargreave's process appears to do away with much of the escape of hydrochloric acid vapours. No loss from broken pots can be experienced; and, so far as I have seen, the charges when drawn do not evolve any perceptible amount of gas. Here the only point of danger is the condensers, and as these are easily surveyed any escape can soon be detected.

Nitrous Gas.—In the style of working adopted when I was in an alkali works, the amount of nitrous fumes that escaped by the chimney was considerable, as Glover towers were not invented, and Gay-Lussac towers were rather out of repute. By the improved methods now in use the amount of nitre is diminished by two-thirds, and consequently so much less remains to escape. Possibly still more perfect means may be adopted so as to make the sulphuric acid process as perfect in practice as it is in theory; but in any case the proportion of this gas to others is small.

By Hargreave's process again all nitrous fumes are done away. What does escape at present is generally sent up the tallest chimney of the works.

Sulphuretted Hydrogen.—This arises from the waste heaps, either by action of the CO_2 of the air intensified by the acid fumes contained in it, or from acid liquors finding their way upon solid waste or the liquid running from the heaps. The action of the air upon the heaps may be prevented by covering the waste as soon as possible with soil, and making the sides as smooth and compact as possible, but the liquid highly charged with sulphide of calcium, which drains from the heaps, is more difficult to dispose of, especially as acid liquids are almost sure to get into the drains which carry it off. The amount of the liquid naturally draining away is rather small to be worked to a profit, but I think that it might be decomposed and nuisance prevented at no great cost.

Chlorine.—This most deleterious gas should, from economical reasons, be narrowly watched. Under the present system of bleaching powder making, no doubt a good deal escapes, both from the pipes which convey the gas, and also in packing the chambers. The former difficulty will continue to be felt until some material for pipes is discovered unacted on by chlorine, non-fragile, and capable of being made in long lengths. The second evil may be greatly diminished by syphoning off the surplus chlorine from the finished powder, and perhaps may be some day removed by some kind of mechanical packing.

As to my third head, namely, the prevention of the escape of these vapours, I think that the previous remarks will have shown that with the exception of SO_2 from coal, they result from leakage or imperfection of apparatus. Any one who knows the difference between perfectly new works and old ones, will at once see that this is the case. Again, with the exception of H_2S, all these gases represent a value in money, and at first it would appear that self interest was all that need be invoked to cause them to be arrested. On the other hand, it must be remembered that to save a shilling at the cost of eighteenpence does not leave a profit, and in many cases it pays much better to patch and have a little loss than to repair thoroughly and have none. Accidents again will unavoidably happen as long as earthenware pipes and lead constantly acted on from the inside are the most prominent materials in the construction of apparatus, and as this is at present unavoidable in many of the processes, these accidents must be taken as part of the system.

In my opinion much injury has arisen from the concentration of works in a small area, and to check the natural tendency in this direction, however hard it may be, is I think of paramount importance. When the vapours of one works mix with those of another, and then of another, a process of concentration goes on, and vapours in themselves almost harmless, when increased in density in arithmetical proportion appear to do mischief in geometrical proportion. In works grouped together it is most difficult to apportion the measure of blame, and each hopes to escape under cover of the rest. As the escape of vapours to so large an extent depends on imperfections of apparatus attendant on wear and tear, if the government take this matter in hand, as they seem paternally disposed to do, the first requisite will be an army of inspectors furnished with fullest powers. Literally despotic sway will have to be given, with authority to order the removal of this, and the renewal of that. Attendance of the inspector almost as constant as that of a Customs officer in a bonded warehouse will be needed, so that the perversity of the British workman may be in some measure checked.

It is to be hoped that in this way whatever expense the manufacturer may be put to he will not, as in the past, be left in the lurch after all, and compelled to pay any damages an enlightened British jury may assess, although he has done all he was called upon to do. He may fairly, I think, demand that he be furnished with a certificate of immunity, and with governmental supervision and management of his works he will feel inclined to ask them to kindly take the whole thing into their own hands and allow him a small pension to look on.

I am utterly opposed to this paternal government and meddling interference in minute details. If crowding of works is permitted, then let the damage inflicted by a given area be paid by that area, and thus a direct impetus be given to each to look keenly after both himself and his neighbours. Let damage be assessed by independent men who will give some consideration to broader views than damage to an isolated field, and will take into account the advantages which accrued to the neighbourhood as a set off to some extent.

Fourthly.—If stringent legislation does follow, what effect will it have? In my opinion not much that will be perceptible in the vegetation around a group of alkali works. Where several works unite their vapours in one dense cloud, trees will still be objects of pity for a couple of miles around, and occasionally a delicate nose will detect an acid whiff at perhaps three miles. All that unavoidable accidents and coal smoke can do will still be done, and it will be hard for the closest inspection to keep pace with the ever increasing area of the works. If works are still allowed to crowd together, I suppose a certain area must be given up to them, as in the black country, and the landowners indirectly recompensed by increased value of land and produce in their neighbourhood. If stringent regulations and continual inspection are to be the order, then increased price must be the result of increased expense, independently of the cost of the inspectors and their reports, and English manufacturers will be weighted in their competition with other nations. I do not say that they will therefore be defeated, but I do think that they should not be more hardly dealt with than the iron manufacturer, and the salt boiler, who in much the same way create a desert around them. Minute regulations as to the manner of carrying on the business, infraction of which would incur penalty and responsibility, would tend to discourage improvements, and act on the alkali trade as old excise rules did on the manufacture of glass. When we consider that the tendency of modern improvements in this branch is all towards the doing away with vapours, Hargreave's process diminishing $HCl+SO_2$, and doing away with nitrous fumes altogether, the ammonia process almost removing all the vapours and making no waste, and Mond's process utilizing the waste in the present process, I think that we may trust competition and small profits to put down waste, and the march of modern science to attack and destroy the evils which remain, without binding the hands of the manufacturer with endless governmental red tape, or smothering his responsibility by setting up a standard beyond which he will have no inducement to go.

MILK GLOBULES, AND A NEW THEORY OF CHURNING.

BY F. SOXHLET.

It is generally supposed that the fat-globules of milk are contained within a thin membrane, which it is necessary to destroy, before the fat itself can be separated and extracted from the liquid in which the globules are suspended. The destruction of this membrane can be accomplished, it is said, in two ways; either mechanically by the operation of churning, or chemically, by the solvent action of some reagent, such as potash or acetic acid. Now if it be true, that, as in the latter case, the action of acetic acid upon milk is really due to a solution of this globule-membrane, then it is clear that more acetic acid must be used than would be required for the mere coagulation of the milk. Experiments, however, show that this is not the case. Again, if some milk be mixed with just enough very dilute acetic acid to convert nearly the whole of its sodium phosphate into acid phosphate, but not sufficient to cause the separation of the casein, and a current of carbonic acid gas be passed through the liquid, perfect coagulation ensues, and the fat may then be extracted by shaking with ether.

These experiments seem, on the one hand, to indicate that the action of the acetic acid is to rob the milk of its emulsive condition, but, on the other hand, to refute the idea that it accomplishes this by the destruction of an enveloping membrane. In the precipitation of the casein by carbonic acid, the membrane theory is inadmissible, because carbonic acid will not dissolve any single albuminous body.

The fact that the milk-globule, in its natural state, cannot be dissolved by ether, may be explained upon the assumption of a peculiar property of adhesion possessed by it, and this view is supported by the following experiment:—if milk be dried in a vacuum over sulphuric acid the fat can be easily extracted from the residue by ether; but if the residue be dissolved in water, the solution resists the action of the ether, just as milk does in its natural state.

Raspail (*Schmidt's Jahrb.*, vol. 24) cites, in proof of the existence of a pellicle investing each globule, that the globules do not flow together. This may be answered by the parallel case of an emulsion of sugar-syrup and oil, in which the oil-drops no more tend to coalesce than the fat-globules in milk; and, similarly, by the case of the oil-drops in the *emulsio oleosa* of the German pharmacopœia, which differ from the fat-drops of milk only in being more transparent.

If quicksilver be shaken up with water, it separates into single globules, which cannot without trouble be reunited, the adhesion of the water to the surface of the globules preventing their flowing together.

It has frequently been asserted that a globule-membrane can be detected by the microscope, and Henle (*Froriep's Notizen*, 1839, 223) stated that a casein-membrane was visible after treatment with dilute acetic acid. The author, however, believes these opinions to be quite erroneous, and asserts that no membrane can be observed by the microscope, even with the aid of the highest powers.

There is another argument which has been advanced in proof of the existence of globule-membranes. Brücke (*Müller's Archiv.*, 1847, 409) first called attention to the remarkable difference in specific gravity between butter-fat and the liquid in which it is suspended—a difference which, he observed, is sufficient to cause the fat to rise to the surface much more rapidly than it actually does. Brücke explained this difficulty by supposing each fat-globule to be enclosed within an envelope specifically heavier than the liquid, a deduction reasonable enough if milk-liquid could be compared to a solution of salt of the same specific gravity; but he had overlooked the fact that, like all albumin solutions, it is slightly gelatinous, a circumstance extremely likely to interfere with the rising of the globules to the surface.

The power of a gelatinous liquid to retain in suspension finely divided substances of a greater specific gravity than itself, was proved very clearly by Scheibler (Zeitschr. d. Vereins f. *Rübenzucker-Industrie in der osterr.-ungar. Monarchie*, xi. Jahrg., p. 435) who [precip]itated the baryta from a solution of barium arabate by sulphuric acid, and found that, after standing for four years, the fluid had remained just as milk-white as it was on the day on which the barium sulphate was thrown down.

From such considerations as these, the author believes the membrane theory to stand in direct opposition to our present chemical and physical knowledge, and he therefore abandons it. With regard to the condition in which the fat-globules exist, he believes that in new milk they are undoubtedly fluid drops, because, at the animal heat, the milk is at a higher temperature than the melting point of butter (34°—37°), and this view seems to be supported by their appearance when viewed under the microscope.

But if milk be frozen at a temperature of three or four degrees below zero, the globules lose their fluidity, and become solid, and remain also in this state after the milk has been thawed. It was found that milk which had been thus treated could be churned into butter in two minutes, whereas to produce the same result with milk in its natural state required eleven minutes, showing that the low temperature had produced the same effect as seven—eight minutes' churning.

The author concludes from this, that in the operation of churning, the liquid fat-globules are brought into the solid condition, but that this change can also be effected by subjecting the milk to a temperature of — 3° or —4°.*

QUICKSILVER.†

BY SAMUEL PURNELL.

At many points in the coast range of California are found deposits of cinnabar of greater or lesser extent. It has, however, been mined successfully in but few places. The reasons are that the metal is seldom found sufficiently concentrated in the rocks to make mining possible; while in the remaining cases the extracted ores are of such low grade that they cannot be profitably smelted. Occasionally small deposits are found that yield very rich ores—60 to 70 per cent.—but it is well known that those deposits which are large and easily mined, are almost invariably composed of ores so poor—1 to 3 per cent.—that they can barely be operated with profit when quicksilver is at a less price than 2*s.* per pound. The price at present being some 1*s.* 8*d.* only, we accordingly see the greater part of our cinnabar mines closed, the furnaces cold, and large concerns—that alone remain at work—making little or no money. Perhaps not more than four or five important mines are now in operation in Calfornia; and, though the public constantly hears of new and great deposits of cinnabar, they are, as yet, practically undeveloped and valueless, and cannot affect the market price of mercury.

That quicksilver will soon rise in value does not seem probable, unless one should look for the still more improbable occurrence of a combination to limit production; and, consequently, the writer thinks that mercury will still farther decline in price, till only those works which can make a profit when it sells below 1*s.* 2½*d.* per pound can afford to remain in operation.

It would appear to be the rule that quicksilver mines grow constantly poorer from the surface down.

Taking the New Almaden, the largest and foremost mine on the Pacific coast, as an example, we find that in 1850 the ores worked yielded, on the average, 36 per cent.; in 1862, 19 per cent.; in 1865, 11 per cent.; in 1870, 5·23 per cent.; in 1873, 4·87 per cent.—constantly growing poorer, while, at this date, the yield is said to be not over three and a-half per cent., and which is considered as low a percentage yield as can be made profitable with the present apparatus, and with quicksilver below 2*s.* per pound. The same is substantially true of the balance of the prominent mines of the coast, and the effect of the anticipated decline will be disastrous to their interests. Then only the small deposits of rich ores could be worked, which would not half supply the home demand, and quicksilver would have to be imported from Europe. In short, the quicksilver interests of the Pacific coast, so far as the developed and well-known mines are concerned, to the ordinary observer appear to be not only on the decline, but in process of extinction.

The celebrated mines of the world are Almaden, in Spain; Idria, in Austria; and New Almaden, New Idria and Redington, in California. The Almaden has been worked more or less since the time of the ancient Romans, and is, without doubt, the most extensive deposit of cinnabar in the world. The mine is now under lease to the Rothschilds of Europe. In 1872, the workings were over 1200 feet deep, and the mine was reported to be in such bad condition that it was thought it could not much increase its then production. The ores are poor—about 5 per cent.—but their abundance and the cheap labour of the country for their extraction and smelting enables the Almaden quicksilver to control the Eastern trade.

The Idria mine has been worked over 400 years. In 1872 its deepest workings were 750 feet. For many years it has been in charge of the Austrian Government, and all the operations of mining and smelting are carried on with the best talent available and the best known apparatus. Hence, the operations at Idria have long been considered as models of completeness, and works elsewhere have imitated their process. The ores average about 3 per cent.

The New Almaden mine, in California, has been worked, more or less, since May, 1846, to date. From tables furnished by Mr. J. B. Randol, the general manager, we learn that the production from 1850 to close of 1875 was 595,882 flasks, obtained from ores yielding from 36 per cent. in 1850 to 3·35 per cent. in 1875. The average of about four tons of ore is raised from the mine to each ton smelted, which are hand sorted.

Statistics of the New Idria and Redington mines are not at hand; but in general it may be said that the ores of the leading mines of California are so poor that they do not now yield, on the average, over 1 or 2 per cent. as they come from the mine. The concentration that is done by hand must necessarily be expensive.

CRESOTIC ACID AND SODIUM CRESOTATE.*

Both of these substances have been experimented with by Dr. C. F. Buss, assistant at the Medical Clinic of the University of Basle, as to their antipyretic action. Cresotic acid being homologous to salicylic acid, led to the presumption that their therapeutic action must likewise be similar. The observed results, especially in cases of fever, leave no doubt that cresotic acid is a most effective antipyretic remedy, corresponding in its actions to quina or to salicylic acid. Sodium cresotate was administered in doses of 6 to 8 gms. (about 1½—2 ʒ). After its administration the patients sometimes complained of a bad taste, but never of disagreeable sensations; sometimes it produced humming in the ears, but very rarely hardness of hearing after a few hours.

Cresotic or carbocresylic acid, $C_8H_8O_3$, is derived from cresol or cresyl-alcohol (C_7H_8O) in the same way as salicylic acid ($C_7H_6O_3$) is from phenol or phenyl-alcohol (C_6H_6O), by passing carbonic acid gas into cresol (or phenol) containing metallic sodium. The cresotic acid crystallizes from its hot watery solution in colourless prisms. It is sparingly soluble in cold water, readily in ether, alcohol, and alkaline solutions. Ferric chloride produces the same violet coloration as with salicylic acid. Comparative experiments will have to be made to determine which of these two acids has stronger antipyretic powers.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE EXPLOSIVES ACT AND CHEMISTS AND DRUGGISTS.

As at this time of the year it is possible that the experience with respect to the mixing and keeping of coloured fires described by MR. SLIPPER, on p. 428, may become, with a disagreeable variation, that of many other chemists and druggists, we think it may be doing good service to again remind our readers in these pages of the law on this subject which was enacted last session of Parliament in the Explosives Act, 38 Vict. cap. 17. It will be remembered that this Act was based upon the report of a Select Committee, and was passed under the gentle stimulus of the Regent's Canal explosion. It might appear that the regulations therein enacted with respect to the manufacture, transit, and sale of gunpowder in various forms had but little to do with the chemist and druggist. But with certain modifications these regulations apply to all other "explosives," and by section 3 it is enacted that the term "explosive" includes, besides gunpowder, dynamite, and other blasting agents, all *coloured fires*, and every other substance used or manufactured with a view to produce an explosive or *pyrotechnic effect*, and every adaptation or preparation of an explosive as above defined. Therefore, bearing in mind the inclusive character of the business of the chemist and druggist in many localities, it is evident that there is a danger that some may be infringing the Act without knowing it.

The details of the regulations under which explosives may be made, kept and sold are too voluminous to repeat here. A full *résumé* of the Bill was given, whilst it was before Parliament, in the *Pharmaceutical Journal* for March 27th last; an abstract of the principal provisions will be found also in the Calendar of the Pharmaceutical Society. Further, the entire Act may be obtained from the the Queen's printers for a small sum. It will be sufficient now to state that every building in which an "explosive" is manufactured, stored, or sold must be registered; that there are stringent provisions as to the maximum amount to be kept in the registered premises, and the manner of keeping it; also that when sold the package must be labelled with the name of the substance, followed by the word "explosive," and that it must not be sold to a child apparently under thirteen years of age. It will be seen also by Mr. SLIPPER'S letter that a person mixing "coloured fires" will be held to be a manufacturer of explosives under the Act, and require to have his premises registered and constructed accordingly, or be liable to a penalty of one hundred pounds.

It is worthy of note that, although the subject has been brought forward in this Journal on more than one occasion, and a special warning was given in our Summary for the year 1875, we have reason to believe that amongst those to whom it is sent our correspondent is by no means singular in being unaware of the risk run in making up and selling so-called "coloured fires." This is only one of many instances giving evidence of the fact that the bearing of information supplied to members of the trade at considerable trouble and expense is overlooked or ignored until it can no longer do the service it might have done.

A CORRECTION FOR THE BENEFIT OF A MEDICAL CONTEMPORARY.

OUR young contemporary, the *Medical Examiner*, has been moved by a tender regard for the welfare of the pharmaceutical body to devote upwards of three columns of its latest issue to a sermon on the subject of "Counter Prescribing." Of course against this we should have nothing to say had the *Medical Times* not also erroneously attributed its text to this Journal. It says that on the 7th instant we reported that the Council of the Pharmaceutical Society had passed a resolution that it would undertake the legal defence "of any chemist or druggist who is threatened with prosecution for prescribing according to long usage." We will not stay to dispute the distorted construction our contemporary puts upon these words, but simply remark that we made no such statement. The resolution which we reported was that which was passed on the subject, and was as follows:—

> "That this Council is prepared to consider the case of any chemist and druggist who is threatened with vexatious proceedings for alleged infringement of the Apothecaries Act, and if the circumstances warrant, to defend the same."

May we expect our contemporary to set us right with its readers?

THE NORTH BRITISH BRANCH.

WE are glad to be in a position to state, concerning the winter arrangements for classes for pharmaceutical students in connection with the North British Branch, to which we referred in a recent editorial note, that the evening courses of lectures on Botany and Materia Medica, delivered in the rooms of the Society at 119A, George Street, and got up merely as an experiment, have been as successful as could be wished. The introductory lecture on Materia Medica was delivered on Monday, November 6th, at 8·30, p.m., by Dr. WILLIAM CRAIG, F.R.S.E., Lecturer on

Materia Medica, Edinburgh School of Medicine. The opening lecture on Botany was delivered by Mr. JOHN SADLER, Royal Botanic Gardens, on Tuesday November 7th, at 8·30 p.m. A brief abstract of Dr. CRAIG'S first lecture will be found in the next column.

SPURIOUS TEA.

IN compliance with an application made at the Mansion House, on Tuesday last, by the Solicitor to the City Commissioners of Sewers, Sir ROBERT CARDEN made an order for a large quantity of bonded "tea," estimated to amount to 40,000 lbs., to be destroyed by fire. The evidence showed that it had been in bond for about nine years, and Dr. SAUNDERS, the Food Analyst for the City of London, certified as to its unfitness for food, some of it being putrid, some partially exhausted, some mixed with sand, and some with 20 per cent. of dried olive leaves. The worthy magistrate expressed his regret that he could not have some Chinese brought before him charged with the offence, but surely it was not necessary to go to China either for olive leaves or sand.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening, November 23rd., at eight o'clock, when the following papers will be read:—"Carnot's Test for Potassium," by Dr. A. SENIER and Mr. HENRY CAMPBELL, and "Questions on Dispensing," by Mr. CAMPBELL.

THE CANTOR LECTURES.

IT is announced by the Council of the Society of Arts that the courses of CANTOR Lectures for the forthcoming session will be on (1) "The History of the Art of Coach Building," by Mr. GEORGE A. THRUPP, commencing on Monday evening next; (2) "The Chemistry of the Gas Manufacture," by Mr. A. VERNON HARCOURT, and, (3) "The Connection of Greek and Roman Art with the Teaching of the Classics," by Mr. SIDNEY COLVIN.

THE ROYAL SOCIETY MEDALS.

THE "COPLEY Medal" of the Royal Society has been this year awarded by the Council to Professor CLAUDE BERNARD, for his contributions to the science of physiology. The "RUMFORD Medal" has been awarded to M. JANSSEN, for his researches respecting the radiation and absorption of light, chiefly carried on by means of the spectroscope. Also a "Royal Medal" has been awarded to Sir C. WYVILLE THOMSON, for his successful direction of the scientific investigations carried on in connection with the cruise of the *Challenger*. The medals will be presented at the Annual Meeting of the Royal Society on the 30th inst.

MUNICIPAL HONOURS.

WE have great pleasure in stating that Mr. S. M. WEBSTER, Pharmaceutical Chemist, has been unanimously elected to the office of Mayor of Warrington for a second term. Although himself a Conservative his re-election, was proposed by members of both parties.

Provincial Transactions.

NORTH BRITISH BRANCH—EDINBURGH.

On Monday evening, the 6th instant, the introductory lecture of a course on Materia Medica by Dr. William Craig was delivered in the rooms of the North British Branch of the Pharmaceutical Society, and on Tuesday the 7th instant the introductory lecture of a course on Botany was delivered by Mr. Sadler.

The following is an abstract of Dr. Craig's lecture:—Some years ago the Pharmaceutical Society recommended pharmaceutical students to prosecute three important branches of the medical curriculum—Botany, Chemistry and Materia Medica—because it was deemed advisable that they should be possessed of a knowledge of these three important branches of science. There could be no doubt that this advice was given for wise and good reasons, for no one could hold a foremost place as a pharmacist who was not well acquainted with botany, chemistry, and materia medica. The more thoroughly a pharmacist was acquainted with these subjects, the better he would be able to perform all his business duties aright. The time had not yet come, but the lecturer believed it would soon come, when not only a knowledge of these sciences will be demanded of all pharmaceutical students, but also attendance on systematic courses of lectures on those subjects before they were admitted to the professional examinations. The tendency of the present day was to insist more and more on the value, not only of knowledge, but of academic training as a requisite for the learned professions. He was glad to see that in this respect the Pharmaceutical Society was endeavouring to raise the status of its members and licentiates. Although attendance on a course of lectures on these subjects was not at present compulsory on pharmaceutical students, yet attendance on courses of lectures on botany, chemistry, and materia medica would do much to help them to pass the examinations which were unavoidable before becoming chemists and druggists. Ever since the Pharmaceutical Society recommended students to prosecute these various branches of science, opportunities had been granted in Edinburgh by teachers for pharmaceutical students to attend their lectures at a reduced fee. As these lectures, however, were either in the morning or during the day, many students could not find time to attend. To meet the wants of such students, and also to oblige pharmaceutical students generally, it had been resolved that this session evening courses of lectures on botany and materia medica should be given. The lectures on botany would be given by Mr. Sadler, of the Royal Botanic Gardens, whilst he (Dr. Craig) would give the course on materia medica. Both courses were to a certain extent under the patronage of the North British Branch of the Pharmaceutical Society of Great Britain, at least in so far as granting the use of the Society's rooms, and also of their ordinary specimens of materia medica.

Turning to the more immediate subject of his lecture, Dr. Craig said materia medica, as distinguished from therapeutics, might be described as comprehending a description of all the substances which are available for the cure of disease or the alleviation of human suffering. It included a description of their source in nature, their physical properties, their chemical composition, and the various forms in which they might be administered, together with their doses and mode of administration. Materia medica was intimately related on the one hand to chemistry, botany, zoology, and mineralogy, whilst on the other it was clearly associated with physiology and the practice of medicine. With no department of science is materia medica more intimately connected than with chemistry. By a knowledge of the chemistry of medicines, it became possible not only to understand their actions and uses, but also to prescribe antidotes when too much of any had been administered. Botany was another branch of study intimately associated with materia medica, most of the substances used in medicine being obtained from the vegetable kingdom. There were about 800 official preparations of medicines in the British Pharmacopœia, and of these nearly 600 were derived in whole or in part from the vegetable kingdom; or in other words, about 75 per cent. of the preparations were more or less connected with vegetable productions; and as it was incumbent on the physician to make himself acquainted with those plants which are deleterious to man, it certainly was of the utmost consequence for the chemist and druggist to be able to recognize those plants which contain poisonous ingredients. He therefore hailed it as a step in the right direction that pharmacists are now encouraging their students in the prosecution of this most interesting and delightful of studies. Zoology also was associated with the study of materia medica, certain articles of medicine being derived exclusively from the animal kingdom. Mineralogy was more important to the student of materia medica than zoology, very many important substances used in medicine being got from minerals, as the salts of silver, lead, bismuth, antimony and mercury. Most of the metals and their salts had important actions on the human frame, and therefore a knowledge of them was necessary to the student of materia medica. It would thus appear that a knowledge of chemistry and botany was indispensable to the proper study of materia medica, whilst those who added to these subjects a knowledge of natural history would find it of considerable advantage in prosecuting the study of this department of science. These three subjects formed the basis on which materia medica rests. It might be said to begin with chemistry, botany, and zoology, and to end in physiology and the practice of medicine.

Dr. Craig then gave a short history of materia medica from the earliest to the present time, and after alluding to the importance of the science to the members of the medical profession, said it followed by a natural process of reasoning that it was of the utmost importance that chemists and druggists should also be well acquainted with the actions and uses of remedies, because the important results for which medicines were prescribed could never be attained unless the physicians' prescriptions were accurately dispensed. Materia medica was the grand connecting link between the pharmacist and the physician. It was, so to speak, common ground to both. It was the duty of the pharmacist not only to dispense accurately the prescriptions of physicians, but also to investigate for them the best modes of administering medicines. It was his duty also, by his knowledge of chemistry, to find out the various constituents of medicines, and if possible their active principles, to investigate the properties of new remedies, and prepare suitable preparations for administration; and these things could never be performed without an enlarged knowledge of the actions and uses of medicines.

In conclusion Dr. Craig said: "Let me urge on you all, as an argument for your studying carefully this subject, that not only physicians, but also the general public, may place implicit confidence in the honesty and accuracy of the chemists dispensing their prescriptions."

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Opening Meeting.

The first meeting of the session of this Association was held in Anderson's University, on the 8th inst., Mr. Daniel Frazer, President, in the chair.

The minutes of the last meeting having been read and adopted, the Secretary intimated the receipt of the *Pharmaceutical Journal*, also the ten guinea present of books from the Bell and Hills Fund of the British Pharmaceutical Conference, together with the portraits of Dr. Pereira, Jacob Bell, and the London and Edinburgh Boards of Examiners, which had been framed and hung up in the library, and moved that the best thanks of the Association be given to the several donors.

The Treasurer intimated the receipt of £1 from Mr. Borland, of Kilmarnock, as a donation to the library fund, to whom special thanks were also voted. It was also intimated that one of the members of Council, Mr. James MacDonald, late of the Glasgow Apothecaries' Company, had died since the annual meeting, in May last. The Council greatly regretted, the loss the Association and the trade generally had sustained in this the early demise of one who had been so much esteemed.

It was agreed that Mr. John Fennick, of Strathbungo, be elected to fill the vacent seat in the Council till the end of the year.

The President then delivered the following—

Inaugural Address.

Gentlemen,—The difficulty experienced by most men who sit down to write an "Inaugural Address" will, I suspect be that of the little man who was asked to hang his hat upon one of the empty pegs he saw stuck along the wall. There were plenty of these, but, alas for him, they were all placed just a "peg" too high for his little arm to reach to. This was my difficulty in choosing a subject for to-night's address. There are plenty of subjects open for discussion by pharmacists, but, alas for me, most of these are beyond my reach; and, were they to have full justice done to them in their treatment, all that are within my reach call for a much ampler leisure for their discussion and elucidation than it has been possible for me to bestow on them at this time. In these circumstances I must throw myself on your kind indulgence while I attempt to give you some sketches of a few of the subjects with which the pharmaceutical world has recently been much exercised. In doing this from my point of view, some corns will have to be trodden upon, but I hope to tread upon them with as gentle a pressure as may be consistent with the giving of a clear and explicit statement of what my own views of the topics under discussion are.

Before entering upon this discussion, I am sure that all present will agree in thinking that our first remarks should be made in regard to the recent meeting of the Pharmaceutical Conference held in our city. That event so overshadows in bulk, as it outweighs in importance all other items of our local history as pharmacists, that I feel confident no apology need be offered for my giving to it the place of honour in my address to night.

The meeting of the Pharmaceutical Conference in Glasgow, and all that that event involved, constitutes an era in the history of our Society—that Society at whose most cordial invitation it assembled here. With all our heart we sent out that invitation—with all our heart we welcomed the members of the Conference who accepted it, and who honoured us with their presence in our midst, and, now that they are gone, and that they and we have returned to their and our wonted occupations, and have all settled down in our own dwelling-places at home, I am quite sure that in expressing my views I am also reflecting yours when I say that with all my heart I look back upon the fifth, sixth, and seventh days of September last as the red-letter days of our calendar, and that no similar event is likely to arise that can displace them from that pre-eminence in our memories.

Our expectations were large, but the reality greatly exceeded them. When we nominated such active and energetic men as Messrs. Kinninmont, Davison, Fairlie, and Stanford, to take charge of the arrangements needed for the reception and entertainment of our expected guests, we little knew the strain to which their powers of organization and entertainment were to be put. Happily for us, however, great though the strain put on their energies was, they proved themselves equal to the occasion, and their efforts, aided by willing and able landlords and an able and gracious captain, were crowned with success alike on land, river, loch, and sea.

We had anticipated a possible meeting of 120 or 140, whereas 175 gentlemen entered their names in the visitors' book at the entrance door of the hall of the Royal Hotel—the meeting place of this year. We thought it possible that 150 or 160 might gather on board of the "Eagle" steamer for the trip down the Clyde. We found the number to be nearer 300.

Not only did the numbers attending the Conference exceed our most sanguine anticipations, the weight was in proportion to the bulk. Not only did the London Council send—with the much regretted exceptions of Messrs. Sandford, Hills, and Bottle—its best known men, including its President and Vice-President, and its most valued and energetic Secretary, but for the first time since the Pharmaceutical Society was instituted, did it, in deference to the meeting of the Conference here, omit one of its stated monthly meetings. When, in addition to so many members of the present Council as favoured us with their presence, men of the mark of Professors Redwood and Attfield, such ex-Councillors as Messrs. Stoddart, Groves, Reynolds, and Sutton, were along with us, along with such other noted pharmacists and men of science as Messrs. Proctor, Brady, Ekin, Benger, and Tilden, and literary men such as the editors of the *Pharmaceutical Journal* and of the *Chemist and Druggist*, no wonder that a meeting with such men gathered under one roof in this northern region, was warmly welcomed by us and that it should have proved, as the saying is, "a complete success." No wonder that some of us, in order to do but bare justice to such visitors, curtailed our night's rest by an hour or two, whilst they were amongst us. That the meeting was appreciated by our friends from south of the Tweed was amply evidenced by the addresses of not a few of them in person when here, and by the editors of the *Pharmaceutical Journal* and of the *Chemist and Druggist*, in their respective Journals; but further, I could occupy not a little of your time by reciting the congratulatory terms in which very many friends have since written to myself. Time will not allow of giving more than one of these, and I give it as the first that reached me, and as a fair specimen of the others—

"We are laid," says the writer of this letter, "under much obligation to all who generously contributed both in money and able and diligent arrangements for our comfort, and so promoting the objects of the meeting,—the advancement of pharmaceutical science, the recognition of the unity of our interests, and the promotion and establishment of mutual goodwill." The writer then concludes thus, "Your noble city, spacious hotels, commodious meeting room, swift steamer, beautiful lochs, lofty hills, band and highlanders, have left impressions not to be soon forgotten."

Here let me say how intensely I myself enjoyed the presence amongst us of very many kind friends whom I meet with so frequently south of the Tweed, and who there so strive to emulate the man "who killed his neighbour by kindness," that sometimes I fear they may succeed, and so spoil what has not already been spoiled in me. The atmosphere in which I moved during the sitting of the Conference here was to me so akin to that of Bloomsbury Square, that had my imagination been only a little less dull than it is, I could almost have believed myself transported to that classic ground.

One more sentence before I leave this part of my address. It is to urge as many of my brother pharmacists of Scotland as may find it possible to cross the Tweed on the 14th of August next, and again—though under a different roof—sit at the feet of Professor Redwood, to listen to his words of kindly advice, of wisdom, and of a knowledge that appears to well from him as from a fountain, ever flowing, ever full.

No doubt the journey from this to Plymouth is a long one, but the journey may be broken. The routes to it are various, and the places of rest on them are numerous. We can look in at Edinburgh or Newcastle, York or London, Bath, Bristol, or Exeter. Around Plymouth, and within an easy distance, will be found scenery that will, in itself, well repay the journey, even to us Scotchmen, who think so much of our hills and our lochs. To name no others, the river Dart with its overhanging woods; the ancient and picturesque town of Dartmouth, and that of the too notorious one of Totnes, with their tortuous and narrow streets, and overhanging houses, have only to be seen to be admired by all who have a love for the antique and the picturesque. I only hope that it may be possible for me to be there myself, and that if so, I may see not a few of you beside me.

Though other matters of a more scientific and of a less political character than the Trade Defence Association might be named as worthy of a place in our opening address, still I think that in the special circumstances under which we meet, it is natural that it should come next in our remarks. It was in our midst that it held its second meeting, and that only two months ago, and it is a society in which not a few here and elsewhere, are deeply interested; and so I feel sure that no one will quarrel with my dealing with the subject, though they may be quite at issue with me in my estimate of the work of the Association itself.

I have not attended any of the meetings of the Trade Association, mainly, though other things also hindered my attendance, because I failed to see an adequate call for its existence. I have a strong fear also that its existence, alongside of the present Pharmaceutical Society, may at some time, more or less near, give rise to still further complications and confusion in a trade already more than sufficiently perplexed and troubled about many things very difficult to adjudicate upon.

Of course I am aware that the origin of the Society is due to the existence of these very troubles, troubles that so sorely afflict the body-pharmaceutic; and I give unbounded credit for singleness of eye to the promoters of the Association. It is my happiness to have the personal acquaintance—I think they will even allow me to say the friendship—of at least two of its earliest, warmest, and most able and judicious supporters, I mean Mr. Reynolds of Leeds and Mr. Jones of Leamington, and I will yield to no one in my admiration of both gentlemen at once for their high personal character, their ability, and their purity of motive.

To what then, it may most fairly be asked, in the Society itself, whilst holding this opinion of its supporters, do you object.

First then, I think that in this case, as in many others, the remedy is worse than the disease it is intended to alleviate, if not to cure. It appears to me, to be not overstating the case to say it is equivalent to the swinging of a huge sledge-hammer by a brawny blacksmith to exterminate a fly that had settled upon the brow of a fellow-workman. No doubt the fly would be exterminated, but what of the unhappy victim of his affection?

Plainly stated the case as it appears to me stands thus: A few—few in relation to the number of pharmacists in our country—cases of actual hardship to some of our number have arisen in the application of recent Acts of Parliament by an unpaid and irresponsible magistracy. The sufferers cried out so lustily, "Police, police!" that the whole pharmaceutic world has been roused from its slumbers. What then are the grievances to which we had been subjected? Here it is that the sale of a "morning tonic" by an unlicensed man is declared to be illegal; there it is the selling of a mixture of lime and sulphur as the very purest of sulphur; and now it is the selling of an effervescing compound under an erroneous name that brings us "poor apothecaries" within the meshes of British law.

Well, I do not say that these are matters of trifling moment. I do say that every such case deserves to be looked into. But, living as we do, not in a lawless country where might overrules the right, but in a land where the law reigns paramount, and where it is administered in the highest possible purity, I do say that the remedy for each case of misapplied law, and so of real hardship, lies within every reach, and that where an aggrieved individual may not himself be able to employ the machinery needed to get justice done to him, there are always, as in the Greenock citrate of magnesia case, brother pharmacists all around who are both willing and able to help; and where the ordinary magistrate or the justice of peace has inflicted an unjust sentence the process to have the erroneous decision reversed is a very easy and cheap one. So far, then, for cases of misapplied law. My friend, Mr. Reynolds, in arguing for the promotion of the Trade Association as a means of getting justice done to the aggrieved parties in such cases, used this illustration:—"A person seized with a sudden illness was not generally the most capable of judging of what was the best remedy in such an emergency. The advice of a friend might often be of extreme value in such a case—and so in this instance." This case was that of the summons issued by the excise against a number of us for selling Liebig's so-called Extract of Beef, without our possessing a wine licence, and the pleading guilty by one of our number to the same. Go to a doctor. The only thing then between us is, what doctor? My friend says go to the Trade Association for advice. I say go to a good lawyer, or to Dr. Elias Bremridge. Instead of going to Drs. Reynolds or Barclay, or Jones, much as I respect them all, I say go to Drs. Adam, Paterson, Anderson, Kirkwood, or Roberton, and be quite sure that if the law has been kept by you, and the decision of the justice or magistrate has been contrary to law, you will speedily have the wrong decision reversed. If you do not go direct to the lawyer, be quite sure that in the long run you will have to land at his door. This was the course taken by those of us who were summoned for selling Liebig's Liquid Extract without a wine licence. How could any society have done better for us? We had, through ignorance, infringed the law, and, though there were circumstances connected with the mode of raising the prosecution by the authorities of which we had much cause to complain, we had no right to complain of its application to our case, and so we did not appeal against the decision given in it. The result was the exaction of a merely nominal fine—fifty shillings—by the authorities.

So far, then, as to hardships inflicted on the pharmacist either through a misapplication of the law by the authorities, or through its application in an unexpected quarter—as in this case of Liebig's so-called Extract of Beef. It will next be asked, how are you to remedy the other class of grievances inflicted within the law itself? The Association is disposed to go to Parliament, and have the Act of 1868 amended, so as to meet both classes of cases. These are not the exact words employed by the Society in its official document, but I am quite sure I have only given a fair statement of the case as put by some of its chief promoters in their published speeches. Let us now look at some of the hardships so much complained of.

The retailing of articles contained in the two poison schedules by co-operative stores is one of these. Well, if that case be proved to be an infringement of the law, and therefore punishable at law, I, for one at least, will go in to-morrow for trying the case. But that is just the difficulty. It is not certain at all that they are infringing the law. In such circumstances, I have no right, in my capacity as a councillor of the Pharmaceutical Society, and so representing a public body, to enter the law courts without first counting the costs and seeing how I am to come out of them. I would not do it in my private capacity, and I do not think my action should be different in my public one.

It is also a subject of complaint that patent medicines and drugs generally are sold by grocers and others. Many argue for their sale being restricted to druggists. I maintain this cannot be. No parliament will venture to enact a law to create such a monopoly in our behalf. Nor, I hold, should it be asked to do so. In my young days the two chief places for procuring patent medicines in Glasgow were an Italian warehouse in Candleriggs and a surgeon's shop in the Irongate. It is also quite well known that in many districts in England booksellers did and still do a large portion of the trade in them. But granting, for the sake of argument, that we might secure a monopoly in the sale of patents and drugs by going to parliament, I say the law of fair play even is against us. If we seek to restrict others from selling drugs and patents, we must, in all fairness, begin by ourselves giving up the sale of a thousand and one articles other than drugs now sold by druggists all over the kingdom. This, I suspect, will be giving two very rich Rolands for one very poor Oliver.

The very last thing I have noticed in the direction of seeking to restrict a trade to those already in it by legislative interference was that of certain mineral water makers, so many of whom are, like myself, also druggists. They met in London only the other week, and this motion was gravely put to the meeting:—

"*Items of business to be discussed.*—1. Whether it would afford better protection to the respectable members of the trade in securing for them higher prices for goods and the safety of their bottles, by having a tax imposed on each manufacturer, thereby decreasing the present existing opportunities for men of no capital or character entering the trade and depreciating it by opening up a reckless and unfair competition, and who also carry on their business with other persons' bottles and cases that are dishonestly obtained?"

The mover of this motion thought that a tax of "from £10 to £50 on each soda water manufacturer would exclude many persons from entering the business," etc., etc. This was not, however, carried, and I only quote it as a mode of letting us see ourselves as others would see us were we, as druggists, to go to parliament to seek for a monopoly in the articles we are supposed chiefly to deal in.

If these soda water makers knew that the troubles of druggists only begun when we got tied, neck and heel, by the Act of 1868, they would hesitate long before seeking to add to their present troubles those entailed by the iron shackles of the law. No, the selfish policy that prompted the calling of a meeting to carry such a motion is a shortsighted one, and would not help the interests even of those who thus sought to interfere with the liberty of others.

The next subject I wish to refer to is the keeping of "open shop" by medical men and surgeons. This, even when lawfully done, is what so many in Glasgow consider to be their special grievance. Well, this is not a new offence under the sun. Sir Walter Scott, in his novel of 'Rob Roy,' refers to an ancient offender in this very thing. Francis Osbaldiston, after the encounter with his cousin Rashleigh, is made by Sir Walter to say—

"On my way to Mr. Jarvie's, whose dinner hour was approaching, I stopped at a small unpretending shop, the sign of which intimated the indweller to be Christopher Nielson, surgeon and apothecary. I requested a little boy, who was pounding some stuff in a mortar, that he would procure me an audience of this learned pharmacopolist. He opened the door of the back shop, where I found a lively elderly man who shook his head incredulously at some idle account I gave him of being wounded accidentally by the button breaking off my antagonist's foil while engaged in a fencing match. When he had applied some lint and somewhat else he thought proper to the trifling wound I had received, he observed, 'There never was a button on the foil that made this hurt. Ah! young blood! young blood! But we surgeons are a secret generation. If it werna for hot blood and ill blood, what would become of the two learned faculties?'" Vol. ii., pp. 116—7.

To let you know how I look upon some aspects of this question, I will here quote a letter written by myself in December, 1868, at the suggestion of Robert Dalglish, Esq., then one of the M.P.s. for Glasgow, and to whom a number of our leading medical men had complained of the Pharmacy Act of 1868, as it then stood.

"*The New Pharmacy Act.*

"To the Editor of the *Glasgow Herald.*

"Sir,—We are by no means surprised at the tone adopted by 'Chirurgicus' when writing in your paper of to-day, in regard to the operation of the Pharmacy Act passed in the late session of Parliament.

"The evil he so justly complains of calls for immediate rectification, and it will doubtless receive it. So far as known to us—and we believe our information on the subject to be substantially correct—there was nothing further from the wish of the chief promoters of the Act—the Pharmaceutical Society of Great Britain—than to hamper the action of the very large body of medical practitioners throughout the country who are also dealers in drugs. As originally framed, and as sent to the House of Lords, by the House of Commons, there was no such restrictory clause as the one prohibiting all parties in Scotland but pharmaceutical chemists, or such chemists and druggists as may now register themselves under it, from dealing in drugs and poisons. On the face of it, such a restriction would be a manifest absurdity. One of the main objects in carrying this Act was to secure the better education of the dispenser of medicine throughout the country; but it never was imagined that a higher standard of education was to be insisted upon in the case of the dispenser than in that of the prescriber."

"The evil complained of arose, we believe, by hurriedly transposing one word for another during the last stages of the bill, and it is quite understood amongst the pharmaceutical chemists themselves, that they, in their corporate capacity shall, on the opening of Parliament, make applications for the amendment of the restrictory clause in question.

"To us it is quite clear that, in thinly populated districts of the country, the public must either get their drugs from the necessarily educated medical practitioner or from the not necessarily educated grocer or general dealer, as such districts are incapable of supporting purely drug businesses. It surely admits of no debate which of these should have the preference?

"We are, etc.

"FRAZER and GREENE.

"*9th December*, 1868."

Regarding the matters referred to in this letter, I ask, if medical men at that time—*before* the shoe began to pinch—had sufficient influence with the government to not only get the Pharmacy Act of 1868 amended in their favour, but to get it held in abeyance by the authority of the Lord Advocate, as they did, till the obnoxious clause was repealed, what possible hope can any one have of Parliament, at our instance, or at that of the Trade Association, again re-enacting such a clause? Here again I say, even if we could succeed in getting it we ought not to ask for such a monopoly. How stands the case? Do we not find, all the country over, in small towns as well as in the largest ones, members of the Pharmaceutical Society itself exhibiting on one side of their shop the much honoured diploma of the Society, while on the other side of it are displayed all the garish paraphernalia of the wine merchant. Only the other day I saw, in a large Scottish town, the lower half of a large window wholly covered with the ordinary olive colour oil paint—so usual in spirit-dealers' premises—and in huge gilt letter the words "Agent for W. and A. Gilbey, Wine Importers and Distillers," and in small letters the name of the agent—we shall say "John Blank, Pharmaceutical Chemist," printed at the bottom of the pane.

I am far from complaining of this. This is a land of liberty. Teas, wines, cigars, stationery, photographs, etc., are regularly dealt in by some of the most respectable members of the trade, as a means of eking out a livelihood that otherwise might be of the scantiest proportions. In short, if the druggist cannot earn a sufficient income in a country village or town without supplementing it by dealing in such articles as I have named, and in a hundred others equally remote from any connection with drugs, even should the articles be, as I but lately saw in the premises of an old fellow-councillor in the South of England, terra cotta vases, statuary, etc., then by all means continue to deal in them. But I say do to others in this thing as you do by yourselves. As you cannot live by merely dealing in drugs, pure and simple, no more can the country surgeon live by merely feeling pulses, and prescribing. They, like ourselves, have to live, and as the supply of them, as of us, is generally above the demand, to make both ends meet they naturally enough add the selling of the medicines prescribed to the prescribing itself. Let then, the surgeon, when he has it, invest his money in an array of bottles, not quite empty, till he can dispense with them as a means of supplementing his income. Indeed, as in many villages and towns, a surgeon-pure, or a druggist-pure, cannot be maintained, I hold that it is for the advantage of the public that the surgeon should keep "open shop." The doctor can do the whole work of the druggist, but the druggist cannot do the whole work of the doctor.

But, while I say so much on the one side, I go as far as anyone here in condemning, as unwarranted, a wholesale rush into our business by medical men in towns such as our own, where there is ample scope for the display of their energies in their own proper field, and where there is certainly no lack of efficient druggists. They ought to aim at taking a higher social position than is compatable with their continuing to keep "open shop." I need not say how utterly I condemn those medical men who lend their names, as it is believed not a few do, to needy outcasts of the Pharmaceutical Society—her rejected candidates—that, under such a covering, they may carry on a business in every true sense illegitimate. This is a scandal of the deepest character, and cannot be too strongly condemned, or too soon put down, could the arm of the Pharmaceutical Society only find a means of reaching them.

Two more grievances of us poor pharmacists, much discussed of late, have to be named, each in a sentence or two.

Exemption of chemists and druggists from serving on juries. Well there is no such exemption that I know of in Scotland. Nor do I see any strong reason for our being so exempt. Certain I am that the evil is not so crying a one as to call for its being made one of the proximate causes for getting up a great society all over the land.

Counter prescribing. Much was being made of threatened proceedings in this matter in Nottingham, but happily these have collapsed. On this subject I simply repeat what I said at the conference in September. No law in the world can prohibit John Brown from prescribing to John Smith on the street or in the exchange. So we need not fear the enforcement of an old, or the enactment of a new law, to interfere with the just privileges of the druggist who does not traverse the well recognized use and wont boundary line that lies between his special work and that of the medical man. I have seen the rough soiled hand of an Irish labourer engaged in the delicate operation of extracting a mote from underneath the eyelid of his fellow-labourer, planted up against the wall of their common shed. Would any surgeon in the world venture to bring the kindly operator "to book" for such an interference with his vested rights? This is a subject that I hold should not cause one hour's uneasiness to any one of us who honestly seeks to attend to his own business, and to leave to others the core of theirs.

Having at such great length spoken of the grievances to protect us from which is the main purport of the Trade Association, it is more than time to grapple, as best I may, with the grounds on which its leading promoters vindicate their support of it.

In brief and in plain terms these are substantially, that the Pharmaceutical Society, either from a defective constitution, or from an ineffective administration of the constitution it at present enjoys, has not in the past been able, and is not in the future expectant to be able, to afford that protection in the prosecution of their trade by chemists and druggists that the exigencies of the case require. A main reason given for this inability or unwillingness on the part of the Pharmaceutical Society to prevent or to remedy the evils I have already enumerated is, that "it only reaches the fringe of the trade," and therefore it is "important to have an organization representing the whole body" (Mr. Barclay, at Glasgow Meeting).

Be it so. But whose fault is it that it is so? Where is the remedy? I maintain that it is to be found in making the Pharmaceutical Society not only representative of the trade, but to embrace the trade in its entire length and breadth. Let all the present outsiders who are really legitimate chemists and druggists join the Society. It is, however, said that many of them cannot afford to pay a guinea a year to enable them to do so. I fear this may be true of too many of our brethren, but surely it is not so of the vast majority of them.

Then, when you have joined the Society, take a deeper interest in the proceedings of its Council, and of its annual meeting, than you have been wont to do, and, if the Council does not represent your views make it do so. You have the whole matter in your own hands. A more popularly elected body never sat. You can change the face of the Council once every year by turning out fourteen of the old and by voting fourteen new men in, if you but so will it. The law is at your back here, if it won't help you in all the directions some would seek its aid in.

Then, too, will the Pharmaceutical Society, when embracing the whole, or the vast bulk of the trade, be able to go to Parliament as it is proposed by the Trade Association by and bye to do, to seek an amendment of the Act of 1868, with some prospect of being listened to. I, too, like the Association, would like to see the said Act considerably amended, though, I fear, in a manner very much in an opposite direction from what I suspect it wants.

But, be that as it may, sure I am of this, that if the Act is to be amended it ought to be done at the instance of the existing legally constituted Society. But I also add this, that if either society, or both together, seek to advance our trade interests at the expense of those of the general public ours will go the wall and those of the public will be preserved, and that by any government that may be approached on the subject. This is a subject in which, in these days, whatever it may have been at one time, "Whig and Tory a' agree."

There is, however, a still wider, deeper objection remaining to be urged against the Trade Association, and that is to the very constitution of the Association itself. I object to it as a step in that reactionary policy that has been manifested of late in too many directions. I mean,—a recurrence to the seeking and enacting of protective laws, laws intended to benefit class rather than national interests. In this is involved a departure from that freedom of trade that I hold to be not only sound in principle, but to be, in the long run at least, by much the wisest course to pursue, even by those seeking no higher aims than their own aggrandisement. This is, I hold, the shortest, surest road to that "success in business" at which all, and so properly, aim.

But some may say, what has this to do with the Trade Association? Very directly it has to do with it. The outstanding, ostensible aim of the Association is not only to protect members of the trade that may be exposed to vexatious and unjust prosecutions in the carrying on of their business, but to extend that protection by prohibiting, by legal enactment, the grocer, the co-operative store, and others, from dealing in patent medicines, etc. What is this but seeking an extension of the monopoly already granted to us for the sale of the scheduled poisons?

This is just what the farmers and the landowners of this country fought so hard for in seeking to maintain the old corn laws as against the farmers of America and of the Continent, who, unlike us in this narrow island of ours, grew more corn than their own countrymen could consume. I need hardly tell even the youngest here how the folly of this opposition has now been demonstrated by the greatly increased prosperity of the British farmer, and the quite enormously enhanced value of land, so that tenant and landlord have alike benefited by the abolition of the old protection laws, while you and I get the benefit in a greatly cheapened loaf. So much, I hold, for having the grand principles of equity, as between man and man, and between nation and nation, as a basis on which to rest our legislation.

Having exhausted all I have to say in regard to the principles on which the Trade Association is based, let me in closing acknowledge the kindly feeling exhibited by its leaders to the Pharmaceutical Society. I do not need to single out names. Suffice it to say that without exception their cordiality and friendship towards it have left nothing in that direction to be desired. Manifestly, and beyond all doubt, they wish nothing but good to it.

Several of the Association's more prominent supporters have said that if they thought it was to be antagonistic, or other than helpful to the Pharmaceutical Society, they would retire from its membership. That they are thoroughly sincere in this expression of friendship there can be no possible doubt.

But if the Association is to go on and to maintain a separate existence, as doubtless it is, how long will it be possible to maintain this cordiality and warmth of friendship throughout its borders?

Who would be so cruel as to hint to that happy bright young couple, on the eve of their marriage, that before many years, it may be before many months, their present hours of bliss will be exchanged for hours of the bitterest possible grief, and possibly of separation?

As I have somewhere read, little harm can come of the protrusion of the jagged pikes of the wheel circling in mid-air, but let the minutest tooth of an interlocked bit of machinery, be it of a watch, or of a locomotive, get out of place, then there is a wrench and a dislocation that throws the whole machinery out of gear. So is it with the two societies of which we have been treating. They have too many things in common, are much too nearly allied in their *personnel* and in their objects, long to walk together without a jar. Questions are most certain to arise of which different views will be taken by the representatives of each, and then comes the question, Who is to yield?

No,—let the two really become one. Let them enter into the marriage relation now, and becoming one, and with one governing and a truly representative head, the whole body, fitly joined together, will move on sweetly and without a jar.

Now it only remains that I apologize for the great length and unfinished character of this address, and to thank you most heartily, as I very sincerely do, for the patience with which you have listened to remarks with which I am well aware many here do not sympathize. But as I always insist on having full liberty of thought to myself, I not only do not grudge it to others, but my whole desire is that every one, not only here in this little world of ours, but in the larger world of politics outside of us, should be "left to the freedom of his own will," without landlord, master, or would-be representative, daring by word or deed, by bribe or threat, to interfere with his holding and expressing his opinion on any and every question before the country.

At the close of the address, which was frequently applauded in course of the delivery, Mr. Fairlie (Hon. Sec.), proposed a hearty vote of thanks to the President for his racy, interesting, and humorous address. He said that he could not agree with Mr. Frazer on very many of the points touched upon, and had time permitted he would have been disposed to criticize, perhaps pretty severely, some of the conclusions Mr. Frazer had come to. He could not help admiring, however, the ability of the paper, and was grateful to the President for having uttered his views on the all important subject of the Trade Association, because it was just by interchange of thought and opinion that a proper understanding was often come to. He therefore, with the greatest cordiality, proposed that the members award the President their best thanks for his address.

Mr. Kinninmont, in supporting the motion, said he had not much fear of any antagonism arising between the Trade Association and the Pharmaceutical Society, otherwise he would not have joined it. He knew from personal experience that there was work for both, and his only regret was that the great bulk of the trade seemed to hold aloof from all associations.

The vote of thanks was then given with acclamation.

It was afterwards arranged that the Council should consider the propriety of having either a conversazione or a supper in place of the annual festival.

It was announced that 26 members had joined the tutorial class, and 15 had come forward to the chemistry class, and that both classes were now in full operation.

This was all the business of importance.

LIVERPOOL CHEMISTS' ASSOCIATION.

The second general meeting, twenty-eighth session, was held at the Royal Institution, October 26, 1876. The President, Mr. A. H. Mason, F.C.S., in the chair.

The minutes of the previous meeting were read and confirmed. Donations of current numbers of the *Pharmaceutical Journal* from the Society, and *Canadian Pharmaceutical Journal* from the editor, were announced to the library, and thanks accorded to the donors.

Messrs. G. H. Damsell and T. A. Wood were unanimously elected members, and Mr. J. E. Tipper was unanimously elected associate.

Mr. Thos. Williams, F.C.S., exhibited piece of a stone which is found in Bolivia, and produced the results of experiments which he had performed on the same, along with its analysis. It is composed chiefly of silicious matter and water of combination, and contains 10·45 per cent. of common salt, some oxide of iron and phosphates. It is easily broken with the hand, impalpably fine, meagre to the touch, does not adhere to the tongue, light drab colour, and burns into a much darker colour. It floats for a length of time on water, and in sinking gives a notable amount of effervescence with a loud hissing noise. Mr. Williams stated that it is found inland, and asked if any member could give it a name, or explain its natural history; and not having had time to examine it further himself, he suggested it might be of microscopical interest, as he held the opinion that it consisted of the remains of marine infusoria (animalcules).

Mr. Edward Davies, F.C.S., considered that this deposit was made up of marine diatoms which had lived in lagoons having connection with the sea; a subsequent upheaval of the land, which is known to have taken place, caused the gradual drying up of these, and in that rainless district it was easy to understand how the common salt was not washed away. He would be glad to receive a little for the microscopical examination.

Mr. Thos. Garside, F.C.S., stated that he had noticed a black residue in dissolving aluminium in alkali, and found out that it consisted of platinum black. He had not determined accurately the amount, but found about ½ per cent.

Mr. James T. Armstrong, F.C.S., had been consulted about certain boilers fed with water from a canal, which showed a much larger consumption of fuel than a similar boiler fed with other water. The cause was incrustation of great thickness, which he exhibited, and gave analysis of two kinds of water that had been employed.

Mr. Garside said that he had seen a deposit produced by water of a canal in which the water only contained four grains of solids per gallon.

Mr. Arthur Haddock had seen a decided beneficial effect by the use of chloride of ammonium on water containing sulphate of lime.

The President exhibited a large sample of artificial vanillin and small packets of sugar containing ½ per cent. as used in Paris for flavouring. He stated that vanilla had fallen 40 per cent. in price in consequence of the discovery. He also exhibited Mr. Stoddart's test for the colouring matter of saffron with hydrochloric acid and sugar.

Mr. E. Forbes Morton exhibited a specimen of millerite (sulphide of nickel), covered with crystals of sulphate of nickel, which had formed upon it in his cabinet.

Mr. Davies stated it would be very interesting to investigate the manner of formation of such crystals.

The third general meeting was held at the Royal Institution, November 9th, 1876. The President, Mr. A. H. Mason, F.C.S., in the chair.

The minutes of the previous meeting were read and signed.

The following gentlemen were unanimously elected members:—Dr. Egerton F. Hall, M.D., Messrs. Joseph Walker and Thos. Hall.

Mr. Edward Davies, F.C.S., etc., read a paper on 'Noxious Vapours from Alkali Works,' which is printed at p. 412.

A lengthy discussion followed the reading of the paper, in which the President, Drs. W. Carter, E. F. Hall and C. Symes, Messrs. T. Garside, F.C.S., J. T. Armstrong, F.C.S., Jas. Simpson, and others took part. A cordial vote of thanks to Mr. Davies, which was given with acclamation, brought the meeting to a close.

CHEMISTS AND DRUGGISTS' ASSOCIATION OF IRELAND.

The annual meeting of this Association was held at the Society's rooms, 172, Great Brunswick Street, Dublin, on Monday evening, October 31. Mr. E. M. Hodgson, President, in the chair. It was decided to continue the classes in connection with the society for the purpose of qualifying for the pharmaceutical examinations. The following are the classes:—Pharmaceutical and General Chemistry, Professor Tichborne; Materia Medica and Botany, Dr. Auchinleck; Classics, etc., Mr. T. Lyons, C.E., T.C.D. The following officers were elected for the year:—President, Mr. E. M. Hodgson; Vice-President, Professor Tichborne; Hon. Secretary, Mr. W. Hayes, Treasurer, Mr. Stanley Oldham; Assistant Secretary, Mr. J. O'Brien; Committee, Messrs. S. Boyd, P. T. Bermingham, F. Froedman, J. Goodwin, G. Grindley, J. T. Holmes, J. Greenfield, R. Simpson; Auditors, Messrs. R. Simpson, C. Johnston. The Society is stated to be in a very prosperous condition.

MEETING OF PHARMACEUTICAL CHEMISTS (IRELAND) IN DUBLIN.

A meeting of pharmaceutical chemists was held at the Molesworth Hall, Molesworth Street, on Monday evening, Mr. C. Mannin in the chair, to take preliminary steps for the formation of a Pharmaceutical Defence Association. Mr. Holmes acted as secretary, *pro tem.*, and read a large number of letters expressing sympathy with the objects of the meeting.

After much discussion it was decided to wait on the Council of the Pharmaceutical Society (Ireland) at its next meeting to urge the necessity of protecting the interests of its licentiates.

Messrs. Mannin, Bennett, Keatley, Ferguson and Keogh, were appointed a deputation for that purpose.

Mr. Grindley, in proposing a vote of thanks to the Chairman, said that all pharmaceutical chemists were very much indebted to Mr. Holmes for the energetic manner in which he had taken the matter up. The meeting was largely attended.

WOLVERHAMPTON CHEMISTS AND DRUGGISTS' ASSOCIATION.

On Tuesday evening, November 7, the first meeting of the present session of the above-named Association was held in the Committee Room of the Agricultural Hall, Wolverhampton. There was but a small attendance. Mr. Fleeming (the President), in opening the proceedings, said he hoped the present session would be as successful as the last. It started under very favourable circumstances, with one exception, viz., the loss of one of the Association's secretaries, Mr. F. Barrett, who had left the town.

The Hon. Secretary (Mr. W. Y. Brevitt) then read the report for the past year.

It commenced by expressing regret for the loss of the valued secretary, Mr. Barrett. The Association had been indebted to Mr. Barrett for nearly all the success it had achieved; had it not been for him it would not have the valuable library it possessed, as with the exception of one or two books they had all been presented by the respective authors, and given at the solicitation of Mr. Barrett. Since the last meeting several students had passed the examinations at Bloomsbury Square, one of them, Mr. Severs, having succeeded in passing the highest examination—viz., the Major. He also succeeded in obtaining a certificate of honour in the Practical Chemistry Class, conducted by Professor Attfield. The Preliminary examination has also been passed by two. The next subject was the classes. Mr. Brevitt said he thought it should be the object of the Association to get as many as possible to join the various classes in chemistry and botany that are constantly being carried on by the Free Library Committee, and at various other places. He felt convinced much good might be derived therefrom, without the anxiety of the financial aspect of the question. Independently of this, he intended to try to have a pharmacopœia class, conducted by himself in Darlington Street. Early in the new year he hoped there would be a popular Christmas Lecture, made as attractive as possible, by a valued friend of the Association. He need scarcely tell the apprentices of the present day that they had their work to do, and it was only by diligent application that they would succeed. There was no doubt that the examinations are more severe than formerly, and he questioned very much the propriety of that step; he thought when more candidates were rejected than passed, it was a sign that there was too much severity exercised. In the selection of examiners he would much prefer men of the stamp of Jacob Bell, Peter Squire, John Garle, and Henry Deane, than those that were selected principally because they have distinguished themselves as students, and have taken the chief prizes. He might be wrong, but he thought they rather expected others to be as clever as themselves. However, when young men saw that some of their fellow-students passed it showed it may be done, and they must then be determined it shall be done.

The Chairman, before distributing the prizes gained by the successful students during the last session, expressed the pleasure it gave him to distribute those prizes. He agreed with the remarks of the Secretary in the report about the stringency of the examinations, which was telling very much against the trade of the chemists in the country. The examinations were so severe that they were driving young men away from the trade, and this would eventually tell fearfully against it. He then distributed the prizes as follows:—

Latin and Preliminary examination prizes—1st, Pereira's Materia Medica' (abridged edition), Mr. Gaskin; 2nd, Squire's 'Companion to the British Pharmacopœia,' Mr. Whiston. Pharmaceutical Chemistry and Pharmacy—1st, Bryant's 'Practice of Surgery,' 2 vols., Mr. Aston; 2nd, Chemical Apparatus, Mr. J. H. Jones; 3rd, Chemical Apparatus, Mr. W. B. Cooley. Botany and Materia Medica—1st, Parrish's 'Pharmacy,' Mr. W. B. Cooley; and 2nd, Dr. Phillip's 'Manual of Materia Medica,' Mr. Watts.

Mr. W. F. Haydon, of Birmingham, the secretary to the recently formed Chemists and Druggists' Trade Association, then read a paper on the objects of that Association. These included the amendments of the Pharmacy Act, and also to deal with the defence of its members from vexatious and unjust prosecutions under the Adulteration and Medical Acts. The Association had urged upon the Pharmaceutical Society the necessity of testing the legality of co-operative traders selling and dispensing poisons.

The paper, which was listened to with the greatest attention, included topics most important to the interest of the trade in general, and after a very interesting discussion, a resolution was passed:—"That the meeting thoroughly approved of the aims and objects of the Chemists and Druggists' Trade Association as described by Mr. Haydon, and pledged themselves to support the same by every means in their power."

After a vote of thanks to Mr. Haydon for his paper, and to the Chairman, the meeting separated.

DOVER CHEMISTS' ASSOCIATION.

A meeting of the members of the trade in Dover was held at the Apollonian Hall, on November 8, when it was decided to form an Association, holding quarterly meetings, and to which the annual subscription should be five shillings.

Mr. W. H. Cotterell was appointed President, and Mr. J. F. Brown Secretary and Treasurer, for the ensuing year.

It was resolved that the President for the time being should represent Dover and the surrounding district on the General Committee of the Chemists and Druggists' Trade Association, the consent thereto of the members residing in the district having been already obtained.

A general opinion was expressed that the Chemists and Druggists' Trade Association should act in concert with the Pharmaceutical Society, through whom either legislative or legal action could be most effectually taken.

The compilation of a dispensing and retail price list for the whole of England was also suggested as a subject deserving its attention at the earliest opportunity.

Although the Dover Association is only now formally constituted several previous meetings had been held, at one of which a dispensing and retail price list, on the basis of the Liverpool list, was agreed upon.

Parliamentary and Law Proceedings.

CHARGE OF SELLING POISON WITHOUT A LABEL.

Mr. A. J. Appleton, druggist, Bolsover, was on Saturday, November 4, summoned by Superintendent Carline, to the Chesterfield County Police Court, for an offence against the Pharmacy Act on the 13th ult.

A woman, named Mary Crowder, deposed that on the day named she went to the defendant's shop for two ounces of cordial or soothing syrup, which she was in the habit of giving her children. She took a bottle with her, and there was no label on it. The defendant's sister served her, and on receiving the bottle back it was labelled, "Soothing Syrup." On taking it home she was about to give some of the contents of the bottle to one of her children, when it refused to have it. Thinking there must be some mistake she smelt the mixture, and found it was laudanum. On the advice of a neighbour, she took the bottle to the police station.

An assistant at Mr. Booth's, druggist, Chesterfield, stated that the bottle produced contained laudanum, and bore a label, "Soothing Syrup." If the contents had been taken in the quantities specified, it would have been sufficient to cause death.

The person who supplied the mixture was called, but was unable to recollect serving Mrs. Crowder. She admitted, however, that the label on the bottle was such as she would have put upon a bottle containing cordial for children, and bore the defendant's name and address.

The defendant said there had evidently been a conspiracy to injure him, or the woman would have taken the bottle back to the shop, and pointed out the mistake, if there had been one, instead of handing it to the police. He contended, however, that a label stating that the bottle contained laudanum might have been put over a cordial label already on the bottle, and that Mrs. Crowder had taken it off as soon as she left the shop.

The Bench declined to believe that version of the case, and fined the defendant £1 and costs, remarking that he might consider himself fortunate that he was not there on a more serious charge.—*Sheffield and Rotherham Advertiser.*

Death through Incautious Subcutaneous Injection of Morphia.

At Southsea, on Saturday, November 4, the Coroner (W. H. Garrington, Esq.) held an inquest upon the body of Annette Ray Frampton, wife of a lieutenant and adjutant in the Royal Marine Light Infantry.

Deceased's husband deposed that his wife was 25 years old, and that whilst at Walmer, in 1871, previous to giving birth to a child, she suffered greatly from sickness. Dr. Woodman, to alleviate this, used morphia by the hypodermic method, always injecting the solution himself. On leaving Walmer the deceased went to London until three months ago, and during a portion of that time continued the subcutaneous injection under medical sanction. After her removal to Southsea, deceased assured him she had entirely given up the use of morphia. On the previous Monday he left home for London and returned the following Thursday, when he found the deceased suffering from convulsions. She grew worse and died the following morning. Since her death several bottles had been found in her wardrobe tied up in a parcel and secreted, together with five or six small cases each containing a hypodermic syringe. He was certain his wife did not know the risk she ran while using the morphia.

A domestic servant in the employ of previous witness deposed to having been sent frequently by her late mistress to Mr. Cruse, chemist, Palmerston Road, for the medicine referred to. On Wednesday the deceased sent her to Mr. Burford Norman, to ask him to re-visit her, as she thought she had symptoms of lock-jaw. He came and gave her a draught. On Thursday morning, between two and three, she got worse, and shortly after the doctor had left the second time she was seized with frequent convulsions, during which the head was drawn forcibly back, and the back was curved. Whenever she took the solution of morphia to her mistress she was told to take it up quietly and put it in the drawer.

Mr. Thomas Harris Cruse, registered pharmaceutical chemist, Palmerston Road, said that at first he refused to serve the solution, but on reference to his junior assistant he was informed that he had been in the service of Mr. Horncastle, and knew that Mrs. Frampton had been frequently supplied with the solution. In August, September, and October, he supplied nine bottles each month, the last being on the 30th ult.

Dr. Norman deposed that when he asked deceased if she had latterly taken morphia, she said she had not except on a very few occasions. He described the state he found deceased in, and stated that when Mr. Henry Burford Norman and Dr. Jackson were called in they discovered on the upper part of both arms, a large number of old scars, which they were informed were the result of hypodermic injections five years ago. There were no recent marks about the arms, but upon both thighs there were a large number of similar marks, and also several marks of recent punctures. Around some of these latter there was a redness of the skin in different stages, and one particularly had the appearance of having been made within twenty-four hours. He was of opinion that Mrs. Frampton died from tetanus, caused by the punctures made in the thighs for the purpose of injecting solution of morphia. He had been shown three syringes, all of which were in a dirty condition, apparently not having been wiped dry after using. The steel needles were in a very rusty state, which would be likely to set up inflammation.

The jury returned a verdict to the effect, "That the deceased died from tetanus, or lock-jaw, caused by inflammation arising from punctures made by the deceased herself, for the purpose of subcutaneous injection of solution of morphia."—*Portsmouth Times.*

Alleged Death through Administration of Laudanum.—Verdict of Manslaughter against a Chemist's Assistant.

An adjourned inquest was held at Grangetown on Saturday last, by Mr. E. B. Reece, the coroner, touching the death of Archibald William Henry Hayward, aged seven months, who died under suspicious circumstances on the previous Monday.

At the first sitting of the inquest the jury, not being satisfied with the evidence adduced, decided that a *post-mortem* examination of the deceased's body should be made, and adjourned the inquest in consequence.

According to the deposition of Matilda Hayward, the mother of the child, it appeared that the child, which seemed healthy when born, became subject to fits when three months old, and had never since been well. She had been in the habit of taking him to the infirmary at Cardiff, and also to medical men. She had been also in the habit of giving deceased continually, soon after his birth, syrup of poppies, in which was always some laudanum, she having been recommended to give that to one of her children when living at Southampton. Mr. Williams, an assistant in Mr. Yorath's shop at Lower Grangetown, had always sold her the syrup of poppies, and she had gone to no other chemist's shop. She had told Mr. Williams that laudanum had been put into the syrup of poppies at Southampton, and he had always put some drops in the medicine she had bought of him, which was always a pennyworth at a time.

The depositions of George Whitfield Williams, living at 44, Stuart Street, Cardiff, chemist's assistant, were then read, after which,

Edward Hayward, father of deceased, was called, and deposed to going on different occasions to Mr. Yorath's shop and being served by Mr. Williams on each occasion with a pennyworth of syrup of poppies, in which laudanum was always put. Mr. Williams used at first to put three drops of laudanum in the medicine, but it having no effect upon deceased witness used to tell him so, whereupon Mr. Williams would always put a larger quantity of laudanum in the syrup of poppies. Last week the amount of laudanum placed by Mr. Williams in the pennyworth was fifty drops. Deceased was always given a half teaspoonful of the mixture as directed.

Dr. D. E. Jones was next examined as to the result of his *post-mortem* examination. He stated that he found the body in a very emaciated condition. Deceased only weighed 6 lb. 11 oz., the average weight for a child of that age being 20 lbs. He found that both lungs were inflamed, and certain portions of the body in a congested state. The stomach was very small and contracted, and would only hold one ounce of food, or two tablespoonsful of anything at a time. In his opinion death was accelerated by taking opium or laudanum, together with the diseased state of the child's body. He was of opinion that if proper medical treatment and necessary care had been taken, and opium had not been administered to him, deceased would have lived.

The Coroner having summed up and pointed out the most important points of the evidence,

The jury, after consulting for over half an hour, could not agree, and the inquest was again adjourned.

On Monday the adjourned inquest was resumed, and Matilda Hayward, the mother of the deceased child, was recalled. In answer to questions from the coroner, she said she did not begin to give the child poppy syrup when it had fits before Dr. Jones saw it. She could not say for certain when she began to administer this medicine. She weaned the child on the Thursday before it died, and then gave it food in a bottle. At this time the quantity of food the child would take was very small.

Edward Hayward, the father, was also recalled, and said the child was in the habit of vomiting food after it had taken it.

Dr. D. E. Jones, in reply to the coroner, said the practice of taking opium for a long time would produce great derangement of the stomach, and in the case of a child would be likely to result in the rejection of food. He thought it possible the child was offered food frequently enough, but, from the condition its stomach was in from the laudanum, was unable to take the food. This state of things might have existed for some weeks past.

This was all the evidence, and the Coroner then summed up the leading points of it to the jury. He pointed out that there could be no doubt the cause of the child's death was starvation, and that from the fact of taking the laudanum its stomach got into such a condition that it could not take any food. The evidence of the father and mother, however, showed that food had been offered to the child frequently enough, and the question for the jury was whether blame attached to anyone for administering the laudanum. If they thought the father and mother were aware of the hurtful nature of the opium they were no doubt guilty of great negligence, but, as many people in their position were ignorant of its fatal effects, there was reason to doubt whether they were well informed on this point. The question also arose whether any culpability attached to Mr. Williams, the chemist's assistant who supplied the medicine containing laudanum; and if the jury were of opinion that he was to blame, it would be their duty to return a verdict of manslaughter against him. They would also have to consider whether the father and mother were aware of the dangerous properties of opium, and if they believed they were it would also be the duty of the jury to include the parents in the verdict of manslaughter.

A girl named Comer was called to confirm the statements of the mother as to frequently offering the child food. She mostly saw the mother offer food to the child both in the morning and the evening, but could not say how frequently food was given to it during the day.

After deliberating about half an hour the jury returned a verdict of manslaughfer against Edward Hayward and Matilda Hayward, the parents of the deceased, and George Whitfield Williams, the chemist's assistant who supplied the laudanum.

The Coroner then committed the accused for trial at the winter assizes, but accepted bail for their appearance, the parents in two sureties of £50 each, and Williams in two of £100 each.—*Western Mail.*

POISONING BY CARBOLIC ACID IN A HOSPITAL.

An adjourned inquest on the body of Christina Fraser, a child who was poisoned in the Wirrall Hospital for Sick Children, Birkenhead, on the previous Friday, was held on Thursday, Nov. 9, before Mr. Churton, coroner, at the Richmond Hotel, Birkenhead.

Mr. Billson, solicitor, watched the proceedings on behalf of the managers of the institution.

Mr. Alfred C. E. Harris, M.B., hon. surgeon, said the deceased was admitted in February last, suffering from dislocation of the spine, and had since been under the care of Dr. Braidwood. On Saturday morning, between seven and eight o'clock, he was called to the child, which he found dead on his arrival. Witness made a *post-mortem* examination of the body on Monday, and found that death had resulted from the effects of carbolic acid. The medical officer did not dispense medicine to the patients. There was a dispenser, who attended daily, and when not in use the dispensary was locked, the matron having charge of the key. Carbolic acid was used in the hospital for surgical dressings, and the quantity on the premises varied. As it was required it was obtained from the dispenser. At this time none of witness's cases required any.

Charlotte Crockett, the night nurse, who administered the poison, said that at half-past ten o'clock on Friday night she gave deceased a supper of bread and milk, and afterwards a small quantity of port wine from a 3oz. bottle which she always found on a tray on the top of the cupboard. The child had to take three ounces of wine every twenty-four hours. Deceased seemed very restless, and at midnight she gave her a small quantity of wine, and again when she asked for something to drink witness gave her some milk. About seven o'clock next morning the child seemed exhausted, and asked if breakfast was ready. Witness, finding there was not sufficient wine in the bottle from which she had obtained the first supply, took down another bottle, thinking it contained the child's wine, and gave deceased some of it. The bottle was not labelled, and resembled the bottles in which wine for the patients was put. It had formerly been one of the wine bottles. (The bottle was produced, and was found to contain carbolic acid.) Witness was not told by anyone that there was carbolic acid in the room. She did not smell anything on pouring the acid out. It was daylight when she poured it out.

Mr. Billson: Did you think you were doing right in making use of another patient's wine?

The Coroner: I think she did quite right, considering the child's exhausted condition; and she thought the bottle contained port wine.

Witness: The bottles of wine are always labelled. I took it for granted that all the bottles in the tray contained wine. I am not a certificated nurse.

Elizabeth Sheard, under-nurse, said that in cleaning out a cupboard in the hospital on Friday night, she thought the bottle produced contained port wine, and she placed it on the tray near the deceased. In answer to the coroner, witness said she was seventeen years of age, and could neither read nor write.

Ann M'Cann, head-nurse, said she only used carbolic acid under the direction and personal superintendence of one of the doctors. No carbolic acid had been used since last June. The bottle produced had remained in the cupboard till brought out by the last witness. It was formerly a wine bottle, but witness had forgot to label it

The Coroner remarked that the case was an extraordinary one, and suggested that the committee of the institution should endeavour to obtain the services of women of greater experience and intelligence than were possessed by the under-nurse, and that such people should both read and write.

The jury returned a verdict of "Death from misadventure." They added the following presentment:—"Great carelessness has been exercised on the part of the officers of the institution in the use of poisons; and we suggest that the committee should in future order that all the bottles containing poison should be labelled as such, and when done with should be returned to the surgery. We also think it incumbent that in such an institution the servants ought to be able to read and write."—*Liverpool Daily Post.*

Poisoning of an Infant by Laudanum.

A case which no doubt was intended by the Crown authorities to act as a warning to nurses in the treatment of infants, was tried before the Sheriff at Selkirk on Saturday last. The accused, Mrs. Scott, acted as nurse on the occasion of the confinement of the mother of a fine strong and vigorous infant. About twenty-four hours after its birth, as the child cried considerably, the nurse gave it three drops of laudanum, telling the mother what she was about to do, and saying that she had done it before, and it would do the child no harm. In a few hours, the child became very ill, and it died fourteen hours after taking the laudanum. The Sheriff, in passing sentence, remarked that there was no reason whatever for thinking that the accused had acted otherwise than with a desire to benefit the child, which, indeed, was the line of defence; but, having in view that there was a good deal of administering of poison by nurses in ignorance of its effects, he passed a sentance of six weeks' imprisonment.—*British Medical Journal.*

Coloured Fires and The Explosives Act.

Sir,—Seeing some correspondence in the Journal about coloured fires, I think it right for the information of chemists, to let them know that the legal advisers of the Metropolitan Board of Works consider that all makers of coloured fires come under the regulations of the "Explosive Substances Act of 1875." Consequently, that mixing a coloured fire, though not explosive, must be carried on in a properly constructed building, precisely such as is used for fireworks, rockets, etc. If I mix a coloured fire composed of nitre, sulphur, and antimony, which by the bye might be a very useful horse medicine, I am liable to be summoned before a magistrate and fined £100. A customer ordered of me 20 lbs. of coloured fire. I mixed it and sent it to him. The inspector from Spring Gardens, in the execution of his duty called on him, took some of the fire, and waited on me shortly afterwards to see what stock I had on my premises, but I had none ready. I went at once to headquarters, saw Mr. Spencer, who very courteously and pleasantly told me, that as these fires were according to the wording of the above Act used in producing a "pyrotechnic effect," the maker or mixer was subject to the same regulations as all manufacturers of "explosive substances." I might register my place of business and buy and sell, but directly I mixed them I became a manufacturer. I did not feel disposed to contest the matter, however harmless and innocuous might be the fires I made, though this interference with what I believe to be the legitimate business of a chemist does at once stop what has been for the last three or four years a very useful and paying part of my business. Because rockets, stars, Roman candles, and many other explosive fireworks, together with coloured fires, have been stored and sold in a careless and negligent manner by licensed retail dealers, therefore, chemists are prevented from mixing and selling coloured fires, which are neither explosive nor dangerous. I suppose we ought to be thankful for the care taken of us by such legislative Acts, but I am free to confess that I am "considerably riled" at such mistaken kindness, as I feel quite capable of conducting my business without dangerous risks.

James Slipper.

November 11, 187c.

Toughened Glass.

Sir,—Some of your correspondents appear to have been very unfortunate with their toughened glass experiences. My experience is quite different, having had a set of tumblers of toughened glass in daily use for the last two months, and without any breakage. Only last week my servant, in taking them out of the glass closet in the kitchen, let one fall without harm on the brick-floor, a height of four feet; it simply rebounded, and rolled away to her astonishment.

Tenbury. J. S.

The Sessional Prizes.

Sir,—"An Intended Second Year's Student" sees no reason for altering a custom that hitherto apparently has worked well. Has it worked well? Were not the silver medals for the lectures last session carried off by a second year's man, causing much dissatisfaction among the first year's men?

He also fails to see the injustice of allowing second year's men to compete with the first year's men. If this is to be allowed, what is to stimulate the first year's man to earnest study? It is few that can afford the luxury of more than one session at the Square; and are they "to be turned empty away," while the silver medals are taken by some gentleman with plenty of time and money to make up for other deficiencies?

That the altered system works well and gives satisfaction among the students in the laboratories is well known. Then why not extend it to the lectures?

A Last Year's Student at the Square.

"*Aquam.*"—The Aq. Sambuci quoted at 8*d.*, is, we believe, that made of the strength of the British Pharmacopœia (one pound flowers to one pound of distillate), and is termed "duplex." That at 4*d.* per pound is half this strength; while that quoted as "triplex" is either imported from South France or made in the proportion of one and a-half pound flowers to one pound of distillate.

M. P. S.—The more volatile portion of petroleum spirit has been used for the purpose mentioned, but the name "gasaline" is by no means restricted to that portion.

J. Edwards.—We shall be happy to publish your recipe, and thus put it in the possession of all our readers without expense to you or them.

P. W.—Probably some substances in each of the classes mentioned.

T. C.—*Brilliantine.*—Recipes for this preparation have been already given in this Journal. The following is one of them:—

Honey	℥j.
Glycerine	℥ss.
Eau-de-Cologne	℥ss.
Rectified Spirit of Wine	℥ij.

E. Bevan.—The preparation you mention is a proprietary one. Beasley gives the following for a Syrupus Hypophosphiticus:—Hypophosphites of lime, potash, and soda, one part each, dissolved with heat in 100 parts of syrup. See also *Pharm. Journ.* [3], vol. v., p. 425.

R. S.—We believe the preparation is made by Messrs. Corbyn.

A. P. S.—A new edition of the *Homœopathic Pharmacopœia* has just been issued, and copies may, we believe, be obtained at the Society's establishment, Great Ormond Street.

"*Apprentice.*"—See the prescriber; the precipitated quinine had probably been strained out before.

Messrs. T. and H. Smith.—Your communication has been forwarded to the publishers.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over the Editorial columns will prevent delay, and the consequent annoyance.

Communications, Letters, etc., have been received from Mr. Graves, Mr. Davis, Mr. Abraham, Dr. Tilden, Mr. Thresh, Mr. Edwards, Mr. Bevan.

SOLVENTS OF SALICYLIC ACID.

BY J. C. THRESH, PHARMACEUTICAL CHEMIST.

To increase the facility with which salicylic acid may be administered, various substances have been proposed, which increase in a remarkable manner the solvent action of water upon it. The salts usually employed for this purpose are, borax, phosphate of soda, and citrate of ammonia, and my experiments were undertaken to ascertain whether or not this increased solubility was due to some chemical decomposition between the acid and the salts employed, and if the solutions thus formed possessed the antiseptic and antifermentative properties of the free acid.

Borax.—This salt is remarkable for its solvent action upon a large number of organic compounds, the nature of which action is not, in most cases, yet ascertained. If borax and salicylic acid be mixed in a mortar, the result is a damp almost pasty mass. The taste at first is simply that of the acid and borax, but in a very short time it begins to acquire a bitter taste, and after a few hours it will be found to be intensely bitter. If a little of the freshly prepared mixture be carefully fused the resulting mass at once becomes exceedingly bitter, and if the proportions employed were one of borax to two of acid, the mass is soluble in about twice its weight of water. A dilute solution of five gr. each of acid and borax, in one oz. of water is devoid of bitterness, and remains so even after keeping a length of time, but stronger solutions soon become bitter. I have failed as yet to ascertain the nature of this reaction, or to isolate the bitter product, unless a crystalline deposit, which is slowly forming in a solution of 2·5 borax, 4 acid, and 50 water, which is evaporating spontaneously, proves to be the substance in question.

Phosphate of Soda.—This salt has not a solvent effect equal to that of either borax or ammonium citrate. One part of salicylic acid requires—

2 parts of phosphate to form a solution with				50	parts water.
2·25	"	"	"	25	"
2·5*	"	"	"	12·5	"

Solutions 1 and 2, are colourless, but the strongest solution has a slight pink tint (characteristic of salicylic salts). Diluted with water, ferric chloride added in excess gives a purple red solution, which also indicates the existence of a salicylic salt, since whilst free salicylic acid strikes a purple colour with ferric chloride, its salts give a deep red coloration with this reagent. No phosphoric acid, however, is liberated, for a single drop of the dilute acid, added to the solution, causes a precipitation of salicylic acid.

Ammonium Citrate.—I first ascertained by experiment that this citrate, whilst increasing the solubility of salicylic acid in water to a much greater extent than sodium citrate, yet possesses no advantages over potassium citrate, and as this latter was more convenient for my purpose, I have employed it in preference.

Table of solubility of salicylic acid in potassium citrate solution—

Sal. Acid	1	Citrate	·75	Water	100
"	1	"	1·0	"	50
"	1	"	1·15	"	25
"	1	"	1·25	"	20
"	1	"	1·4	"	12·5
"	1	"	1·5	"	7·5

A stronger solution than the last solidifies upon cooling, but the nature of the mass I have not yet ascertained. It gives reactions indicative of free and combined salicylic acid, and of combined citric acid, but not of free citric acid. An alcoholic solution of potassium salicylate, mixed with a similar solution of citric acid, gives a precipitate of potassium citrate, which readily dissolves on the addition of a little water, and the solution thus formed is miscible with water, without precipitation of salicylic acid. 1 dr. Acid. Salicylic, 3½drs. Sp. Vin. Rect., 1 dr. Pot. Cit., and 3½ drs. Water, form a solution miscible with water in all proportions, and 2 drams of which contain 15 grs. of the acid. In this solution diluted acetic acid gives no precipitate, citric acid causes a precipitate to form slowly, mineral acids throw down the salicylic acid instantly. Ferric chloride colours the fluid purple red.

To ascertain the antiseptic value of the solutions formed by aid of these salts I added them to a number of infusions (malt, quassia, calumba, etc.), to grape juice, and flour paste, and so far as I can tell after a lapse of two months, with the exception of flour paste and grape juice, the solutions are equally as fresh as those prepared with free salicylic acid.

To test their antifermentative powers I prepared over thirty mixtures of flour (1oz) and water (½oz), with 20 grains of German yeast in each and added thereto various proportions of free salicylic acid, of potassium salicylate acidified with acetic acid, and of salicylic acid dissolved by aid of borax, phosphate of soda, and citrate of potash, and in the cases where no fermentation ensued I confirmed the result by repetitions of the experiments.

The smallest quantity of free salicylic acid which uniformly prevented the rising of the dough was 1 grain. The acidified salicylate of potash had not the slightest effect unless added in large proportions. 1 gr. of acid in borax solution was equally as powerful as the free acid. A similar quantity dissolved by aid of ammonia citrate or sodium phosphate only retarded for a variable time the fermentation, but in both cases 1¼ gr. was found effectually to arrest it.

It is therefore evident that some reaction as yet undetermined does take place between the salicylic acid and the salts employed as its solvents, yet that in whatever state the salicylic acid exists in the above named solutions, it is capable of exhibiting in a high degree all those properties which have conferred upon it such notoriety.

Buxton, Nov. 6, 1876.

* Three drams would contain a full dose (fifteen grains nearly) of salicylic acid.

COMPARATIVE EXAMINATION OF THE MORE IMPORTANT COMMERCIAL VARIETIES OF GALBANUM AND AMMONIACUM GUMS.*

I. GALBANUM.

BY EDWARD HIRSCHSOHN.

(*Continued from page* 391.)

7. *Behaviour towards Reagents*—Among the qualitative reactions to which galbanum was submitted by the author, those with alcohol and sulphuric, hydrochloric and nitric acids, merit

* From a memoir for which the gold "Suworow" medal has been awarded by the Medical Faculty of the University of Dorpat. (*Pharmaceutische Zeitschrift für Russland,* April 15, 1875, p. 225.)

attention, because not only do they enable galbanum to be distinguished from ammoniacum, but also from other resins and gum resins; also, chloride of lime, although it produces no special appearance with galbanum, may be used in this respect to distinguish galbanum from ammoniacum.

Upon moistening small pieces of the gum resin with a few drops of alcohol, and treating them with concentrated sulphuric acid, there resulted in every case a chestnut-brown solution which was carmine-red at the edges, whilst the gum resin was more or less coloured dark green to greenish blue, with the exceptions of Nos. 1, 2, 3, 4, 15, 17, and 24,* which showed a brown-black colour. An addition of water caused the separation of a dirty violet coloured body. Upon treating this solution of the resin in sulphuric acid with three to four times its volume of 95 per cent. alcohol, there was formed with the Persian sorts, Nos. 1, 2, 3, 4, 15, 17, and 24, a clear yellow brown solution, whilst the Levant sorts, Nos. 5, 6, 7, 11 and 12, gave a more or less intense blue violet, and Nos. 8, 9, 10, 13, 14, 15, 16, 18, 20, and 21, a red violet solution.

When moistened with alcohol, and treated with hydrochloric acid (sp. gr. 1·12), Nos. 5 to 9, 12, 13, and 16, showed a faint rose colour, which after half an hour in Nos. 5 to 9, 13 and 16, passed into red violet, and in No. 12 to light blue. Nos. 11, 14, and 18 to 21, showed a violet colour, which in No. 19 passed in half an hour to light blue, the others changing into blue violet. In Nos. 1 to 4, 15, 17, and 24, the colour was yellowish brown, becoming more or less red after half an hour. No. 10 at first showed no change, but after half an hour showed a faint violet tint. Nos. 22 and 23 formed slightly yellow coloured solutions, No. 22 afterwards acquiring a very faint rose colour, but No. 23 undergoing no further change. Small pieces of resin treated with a saturated solution of chloride of lime underwent no change. When equal volumes of tincture of galbanum (1 part of gum resin in 5 parts of 95 per cent. alcohol) and pure hydrochloric acid (sp. gr. 1·12), or nitric acid, were mixed, there resulted a turbidity and coloration of the mixture, as shown in the following table:—

No.	Description.	Hydrochloric Acid.	Nitric Acid.
1	Per. Astrachan	Light red brown.	At first scarcely any colour, gradually rose, and finally red violet.
2	„ Kasan	Same.	At once rose, passing gradually to red violet.
3	„ Institut	Same.	Same.
5	Lev. Institut	Blue violet.	Yellow red, soon blue violet.
8	„ Hamburg	Violet.	Blue violet.
10	„ Hamburg	Almost colourless.	No change.
11	„ Dorpat	Blue violet.	Like No. 8.
12	„ Nisch.	Violet.	Like No. 8.

Other gums and gum resins were examined by the author with the same reagents, but with the exception of sagapenum none behaved similarly to galbanum.

8. *Amount of Mineral Constituents and Water.*—For the estimation of the ash a quantity of the resin was mixed as thoroughly as possible, and then 2 to 10 grams taken, according to the purity. The combustions were rather troublesome, the last portion of carbon being difficult to remove.

In each case the ash consisted of small quantities of alkaline chlorides, sulphates and phosphates, rather much calcium carbonate, a little ferric oxide, and more or less ferruginous sand. The least sand was contained in Nos. 1, 2, 5, 8, 11, 14 and 16; Nos. 3, 4, 7, 9, 10, and 13, contained more; and No. 12 the most. These data show that all sorts are not collected with equal care, and that sand is introduced into many through carelessness or adulteration.

The estimation of the moisture was very difficult, several methods were tried without arriving at perfectly satisfactory results. An estimation in the ordinary way, by heating the substance to 110° C., was hindered by the presence of the volatile oil. To remove this obstacle as much as possible, a small quantity was weighed and mixed with sand, and treated with petroleum ether in a small displacement apparatus, until nothing more was taken up; the residue was then heated (in the displacement apparatus) at 110° C. until it no longer lost weight. The loss of weight then represented the moisture plus the volatile oil, and from this the amount of oil, obtained by a separate operation, was deducted.

An attempt to remove the moisture by exposing a weighed portion mixed with sand in a watch-glass over sulphuric acid until the weight remained constant, was unsatisfactory. The figures obtained were not reliable in all cases, as, especially in the Persian, a small quantity of volatile oil was lost.

Finally, the moisture was estimated from the loss after a weighed quantity mixed with sand had been treated with petroleum spirit, ether, alcohol, and water, and the residue dried at 110° C. The figures obtained in this way gave the most satisfactory results, and agreed very well with those obtained by the first method. The results obtained by these two methods, and the percentage of ash are shown in the following table:—

No.	Description of Galbanum.	Ash.	Moisture 1st method.	Moisture 2nd method.

9· *Distillation with Water.*—These experiments

* See before, p. 390.

were only carried out with those sorts of which a certain quantity was available. The distillation was effected with the vapour of water from a glass retort placed in a sodium chloride bath. The steam was introduced by means of a tube bent twice at right angles, the longer end of which passing through the tubulure reached almost to the bottom of the retort, whilst the shorter end was connected with a flask containing boiling water. The water passing over with the volatile oil was poured back into the retort as long as any oil drops passed over.

The following sorts were used—

No.	Description of Galbanum.	Quantity used.	Amount of Oil.	Per ct. of Oil.
		Grams.	Grams.	
1	Persian, from Astrachan . .	50	6·89	17·38
2	„ „ Kasan . . .	100	14·74	14·74
8	In granis, „ Hamburg, 1873	50	2·59	5·18
11	In massis, „ Dorp. Pharm. .	100	4·06	4·06
12	„ „ Nowgorod . .	50	3·12	6·24

The oil from Nos. 1 and 2 passed over with the water vapour very easily, No. 1 in the proportion of one part of oil to 2·8 parts of water; that from the other sorts much more slowly.

All the volatile oils were neutral to litmus paper. With the exception of No. 11, which had a faint yellow colour, they were perfectly colourless; they refracted light rather strongly, and had a strong smell of galbanum, which in Nos. 1 and 2 appeared to be mixed with that of rosemary and turpentine. The sp. gr. at 17° C. of Nos. 1 and 2 was 0·8673; Nos. 8 and 12, 0·8890; and No. 11, 0·9004.

Examined in a Wild's polaristrobometer, with a 50 mm. column, No. 1, gave with the sodium light a deviation of a beam of polarized light 8·3 to the right, showing a specific rotatory power of 19·116°; No. 2 gave 7·1, or a specific rotatory power of 16·373°.

Concentrated sulphuric acid coloured the oils Nos. 1 and 2 citron yellow; Nos. 8, 11 and 12 orange red, which after 24 hours became blood red. Shaken with nitric acid (sp. gr. 1·2) the oils were coloured yellow, and after longer standing formed a yellow resinous mass, which, after washing off the acid, dissolved partly in water, imparting to it an intensely bitter taste. A portion of this resinous substance, heated to dryness and then boiled with water gave no reaction of umbelliferon.

Iodine was dissolved by the oils with a red brown colour, which colour, if only a small quantity of iodine had been added disappeared upon heating.

Upon dissolving one drop of oil in twenty drops of alcohol saturated with hydrochloric acid gas, Nos. 1 and 2 took a rose colour which gradually passed into violet; whilst Nos. 8, 11 and 12 were coloured light brown and gradually became darker. Also, one drop of oil dissolved in twenty drops of 95 per cent. of alcohol with five or six drops of concentrated sulphuric acid added gave with No. 1 and 2 no colour, but a milky turbidity; with Nos. 8, 11 and 12 a red violet colour and turbidity.

Some drops of the oils exposed on a glass plate to bromine vapour were coloured yellow. Frohde's reagent produced a similar colour.

Chloral mixed with chloral hydrate dissolved the oils from Nos. 1, 2, 11 and 12 with a faint yellow red colour, passing into olive green; the oil from No. 8 remained yellow red after standing.

An oil from Persian galbanum, about twenty years old, from the collection of the Pharmaceutical Institute, was of a dark yellow colour, and had a galbanum-like odour recalling at the same time that of turpentine. It specific gravity at 15°C. was 0·9500 and it rotated the polarized beam in a 50 mm. column 5·55° to the right. Petroleum spirit dissolved this oil only partially; a largish quantity of yellowish white flocks separating. Strong sulphuric acid dissolved it with an orange red colour, which at the edges changed gradually into red violet, and finally into blue, the liquid itself becoming blood red. A solution of bromine, ether or chloroform added, produced a beautiful red violet colour in the solution, which gradually changed into a beautiful blue. Drops of the oil exposed to bromine vapour were coloured a magnificent violet, which after standing exposed to the air passed to blue and eventually to green. A portion of this oil being submitted to distillation the first drops passed over at 165° C., and had a strongly acid smell and reaction. The thermometer gradually rose to 180° when the greater portion distilled over, and at 200° the first yellow drops were noticed. At 260° the retort was suddenly filled with blue vapour, and some drops of blue oil appeared. The residue, which was a thick dark yellow oil, when boiled with water and filtered hot, gave a strongly fluorescent liquid, the fluorescence being intensified by the addition of potash solution (umbelliferon).

Another sample of this oil was distilled with steam, and passed over in the proportion of 1 part of water to 1·13 part of oil. The oil thus distilled was colourless and neutral, had a sp. gr. of 0·8800 at 15° C., and a specific rotatory power of 22·045° to the right. The accompanying water had a faintly acid reaction, and gave no reaction with hydrochloric acid. The examination for formic and acetic acid, with sulphuric acid and alcohol, gave negative results. The aqueous liquid remaining in the retort reacted strongly acid, and upon the addition of concentrated hydrochloric acid gave a red colour, passing through violet into blue. The resinous residue in the retort, separated from the liquor and heated to 200° C., gave crystals of umbelliferon, and a blue oil. As the freshly distilled oil is free from umbelliferon, these crystals must be considered a decomposition (oxidation) product of galbanum oil.

Another sample of oil, in the collection of the Dorpat Pharmaceutical Institute, from Zeise of Altona, and prepared from Levant galbanum, behaved similarly towards reagents, and in distillation. Its sp. gr. at 15° C. was 0·9545, and its specific rotatory power was 10·058 to the right.

(*To be continued.*)

THE DISPENSING OF COPAIBA RESIN.

BY ALFRED BALKWILL.

The following form of exhibiting copaiba resin we have found give satisfaction to the prescriber and his patient.

It is no trouble to make, and the mixture in elegance of appearance, permanence, and therapeutic action, is preferable to that of any form that we have met with.

℞ Resinæ Copaibæ . . . . . . ʒiss.
Ol. Amygdal. Dulc. . . . . ʒiv.
Mucil. Acaciæ . . . . ʒiss.
Liq. Potassæ . . . . ʒss.
Ol. Cinnamomi . . . . guttæ vi.
Aquam . . . . ad ℥vi.

A sixth part three times a day.

Dissolve the resin in the almond oil with gentle heat, then add the liq. potassæ, and form an emulsion.

SYRUP OF COFFEE.*

BY ROBERT H. BERNHARDT, PH.G.

The preparation of this elegant syrup has long been within the province of the pharmaceutist; yet, with all the various formulæ for its production, contributed from time to time, it has not yet attained any appreciable degree of perfection. Its liability to fermentation has continually been a barrier to its more general adoption.

Syrup of coffee, like some other officinal syrups, is possessed of little or no medicinal value. Its importance as a pharmaceutical preparation lies exclusively in its remarkable power of disguising the taste of nauseous medicines, and the delicate flavour it imparts as an adjunct or diluent.

The following formula, in which is used the process known as "cold percolation," I have found after many experiments the most appropriate:—

Take of

Roasted Coffee	2 troy ounces.
Crushed Sugar	28 „ „
Distilled Water	a sufficient quantity.

Moisten the coffee, previously reduced to a moderately fine powder, with half a fluid ounce of distilled water; introduce it into a conical glass percolator, and gradually pour distilled water upon it until sixteen fluid ounces of infusion have passed. Add this to the sugar contained in a glass percolator, in the orifice of which a piece of soft sponge has been introduced; and in order to prevent the immediate escape of the liquid, a cork is to be tightly fitted in the tube of the percolator at the bottom. The whole is then to be closely covered and set aside for about two hours, or until the sugar has dissolved down to half its former bulk. Then the cork can be removed, and the liquid allowed to drop. If the liquid has all passed and there still remains a quantity of undissolved sugar in the percolator, pour it again upon the sugar until the desired result is effected. This last proceeding is, however, entirely unnecessary and only occupies time; an essential precaution, and on this simple mechanical contrivance depends the success of the entire process, is to carefully insert the sponge in the orifice—not too tightly, but also not too loosely—*just sufficiently close to allow the syrup to pass drop by drop.*

It is also requisite to the immediate transparency of the preparation that the infusion obtained by percolation should be perfectly clear; to accomplish this in the quickest and most convenient manner it is only necessary to close the orifice of the percolator with a wad of dry, well compressed cotton, tightly inserted.

It will be noticed that there is not the slightest degree of heat used in preparing this delicious syrup—further than in the parching of the coffee—and the transparency, reliability and beauty of the product cannot be surpassed by any generally known formula.

The strength of this preparation can be made as individual fancy or desire may dictate. The above affords a very handsome dark-brown coloured liquid, pretty well impregnated with the odour of coffee, and for ordinary purposes serves exceedingly well. For disguising the bitter taste of alkaloids, etc., I would, however, recommend a preparation double the strength of the above; this is easily obtained by simply substituting twice the amount (four troy ounces) of coffee and treating as directed in the general formula.

* From *The Druggists' Circular and Chemical Gazette*, September, 1876.

PIGMENTUM NIGRUM, THE BLACK COLOURING MATTER CONTAINED IN HAIR AND FEATHERS.

At a recent meeting of the Chemical Society, a communication was made on the above subject by Messrs. W. R. Hodgkinson and H. C. Sorby, of which the following is an abstract:—*

When perfectly white hair or feathers are heated gently with dilute sulphuric acid for some time they completely dissolve, but if black or brown feathers or hair are thus treated an amorphous black residue is obtained. This substance, which exists only in very small quantity in the blackest feathers, may be conveniently prepared from rook's feathers (which yield about one per cent.) which have been separated from the central rib, and thoroughly cleaned from waxy and fatty matter by treatment with alcoholic ammonia. On digesting them with successive quantities of dilute sulphuric acid for several days, until the acid ceases to be coloured by red or brown soluble colouring matters, a black residue is obtained, which, after being thoroughly washed with dilute hydrochloric acid at 80° C., and then with water, is dried, and the last trace of fatty matter finally removed by treatment with boiling alcohol and ether. On analysis it gives numbers agreeing very well with the formula $C_{18}H_{16}N_2O_8$. It is not acted on by dilute acids or alkalies, but nitric acid slowly oxidises it. It forms new compounds by the action of bromine, one of which is soluble in water, and gives a characteristic absorption spectrum.

In reply to a question from the president, Mr. Sorby said he had regarded the subject of the colouring-matter of hair and feathers more from a biological than from a chemical point of view. Having found that a black residue was left on heating feathers with the dilute acid, Mr. Hodgkinson had undertaken to investigate chemically the nature of the substance. The black pigment was found in black, brown, and dark red hair, but in the latter it was associated with a brown pigment soluble in dilute sulphuric acid. In very bright red hair he had also found a pink colouring-matter. The feathers of birds were of two kinds, namely, those which contained the *pigmentum nigrum*—including the iridescent feathers, such as those of the peacock, which are really black—and another class of feathers, like those in the crest of the crowned crane, which are not iridescent, but contain various coloured pigments. He considered it very important, from a physiological point of view, that this matter should be more fully investigated. With regard to the pigment of the negro's skin, he had not examined it, but had no doubt that it would prove to be identical with that found in the hair.

Mr. Sorby exhibited a specimen of *pigmentum nigrum*, and also specimens illustrating the colours obtained with this pigment and others soluble in the dilute acid.

Professor Church said his attention had been entirely directed to the feathers in twelve species of turacoa, in which the red parts of the feathers were coloured by turacin. This differs in an important point from the *pigmentum nigrum*, in that its ash consists wholly of oxide of copper. The amount of copper present in turacin is considerably larger than he had formerly stated: this was owing to the fact that when turacin is distilled a red coloured substance passes over which contains copper. This, unlike turacin, is insoluble in ammonia, but soluble in ether.

THE SEEDS OF RICINUS COMMUNIS.†

BY EMIL LOUIS BOERNER, PH.G.

The acrid principle of *Ricinus* seeds is but in a slight degree extracted in the expression of the oil, and the residual marc, as left by the manufacturer of castor oil, would, therefore, contain the greater portion of it, and was the material operated upon.

The coarse particles, which were liable to interfere with

* *Chemical News*, Nov. 10, p. 203.

† From the *American Journal of Pharmacy*, November 1876.

percolation, being rejected, four different portions, of 1000 grains each, were treated respectively with gasolin, bisulphide of carbon, ether, and alcohol, until exhausted; the various menstrua evaporated, and the residues weighed, yielding from gasolin 6·9 per cent.; bisulphide of carbon, 11·77 per cent.; ether, 14 per cent., and alcohol, 21·2 per cent. The first three appeared to be pure oil, and were of a light yellow colour, while the alcohol residue was much darker, and contained considerable colouring matter, which was deposited upon standing.

The marc which had been exhausted with gasolin was further treated with bisulphide of carbon, resulting in an additional 5·37 per cent. of oily residue from which, after a few days' standing, acicular crystals separated, that were insoluble in gasolin, partly soluble in ether, and in alcohol. A second attempt to obtain the crystals was unsuccessful. That portion of marc which had been treated with bisulphide of carbon yielded nothing to gasolin upon subsequent treatment with this menstruum.

A portion of exhausted marc was macerated with water until decomposed, requiring for the process about fourteen days. It was then strained, to separate coarser particles, and distilled; the distillate, having an acid reaction and an odour resembling that of decayed cheese, was treated with carbonate of zinc and filtered; upon concentration of the filtrate, crystals of butyrate of zinc separated. Both crystals and mother-liquor, when shaken with sulphuric acid and alcohol, immediately developed, in a marked degree, the odour of butyric ether. A portion of this ethereal liquid, neutralized with ammonia was unaffected by the addition of ferric chloride, thus indicating the absence of an acetate.

An experiment was made similar to the one of Professor Tuson, in which he found a crystallizable substance supposed to be an alkaloid.

A portion of the marc was boiled with successive portions of water, the several liquids strained through muslin, and the resulting decoction evaporated to the consistence of a soft extract, which was exhausted with boiling alcohol. Upon standing, a substance of a resinous appearance, but soluble in water, separated from the filtrate, and was removed by a second filtration. The filtrate was concentrated, and, as no crystals separated, magnesia was added, the mixture evaporated to dryness, again exhausted with boiling alcohol, and filtered, when, upon concentration and a few days' standing, colourless crystals, having the form of rectangular prisms and tables, separated, answering to the appearance of those obtained by Professor Tuson. These crystals where slowly soluble in hot water. In an acidulated solution of the crystals, phosphomolybdic acid, tannic acid and iodohydrargyrate of potassium produced neither a precipitate nor a coloration; while in the mother-liquor precipitates were at once formed by the two first-named reagents, but by the last one only after some hours, and in amount about one-eighth that formed by phosphomolybdic acid. The mother-liquor, when heated with solid hydrate of potassium, developed the odour of ammonia. From these results the writer concludes that the crystalline substance in question is not an alkaloid.

A substance resembling emulsin was obtained by forming an emulsion of the marc with water, adding an equal bulk of ether, and agitating repeatedly during twenty-four hours, when, upon standing, the liquid separated into two layers; the supernatant liquid being removed, alcohol was added to the other, which precipitated the emulsin. This emulsin, with amygdalin, in the presence of water, developed the odour of hydrocyanic acid after several days' standing. The result of Mr. H. Bower (*American Journal of Pharmacy*, 1854, p. 208) is confirmed by this experiment.

The residue obtained from the alcoholic percolate having deposited a semi-solid portion, largely composed of colouring matter, was agitated with ether, which took up the oil. The part left undissolved by the ether was treated with successive portions of alcohol until but a few grains were left; this, containing a number of minute crystals, and having a very sweet taste, was dissolved in water. The application of Trommer's test proved the presence of sugar. A drop of the aqueous solution, placed on a microscope slide, and evaporated, plainly revealed the presence of cane sugar.

As the best authorities agree in placing the amount of fixed oil obtained from the kernals of the seeds at less than 50 per cent., it would seem that, as more than 11 per cent. is obtainable from the marc as rejected by the manufacturer by treatment with bisulphide of carbon, the latter oil could be produced at a less cost than an inferior quality of the expressed article, and answer the same purpose for use in the arts.

The writer intends making further experiments to determine the amount of butyric acid obtainable from the marc, by a process similar to the one above described.

IPECACUANHA AND VANILLA CULTIVATION IN INDIA.

The following notes on the cultivation of vanilla and ipecacuanha in India we gather from Dr. King's recently received report on the Calcutta Botanic Gardens. With reference to the former, Dr. King says, "some very sanguine forecasts having been made of the future of vanilla cultivation in Bengal, a number of plants were two years ago put out in the Calcutta Garden under sheds similar to those in which the pepper vine is grown. The growth of these plants has not been satisfactory, probably from over-shading, many have, therefore, been recently put under the shade of mango trees. The finest old vanilla plants in the garden grow against a north wall. One of these was this year laden with pods, but an unusually high temperature for a day or two caused them to drop prematurely. Recent as well as former experience leads me to think that vanilla will never become a staple product of Bengal." With regard to ipecacuanha, quantities of plants, it seems "have been sent to Ceylon, to the Neilgherries (for trial at Barliar, a garden in a hot, low valley below Coonoor), and to Burmah. It is to be hoped that a locality may soon be found where this invaluable specific for one of the worst of tropical diseases can be profitably grown as a crop. I fear it cannot be thus grown so far north as Bengal. The secret of successful propagation being now perfectly understood, any number of plants can be sent out. During the year I supplied a quantity of the drug itself (the dried root) to the surgeon-general for trial in hospital practice. This was carefully administered in cases of dysentery by Dr. Crombie, late officiating physician to the Medical College Hospital, and was pronounced by him to be quite as efficient as the best South American drug."

SIUM LATIFOLIUM.*

BY NATHAN ROGERS, PH.G.

Attention having been recently directed to this plant (see *American Journal of Pharmacy*, 1873, p. 371), the writer concluded from its stated marked poisonous properties to subject the plant to a chemical examination.

The water parsnip is an aquatic plant very common in the swamps and along the water courses of the valleys of the Pacific slope. Its root is creeping,† stem erect, angular, leaves pinnate, leaflets ovate, lanceolate, sessile

* From the *American Journal of Pharmacy*, November, 1876.

† This statement does not agree with the brief description given by Mr. A. R. Porter on page 174 of this volume. The root examined by the latter had been sent by Dr. C. B. White, U.S.A., to Mr. F. B. Power.

smooth, serrate, sometimes pinnatifid; flowers white' large rayed, involucres many-leaved, umbels terminal. The leaves of the plant, when found growing in water, are generally bipinnatifid. In appearance, growth, odour, and taste it is closely allied to its innocent congener, the *Pastinaca sativa* On account of this resemblance, it has frequently been productive of dangerous results, when eaten through mistake for the harmless and nutritious tuber of that edible species.

The root being considered the most active part of the plant, it was deemed proper to subject that part to a chemical examination.

A portion of the root, cut up fine, was introduced into boiling water, contained in a retort, and a volatile oil obtained, which had a light straw-colour, neutral reaction and possessed a pungent odour, resembling somewhat the peculiar odour of carrots. A cold infusion of the fresh root, acidulated with hydrochloric acid, and filtered, to separate a precipitate, failed to give a precipitate with iodohydrargyrate of potassium; but when distilled with an excess of potassa solution, a perfectly clear and colourless distillate was obtained, possessing a strong alkaline reaction and peculiar mouse-like odour, somewhat similar to that of conium; after neutralization with hydrochloric acid, however, not the slightest precipitate was occasioned by phosphomolybdic acid, iodohydrargyrate of potassium or potassium cadmic iodide.

The neutralized distillate was next concentrated on a water-bath, and then allowed to evaporate spontaneously over sulphuric acid, which resulted in the deposition of long, slender, colourless needle-shaped crystals. On the addition of milk of lime a peculiar alkaline volatile principle was instantly liberated from its combination, and distinctly recognized by its disagreeable mouse-like odour, and the property of restoring the blue colour to reddened litmus.

Following Wittstein's process for preparing pastinacina, the alkaline distillate was freed from the volatile oil, neutralized with sulphuric acid, evaporated and treated with etherized alcohol to remove ammonium sulphate, the filtrate evaporated to a syrupy consistency and distilled with solution of potassa, gave a distillate which possessed an alkaline reaction, a urinous odour and a pungent taste. After neutralizing with sulphuric acid, needle-shaped crystals were obtained. This *alkaloid* appears to be analogous to pastinacina.*

A spirituous tincture of the root was mixed with water, and the alcohol and volatile oil distilled off; the dark reddish-brown resin removed from the aqueous liquid was soluble in ether and alcohol, and produced in the throat an unpleasant, burning sensation. Weak ammonia dissolved from this *two acid resins*, which were precipitated, the one by acetate, the other by subacetate of lead. The portion insoluble in ammonia consisted in part of *an indifferent resin*. It was dissolved in alcohol, precipitated by a spirituous solution of lead acetate, the precipitate decomposed by sulphuretted hydrogen, and the sulphide of lead treated with boiling alcohol, from which, on cooling, shining colourless needles of a neutral principle separated, which were insoluble in pure and acidulated water, but soluble in ether, and from platinum foil volatilizable without charring. The aqueous filtrate from the resin obtained above was evaporated, and the residue incinerated; the ashes contained salts of *potassium*, *sodium*, *calcium*, and *magnesium*.

On examining a section of the root under the microscope, *starch granules* were found to be quite plentiful around the medullary sheath and near the cortical portion. They polarized but feebly, were oblong, different in size and quite small. *Sugar*, *albumen* and *gum* were found in the cold infusion by appropriate tests.

* Wittstein's pastinacina has an insignificant (unbedeutend) and scarcely somewhat acrid (scharf) taste. See 'Buchn. Repertorium,' vol. 68, p. 18.—ED. A. J. P.

Medicinal Effects.—From experiments made upon dogs, the volatile alkali and the neutral crystallizable principle were both found to be perfectly inert, while the resinous mass, in ten grain doses, was found to lessen the frequency and the force of the heart's beat, producing also dizziness, vomiting and purging, with slight convulsive movements. These poisonous symptoms having gradually disappeared, the animals were left in a prostrate, weakened condition, from which they slowly recovered.

PHARMACY ACT, 1868.

RECTIFICATION OF THE REGISTERS OF PHARMACEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS.

We are requested by the Registrar to publish the following List of persons whose names will be erased from the Register unless they communicate with him on or before 30th December next.

Those marked (*) are Pharmaceutical Chemists.

Abbott, Joseph Ortzen	24, Alfreton Road, Nottingham
Addis, Philip	4, Sussex Villas, Warner Road, Camberwell, Surrey.
Aldridge, Joseph	105, North Street, Leeds.
Allcock, Samuel	Toton, Notts.
Allen, John	145, Moseley Street, Moseley Road, Birmingham.
Ancell, Theodore Robert	13, Berners Street, Oxford Street, London, W.
Anderson, John Watson	Chester.
Andrews, Richard	High Street, Rainham, Kent.
Arnall, Thomas	Franchise Street, Wednesbury, Staffs.
Aston, Edward	Ton-y-Pandy, near Pontypridd.
Armstrong, John	Maryport.
Atkinson, Richard	Skipton, Yorks.
Attwater, Thomas Chipping	Church Street, Liskeard.
Attwell, Arthur	28, Nassau Place, Commercial Road, London, E.
Baines, Wililam Duckle	4, Museum Square, Wisbeach.
Balfré, Juan Morday	13, Handcroft Road, West Croydon, Surrey.
Bannister, Benjamin Newnham	20, Delancey Street, Camden Town, London, N.W.
Barker, Frederick Griffiths	242, Oxford Street, Stepney, London, E.
*Barkley, William	3, Langham Place, London, W.
Barlow, Thomas	Nottingham.
Barns, Joseph	79, Old Street, Ashton-under-Lyne.
Barr, Thomas James	40, Dublin Street, Edinburgh, N.B.
Bartleet, John	55, King Henrys' Walk, Mildmay Park, London, N.
Beale, Benjamin Sturge	70, Bridport Place, Hoxton, London, N.
Beale, Joseph Foley	70, Bridport Place, Hoxton, London, N.
Bell, James Alexander	Nelson-in-Marsden.
Bell, John Armour	5, Salisbury Street, Edinburgh, N.B.
Blagg, George Denby	165, Lorrimore Road, Walworth, Surrey.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 25, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE EXAMINATIONS.

WITH the close of the present year, the time will have arrived when an important alteration, provided for in the revision of the Bye-laws effected by the Special Meeting of the Pharmaceutical Society, held in May, 1873, will take place in the conditions under which candidates can present themselves for the Major and Minor examinations. Up to the present time it has been sufficient for a candidate to answer, to the satisfaction of the examiners, any questions that may be put to him in the examination room to entitle him to have his name included in the pass list. But after the 31st of December next, in compliance with clause 16, section X. of the Bye-laws, no person will be allowed to pass the Major or Minor examination unless he shall also satisfy the examiners that for three years he has been registered and employed as an Apprentice or Student, or has otherwise for three years been practically engaged in the translation and dispensing of prescriptions.

As the discussion upon this subject was brought to an end by the vote passed three and a half years ago,—that being the interval allowed to prevent any cases of hardship arising from a too sudden alteration,—it would be improper to refer here to the points of controversy in respect to this change. But a hope may be expressed that the obtaining of this additional guarantee of the practical nature of the examinee's knowledge will prove acceptable to the pharmaceutical body generally. In fact, as has been pointed out, the same test in a more or less modified form is almost always used by a pharmacist engaging an assistant, who asks, "Where have you been employed, and how long?"

It may be useful to state here that in order to carry out the provisions of the bye-law a declaration to the above effect will have to be made by every candidate previous to entering his name for an examination. A form of declaration will be prepared and copies of it may then be obtained upon application to the Secretary, at 17, Bloomsbury Square.

Another alteration in connection with the examinations, that will come into operation with the new year, is one that will interest mainly incompetent candidates. It has been generally admitted by those best acquainted with the details of the examination room, that of the candidates who fail to pass the examinations many come up in a very unprepared state, and it has even been suggested that some have made a kind of preliminary visit as an experiment. As it has hitherto been the practice to return to a candidate failing to pass either of the examinations the fee, less one guinea, and as the retained guinea does not cover the bare average cost per candidate in the Major or Minor examination, it is a fact that a large part of the expense of these premature experiments has fallen upon the Pharmaceutical Society. In defence of this nothing could be fairly urged even in the interests of the unsuccessful candidates themselves. In February last, the Council therefore, after a full discussion, and on the motion of its then Treasurer, resolved that on and after the 1st of January, 1877, should a candidate fail to pass an examination for which he presents himself, the fee shall not be returned, but he shall be permitted to present himself for examination at a subsequent meeting of the Board on payment of two guineas for the Major or Minor examination, or one guinea for the Preliminary or Modified examination, provided he presents himself within one year from the date of his failure.

The effect of this resolution, as is evident, will be to ensure a greater probability that all candidates will come up with a *bonâ fide* and reasonable expectation of passing, at any rate within a moderate time; and also, in the event of a second examination being necessary, that the expense should fall upon the person through whose want of proper preparation it has been incurred.

It should further be observed that although an unsuccessful candidate is permitted to present himself again for examination upon payment of the smaller fee, he must do so within the period of one year from the first failure, or the full fee will again become payable.

THE RECTIFICATION OF THE REGISTER.

THE long list of names published on the preceding pages shows that after an interval of two years the Registrar under the Pharmacy Act finds it necessary to exercise the power entrusted to him with a view to the correct keeping of the Registers of Pharmaceutical Chemists and Chemists and Druggists. The list includes the names of nearly three hundred persons, from whom two registered letters sent to their addresses as at present recorded in the Register have failed to obtain any response. Formal notice is therefore now given by the Registrar that, unless these persons communicate with him before the 31st of December next, he will proceed to erase their names from the respective Registers. As on former occasions we would ask our readers to scan the published list, and if they are able to give information respecting any of the persons mentioned therein, to forward it to the Registrar.

It may be noted that the number of names now published is almost identical with that of those published two years since, after a similar interval of two years, so that probably this represents what may be expected to be the average expenditure of money and time thrown upon the Pharmaceutical Society in carrying out the provisions of the Pharmacy Act in this direction. As, however, there is always a large proportion of these defaulters—on the last occasion one-third of the whole number—who at last send the needful corrections, and thus save their names from being erased, we again express our regret that at present there is no provision for making such persons repay the expense to which the Society has been put by their negligence.

THE SALE OF METHYLATED SPIRIT.

THE report, on p. 445, of the prosecution in Glasgow for the improper sale of methylated spirit presents more than one point of novelty and interest. No one can read the evidence so plainly pointing to the springing up of a most degrading and disgusting custom without sympathizing in any attempt to bring the strong arm of the law down upon those who would so pander to the weakness of their fellow creatures. But it is necessary to be just as well as generous, and without offering the shadow of an excuse for a colourable sale, we must at once protest that to throw upon the seller of methylated spirit, as the Glasgow magistrate's remarks as reported would imply, the onus of ensuring that the spirit sold should not be applied to improper purposes would be a burden that the law does not and ought not, in our opinion, to impose. Section 6 of the Act 24 and 25 Vict. cap. 91, makes it penal to sell spirit that has been once methylated "for use as a beverage, or for mixing with a beverage. But this is very different from making the seller responsible for the acts of his customer after the sale has been effected, unless there be evidence that he had prior knowledge of his probable intention.

AN OLD REMEDY WITH A NEW APPLICATION.

THE *Lancet* quotes a description by Dr. GEORGES DAREMBERG of a visit to a famous but irregular practitioner of Algiers. Dr. DAREMBERG must have been satisfied with the amount of respect shown to him, as immediately he entered, the master of the house and his whole family prostrated themselves on the ground before the supposed patient. He seems to have belonged to the same school as the Nottingham detective who has recently won a temporary fame; for not being troubled with an ailment he invented one for the occasion. Having satisfied himself that the medicine man's knowledge was *nil* he told him that he had an ailment of the stomach. A vast number of vials and flint stones seemed to constitute the visible stock in trade, but the prescriber had other resources also. Telling his patient to apply a piece of meat to his chest, he explained to him the situation thus: "You have a dog which gnaws your system; give him a good bit of meat, and he will gnaw that instead of your stomach." Dr. DAREMBERG appears to enjoy a fling at *la perfide Albion*, since he says that this Algerian practitioner is much resorted to by European, and *especially* English, residents.

A PROPOSED LEGAL ALCOHOMETER FOR FRANCE.

THE subject of the inconveniences resulting from the absence of any authoritative regulations respecting the construction and verification of instruments used in testing the alcoholic strength of liquids has recently been brought before the French Chamber of Deputies. One illustration quoted is, that although exporters of eau-de-vie are compelled by law to declare its strength within a margin of 1 per cent. under a penalty of from 500 to 5000 francs, it is not rare to see two instruments applied successively to the same eau-de-vie give indications differing by as much as five per cent. To remedy this state of things a *projet de loi* has been drawn up, and has been reported upon favourably. It provides that in all transactions, either public or private, after the 1st of January, 1877, Gay-Lussac's centesimal alcohometer shall be used, and that these instruments shall be first officially verified as being correct. There is also appended to the bill an official table indicating the variations according to the degrees of temperature.

GERMAN PHARMACEUTICAL STATISTICS.

THE *Pharmaceutische Zeitung* of the 18th inst. reports that, according to the official statements, 233 pharmaceutical candidates have proved their claims to the title of "*Apotheker*" in the German Empire during the examination year 1875–76. Of this number 114 passed in Prussia, 49 in Bavaria, 22 in Saxony, 11 in Wurtemburg, 9 in Baden, 5 in Hesse, 5 in Mecklenburg, 3 in the duchy of Saxony, 6 in Brunswick, and 9 in Alsace-Lorraine. During the same year 653 medical men, 8 dentists, and 82 veterinary doctors passed. The number of Apothekers is much smaller than in the three next previous years, the figures for those years being 347, 453, and 413; whilst on the other hand the number of medical students who have passed shows no falling off. Our contemporary appears to think the falling off in the pharmacists is due to the fact that under the present concession system, by which the number of pharmacies in Germany is strictly limited, it is not possible for so large a number as 400 annually to obtain an independent position. With only about 4000 concessions in the whole empire this would require that on the average every pharmacy should change hands once in ten years. Judging from the fact that the gaps in the ranks of about 12,000 medical men are filled by 650 recruits yearly, it is thought that an addition of from 200 to 250 young pharmacists yearly should suffice for the wants of one third of the number of pharmacies.

THE SCIENTIFIC RESEARCH FUND OF THE CHEMICAL SOCIETY.

WITH respect to a rumour to which we recently referred in connection with the above fund, we are informed that the Grocers' Company having been satisfied that the Chemical Society had already in hand the sum of £2000 subscribed for the purpose of fostering scientific research has now increased it by a donation of £1000.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The second general meeting of this Association during the present session was held on Wednesday evening, November the 15th, in the Library of the Association; the President, Mr. Yewdall, occupying the chair. After the usual preliminary business, and the election of Mr. Chadwick as a member and Mr. Highmoor as an associate, "A Biological Essay" was read by Mr. Jas. Abbott, of which the following is a short abstract:—

The study of biology includes both animals and plants. The chemist, geologist, mineralogist, and physicist deal with *dead* matter; the biologist with living. Dead matter, such as crystals, increase by additions to their exterior, consist of homogeneous parts which have no definite and fixed relation to each other, and are bounded by straight lines and plain surfaces; they are *formed*—do not grow. Organic bodies, on the other hand, consist of organs which go to make an individual—as a horse, or a tree. They grow, assimilate, and proceed from parents like themselves. Every living body possesses the power of taking into its interior certain materials foreign to those composing its own substance, and of converting them into materials of which its body is built up. The actions of living beings are accompanied by a corresponding destruction of the matter by which these actions are modified. Dead matter is completely passive. Types of life may be illustrated and explained by torula, bacteria, protococcus, and amœba. All living beings require oxygen, and if a fluid contains sugar, torula can decompose it, taking its oxygen from it, liberating carbonic acid, and forming alcohol, etc. Bacteria bear the same relation to nitrogenous substances that torula do to saccharine. Protococcus having chlorophyll in addition, can decompose carbonic acid, assimilating the carbon and giving off oxygen, and can also flourish in rain water containing tartrate of ammonia and earthy salts. Amœba are dependent on manufactured material, take in solid particles of food, which plants never do, and are distinguished as animals by never becoming enclosed in a cellular sac; neither can they manufacture protoplasm from inorganic materials. The life history of these and other forms were then briefly sketched.

A cordial vote of thanks was given to Mr. Abbott for his very able essay, on the motion of Mr. Knowles, seconded by Mr. Hallowell.

HULL CHEMISTS' ASSOCIATION.

The first meeting of this Association was held at the Cross Keys Hotel, on the 16th inst., Mr. C. B. Bell, President, in the chair. Mr. J. F. Smith was elected Vice-President, in the place of Mr. W. Staning, who had declined the honour conferred upon him at the Annual Meeting.

The President then delivered the following inaugural address:—

Gentlemen,—It is usual for a newly-elected president to say a few words to his constituents on the first meeting after election. I therefore take this opportunity of expressing to the members of the Hull Chemists' Association my heartfelt thanks for the very great compliment they have conferred on myself by placing me in the presidential chair for the second year. By your placing me there a second time I feel that my labours during the past year on your behalf have met with your approval, and I trust that at the expiration of my year of office I shall have done nothing to forfeit the confidence you have placed in me, and I ask with confidence the kind assistance and co-operation of my colleagues on the executive in all matters affecting the interests of our trade, and in promoting goodwill and brotherly love with every chemist in the town.

I may make this promise, that I shall endeavour to preside over our meetings impartially, allowing all a fair expression of opinion, and in return asking that the chair shall be supported.

To me, gentlemen, there is a matter of very deep regret, and I am sure you will all coincide with that regret, and that is, our educational classes are not supported by the assistants and apprentices in the liberal manner which they ought to be. I wish they could see the great advantages that would accrue to them by devoting more time to study than at present they appear to do, leaving the education of the mind until they go to the metropolis. I can assure you, brethren, that as one of the founders, and I believe I may take some credit to myself as one of the pioneers of the educational movement in this town, it is with deep anxiety I notice this seeming apathy.

In the annual report read before the members in the year 1869, the following passage occurs, written by your then secretary: "And during the forthcoming year your committee earnestly hope that arrangements will be made for the better education and advancement of apprentices and assistants; since the passing of the Pharmacy Act this is more important and very much to be desired." I have read you the paragraph so that you may see I am not encroaching on anyone else; but I must bear my testimony to the spirit and energy with which the then incoming president (Mr. Baynes) took the subject up, and how he laboured to bring the classes to a success. To your present and immediate past executive, it is a matter of the very deepest regret, that the young men of the present day do not make use of the facilities offered them, especially when we contrast the excellent and modern fitted laboratory which Mr. Baynes, Jun., has placed at the service of the students. I would therefore ask principals who may have youths attending the class, to impress upon them the advisability of taking every advantage they can of Mr. Baynes' kindness, knowing that it will amply repay them for the time they may devote to their studies. I can only place it to apathy on the part of the junior members of the trade, when I reflect that prizes of greater value have been given by this association than by any other similar one, and for smaller results. I trust that a brighter educational era is before us, and that Hull will send to Bloomsbury Square more than one or two, who will return with pharmaceutical honours of the highest grade.

Turning to matters more especially affecting ourselves, I will first allude to the establishing of the Trade Defence Association, and I must congratulate the promoters upon the great success which has attended their efforts, in the number of subscribers, and the amount of money that has been given in donations. I would advise every chemist in Hull and the district to join it. If any illustration is requisite to point out the advantages for joining it, need I point to anything more than the action taken in the Nottingham case? As that case may not be known to all I will give the particulars. A short time ago summonses were applied for at the Nottingham Police Court against three chemists in that town for prescribing; in each case a bottle of medicine and a gargle were obtained. As soon as it was ascertained that they were likely to be proceeded against, the chemists immediately reported what had occurred to the Executive Committee at Birmingham; the Secretary went to Nottingham and thoroughly investigated the cases of threatened prosecution, and it must be a matter of congratulation to the Executive Committee to find that their first efforts were the means of the summonses being withdrawn.

As most of you are aware, a Medical Defence Association has been established in this town, and no one will deny but that it can do much good if it is wisely directed, for it is well known that in all large towns there are some who use titles they are not entitled to use, and that the ignorant and uneducated are too frequently victimized by these sharks on the medical profession. It has been rumoured that this Medical Association is about to prosecute some of our trade for prescribing over the counter. After carefully considering the Apothecaries' Act of 1815, I am unable to find anything in it to cause us much anxiety on that score—of course I mean for prescribing simple remedies over the counter. If a chemist visits, gives certificates or papers stating cause of death, then he does render himself liable and places himself under the tender mercies of the Medical Association. If the trade carry on their business in the legitimate way they will have no cause for fear in the future.

The next subject I wish to allude to is one that of recent years has frequently been to the fore, I refer to the sale of patent medicines by grocers, and as this matter was considered by your past committee, and nothing could be done to prevent anyone selling at cost price, it is highly desirable that the trade should maintain its independence in this instance and continue to sell at the legitimate price. I regret much to learn that one chemist is disposed to lower the prices so as to compete with grocers, for a chemist cannot fairly compete with them; their articles are in everyday demand whilst his are required occasionally, and the sale is very limited. A person may be tempted to buy 4 or 6 lbs. of sugar to save a ½*d*. per lb., he will require sugar every day, but who will purchase three bottles of medicine to save 3*d*. or 6*d*.?

At the present time our trade is in a very unsatisfactory condition; most of the articles of our trade have increased in price; rents, rates, and taxes are higher, coals and gas are dearer, assistants' salaries and errand boys' wages are larger, and living expenses generally have considerably increased during the last few years, and to meet this increased expenditure, competition, and in some cases unnecessary competition, has of necessity reduced the legitimate profits. The trade being now a more educated body, and the expense of learning the business having increased, it is much to be deplored that our future prospects are not of that healthy nature that could be desired.

I regret that my remarks on the future have been of so dismal a character, and I hope I may be wrong in some of my impressions, and this, to a great extent, may be brought about by the sinking of petty animosities, narrowness of views, jealousy, etc., of fellow traders, by the expansion of more liberal minds, by working shoulder to shoulder, for union is strength, and the determination of upholding the dignity, the honour, and the respectability of a trade which is just passing away into an heterogeneous mixture of trades.

At the close of the address, Mr. Myers proposed a vote of thanks to the President for his excellent address. Messrs. Walton and Myers supported the same, and it was agreed to unanimously.

It was afterwards decided that the Committee should make arrangements for the annual banquet, and that they should also meet to discuss the patent medicine question, and this concluded the business for the evening.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of the Chemical Society was held on Thursday, 16th November, 1876. Professor Abel, F.R.S., President in the chair. After the names of the visitors had been announced, and the minutes of the previous meeting read and confirmed, the names of Messrs. Edward Horatio Walker Sweete, and Channell Law were read for the third time; they were then balloted for and duly elected.

The first paper "On Barwood," by the late Professor Anderson, was then read by the secretary. On extracting barwood successively with ether and with alcohol, and evaporating the solution, a crystalline compound *baphnin*, $C_{24}H_{20}O_8$, is obtained, together with amorphous substances of a red colour. When baphnin in alcoholic solution is treated with lead acetate, a white precipitate of lead baphate is obtained, together with *baphinitin*, $C_{24}H_{24}O_6$, which remains in solution; a similar decomposition takes place on submitting baphnin to the action of a solution of potassic hydrate. *Baphic acid*, $C_{24}H_{22}O_{10}$, may be obtained from the lead precipitate by decomposing it with sulphuretted hydrogen. The author also obtained another compound, *baphinitone*, $C_{24}H_{26}O_6$, which by the action of bromine yielded a tribromous derivative $C_{24}H_{23}Br_3O_6$.

The President having thanked Dr. E. J. Mills for communicating this paper to the society, Dr. C. R. A. Wright gave a short abstract of Part I. of his memoir on "The Alkaloids of the Aconites: On the Crystallizable Alkaloids contained in *Aconitum Napellus*." After referring to his preliminary notice on the subject containing an account of *pseudaconitine*, $C_{36}H_{49}NO_{11}$, the uncrystallizable alkaloid of *A. ferox*, which however yields well defined crystallizable salts, he stated that very different results were obtained with *A. Napellus*. In one batch of one cwt. of roots which was worked up, two alkaloids were found, one of which, existing in comparatively small quantity, readily crystallized from ether, whilst the other did not; the latter, however, yielded crystalline salts which have a bitter taste, but do not produce the peculiar prickling of the tongue so characteristic of aconite roots. This base which is comparatively inert, may be called picraconitine, $C_{31}H_{45}NO_{10}$. The crystalline base *aconitine*, $C_{33}H_{43}NO_{12}$, which possesses high physiological activity, can only be obtained pure after repeated crystallization, first in the free state and then as a salt, finally liberating the base by ammonia or an alkaline carbonate. In a second quantity of two cwts. of the roots worked up to a condensed extract by Messrs. Hopkins and Williams, according to Duquesnel's process, only one crystallizable alkaloid, aconitine, was found. The hydrocloride, hydrobromide, and gold salt of this base, all of which are crystalline, were prepared and carefully examined.

The President thanked the author for this communication on a subject so important, both from a chemical and medical point of view, and hoped he would soon be able to lay before them the results of his experiments on the change produced on the alkaloid by various reagents.

Mr. David Howard remarked that it was a point of peculiar interest to ascertain how far the difference in the alkaloids was due either to diversity of species or to diversity of growth, occasioned by difference of climate or soil.

Mr. W. N. Hartley, Mr. C. E. Groves, and Mr. W. H. Perkins, called the attention of the members to marked differences produced in plants from circumstances of climate, soil, season of collecting, etc., which had come within their own personal experience.

Mr. J. Williams said he had every reason to believe that the different batches of aconite roots employed had grown wild in Switzerland, and were even from the same bale. He was of opinion that the different results obtained were due to altertions produced during the process. In the first extraction a stronger acid was used, it was heated for a longer time, and having been made much more dilute, had to be concentrated more; it was not improbable that the picraconitine was really an alteration product of the aconitine.

Dr. Wright replied that he had at first been inclined to believe that picraconitine was an alteration product formed by the action of hydrochloric acid on the aconitine, but Mr. Groves, of Weymouth, on extracting different samples of the roots by the same process, had in one instance obtained picraconitine, whilst in others it was not found. It would be interesting to ascertain if any alkaloid could be obtained from the marc, it was possible that the aconite existed in the extract in the form of a compound similar to a glucoside.

The next paper was by Mr. G. S. Johnson "On Potassium Triiodide." This was obtained by dissolving iodine to saturation in an aqueous or alcoholic saturated solution of potassium iodide, and evaporating slowly over sulphuric acid. At first, potassium iodide was deposited in cubes coloured by free iodine, but these after some days were succeeded by lustrous prismatic crystals of the triiodide KI_3 resembling iodine in appearance. It is very deliquescent, and is decomposed by water with liberation of iodine, but may be crystallized from alcohol. Two fine specimens of the crystals were exhibited.

The last communication was "On the Coal Gas of the Metropolis," by Mr. T. S. D. Humpidge. The gases examined were those of the Imperial, five of the Chartered collected at different stations, and the Cannel gas supplied to the Houses of Parliament, all during the month of May, 1876. The illuminating power was taken, and the gas carefully analysed, determinations being made of the carbonic anhydride, oxygen, nitrogen, marsh gas, carbonic oxide and the hydrocarbons absorbed by sulphuric anhydride. From a comparison of the results with those obtained by Dr. Frankland in 1851, twenty-five years ago, the author is of opinion that the gas now delivered in London is no better than it was then, and that the increase in illuminating power announced from the various testing stations, is to be attributed to improvements in the test burner. A comparison of the present referees' test burner with that used prior to 1860 showing a difference of more than three candles.

Dr. Frankland remarked that it seemed rather a melancholy fact, that although Parliament had spent much time and trouble on the matter, and had raised the standard from 14 to 16 candles, yet the gas was substantially the same as in 1851, and we were actually no better off now than we were then.

Mr. W. Valentin said most of the photometric observations had been made in the morning or in the afternoon, when the gas was perhaps not so good as it was in the evening, the time when the Act of Parliament provides that it should come up to the standard of 16 candles. Some, at all events, of the percentage of hydrocarbons was due to napthalene, and not to olefines or benzene; this was a source of great inconvenience by causing obstructions in the service pipes, etc.

In reply to a question by Mr. Vernon Harcourt, Dr. Frankland said, in his experiments he had found that for a given quantity of hydrocarbon vapour, diluted with a mixture of marsh gas and hydrogen, the illuminating power was sensibly the same whether the diluent contained 60, 25, or only 15 per cent. of marsh gas, from which he concluded that marsh gas was as much without illuminating power as hydrogen. There could be no doubt that benzene gave a very much higher illuminating power than hydrocarbons of the C_nH_{2n} or C_nH_{2n+2} series; but he could not understand Berthelot's statement that coal gas owed its illuminating power chiefly to benzene. Although this might be true of the Paris gas, it certainly was not of the London gas. He might state that all the gases mentioned in his report in 1851 were collected in the day time, and the photometric power determined in the day; on reference to Mr. Humpidge's results, it would be seen that one of his determinations made at 9.30 a.m. came fully up to the standard, as it was 16·3. He thought the most important point in the paper was that it showed that the apparent increase in illuminating power was really due to the improvement of the test burner, which with the same gas gave a light of 16 candles instead of 13 as the old one did.

Mr. Wills said his experience did not bear out the statement that the gas was no better now than it was 25 years ago. He was in the habit of examining the gas made by several of the large companies; they now supplied a gas up to the standard of 16 candles instead of 12 candles as in 1851; of this increase only two candles was due to improvement in the burner, and not three as stated by Mr. Humpidge, leaving a clear gain of two candles.

The President, after some remarks on the gas manufactured at Woolwich by the Government, adjourned the meeting until Thursday, 7th December, when the following papers will be read:—1. "Analysis of a species of Erythrophyll," by Professor Church. 2. "On Phenylene-diamine," by Dr. Otto Witt. 3. "On Calcium Sulphate," by Mr. Hannay.

PHILADELPHIA COLLEGE OF PHARMACY.

The first meeting of the session was held on the 17th of October, Professor Remington in the chair.

Syrup of Liquorice Root.—In the course of the meeting a paper was read, by Mr. A. P. Brown, on a method of preparing syrup of liquorice root and "brown mixture." The author having had occasion to make some ammoniacal glycyrrhizin, it occurred to him that the use of ammonia in preparing syrup of liquorice root would be an advantage, he therefore devised the following formula:—

Take of

Liqourice Root	4 troy ounces.
Cold Water.	q. s.
Water of Ammonia . . .	1 fluid ounce.
Granulated Sugar. . . .	13 troy ounces.

Grind the root in a mill, and place it in a wide-mouth bottle, with a tightly-fitting stopper, pour upon it one pint of water, mixed with the water of ammonia, macerate for forty-eight hours, then transfer it to a funnel, and allow the liquid to drain from it, and add sufficient water, until two pints of liquid has passed; allow it to stand until the particles have subsided, then decant and evaporate to eight fluid ounces, filter, and having added the sugar, dissolve it with the aid of heat.

Experiments were made with the ordinary liquorice root and the Russian peeled root, and of the two the syrup made from the Russian root was decidedly the finest. The cortical portion of liquorice root is acrid, without possessing the peculiar virtues of the root; the Russian root, being deprived of the epidermis, will therefore make the best preparation.

The syrup thus prepared is of a dark-brown colour, and contains all the sweet principles of the root without the starch and other inert matter.

Sulphate of magnesium, iodide and bromide of potassium lose most of their taste when mixed with this syrup.

The author said he had also made and used ammoniacal glycyrrhizin to mask the bitter taste of quinia; two drachms of the glycyrrhizin are dissolved in one pint of syrup, then to each fluid drachm is added one grain of quinia sulphate. In making ammoniacal glycyrrhizin care must be observed to use chemically pure sulphuric acid in the precipitation, and in the preparation of the compound mixture of liquorice, by the process suggested, an excess of ammonia must be avoided. In answer to an inquiry as to what is sweet syrup of quinia as used in Baltimore, the chairman suggested that it might be a mixture of syrup and tannate of quinia, the objections to which he stated, or one of undissolved sulphate of quinia in very thick syrup.

The author has also prepared a brown mixture from liquorice root and ammonia by the following process:—

Take of

Liqourice Root	4 troy ounces.
Water of Ammonia	1 fluid ounce.
Water	q. s.

Proceed in the same manner as for syrup of liquorice root, but instead of evaporating to eight fluid ounces, evaporate to twelve fluid ounces, and mix this with the gum arabic, sugar, and other ingredients. Lastly, add water of ammonia until a clear solution is obtained, taking care not to add an excess. Brown mixture, prepared by the above process, is of a brownish-yellow colour, and almost entirely free from sediment.

ROYAL SOCIETY.

Chemical Work done on Board H.M.S. 'Challenger.'

BY J. Y. BUCHANAN.*

Observations on the Specific Gravity of Sea-Water.

As the value of these results depends to a great extent on the nature of the means taken to collect the water, and on the delicacy of the instrument used for determining its specific gravity, I shall shortly describe them both.

The samples of water are collected either in an ordinary canvas bucket, or in one of two kinds of metal "water-bottle," according as it is to be taken from the surface or from depths below it. The use of the ordinary hand-bucket needs no explanation. When water is to be obtained from the bottom, the "slip" water-bottle is used. This instrument is a Swedish invention, improved by Dr. Meyer, of Kiel, who without doubt has described it, and by Messrs. Milne, of Edinburgh, who furnished those on board the 'Challenger.'

Water from intermediate depths is obtained in a much lighter instrument, which, with a drawing and the method of using it is fully described in a paper presented to the Royal Society in the early part of 1875, of which an abstract has been published in the 'Proceedings,' No. 160. It consists of a metal cylinder furnished with stopcocks at both ends. The levers by which these stopcocks are turned are connected by a straight rod, so that they are simultaneously either open or shut, or at least at the same phase of being open or shut. When water is to be collected by its means, the stopcocks are opened and the instrument sunk to the required depth, having been previously securely fastened to a sounding-line. The operation of sinking must be carried on without a check, owing to the peculiarity of the closing apparatus. When the required depth has been reached, the line is checked, hauled in a few fathoms, let go again, and finally brought to the surface by means of a donkey-engine. The rod connecting the stopcocks is furnished with a metal plate, which, during the descent, is retained in a vertical position by the passage of the water on both sides of it. When, however, the direction of motion is reversed, the plate falls down into a horizontal position, when, by its passage through the water, it exercises such a downward pressure on the rod that the stopcocks are closed. Arrived at the surface, it contains the water which it had enclosed at the depth in question. A small safety-valve allows of the escape of the surplus water, which, owing to the greater density of the water below the surface, it has enclosed in excess of what it can hold at atmospheric temperature and pressure. The apertures of the stopcocks being necessarily smaller than the diameter of the cylinder, the efficiency of the instrument in really changing the water as it descends was tested before leaving England in a freshwater lake, the water with which it was filled at the surface containing some yellow prussiate of potash. It was found that the water fetched, under these circumstances, from depths over $1\frac{1}{2}$ fathom was unacted upon by solution of perchloride of iron. The rate, therefore, of change of water is satisfactory, as we can be certain of obtaining an average sample of the last two fathoms passed through by the instrument.

Representing the specific gravity of distilled water at 4° C. by 100,000, I found that of ocean water at 15°·56 C. to vary between the extremes of 102780 and 102400; so that, to be of any value at all, the possible error in the results must not exceed 10. The hydrometer used for these observations is fully described in the paper above referred to. Its description is briefly as follows:—

The stem, which carries a millimetre-scale 10 centimetres long, has an outside diameter of about 3 millimetres, the external volume of the divided portion being 0·8607 cubic centimetre; the mean volume of the body is 160·15 cubic centimetres, and the weight of the glass instrument is 160·0405 grammes. With this volume and weight it floats in distilled water of 16° C., at about the lowest division (100) of the scale. In order to make it serviceable for heavier waters, a small brass table is made to rest on the top of the stem, of such a weight that it depresses the instrument in distilled water of 16° C. to about the topmost division (0) of the scale. By means of a series of six weights, multiples by 1, 2, 3, 4, 5, and 6 of the weight of the table, specific gravities between 1·00000 and 1·03400 can be observed. It is not necessary that these weights should be accurate multiples of the weight of the table; it is sufficient if they approach it within a centigramme, and their actual weight be known with accuracy. The weights of the table and weights in actual use are:—

Weight of table		0·8360	gramme.
Weight of weight No.	I.	0·8560	„
„ „	II.	1·6010	„
„ „	III.	2·4225	grammes.
„ „	IV.	3·1245	„
„ „	V.	4·0710	„
„ „	VI.	4·8245	„

For oceanic waters the hydrometer is always used with the table and either No. IV. or No. V. weight.

When the mechanical part of the construction of the instrument was finished, with the exception of the closing of the top of the stem (which instead was widened into a funnel-shape large enough to receive the ordinary decigramme weights), the calibration of the stem was effected by loading the stem with successive weights, and observing the consequent depressions in distilled water of known temperature. This done, the top was sealed up and the instrument carefully weighed. The expansion of the body with temperature was determined in a similar manner by reading the instrument in distilled water of various temperatures. The coefficient of expansion of the glass was then found to be 0·000029 per degree Centigrade.

For using this instrument at sea about 900 cub. centimetres of sea-water are taken, and the containing cylinder placed on a swinging table in a position as near the centre of the ship as possible. The observation with the hydrometer, loaded with the necessary table and weight, is then effected in the ordinary way, the accuracy of the readings being but little affected by rolling; pitching, however, is found to have a distinctly disturbing effect; and when it is in any way violent, it is advisable to store the specimen of water till the weather improves.

The temperature of the water at the time of observation is determined by one of Geissler's "normal" or standard thermometers, graduated into tenths of a degree Centigrade; and it is essential for the accuracy of the results that the water, during the observation of the hydrometer, should be sensibly at the same temperature as the atmosphere, otherwise the changing temperature of the water makes the readings of both the hydrometer and the thermometer uncertain. At low temperatures (below 10° or 12° C.) a tenth of a degree makes no sensible difference in the resulting specific gravity; but at the high temperatures always found at the surface of tropical seas, rising sometimes to 30° C., the same difference of temperature may make a difference of 3 to 4 in the resulting specific gravity.

Having obtained the specific gravity of the water in question at a temperature which depends upon that of the air at the time, it is necessary, in order that the results may be comparable, to reduce them to their values at one common temperature. For this purpose a knowledge of the law of expansion of sea-water with temperature is necessary. This had been determined with sufficient accuracy for low temperatures by Despretz and others; but as the temperatures at which specific-gravity observations are usually made are comparatively high, their results were of but little use, directed as they were chiefly to the determination of the freezing and maximum-density points. When the late Captain Maury was developing his theory of oceanic

* From the 'Proceedings of the Royal Society.'

circulation, owing to difference of density of the water in its different parts, he found the want of information on this important subject. At his request the late Professor Hubbard, of the National Observatory, U.S., instituted a series of experiments, from which he was enabled to lay down a curve of the volumes of sea-water at all temperatures from considerably below the freezing-point to much above what obtains even in the hottest seas. The results are published in Maury's 'Sailing Directions,' 1858, vol. 1, p. 237, and have evidently been carried out with great care. The composition of different oceanic waters varies, even in extreme cases, within such close limits, that the law of thermal expansion is sensibly the same for all of them; of this Hubbard's experiments afford satisfactory proof. In the table which gives the results of all his experiments he takes the volume of water at 60° F. as his unit. In order to avoid much useless calculation, I have been in the habit of reducing my results to the same temperature (15°·56 C.), while, for a like reason, I have retained the specific gravity of distilled water at 4° C. at the unit. The choice of a common temperature to which the results should be reduced, and of a unit of specific gravities, is a purely conventional matter; and in choosing the above-mentioned ones, in the first instance, I was moved solely by a desire to save calculation. For every water, however, there is one temperature to which it would be natural to reduce its specific gravity, namely, the temperature which the water had when in its place in the ocean; and in this sense all my results during the cruise have been reduced. Hubbard's table of the change of volume of a mass of sea-water with change of temperature enables us very easily to reduce any observed specific gravity from the temperature of observation to any other temperature, say 15°·56 C. In the paper it is transcribed from the 'Sailing Directions.'

In the following table the volumes for every centigrade degree from —1° C. to +30° C. are given :—

Temp. ° C.	Volume.	Temp. ° C.	Volume.	Temp. ° C.	Volume.	Temp. ° C.	Volume.
−1	0·99792	+7	0·99853	+15	0·99987	+23	1·00194
0	795	8	866	16	1·00010	24	224
+1	799	9	878	17	034	25	256
2	804	10	893	13	059	26	288
3	812	11	910	19	086	27	320
4	820	12	927	20	111	28	352
5	830	13	947	21	137	29	385
6	840	14	967	22	164	30	420

By means of the results given in this Table a chart of isothermals was constructed, giving by inspection, as soon as the specific gravity at any one temperature is known, its reduced values at any other. In this way the specific gravity of every water has been reduced to its value at 15°·56 C. and at the temperature which it possessed when in its place in the sea.

The results obtained since leaving Teneriffe on 15th February, 1873, are given in a series of Tables, in which those relating to surface-water are collected together and grouped in sections, as Teneriffe to St. Thomas's, St. Thomas's *viâ* Halifax to Bermuda, and so on. Those relating to bottom-water are collected in larger groups—the first containing all those observed in the Atlantic, the second those in the Southern, the third those on the western side of the Pacific Ocean, and the fourth those observed between Japan and Valparaiso. Where series of observations on waters from intermediate depths have been obtained, each series is given by itself. By far the greater number of the observations relate to surface-water, the specific gravity of which was, as a rule, taken once a day when at sea, the temperature of the water being at the same time observed with the standard thermometer above mentioned.

With a single exception, off the coast of Brazil, the densest water which we have met with in the ocean was found on the section from Teneriffe to St. Thomas's in the heart of the north-east trade-wind territory, where, from the strength and dryness of the wind, the amount of evaporation must be very large. Round about the Canary Islands the mean specific gravity was found to be 1·02730; to the westward it rises steadily until in longitude 28° W. it has reached 1·02762. Between longitude 28° W. and 54° W. the mean specific gravity is 1·02773, the maximum being 1·02781. On approaching the West Indies it rapidly falls off to an average of 1·02719 in the neighbourhood of St. Thomas's; and if we take into account all the observations made on the western side of the Atlantic, from St. Thomas's northward to the edge of the cold water which separates the Gulf-stream from the coast of America, we obtain the same average, 1·02719. Between Bermuda and the Azores an almost perfectly uniform specific gravity was observed, the mean being 1·02713, and the extremes 1·02694 and 1·02727. As Madeira is approached the specific gravity rises until it reaches 1·02746 close to the island itself. The mean specific gravity on the eastern side of the North Atlantic, between the latitude of St. Thomas's and that of the Azores, is 1·02727, or slightly higher than that of the water on the western side.

After leaving the Cape Verd Islands, the ship's course lay almost parallel to the African coast, and at an average distance of about 200 miles from it. Proceeding thus in a south-easterly direction, the specific gravity fell rapidly from 1·02692 off St. Iago on the 10th August, to 1·02632 on the 12th, after which it retained the low mean specific gravity of 1·02627 until the 21st August, when the course was changed to a westerly one along the equator. The specific gravity of the water on this day was the lowest hitherto registered for a surface-water; it was 1·02601, in lat. 3° 8′ N., and on the boundary line between the equatorial and Guinea currents. The same low specific gravity was observed in following the equatorial current as far as St. Paul's rocks, after which it quickly rose as the Brazilian coast was approached; and the maximum of 1·02786 was obtained on the 26th September, when off the entrance to Bahia, in latitude 13° 4′ S.

The observations in the South Atlantic were limited to a line down the western side as far as the Abrolhos Bank, and thence across to the Cape of Good Hope. In the region of the south-east trade-wind, therefore, we have only a few observations close to the coast; and as we have seen in the North Atlantic, on the voyage from Teneriffe to St. Thomas's, the specific gravity is higher in mid-ocean than either on the east or the west side, so in the South Atlantic it is possible that the same may hold good. From the Abrolhos Bank to Tristan d'Acunha the specific gravity sinks steadily from 1·02785 to 1·02606, and from Tristan to the Cape of Good Hope, along a course lying between the 35th and the 37th parallels of south latitude, the mean specific gravity was 1·02624. Between the same parallels of north latitude the mean specific gravity was 1·02713.

It must be remembered that the results obtained can only be held good for the season of the year in which they were observed, and that the observations in different latitudes were made in different seasons, and, further, that all the observations north of the line as far as 20° N. were obtained on the eastern side, and those to the southward of it as far as 30° S. were obtained on the western side of the ocean; so that it would be unwise to attempt to draw any general conclusions from such imperfect data. Considering, however, our four parallel sections, we have at least this positive result—that in the month of June and mean latitude 36° N. the surface-water in mid-ocean has a mean specific gravity of 1·02713, that in the months of February and March and mean latitude 22° N. the mean surface specific gravity is 1·02773, that in the month of August and mean latitude 2° N. it is 1·02624, and that in the month of October in mean latitude 36° S. it is 1·02621.

On the way to and from Halifax in the month of May some observations were obtained in the cold water with which the north-eastern coast of America is surrounded, the mean specific gravity being 1·02463. On the 1st May in the Gulf-stream the specific gravity of the water was 1·02675, and the temperature 23°·9 C.; and the next day it was 1·02538, and the temperature 13°·3 C. If the results be reduced to their values at the respective temperatures of the different waters, we have for the specific gravity of the Gulf-stream water 1·02445, and of Labrador-current water 1·02584; so that the fall of temperature very much more than counterbalances the want of salt in the water. In the same way we find the mean specific gravity of the water referred to the temperature which it has in the ocean to be—in latitude 36° N. and month of June 1·02548, in 22° N. and months of February and March 1·02592, in 2° N. and month of August 1·02335, and in 36° S. and month of October 1·02659.

Leaving Simon's Bay on the 17th December, 1873, the ship proceeded in the direction of the Marion Islands. Immediately outside the Cape the warm water of the Agulhas current was met with, which possessed a comparatively high specific gravity, averaging on the 18th, 19th, and 20th December 1·02657 at 15°·56 C., and 1·02477 at the average temperature (21°·9 C.) of the water. As we advanced in a southerly direction, the specific gravity as well as the temperature sank rapidly; and on the 26th, when off the misty and snow-capped islands of Marion and Prince Edward, the surface was 5°·3 C. and the specific gravity 1·02518. After leaving these islands, and until on the way northward to Australia we had passed the 50th parallel of south latitude, the specific gravity of the surface remained remarkably uniform. Between the Marion Islands and Kerguelen's Land the average specific gravity was 1·02512, between Kerguelen's and the edge of the pack-ice it was 1·02506, along the verge of the pack ice it was 1·02476, and between the pack-ice and the 50th parallel it was 1·02514; thence to the Australian coast it rose daily, reaching 1·02638 off Cape Otway. Except when amongst loose ice, there was hardly any variation at all in the specific gravity all the way between Marion Island and the 50th parallel; when amongst the ice the specific gravity was liable to sudden and considerable fluctuations, going down on the 14th February to 1·02419, and on the 18th to 1·02418, the ship being on both occasions surrounded by broken pack-ice. During the same trip the specific gravity at the temperature of the water was also very uniform, the mean being 1·02690.

Leaving Sydney a loop-like course was made, by way of New Zealand, Tongatabu, and the Fiji Islands, back to the Australian coast at its northernmost point, Cape York. The mean specific gravity of the western part of the sea between Australia and New Zealand was 1·02647, and that of the eastern part 1·02622, while in Cook's Strait itself it was only 1·02593. Between New Zealand and the Kermadecs the average specific gravity was 1·02630, and between the Kermadec Islands and Tongatabu it was 1·02651; round the Fijis it was 1·02[illegible]61; and between the Fijis and Cape York a very uniform specific gravity was maintained, the mean being 1·02643. We thus see that in the western part of the Southern Pacific the specific gravity of the surface-water is very uniform, varying but little with latitude, showing a very marked difference from the Atlantic Ocean, a difference which was observed to obtain in all parts of the Pacific.

From Cape York to Hong Kong the course lay through the remarkable series of so-called enclosed seas. The mean surface specific gravities in these seas were as follows:—In and around Torres Straits, 1·02655; in the Arafura Sea, 1·02549; in the Banda Sea, 1·02603; in the Molucca Passage, 1·02517; in the Celebes Sea, 1·02562; in the Sulu Sea, 1·02496; in the sea enclosed by the Philippine Islands, 1·02532; and in the China Sea, 1·02518. On the way to Hong Kong we traversed the Sulu and China seas just at the time when the south-west monsoon had ceased and the north-east one began to blow. When we returned by the same route as far as the south point of Mindanao, the north-east monsoon had already persisted for more than two months; and the effect of the comparative dryness of this wind is very evident in the surface specific gravities. The following average values were found:—In the China Sea, 1·02534; in the Philippine Sea, 1·02532; and in the Sulu Sea, 1·02570. On the other hand, the few observations made in the northern part of the Celebes Sea showed a diminution of specific gravity, the average being 1·02496. Outside the south point of Mindanao a strong and steady north-easterly wind was met with, and for the next ten degrees in longitude the mean specific gravity was 1·02596. On nearing the coast of New Guinea the specific gravity went down rapidly, averaging for a few days before our arrival at Humboldt Bay 1·02519. That a very large river must here empty itself into the sea was evident from the amount of drift-wood with which the sea was covered, and from the superficial distribution of the light water. The specific gravity of water at 50 fathoms below the surface was almost perfectly uniform, varying from 1·02611 to 1·02636 during the whole cruise from Mindanao to Admiralty Island. When about twenty miles off Humboldt Bay the specific gravity of the water fell as low as 1·02420. Between Humboldt Bay and the Admiralty Island the surface specific gravity was very uniform, varying from 1·02583 to 1·02600, except in one position (latitude 2° 30′ S., longitude 144° 7′ E.), where it fell to 1·02554; but a series of observations on waters taken from different depths at this position showed at once the superficial nature of the variation; the water at 10 fathoms from the surface had a specific gravity of 1·02580. Although there was here no drift-wood to be seen, I have little doubt that we had to do with warm water, although the nearest point of New Guinea was at least 80 miles distant; and indeed Captain Scoresby, who sailed along this coast much closer in shore, observed in this part large quantities of drift-wood, and inferred the existence of a large river in the neighbourhood.

North of Admiralty Island the specific gravity is somewhat higher; between the equator and 3° north latitude the mean is 1·02648; thence all the way north to Japan it remains very uniform, the mean being about 1·02600.

Leaving Japan in the month of June, the course lay entirely between the parallels of 34° and 40° N. as far as the meridian of 155° W. The specific gravity was slightly greater on the western side of the ocean than on the eastern. The following mean specific gravities were observed for every ten degrees of longitude:—

140° to 150° E.	1·02586.
150 to 160	1·02574.
160 to 170	1·02585.
170 to 180	1·02568.
180 to 170 W.	1·02569.
170 to 160	1·02544.
160 to 155	1·02532.

Arrived at 155° W. longitude, a southerly course was pursued by way of the Sandwich Islands and Tahiti, when the following mean specific gravities were observed:—

35° to 25° N.	1·02618.
25 to 15	1·02593.
15 to 5	1·02574.
5N. to 5 S.	1·02649.
5S. to 15	1·02658.
15 to 25	1·02699.
25 to 35	1·02620.

Whence it will be seen that the minimum value is reached between 15° and 5° N. latitude, the lowest value actually observed having been 1·02488 in latitude 7° 26′ N. The maximum to the south between 15° and 25° is very much more pronounced than that to the north of it; in fact round about Tahiti is the only spot in the Pacific where I have observed the specific gravity reaching 1·02700; the actually highest observed value was 1·02728 on the 3rd October, when the ship was being swung a few miles off Papeete Harbour.

The easterly course to Valparaiso was made principally between the parallels of 35° and 40° S. latitude. From 125° W. longitude to Valparaiso the mean specific gravity was 1·02534, the maximum being 1·02552 and the minimum 1·02513.

A large number of observations on the specific gravity of the waters at the bottom and intermediate depths have been made. In a preliminary report like the present it would be out of place to enter upon the discussion of so extensive a subject, even did the time at my disposal admit of my attempting it. I therefore content myself with giving the numerical results. It is to be hoped that in the homeward cruise through the Atlantic a more complete series of observations in this direction may be obtained, as those obtained on the way out were only sufficient to show that this ocean, and especially its northern part, differs greatly from the rest of the world-sea in density, as it does in temperature and in many other particulars. As a general rule, in both oceans between the parallels of 40° N. and 40° S. the specific gravity (reduced to 15°·56 C.) is greatest at or near the surface, and decreases more or less regularly until a minimum is reached, generally about 400 fathoms from the surface, when there is a slow rise, the bottom-water being rather heavier. This general law obtains in the Pacific and in the South Atlantic; but from the few observations obtained in the North Atlantic, there are indications of a departure from it. Although in the case of surface-water the variations of specific gravity with latitude are very considerable, more especially in the Atlantic, the water below 200 fathoms presents great constancy, the variations being comparable with those of the temperature at the same depths. In intertropical regions, and generally where there exists alternating wet and dry seasons, there are usually more than one maximum and minimum in the series between the surface and the bottom. How long it takes in quiet seas for fresh water to diffuse downwards in the sea, will be seen by inspection of the results obtained on the 22nd February, 1875, above referred to, when about 80 miles off the mouth of one of the large rivers of New Guinea, and the sea covered with drift-wood. The specific gravity was at the surface 1·02537; at 10 fathoms, 1·02578; at 20 fathoms, 1·22584; at 40 fathoms, 1·02594; at 50 fathoms, 1·02636; and at 100 fathoms, 1·02658, where it obtained its maximum, the temperature being sensibly the same down to 50 fathoms, namely from 28° C. to 28°·4 C.

Parliamentary and Law Proceedings.

The Sale of Methylated Spirit.

At a Justice of Peace Court held in Glasgow, on Monday last, Robert Fulton, oil and colour merchant, London Street, was charged with a contravention of the Excise regulations, in selling on one occasion a greater quantity of methylated spirits than was permissible under his license, which only warranted the sale of not more than one gallon; and also on two separate occasions having supplied four gills of methylated spirits to two men for drinking purposes, and as a beverage. For the offence of selling a greater quantity than was allowable the penalty was stated at £50; and for the "beverage" contravention the penalties were put at £200—in all, £250. In reply to the Bench,

Mr. Fulton said he sold the spirit regularly as methylated spirit. He was not much in the shop himself, but there was a girl there who sold the spirit daily. He understood that he could not sell more than one gallon at a time, and he believed that his girl followed that rule. He was not aware that any person ever got two gallons at a time, from any of his employés. As to the matter of the spirit being sold as a beverage, they sold them to a number of persons who came for them. These persons were polishers and hatters, and they were very much annoyed with them. He had turned away as many as eight and ten at a time. He never suspected that the people were drinking the spirit. His conscience would not have allowed him to supply them had he suspected that they did do so. He told his employés not to supply the spirit to people who did not appear to be dealing honestly, and they frequently required to call in the aid of the police to put some of these persons out. He was not guilty of trafficking in the spirit as a beverage, and he was not aware that it was illegal to sell the spirit in small quantities to all and sundry.

The Fiscal: There has been a regular trade in it.

Bench: Did you know you were breaking the law?

Defendant: No.

The Fiscal: The statute is quite clear on the point.

Defendant: How could I know that the people who got the spirit were going to use it as a beverage? They came in and asked for methylated spirit, and that fact did not convey the impression that it was to be used as a beverage. He would have insulted, he thought, any man had he asked him if he was going to drink the spirit.

James Aitken, private detective, spoke to the fact of having in September last received information that a number of people were regularly to be seen drinking some kind of spirit in the Green and the closes adjoining London Street entrance. He was told also that the drink was methylated spirit, which cost 3*d.* a half-mutchkin. He made inquiries, and learned that the spirit was obtained from the defendant's shop. The persons who were drinking the stuff were of the lowest class, and generally hailed from High Street and the Saltmarket. He asked the people whom he found drinking the spirit where they got it, and they told him it was in Fulton's. He went there, asked for a gill, and got it from a young woman, being asked no questions. He also sent in other persons for spirit, and they got it. He asked only for spirit, not methylated spirit. He communicated with the Excise, and was present when witnesses to be called were sent into Fulton's shop for and obtained small quantities of methylated spirit.

Four ordinary half-mutchkin bottles, a large black quart bottle, and a two-gallon jar—all containing methylated spirit—were produced, and the witness identified the half-mutchkin bottles as those used on the occasions to which he had referred.

John Leggatt, assistant private detective, in the employment of Aitken, said he knew defender's shop, and went there on the 9th October last with a common half-mutchkin bottle (produced), and bought a half-mutchkin of spirit, for which he paid 3*d.* He was served by a young woman, who asked no questions. He tasted the spirit outside the shop and found that it was methylated. He went there again on the 12th and saw a witness named Lindsay go in three times, and as often get a supply of spirit. He knew that people were in the habit of going in there for spirit and drinking it. The people who did so were of a low class.

John Lindsay, tailor, Main Street, Calton, said he knew the defender's shop, and had been several times there purchasing spirit.

The Fiscal: There is a bottle of stuff, taste it? (Having done so)—Is that like what you got?

Witness: That is the stuff. He was in the habit of drinking it as a beverage. He knew other people who did the same thing. He had drank as much as half a gill at a time, and he supposed he took as much as he could get, more or less. He had drank as much as two half-mutchkins. The price was 3*d.* the half-mutchkin; the whisky he used generally cost him one shilling the half-mutchkin. He purchased three half-mutchkins on 12th October at the instance of the witnesses Aitken and

Leggatt. The first time he asked for spirit, and put down the bottle and the money, but on the other occasions he simply put down bottles and money and said nothing. He got the drink without any difficulty, and was supplied by a young woman. He had heard of other persons being refused, and the reason was, he believed, that they were under the influence of drink. He was quite sober when he went for the spirit and got it. He became acquainted with Aitken and Leggatt, the detectives, while he was in prison. He had drank some of the stuff and got himself into a scrape. He did not think he would have got into the scrape had he not taken that stuff.

John M'Gowan, chemical officer to the Board of Inland Revenue, Glasgow, said he examined the contents of the two-gallon jar and five bottles produced, and found that they were filled with methylated spirit. Methylated spirit was a mixture of spirit of wine and wood spirit. It was used for manufacturing purposes.

William M'Nair, inland revenue officer, went to the defendant's shop in London Street on the 13th September, and asked how the spirit was sold. Being informed that the price was 3*s.* 6*d.* the gallon, he asked for two gallons, which were furnished him in jar produced. No inquiries were made as to what purposes he intended to apply the spirit, and he offered no explanations. He was dressed in plain clothes.

For the defence, Jessie Muir, who kept shop for defendant, said she had been strongly enjoined on entering his employment not to sell more than a gallon of spirit to any one at a time, and not to sell any quantity to any person whom she suspected as being likely to drink the spirit. She had frequently to get people ejected who wanted spirit, and whom she refused to serve.

This and the other witnesses for the defence testified that Mr. Fulton had repeatedly cautioned them not to sell small quantities of spirit to any other persons than those who were intending to use them for polishing or other purposes; that they had frequently great difficulty in keep low-like characters out of the shop, people who apparently intended to drink the spirits; that the police had more than once been called in to interfere, and that no one who got the spirit was ever known to have consumed it.

Mr. Douglas then craved for a conviction. He said the case was brought up under the Act 24 and 25 Victoria, chapter 91, which stipulated that methylated spirit was to be used for art and manufacturing purposes solely, and a special provision was added prohibiting its use as a beverage. He thought the various counts had been clearly proved. There was not the least doubt as to the wholesale cases, and the retail one was proved by the defendant himself, who showed that large numbers of dissipated people were in the habit of calling at his shop for the drink. That proved the reputation of the place. The defendant was bound to be satisfied that the spirit was got for no other than manufacturing purposes. He was clearly responsible for seeing that it was not used for other purposes, and if he failed so to satisfy himself then the responsibility of that neglect lay on his own shoulders, and he must take the consequences. If people in Mr. Fulton's position were allowed to sell this spirit to all and sundry without satisfying themselves for what purpose the stuff was to be used, then a most dreadful intoxicating nuisance would be introduced, because the difference in price was sufficient to induce such people as had been referred to to buy the drink for consumption.

Mr. Fulton said he was not aware that it was illegal to sell any small quantities to people for working purposes, and he had done all he could to see that none who were likely to drink the spirit received a supply.

Mr. Miller (magistrate) said it was his duty to make himself acquainted with the law, and to see that in trading in any article he was not infringing the statute.

The Court then retired, and after a brief adjournment returned, and

Mr. Miller intimated that all the three counts were found proved as libelled. The Bench were disposed to inflict the lowest penalty allowed, which was the fourth of each sum in each count, amounting in all to £62 10*s.* They had no power to impose a less sum, and the judgment of the Court was for the amount stated.—*Glasgow Herald.*

PROSECUTION OF A CHEMIST AND DRUGGIST FOR A BREACH OF THE APOTHECARIES ACT.

In the High Court of Justice, Exchequer Division, November 21, Sittings in Banco, before the Lord Chief Baron and Barons Cleasby and Huddleston, the case of the Society of Apothecaries *v.* Witherington, came on for hearing.

This was an action brought to recover a penalty of £20, under the Apothecaries Act, from the defendant, who had not obtained the necessary certificate.

The defendant resided and carried on business as a chemist and druggist at 410, Wandsworth Road, and attended various persons in the neighbourhood, and prescribed for complaints of various descriptions. In reply, he alleged that he was protected by various statutes.

Mr. L. Glyn and Mr. A. Young appeared on behalf of the plaintiffs, while the defendant appeared in person.

Several witnesses were called to prove that the defendant had contravened the Apothecaries Act (55 Geo. III.), and a surgeon for whom the defendant said he had acted denied that he had authorized the defendant to act as his assistant on such occasions.

The defendant, in addressing his lordship, urged that clause 30 of the Act necessitated the action being brought in the county in which the contravention, if any, had occurred.

Mr. Young replied that the clause referred applied to prosecutions instituted against persons who complied with the Act, and not to those brought against persons who contravened the statute.

The defendant then contended that clause 28 protected him from prosecution, inasmuch as he held a certificate as a chemist and druggist.

The learned judge, however, ruled otherwise.

The defendant further stated that he had only acted as the assistant of a surgeon, and contended that the present action was merely a malicious prosecution.

The jury returned a verdict for the plaintiffs for £20.

Judgment was given accordingly.—*Daily Telegraph.*

THE ALLEGED POISONING OF A CHILD AT CARDIFF.—THE CHEMIST'S ASSISTANT COMMITTED FOR TRIAL.

At the Cardiff Police Court, on Wednesday, November 16 (before Mr. R. O. Jones), Edward and Matilda Hayward, man and wife, and George Whitfield Williams, chemist's assistant, were brought up on remand, charged under the coroner's warrant with causing the death of Archibald William Henry Hayward, aged seven months, the child of the two first-named prisoners.

The magistrates' clerk intimated that the charge against the parents of the deceased would be withdrawn, as there was no convicting evidence against them.

They were accordingly discharged, after which the evidence of Hayward and his wife, and Mr. Jones, surgeon, was taken. This was to the same effect as reported last week (p. 426).

The prisoner had nothing to say in answer to the charge, and his solicitor not wishing to call any witnesses for the defence, Mr. R. O. Jones committed him to take his trial at the Winter Assizes, bail being allowed as before, in two sureties of £100 each, and prisoner himself in one surety of £50.

Alleged Attempt to Murder.

At Hampstead Police Court, on Thursday, Nov. 16, Eugene Cousté was brought up on remand charged with attempting to murder his two children by causing poison to be administered to them.

Professor Theophilus Redwood, of 17, Bloomsbury Square, deposed that on the 23rd of October he received from Superintendent O'Loghlen two bottles containing liquid, with instructions to make a careful analysis. Mr. O'Loghlen told him it was suspected that the contents of one or both bottles had been used, or had been intended to be used, for a felonious purpose. Witness made a careful examination of the liquid in each bottle and came to the conclusion that in neither case was there any poison. He made a further examination of some vegetable substance—he believed Peruvian bark—which he found in one of the bottles, and upon submitting it to microscopic examination found that it was incrusted with small crystals, for the presence of which he could not at all account. Witness called on Mr. O'Loghlen and told him that he had made this additional discovery, and that he had not been able to submit these crystals to analysis. Witness was at that time engaged every day and for five days at Westminster Hall on a trial. He set to work as soon as possible at the analysis. The crystals consisted principally of sulphate of potash, a salt which, when administered in rather large doses tc women and children, was capable of producing effects similar to those which had been noticed in the prisoner's children. Several fatal cases had occurred through the administration of that salt in rather large doses. But the quantity here was wholly insufficient to account for such effects. There was nothing of a poisonous nature in the excreta, nor could he find any indication of pain or internal irritation in the children themselves.

Mr. Wontner, who appeared for the Treasury, said he did not wish to carry the prosecution any further.

The Bench discharged the prisoner, remarking that they had thought it a case requiring investigation, and that the police were quite justified in the course they had taken.—*Times.*

Review.

Chemistry: General, Medical and Pharmaceutical, including the Chemistry of the U.S. Pharmacopœia. A Manual on the General Principles of the Science and their Applications in Medicine and Pharmacy. By John Attfield, Ph.D., F.C.S., etc. Seventh Edition. Philadelphia: Henry C. Lea. 1876.

It falls to the lot of but few authors to issue so many editions of a scientific manual within ten years as have been issued by the Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain. In 1867, he tells us in the Preface, the first edition of his now well-known book was issued, and already seven large editions have been produced, the last six alternately in this country and the United States. We have so recently noticed in these columns the sixth edition, of which the seventh is a revised form, suited specially for the United States, that there is little left to say here other than to reiterate that for pharmaceutical students seeking a good groundwork of chemical knowledge that will enable them to pass creditably the Minor or the Major, or for medical students wishing to meet the increased stringency of the examinations of the Royal College of Physicians and other medical bodies, this book is better suited than any other with which we are acquainted.

No doubt a part of the success must be attributed to the author's tact in illustrating the bearing of chemical science on the materia medica and pharmacy of all the Pharmacopœias used by English-speaking countries. In this edition have been inserted notices of some forty substances which are official in the Indian, but not in the British Pharmacopœia, and it is now claimed that the work "includes the whole of the chemistry of the British Pharmacopœia, of the Pharmacopœia of India, and of the United States Pharmacopœia." We say "claimed," because we confess upon looking to see what was said respecting an article included in the primary list of the U.S. Pharmacopœia, and which has recently acquired some favour in this country,—Gelsemium,—we failed with the help of the index to find any allusion to it or the chemical principles attributed to it.

There are spots in the sun, however, and we have noted two or three little things that appear to us to be blemishes in Dr. Attfield's book. In the opening sentence of the introduction it is alleged that all substances of which our earth and atmosphere are composed may be resolved into sixty-three forms of matter. In the sixth edition it was more cautiously and, we think, correctly, said that sixty-three elements have been proved to exist. Is this a breaking forth of the "old Adam" of a still earlier edition or is it intentional? Because in point of fact M. de Boisbaudran's "gallium" added to the list given would make sixty-four; and even if this alleged discovery be not eventually substantiated, though at present it appears to be accepted, perhaps another might be made at some time that would be more fortunate. Another point is that the name and corresponding constitution of "croton-chloral" is retained, although twelve months since Dr. Liebreich admitted that a mistake had been made and that the substance known and used under that name was really butyl chloral. Finally, is it quite correct to say that hydride of salicyl (the essential oil of meadowsweet) may be prepared artificially by the oxidation of salicin?

Obituary.

Notice has been received of the deaths of the following:—

On the 22nd of August, 1876, Mr. Joseph Longfield, Pharmaceutical Chemist, Leeds. Aged 47 years. Mr. Longfield had been a Member of the Pharmaceutical Society since 1853.

On the 20th of October, 1876, Mr. Frederick Alfred Price, Chemist and Druggist, Foulsham, Norfolk. Aged 34 years.

On the 31st of October, 1876, Mr. Edward Evans, Chemist and Druggist, Sheerness. Aged 54 years. Mr. Evans had been a Member of the Pharmaceutical Society since 1872.

On the 5th of November, 1876, Mr. Emanuel Taylor, Chemist and Druggist, Bradford-on-Avon. Aged 62 years.

On the 6th of November, 1876, Mr. Thomas Ditchfield, Chemist and Druggist, Chorley. Aged 49 years.

On the 9th of November, 1876, Mr. John Beedzler, Pharmaceutical Chemist, Norton Folgate. Aged 27 years. Mr. Beedzler had been a Member of the Pharmaceutical Society since 1872.

On the 10th of November, 1876, Mr. William Balk, Chemist and Druggist, Hull. Aged 63 years.

On the 10th of November, 1876, Mr. Jonathan Mathers, Chemist and Druggist, Glasinfryn, near Bangor. Aged 67 years.

On the 14th of November, 1876, Mr. John Fife, Chemist and Druggist, High Street, Sheerness. Aged 63 years.

On the 17th of November, 1876, Mr. Henry William Etchells, Chemist and Druggist, Chorlton-on-Medlock. Aged 36 years.

Notes and Queries.

[529]. OL. VIRIDE.—In answer to the query of "J. S. W." I give the following recipe for Green Oil:—

℞ Pulv. Æruginis Æris . . . . ℥iv
Olei Lini . . . . Cj

M. et agit sæpius.

S. F. Nottingham.

[530]. INDIA RUBBER CEMENT.—During my bicycling days I used the following for fastening the india rubber on the tyre and found it answer very well. One part of Shellac to ten parts Liq. Ammon Fort. ·880 to be put in a wide-mouth bottle in a warm place and frequently shaken for three or four weeks; it first forms a transparent mass, but afterwards becomes fluid. Also a solution of glue made into a paste with whiting I have found very good.—J. Munday.

Correspondence.

Toughened Glass.

Sir,—In the hope that the cause may be discovered why toughened glass does not realize the expectations formed of it, will you kindly allow me to give my experience respecting a couple of one ounce toughened glass measures I bought to try if it was really true they possessed the wonderful strength it was asserted they did. As soon as they came to hand I threw one of them a distance of several feet on the wood floor, and found to my very great pleasure that it remained intact, and have tried the same experiment with it many times since, sometimes to a distance of more than ten feet, besides using it in the ordinary routine of business; but on throwing the other not quite so far it was at once broken into scores of fragments of a crystalline appearance, and without the sharp cutting properties of ordinary fractured glass, from which, and the varied experience of your other correspondents on this subject, it is evident that toughened glass when properly made does possess the properties claimed for it, but that from some cause a flaw sometimes occurs in its manufacture.

It is to be hoped that this cause will soon be discovered, and doubtless the manufacturers will endeavour to do so; in the meantime they had better test all glass sold, in the rough and ready manner I adopted, if they wish the public to believe in its wonderful virtues.

While writing you it may be of service to some of your readers to mention an excellent mode I have adopted for some time past at the suggestion of a friend of mine, rejoicing in the name of "Goodenough," to remove tight stoppers from bottles, which is to put a few drops of olive oil around the side of the stopper, and apply heat to the neck of the bottle; during its momentary expansion the oil finds its way between the stopper and neck of the bottle, and of course the stopper can at once be removed.

I have used this plan with unvarying success, even after trying all the other means usually adopted.

James S. Hicks.

Looe, Nov. 20, 1876.

Sir,—Having occasion to return one-quarter dozen toughened glass tumblers for mineral waters at 1*s.* 10*d.* each, packed in straw, I am advised that only one has stood the ordeal of carriage.

A fall of a yard on a boarded floor has proved too much for them; after a few trials they have gone to shivers.

C. C.

Mirfield, Nov. 21, 1876.

A. B. S.—Take the specific gravity with a hydrometer or a specific gravity bottle.

"*Scando.*"—Any good work on the subject would do; the principles laid down are the same in all.

"*Associate.*"—We believe that the only way of obtaining an appointment as a dispenser in the army is by first enlisting as a private in the Army Hospital Corps. Upon attaining the rank of serjeant a man who has qualified himself to act as a compounder of medicine is then eligible to be appointed a dispenser, if there be a vacancy, with an allowance of one shilling daily beyond the ordinary serjeant's pay. For further particulars, see the *Pharm. Journal* for July 26, 1873, p. 79.

"*Sufferer*" and "*B. B.*," who have not sent their names and addresses, are recommended to forward their questions to the editor of a dental journal.

S. F. Nottingham.—See the answer given in the Journal for January 22 last, p. 598.

W. T. T.—Hassall's 'Food and its Adulterations,' published by Longmans.

"*Apprentice.*"—"Leptandrin" is the name given to a resinous substance obtained from the root of *Leptandra Virginica*, Nuthall, or "culver's root," by precipitating a 90° per cent. alcoholic tincture with water. The root is included in the primary list of the materia medica of the United States Pharmacopœia. Leptandrin is said to act as a cathartic and a cholagogue.

A. P. S.—There is nothing illegal in such sales.

A. Z.—Apply to the Secretary at Apothecaries' Hall.

"*Apprentice*" (Canonbury).—See Mr. Pocklington's article on Glycerine Jelly in the Journal for November 21, 1874 (vol. v., p. 401).

"*O. H.*, 49."—Your communication has been received; the address is quite correct.

"*Aggrieved.*"—You should have seen that your name was removed. Section 12 of the Juries Act, 33 and 34 Vict., Cap. 77, provides that "No person, whose name shall be in the Jury Book as a juror, shall be entitled to be excused from attendance on the ground of any disqualification or exemption, other than illness, not claimed by him at or before the revision of the list by the justices of the peace, and a notice to that effect shall be printed at the bottom of every Jury list.

Communications, Letters, etc., have been received from Mr. White, Mr. Kinninmont, Mr. Gibbs, Mr. Jackson.

The following journals have been received:—The 'British Medical Journal,' November 18; the 'Medical Times and Gazette,' November 18; the 'Lancet,' November 18; the 'London Medical Record,' November 18; 'Medical Press and Circular,' November 18; 'Nature,' November 18; 'Chemical News,' November 18; 'Gardeners' Chronicle,' November 18; the 'Grocer,' November 18; 'Journal of the Society of Arts,' November 18; 'Grocery News,' November 18; 'Produce Markets Review,' November 18; Practical Magazine,' for November; 'Educational Times,' for November; 'British Journal of Dental Science,' for November; 'Journal of Applied Science, for November; 'American Journal of Pharmacy,' for November: 'Pharmacist,' for November; 'Canadian Pharmaceutical Journal,' for November; 'Moniteur Scientifique,' for November; 'Pharmaceutische Zeitung,' for November 18; Sanitary Record,' for November 18; 'Medical Examiner,' for November 23.

NATURE'S HYGIENE.

THE HYGIENIC INFLUENCES OF THE PINE AND EUCALYPTUS.

BY CHARLES T. KINGZETT, F.C.S.

In our times, when nations, by reason of their commercial pursuits and other tendencies present crowded populations, it is matter of the greatest importance to understand well, the means resorted to for preserving the health of communities; and in doing this, undeniable advantage is gained by studying what I have termed above, Nature's Hygiene.

The subject, however, is so broad in its aspects that here it will be best to single out a few specific points and to consider certain investigations which have led to their elucidation; after this it will not be without interest to dwell shortly upon some results that may be expected to follow in their train. It was soon after the discovery of oxygen, in 1774, that Van Marum, of Holland, observed that when electric sparks were passed through this gas it acquired a peculiar smell, and Cavallo went further than this and found that the product possessed also great disinfecting powers.

In 1826, Dr. John Davy recognized the existence of a principle in the atmosphere which he considered to be identical with the foregoing, but our knowledge on all these matters was but slight until M. Schönbein, of Basle, established the existence of ozone and investigated its properties more precisely. Since that time many chemists, including Andrews and Brodie, have worked upon this subject, and while during these various researches certain errors have escaped detection, they may be said to have established the true nature of ozone. Without entering into minute chemical considerations, it is sufficient to remind the reader that ozone is an allotropic modification of oxygen, with the molecular volume O_3, compared to oxygen, which is O_2.

In the year 1818 Thénard discovered peroxide of hydrogen, H_2O_2, a substance which, so far as its properties are concerned, admits with difficulty of being distinguished from ozone.

Meanwhile Dr. Davy's observations regarding the presence of so-called ozone in the air were repeated again and again, and simultaneously the belief grew and intensified among men, that ozone as it exists in the air constitutes the great purifying influence in nature. It is therefore not surprising that various investigators have estimated, or endeavoured to estimate, the amount normally and abnormally present, but have also done this having regard to the intensity and direction of the wind, etc. Moreover, tables upon tables have been constructed pretending to establish a relation between certain diseases and the absence of ozone from the air. In fact mortality from various zymotic diseases has been considered to stand in direct relation to the amount of ozone present in the air in certain places at certain times.

Nevertheless, the presence of ozone in the air has never been indisputably established, though there can be little doubt of its existence; but its amount certainly has never been correctly estimated, for, as before said, no method yet proposed is competent to distinguish between ozone and peroxide of hydrogen as they occur in the atmosphere.

But the public has faith in this old theory of health as preserved by ozone, and inasmuch as they are informed by their medical advisers that sea-air is associated with an unusually large amount of it, they migrate annually in the most methodical manner to various sea-side resorts; the more so, no doubt, on account of other charming associations inseparably connected with the sea-side.

At the last meeting of the British Association, Mr. E. M. Dixon read a paper before the Chemical Section, in which he claimed to have invented a new method of estimating atmospheric ozone. As regards his apparatus I will pass over its consideration for what is far more important—his method. This may be said to consist in passing air through a solution of iodide of potassium together with a known amount of arsenite of potassium or arsenite of sodium. The amount of ozone, therefore, contained in a given amount of air is arrived at by a determination of the arsenite left unoxidized. Apart from all other considerations this method, as the writer then pointed out, does not distinguish between peroxide of hydrogen, chlorine, and ozone, etc., so that if Mr. Dixon took his apparatus to St. Helens, in Lancashire, he would, by his method, find unusually large amounts of ozone so called at times, especially when a still is being charged in the neighbourhood of the observing place. Moreover the method is by no means novel. I have employed a similar method for certain purposes during some years past, with this exception, that instead of using arsenite of sodium I have employed the hyposulphite. But for the sake of scientific accuracy it would be well, in the first place, to ascertain whether a current of air drawn through *arsenite* of sodium solution would not oxidize it to *arsenate*. Passing from this digression, it should be stated that it came to be commonly believed, in the process of time, that all slow oxidations were attended with the formation of ozone. Among such oxidations were included that of turpentine and the essential oils generally. Kosmann and Daubeny found that the green parts of plants also gave rise to the production of ozone, but not so in the case of the flowers. But it must be added that the real proof of the nature of this active principle was not forthcoming, for the methods of identification employed did not differentiate between peroxide of hydrogen and ozone. Personally I have great reason to believe plants do not produce ozone, but peroxide of hydrogen. Having made myself acquainted with the whole history of these matters so briefly sketched here, and others, I some years ago commenced a research which had for its immediate object the elucidation of the nature of that active principle which is formed when turpentine and other oils and substances undergo atmospheric oxidation.* The following among many other bodies were thus studied—turpentine, hesperidene, myristicene, wormwood oil, cymene, menthene, and the ethers, etc. Apart from the determination of a *law* which was discovered by these researches continued over a period of four years, and without entering into other scientific technical considerations, I may here mention one fact. It was thus established beyond doubt that all bodies of the chemical formula $C_{10}H_{14}$, or $C_{10}H_{16}$, give by atmospheric oxidation peroxide of hydrogen, and *never* ozone.

* *Journal Chemical Society*, June, 1874; March, 1875; *Chemical News*, vol. 32, p. 138, and vol. 34, p. 127; *Moniteur Scientifique*, November, 1875, Feburary, 1876, etc., etc.

For many years a health-preserving influence has been ascribed in various districts to the presence of pine forests, and more especially of late years the Australian eucalyptus gum tree has enjoyed a like reputation.

Thus Mr. R. D. Glover* relates that by planting the eucalyptus in the cloisters attached to an old monastic institution in the Campagna, the place was rid of the pestilent malaria which had hitherto rendered it desolate and uninhabited. Similar evidence is forthcoming from places in the vicinity of the Douro in Spain.

On the 30th of April last, Dr. Fedeli presented a paper, on the properties of the *Eucalyptus globulus* to the Roman Academy of Medicine,† and adduced much stronger evidence, showing that the plant possessed powerful virtues as a febrifuge. Wherever the plant has been cultivated, endemic malaria has henceforth disappeared. Dr. Fedeli also described the curative powers of various preparations made from the plant, notably the alcoholic tincture.

Since Dr. Fedeli's paper was published the Italian Government has supplied landholders with large quantities of slips of the tree for forming plantations in all malarious districts. It has been difficult to understand these virtues of the eucalyptus, but my recent researches on the oxidation of essential oils have led to an explanation as interesting as it is simple.

The various species of pine or fir tree have a wide geographical distribution, and the reason in nature for this will be seen immediately. All these trees secrete oils consisting originally of hydrocarbons, known in science as terpenes; but for our present considerations they may be collectively and individually regarded as turpentine. Turpentine is indeed distilled largely from the oily and resinous matters formed in these trees, while oil of eucalyptus has been shown by A. Faust and J. Homeyer‡ to consist mainly of a terpene and cymene ($C_{10}H_{16}$ and $C_{10}H_{14}$).

Now, if these naturally-secreted oils be allowed to remain in the tree, they volatilize in great measure, and undergo oxidization in the atmosphere. Some part, however, is polymerized and oxidized by the air while yet in the tree, and thus are produced those resinified substances and camphors which generally accompany the natural oils.

Returning for a moment to my investigations, I found that when turpentine was exposed to a current of air in the presence of water, and especially at summer temperatures, oxygen was absorbed, part of the oil resinified, and the rest was oxidized into a compound unstable in the presence of water, and splitting up thereby into peroxide of hydrogen and camphoric acid.

Now peroxide of hydrogen has been acknowledged for a long time to be one of the most powerful disinfectants known to chemists, but its mode of preparation has been so expensive in the past that it could not be used for sanitary purposes. But as regards its efficacy in this respect medical and chemical literature abounds with the proofs. In this direction, the name of Dr. Day, of Geelong, deserves especial mention.

Lately, salicylic acid has been recognized as a powerful antiseptic (*not* disinfectant), but its slight insolubility in water and certain other properties, especially its price, have militated against its large employment. It is curious to know that camphoric acid, which is allied chemically in certain respects to salicylic acid, has also similar and equal powers of preservation,* while it is more soluble in water; it is also expensive as made in the ordinary way. But by the process I have indicated it is obtained side by side with peroxide of hydrogen in the state of a solution having a pleasant aromatic odour, and which, be it remembered, is both an antiseptic and a disinfectant.

These considerations have led me to conclude that the health of districts where the pine or eucalyptus abounds arises from the influences excited by the peroxide of hydrogen and camphoric acid produced naturally by these trees, and, in short, the process I have indicated is but the repetition in the laboratory of what must occur in every individual tree.

This brings me to one other consideration. It has been observed that wooden hospitals are particularly efficacious as inducing rapid convalescence; and here again the fact admits only of explanation by a knowledge of my researches. The resinous and turpentine-like bodies existing in the wood, under ordinary atmospheric conditions, give rise to peroxide of hydrogen and camphoric acid, two substances, the one of which I have proved to be a most powerful disinfectant, and the second an equally strong antiseptic.

More recently, I have conducted, together with my friend, Mr. Zingler, some larger experiments upon turpentine, and we have found, after corroborating all our former conclusions, that by simply imitating nature as far as possible, that is, by exposing a mechanical mixture of water and turpentine to a current of air at normal summer temperature, we can readily obtain a solution containing peroxide of hydrogen, camphoric acid, etc., with all the characters to which we have previously alluded. The solution is an aqueous one containing no oil of turpentine; it appears to be non-poisonous, and is absolutely without harm to textile, linen, or other fabrics. It does not injure carpets or furniture when applied to them, and is slowly but perfectly volatile. It is hoped shortly to produce large quantities on a manufacturing scale, for use in watering roads and streets, and in private houses, public hospitals, urinals, etc., etc.

In conclusion, it may be said that this is perhaps the first instance on record in which a natural process of atmospheric purification has been imitated to perfection, until in fact, there can be repeated on a commercial scale that which, in pine and eucalyptus forests, constitutes one of the most efficacious processes of Nature's Hygiene.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 351.)

SUCKMUNIYA, OR BAZAAR SCAMMONY.

That sold in Bombay is all fictitious. It is said to be made in Surat; it does not in the least resemble any kind of genuine scammony; it occurs in irregular fragments of a bright green colour, somewhat translucent at the edges and having a resinous fracture; its odour and taste are suggestive of common resin. Rectified spirit dissolves the resin and leaves a residue of green colouring matter and gum; the former is evidently of vegetable origin. It is difficult to ascertain what is the purgative principle in this mixture—possibly some resin derived from one of the Convolvulaceæ. Sometimes a black Sukmuniya is met with; this is also spurious, and is resinous in taste and smell, but has a more earthy appearance than the green variety. Rectified spirit dissolves out a quantity of resin and leaves a black residue which, under the microscope, is seen to be made up of tufts of vegetable hairs (Mucuna ?), numerous small carbonaceous particles, and small irregular crystalline particles. Treated with dilute hydrochloric acid it effervesces feebly after a a short time; with strong acid it effervesces strongly at once and the vegetable matter is destroyed and forms a green solution. In Persia genuine scammony is to be found, but I have never been able to ascertain whether it is produced in that country or imported. The Bombay article is evidently quite unfit for medicinal use.

LUFFA AMARA.—*Local name*, RAN TURAI.

The vine resembles that of the cultivated Turai. The fruit is smooth, from 3—5 inches long, ovoid, marked with ten prominent, sharp, longitudinal ridges. At the apex of the fruit is a small operculum rather more than half an inch in diameter which is deciduous. Internally it is filled with white spongy pulp, of a cucumber odour. The seeds are grey and marked with small irregular black prominent specks. The leaves are bitter, the fruit only slightly so. The former I have seen used as an external application to sores in oxen. I have no experience of the effects of this plant when given internally.

CANNA INDICA, CANNA LUTEA, CANNA DISCOLOR.—*Local name*, KIMUSKI.

These three distinct varieties are found commonly in the Bombay Gardens. *C. lutea* is stated in the 'Bombay Flora' to be the source of tous-les-mois. I have examined its starch and find it to correspond exactly with the commercial article. I have never known the starch to be prepared here. The rhizomes of *C. Indica* and *C. discolor* yield a similar starch, but they also contain a good deal of colouring matter, from which the rhizome of *C. lutea* is almost free.

MANGIFERA INDICA.—*Local name*, AMBA.

Mango gum occurs in irregular shaped pieces some of them stalactiform and shining; it is black easily broken; the fractured surface is dull, the odour faint and gummy; it is entirely soluble in cold water, forming a solution of the colour of tincture of iodine and very slightly viscid. A resinous exudation occurs upon the fruit of this tree having the colour and odour of turpentine. Neither of these substances appears to have any medicinal value.

SPONDIAS MANGIFERA.—*Local name*, JUNGLI AMBA.

The gum is yellowish, principally in stalactiform pieces, with portions of bark adhering; placed in water it swells into a bulky jelly which is almost tasteless; a small portion is soluble.

CALOPHYLLUM SPURIUM.—*Local name in Canara*, BABBE.

This tree is abundant in Canara, but does not appear to be found in other parts of the Bombay Presidency; the gum occurs in large translucent irregular lumps of a yellowish colour; it is of horny texture, somewhat brittle, without odour; the taste is soapy. When placed in water it gradually softens, and finally disintegrates into a fine granular matter which floats in the form of flaky particles of a dirty white colour, and numerous oil globules which gradually collect upon the surface; the water dissolves a small portion of the gum and becomes slightly viscid.

CAREYA ARBOREA.—*Local name*, KUMBHA.

The gum resembles mango gum in appearance, but forms with water a much thicker mucilage of a dark brown colour.

GARCINIA Sp. ?—*Canarese name of drug*, ARASINA GURGI.

Through the kindness of Dr. Davies, civil surgeon, Canara, I have received a specimen of the gamboge collected there. It is in irregular fragments, and appears to have been collected upon leaves, portions of which still adhere to it. The finer pieces have the colour and consistence of Siam gamboge, but contain many impurities, such as portions of wood and leaves. Fully half the sample is of a dirty yellowish brown colour, and has a spongy structure; this portion, treated with rectified spirit, gives a clear deep orange solution like ordinary gamboge, but leaves a copious greenish yellow marc, which appears to be chlorophyll. As at present collected this gamboge is too impure for commercial purposes. In the Bombay market the ordinary pipe gamboge is alone met with.

ALOE Sp. ?—*Local name of drug*, ELIA.

There are many qualities of aloes met with in this market. Excluding Socotrine, the kind most worthy of notice is known as Jafferabad aloes; it is manufactured at a town of that name on the Kattiawar coast, belonging to the Hubshis of Jinjeera, a family of African origin. I have not yet been able to get an authentic specimen of the plant. The drug in mass is black; it has a glassy fracture; thin pieces are yellowish brown and translucent; the powder is of a dull yellow, the odour powerfully aloetic with some aroma; when treated by Histed's process for aloin it affords a fair yield. The aloin when brought into contact with nitric acid gives a deep red colour which is permanent; tested with sulphuric acid and afterwards exposed to nitric fumes no change in colour takes place. Its reactions are then the same as those of barbaloin; they may be obtained with the crude drug, which is remarkably free from impurities. Jafferabad aloes may well replace Barbadoes in India. The price is about Rs. 14 per hundredweight.

CALOPHYLLUM ELATUM.—*Local name*, SIRPOON.

The gum is black and opaque and much mixed with pieces of corky bark; it has a feebly astringent taste, and is very soluble in cold water. Professor

Lyon, F.C.S., chemical analyst to the Government, has been much interested by this remarkable gum, and has kindly favoured me with the following remarks:—

"It yields to water a yellow brown solution, exhibiting a strong blue fluorescence.

"If the gum is steeped in water for some time the solution becomes very dark in colour. Alum followed by carbonate of soda throws down apparently some of the brown colouring matter without interfering with the fluorescence, as after precipitation in this way the solution, although lighter in colour, is very strongly fluorescent.

"A solution purified by alum in this way has its fluorescence immediately destroyed by acid and restored again by alkalies. Examining its absorption spectrum it is found that while fluorescent the solution gives a broad absorption band at the violet end of the spectrum, extending to about G; this band disappears on destroying the fluorescence by acids, but reappears on addition of alkalies.

"The solution of the gum does not appear to rotate polarized light. The gum itself communicates only a very faint fluorescence to rectified spirit."

GYNANDROPSIS PENTAPHYLLA.—*Local name,* KANPHOOTEE.

A very common plant on cultivated ground; leaves, five foliolate, with obovate leaflets; flowers white; stamens very long, purple; capsules round, tapering towards the point, which is surmounted by the style. The whole plant is viscid, and is covered thickly with glandular hairs; it has a strong peculiar odour, something like essential oil of mustard. The seeds are black, smaller than mustard, and rough from numerous little horn-like projections; they have hardly any taste. The juice of the plant, like that of *Polanisia icosandria*, is used in purulent discharge from the ears. The leaves have an acrid peppery taste.

(*To be continued.*)

HISTORICAL NOTES ON OPIUM.*

From a paper on this subject, by Dr. Otto Billinger, of Munich (*Inaugural-Dissertation*, München, 1876), which contains an interesting *résumé* of the history of opium in ancient and mediæval times, we have prepared the following abstract, and have added to it some commentatory and occasionally emendatory notes of our own, wherever it has seemed to us to be necessary.

The author's aim was not to present a complete history of the drug, as this would involve a study of the chief medical works of all nations, from Suçruta and Charaka† down to our days, but to give merely the main data from ancient and later writers, collected by him.

We find opium mentioned already in the oldest medical writings of the Hindus, besides aconite, hashish and other narcotics, under the name *aiphena*.* It was principally in use in cholera, against which Charaka, in his 'Ayurveda'† recommends a mixture of assafœtida, adstringents, rock-salt, white pepper, and opium.‡

Egypt was celebrated already in ancient times for its excellent opium. Galen especially praises that raised at Thebes as particularly efficacious. The same is done by the later Arabic physician Avicenna. Opium was a principal remedy of the Egyptians, together with bloodletting, squills, and the mysterious Kyphi.§

* From *New Remedies*, August 15, 1876.

† All current works of reference still continue to ascribe a very great antiquity to these medical authors. The fact is, however, that we only know the works, *which we possess* under their names, to have been composed *not later than the 8th century after Christ*, at the end of which *Ibn Beithâr* and *Albirûni* translated the work of Charaka, and (according to Ibn Abi Uçaibiah) also that of Suçruta into Arabic. It is very probable, from internal evidences of the works, that various theories and practices have been borrowed from the Greeks (see *R. Roth, Zeit. D. Morg. Ges.* 26, 441), although the measures and weights which the physician is ordered to use are those in use in Magadha and Kalinga, that is, in the eastern districts, which have never come into contact with the Greeks. As to Charaka, the legend relates that "Cesha, the snake-king, who was in possession of the *Ayurveda*, descended upon earth on a visit of curiosity. Seeing so much suffering and death, he felt compassion, and thought of a plan to alleviate these evils. He became the son of a Muni ('holy seer'), and received the name of Charaka. From the works of the ancient physicians Agniveça and Atreya he composed a new one." Suçruta is reputed to have been the son of Viçvamitra and the disciple of Dhanvantari. But it is utterly impossible at present to fix the dates at which these works have been composed, for Hindu chronology is in a very unsatisfactory condition, owing partly to the didactic poetical form, in which most of the literature is composed, and which does not permit much interlarding of dates,—but mainly to the desire of the leading caste to ascribe the real origin of all knowledge and science to divine agency, which was accomplished by establishing a relationship of the reputed authors with the deity, whereby all inquiry after the date of their real existence was obviated and often made impossible. Charaka's work exists so far only in manuscript; Suçruta's 'Ayurveda' has been published in the original in Calcutta, 1835–36, and in Latin translation by Fr. Hessler in Erlangen, 1844–50, and notes by the same, 1852–55. Wise's 'System of Hindu Medicine,' is a compilation, made for the author by some medical Pandits, chiefly from the work of Bhâva, the son of Miçralatakana, and contains many erroneous statements, as may be seen by a comparison with the original (see Aufrecht 'Cat. Cod. Sansc.,' p. 311).

* This word should be written *aphena*, and occurs with the meaning of "opium" only in very late writers, for instance, in the 'Râjanirghanta,' a medical dictionary, composed by Haraharipandita, of Cashmeer, a few hundred years ago. *It is not found* in Charaka or Sucruta. The Sanscrit aphena really means "foamless," and has afterwards been stretched to ahi-phena, "snake-foam," as a name for opium. It is also called âphûka, and niphena, ("foamless.") Of course, the coincidence of the borrowed word, with a real Sanskrit word, having a meaning of its own, is accidental. It is also called khaskhasa-rasa ("poppy juice").

† *Ayurveda* is the general term for "medical science." It is considered to be a supplement to the 'Atharvaveda,' and is divided into the following eight branches:—1, surgery; 2, diseases of the head and its organs; 3, diseases which affect the whole body; 4, mental diseases (ascribed to demoniacal influence); 5, diseases of children; 6, on antidotes; 7, on elixirs; 8, on the means to invigorate the generative powers.

‡ This is a mistake. The receipt, to which reference is made here, is very common in Hindu medical works, and contains: *haritaki* (myrobalans), *hingu* (assafœtida), *souvarchala* (Sochal salt), *vacha* (calamus), and *ativisha*. The latter word, meaning "very poisonous," has, together with its synonym *upavisha*, been later used of poisons generally, and perhaps of opium (according to Monier Williams' 'Engl. Sansc. Dict.,' s. v.). But there can be little doubt that it means here *Aconitum ferox*, as usual. See Haughton's 'Beng.-Sansc. Dict.,' s. v., and Wallich's 'Plantæ Asiat. Rar.' (where the plant on plate 41, however, is *A. Napellus* and not *ferox*).

§ We have, thus far, no direct testimony that the ancient Egyptians were acquainted with opium, although the latter Greek writers make allusions to it. According to Unger's investigations (1857), Thebaic opium was unknown to the ancient Egyptians. Squills very likely occur in the *Papyros Ebers*, but the corresponding term of the original has not yet been recognized. On the composition of *Kyphi*, see *Medical Record*, April 15, 1876.

The Israelites probably learnt the use of the remedy from the Egyptians, although theriac is only met with in the Talmud, the medical portions of which are taken from Greek sources.*

The knowledge of opium, like that of many other useful agents, reached the Greeks probably from the Egyptians. Homer already mentions a "pain-assuaging" drink,† the preparation of which Helena learned from Polydamna, the wife of Thon, king of Egypt.

The writings of Hippocrates‡ do not mention opium, but allude merely to the use of poppy-seed.

The Alexandrian physicians, however, already are acquainted with it. According to Dioscorides, Erasistratus§ treated snake-bites by a mixture of opium and castoreum, but forbids it in affections of the eyes and ears.

Andreas of Karystos,|| a pupil of Herophilus, and court-physician of Ptolemæus Philopator, according to Dioscorides, one of the most celebrated pharmacologists of his time, first drew attention to the adulterations of opium.

Apollonius¶ is stated by Galen to have used opium likewise in combination with castoreum.

Among the empirics, Heraclides of Tarent** deserves particular mention, on account of having studied the effects of opium, and having established exact indications for its use.

About this time Nicander of Kolophon†† composed a poem in hexameters, entitled 'Alexipharmaca,' in which he first draws attention to the sudorific properties of opium.

The word opium is probably of purely Greek origin; at least it is generally considered to be the diminutive form of ὀπός, "juice."*

We have to mention here one of the most remarkable medical writers, namely, the well-known Mithridates,† king of Pontus. He is famous through the peculiar experiments which he made upon his own body with various poisons and antidotes. He kept a record of his observations, and after the downfall of his empire, and his death, these "memoirs" (ὑπομνήματα) fell into the hands of the victor, Pompeius, who caused them to be translated into Latin by his manumitted slave, the grammarian Lenæus.‡ This work contained the formula of the general antidote, called after its inventor, "Mithridatium;" it contained 40–50 ingredients, the principal of which was opium. In later times a few other ingredients were added, and the preparation formed the celebrated theriac.

The Romans seem to have received the opium through Greek physicians. The first of these of whom we have a somewhat more detailed knowledge, was Asclepiades,§ who was held in great repute at Rome. Galen says of him that he also used opium in combination with castoreum. He also relates of the Methodists,|| a school which had accepted many theories of Asclepiades, that, after they had succeeded in allaying pain by the drug, and the patient happened to die under its influence, they still boasted of having cured the disease. The author through whom we are best informed in regard to this sect is Cælius Aurelianus,¶ a physician who lived at the end of the fourth century, A.D.

Plinius, as well as Dioscorides, makes a distinction between opium and meconium, while Galen already uses the two terms as identical.** At the time of Plinius†† the use of opium seems to have been already quite extended; but the scientific treatment of diseases had already begun to make room to unthinking empiricism and to faith in quacks and nostrum vendors. One of the most noted of these, Philo of Tarsus,‡‡ invented an opiate called after him Philonium; and Andromachus of Creta,§§ the court

* The fact that no earlier Hebrew authority than the Talmud mentions theriac appears to prove that the Israelites were unacquainted with opium, and that the Egyptians, with whom they had warlike and commercial intercourse, were—at least at the time of the captivity of the Jews—likewise unacquainted therewith.

† Odyss., 4, 220-221: Εἰς οἶνον βάλε φάρμακον, ἔνθεν ἔπινον, νηπενθές τ' ἄχολόν τε, κακῶν ἐπίληθον ἁπάντων, "Then he threw into the wine, of which they drank, a grief-allaying remedy, soothing and causing obliviousness of all evils." It must, however, not be forgotten, when drawing chronological conclusions from Homer, that the text of the Homeric poems, as we possess it, has only been permanently established by Peisistratus (died 527 B.C.), and has received further modifications by later Alexandrian "diaskeuasts." On the Homeric *Nepenthe* we possess a number of monographs, the most curious of which are the first one, written about 1620, by Petrus Lasena, a lawyer of Naples, and another by J. G. Graevius (8vo, Frankf., 1689), who concludes it to have been a preparation derived from *Oenopia* or *Oenothera*. See also 'Acta Erud. Lips.,' Nov., 1689, pp. 575–578.

‡ Born at Kos about 470 B.C., died about 356 at Larissa. It is necessary to be very cautious in drawing any *chronological conclusions* from the works which we possess under his name, as the genuineness of none of them can be established beyond doubt. They, however, undoubtedly correctly represent his ideas, and may have been based upon genuine writings of his.

§ Born at Ioulis upon Keos, court physician of Seleucus Nikator, of Babylonia, about 304 B.C.

|| About 216 B.C. See 'Polyb.,' 5, 81. 'Athen.,' 3, 115, e; 7, 312, d.

¶ There have been a number of celebrated physicians of that name. The one meant is probably the pupil of Herophilus, and lived about 220 B.C.

** About 250 B.C. Wrote περὶ σκευασίας καὶ δοκιμασίας φαρμάκων, 'On the Preparation and Examination of Remedies.'

†† About 150 B.C. Wrote two poems: θηριακά, 'Remedies against snake-bites, etc.,' and ἀλεξιφάρμακα, 'Antidotes against Poisons.' The first word "*theriaca*," means really, "remedies against wild or poisonous animals," from θηρίον, "the beast;" later it was employed of special remedies and has finally come to mean a preparation of opium.

* Ὀπός, etymologically related to Latin sap-io, German Saf-t, English sap, is commonly used of the sap of the fig-tree, used for curdling milk. Later Greek writers use the terms ὄπιον, ἐπιούμ, ἄφιον and πιόν, according to Du Cange. An Opium Cyrenaicum is mentioned by Theod. Priscian., 112, D. See also Meyer's 'Gesch. d. Bot.,' II., 37, III., 70. The Sanscrit names were mentioned above in note 2. The Chinese terms, also derived from western nations, are O-fuyung, Ya-pien, O-pien. See 'Pharmacographia,' p. 41.

† Lived 121-64 B.C. The φάρμακα Μιθριδάτεια are mentioned by *Appianus de bell. Mithrid.*, 248, where he relates that M., intent on self-destruction, attempted suicide by poison, but failed on account of being proof against it, and took his life by throwing himself against the point of his sword.

‡ See 'Sueton. de ill. Gramm.,' 15, *Plin. h. n.*, 24, 9, 41.

§ Asclepiades Eretricus (that is, the follower of the Eretrian philosopher, Menedemos), from Bithynia, physician, philosopher, and teacher of rhetoric; friend of Licinius, Crassus; about 100 B.C.

|| Those who treated disease in a methodical, systematic manner, as opposed to the empirics.

¶ Born at Sicca, in Numidia; lived in the *second* century, A.D. We possess two of his works; 3 books on acute diseases, and 5 books on chronic diseases.

** Meconium is an extract of the poppy-leaves and heads; opium the inspissated juice of the capsule. *Plin.* 20, 18, 76. 25, 10, 81. 19, 8, 53 ("used often for self-destruction"). 'Dioscor. de Mat. Med.,' 4, 65.

†† Born at Novumcomum, 23 A.D. Lost his life during the eruption of Vesuvius, 79 A.D.

‡‡ About 75 A.D. Τὸ Φιλώνειον is mentioned by *Galen*, ed. Bas., IV., p. 215, and *Celsus*, 6, 6, 3; according to the latter it consists of washed white of lead, spodium (tutty), gum, and roasted opium ("poppy-tears").

§§ About 60 A.D. 'Galen de Antidotis,' ed. Bas., I., p. 433. 'Fabric. Bibl. Gr.,' IV. 356.

physician of the emperor Nero, completed the transformation of the mithridatium into theriac, by adding various new ingredients, among them chiefly the flesh of vipers. The latter became a precious article, and in some places slaves are said to have been exclusively occupied with the chase and capture of these reptiles.

Among the writers on pharmacology, we must notice particularly Scribonius Largus* and Dioscorides.† The latter exactly describes the manner of incising the capsules, and collecting the juice, which latter he calls ὀπίζειν. He also refers to the adulteration of the drug with the juices of glaucium and lactuca, fat, and gum. As antidotes he recommends oxymel and salts. He also observed that the odour of the drug invades the whole body of the person who has taken it, which statement is repeated afterwards by Paulus of Ægina.

Galen‡ held opium in great esteem. He disapproved the roasting process to which it was often subjected, and usually combined it with castoreum, or gave it mixed with generous old wine. . . . Galen's teachings were followed for a long time with the most scrupulous exactness, and especially Alexander of Tralles (sixth century)§ and Paulus, of Ægina,|| two Byzantine physicians, are mentioned here.

Based upon the medical system of the Greek physicians is that of the Arabs. The science was cultivated and propagated among the latter through the learned schools founded by the Nestorians in Asia Minor. As the cultivation of certain branches of the medical art, however, is in conflict with Muhammedan religious views and customs, Arabic physicians with preference cultivated pharmacodynamics, and we owe to them many valuable additions to our materia medica. Theriac is one of their favourite remedies; the celebrated Arabic philosopher, Averroës¶ even wrote a Tractatus de Theriaco. Wonderful cures are related of this compound; so it is related of the Khalif Al-Motawekkil,** that he caused his guests at table to be bitten by poisonous snakes, in order to be able to cure them afterwards by some extra-powerful theriac.

The most celebrated of the Arabic physicians, Avicenna,* recommends opium especially in diarrhœa and diseases of the eye. The maximum dosis is 2 danich, which is, according to Wedel's 'Opiologia,' as much as one scruple. Serapio† gives it in doses of 1 to 2 danichs; the dosis letalis, according to the latter is, 2 ʒ. Avicenna himself met his death by an overdose of the drug.

Maimonides,‡ the pupil of Averroës, recommends theriac in all varieties of poisoning; and Ibn el Beitar,§ the greatest botanist of the Arabs, who treats of opium at great length, follows Galen in recommending castoreum as its antidote and corrective.

Theriac was used as a popular house remedy during the period of reformation under the name of "triackel" (=treacle), and the dealer was simply called "triackelmann" (treacle-man). But gradually the more intelligent physicians began to discourage the use of it, and in later times the aid of the police had to be employed to prevent its being used. It was prepared for the last time at Nuremberg as late as 1754; at Würzburg in 1736, under many ceremonies; and at Paris in 1787. In the first-named city it had been prepared for the first time under supervision of the senate and many ceremonies, between Nov. 9, 1594, and Jan. 10, 1595, for it was regarded as the master-work of the apothecary. It is yet much used in the East. Theriac having thus entirely superseded the pure opium during the Middle Ages, the latter had to be, so to say, rediscovered. This was accomplished by the school, by which the Galenic system was overthrown, and the chief representative of which is Theophrastus Paracelsus.|| The latter introduced a more simple form of opiates, being opposed to complicated remedies. He named his preparation "laudanum," the etymology of which is dubious. The opponents of the "chemists" explained it by *lauda non!* (bad Latin for "do not praise"); the "chemists" themselves regarded it as an abbreviation of *laudatum opiatum* ("the praised opiate"); others have endeavoured to find in it a corruption of *anodynum* with prefixed article, thus: *l'anodynum.* It is, however, more probable that the word is a corruption of *ladanum*, which denotes a vegetable resin, previously much in use.¶

The rest of the paper follows the history of opium down to the time of Sertürner, and we reserve it for another occasion.

* Scribonius Largus Designatianus, author of a work 'De Compositione Medicamentorum,' accompanied the emperor Claudius upon his expedition against Britain (43 A.D.) as physician.

† Pedianus Dioscorides, from Anazarbos, in Cilicia, lived shortly before Plinius. We possess his five books, περὶ ὕλης ἰατρικῆς, On Materia Medica.

‡ Claudius Galenus, born at Pergamum, 131 A.D., died some time between 200 and 203 A.D. Of his medical works, one hundred, of various contents and extent, are preserved and considered genuine; 18 are doubtful, 19 are only in fragments, and 24 others ascribed to him are spurious. A new critical edition, by Professor Iwan Müller, is being published.

§ Alexander, from Tralles in Lydia, physician at Rome. Wrote 6 books of 'Therapeutics.'

|| Very little is known of him. Best edition (English, with commentary), by Francis Adams. 3 vols. Sydenham Society publ.

¶ Latinized from Ibn Rushd. Born at Cordova, 1126, died at Marocco, Dec. 12, 1198. His writings, only preserved in Latin translation, are chiefly commentaries to Aristotle, and also of medical contents, as, for instance, his 'Colliyât,' or 'Medical Therapeutics.' Best ed., Venice, 1489. In 11 fol. vols. A hope of obtaining the original has lately been raised. Napoleon Ney, namely, French Special Commissioner in Africa, for some time has tried to revive the old trade connections which once existed between the coast of the Mediterranean and the tribes of the Sahara. For this purpose he studied the old Italian and Arabic authors, from whom he learned that Tlemcen, Oran, Bougie, Constantine, and Tunis once yielded to European merchants ivory, gum, indigo, etc., and received in return linen, silks, glass and metal wares, and arms. And he found the surprising statements, that caravans, which penetrated as far as the Tschad Lake, *carried thither manuscripts of European classic works.* And the learned traveller, Henry Duveyrier, the most thorough expert of the western Sahara, is convinced that the *library of the Sudanian Sultan at Sokoto contains the works of Greek and Arabic physicians, and even a translation of Aristotle.*

** 847-861 A.D.

* Latinized from Ibn Sina. Full name, Abu-l-Ali Ibn Sina; born 980, at Alfsenna, in the present province of Bochara, died at Hamadan, 1037 A.D. His medical 'Canon' formed the basis of medical and therapeutical knowledge for centuries afterwards.

† There were two Serapios. One is Yahya ben Serabi, or the elder S., of Damascus; and the other, who is meant here, is Ibn Serabi, who lived about 1090 A.D. His work is entitled 'Kitâb ul-adwiyta '-mufradit,' "*de simplici medicina.*"

‡ Moses ben Maimon, vulgarly called Rambam, the great Jewish rabbi, born at Cordova about 1131. Died 1204. He was a physician (in Egypt) and a great authority in law and philosophy.

§ Abu Muhammad Abdallah ben Ahmed, of Malaga, known by the short name of Ibn Beithar. Died 1248.

|| Phillippus Aureolus Theophrastus Paracelsus von Hohenheim. Born 1493, near Zurich, died at Salzburg, Sept. 24, 1541.

¶ Ladanum, or Labdanum, is a resinous exudation of *Cistus Creticus* L., *C. Cyprius*, Lam., and *Cistus ladaniferus*, L. This is occasionally written *laudanum*, as, for instance, in Plin. 'Valerian,' 1, 1, fol. 13 (see Langkavel 'Beitr. zur Gesch. der Botanik,' p. 13), and in rabbinical works of the Middle Age. The Talmudic equivalent is *lidna* 'Ketubot,' 77, where it is named as remedy for running eyes and nose), and it is identical with *Heb. lot* (1 *Mos.*, 37, 25). The Mishna ('Shebût,' 7) identifies it by saying that it comes from the Cistrose.

THE ROOT OF EUPHORBIA IPECACUANHA.*

BY PHILIPP H. DILG, PH.G.

The author collected the root in New Jersey late in September, and on repeating some of Mr. Petzelt's experiments (see *Pharmaceutical Journal*, vol. v., 1873, p. 158) did not obtain any reaction for glucose until after the decoction had been boiled with an acid.

The alcoholic extract obtained by spontaneous evaporation was of a light-brown colour and contained some crystals; ether extracted from it some oil and waxy matter, and a compound, which, on evaporation from petroleum benzin, yielded clusters of radiating crystals.

On percolating the root with petroleum benzin and evaporating the menstruum, a yellow tenacious mass, intermingled with thin colourless needles, was obtained. This benzin extract was completely dissolved by chloroform and bisulphide of carbon, the latter solution being turbid; ether dissolved it partially, leaving a white flakey residue, and alcohol acquired a yellow colour without affecting the shape of the extract, which appears to consist mainly of caoutchouc. From the alcoholic solution a warty crystalline mass was obtained, which responded to the test for euphorbon as given by Flückiger ('Pharmacographia,' p. 504).

The author did not succeed in isolating the emetic principle, and in concluding his essay he states that only two houses in this city quote *Euphorbia Ipecacuanha* in their price lists, but one only had it in stock, charging for it 75 cents per pound. On examining a dozen price lists from eclectic druggists in different parts of the country, one from Boston was the only one quoting it, and from that house a package was obtained, marked *Euphorbia Americana*, but containing the root of *Gillenia stipulacea*.† If it was ever used to any extent, the drug has evidently become obsolete and might well be dropped from the Pharmacopœia.

THE POISONOUS ACTION OF ALCOHOLS.‡

BY DUJARDIN-BEAUMETZ AND AUDIGÉ.

This paper gives the results of experiments on the poisonous action of alcohols on dogs. The authors find that, of the alcohols produced by fermentation. the amount required to cause death within twenty-four hours varies with the atomic composition. The fatal dose per kilogram of weight of the animal, administered by the stomach (I), and by hypodermic injection (II), was found to be:—

	I.	II.
Of ethyl alcohol . . .	7·75	8·00 grams.
„ propyl „ . . .	3·13	4·02 „
„ butyl „ . . .	1·74	2·15 „
„ amyl „ . . .	1·48	2·02 „

Experiments with other monatomic alcohols led to the following results:—

Methyl alcohol is more poisonous than ethyl alcohol, the fatal dose being five grams per kilogram of weight of the dog.

Heptyl and octyl alcohols vary in their action according as they are administered in the pure state or diluted with ethyl alcohol. The fatal dose of the pure substances is about the same as that of ethyl alcohol; but when diluted to ten times their bulk with absolute alcohol, the doses of 2·3—2·5 grams of heptyl alcohol, and 2—2·2 grams of octyl alcohol per kilogram of weight were found sufficient to cause death.

Cetyl alcohol, being insoluble, is not poisonous.

* From the *American Journal of Pharmacy*, November, 1876.

† Our experience has been similar to that of Mr. Dilg; several years ago we were unable to find this root in the market, and on several occasions were supplied with the root of *G. stipulacea*.—*Ed. Am. J. P.*

THE INTERNATIONAL CONGRESS OF THE MEDICAL SCIENCES.

THE MEDICAL EMPLOYMENT OF IMMEDIATE CHEMICAL PRINCIPLES.

The following report presented to the pharmacy section of the late Medical Conference at Brussels has just been published in the 'Transactions.'

Considered in its origin and progress, chemistry is a grand science. Commencing in the lowest practices, and the irrational and empirical processes of alchemy, it has now extended its domain and incontestable influence over all the branches of human knowledge; over the theoretical natural sciences, from botany to geology, and even to astronomy; over the applied sciences, through every industry to the art of healing poor humanity. What a revolution this vast science has occasioned in old and venerable medicine, galvanized, as it were, and roused from its genteel routine! What activity and what energy it has communicated to modern medicine, formerly so drowsy! What force and richness its products have given to the arsenal of Hippocrates—in former days nearly reduced to the employment of plants under the name of simples, but now armed with agents of fearful activity! What a reform in that art, of which the impotency, in the state of palliative medicine, was scarcely able to attack the symptoms of the malady, but which, now become a curative medicine, and provided with new weapons, can attack valiantly in their causes the ills of the human race!

The mission of chemistry in medicine is, however, still far from being accomplished. It has only just commenced; the organic portion, that which is the richest, is scarcely outlined, and yet it has furnished our art with the most heroic remedies. To it we owe quinine, morphine, veratrine, santonin, atropine, without counting a large number of other principles, and modern science demands from vegetable chemistry, every day, new resources with which to combat the powerful army of maladies that attack living beings.

It may be asked whether this movement ought not to be encouraged, and whether it is not even necessary to give a strong impulse to this tendency that has revealed itself to abandon crude vegetable matters and their galenical preparations, in order to substitute for them the chemically definite immediate principles which science knows how to separate, such as the alkaloids, glucosides, etc.

This question is of sufficient importance to be submitted for discussion by learned bodies. It is desirable to examine what utility there would be in encouraging and extending the employment of chemically definite immediate principles, and multiplying their preparations in the Pharmacopœias.

Such an extension would have for its consequence to restrain the employment of plants in their natural state, or their galenical preparations, which are sometimes inert and inferior. It requires, therefore, to be considered whether, on the one hand, the use of these galenical preparations presents inconveniences, and what they are; on the other, whether the employment of immediate principles, chemically isolated, would offer any advantages in medicine.

§ 1. *Confusion and Want of Clearness in the Action of Complex Medicines.*—"Therapeutics," says Claude Bernard, "offers already enough difficulties by itself, without augmenting them by the employment of compound medicaments giving only variable results." Who has not deplored the sad path of empiricism in which ancient medicine was engaged seeking an universal remedy, and heaping up in its absurd quackeries agents the most opposed, wishing to profit from the complex and contradictory actions of the components to create a panacea endowed with the most incompatible properties? Who has not noticed also, since the progress of modern chemistry, that many drugs furnished by nature, and improperly called "simples," are themselves assemblages of diverse substances and immediate principles, possessing different, and sometimes opposite, therapeutic properties? It is known that liquorice contains an irritant resin, and at the same time an emollient saccharine principle. From marine plants, employed as depuratives, are now extracted concurrently, the iodides, depuratives *par excellence;* the bromides, considered at first as substitutes for the iodides, but soon recognized as possessing sedative powers quite different; and finally, the chlorides, which always accompany the bromides in plants, but which in the present day are, nevertheless, accused of destroying their therapeutic action.

What medical man has not encountered, while employing certain medicaments, effects so diverse, sometimes so singular, as often to throw into confusion the most wisely reasoned and best applied therapeutics? These apparent anomalies are due to the presence of immediate principles in varying proportion, and it is in a study of these principles that an explanation of the facts must be sought. We will cite only a single example, perhaps the most curious, namely, opium. The extract and laudanum, the two galenical forms most commonly employed, give sometimes in their therapeutic application effects so different that in medical works the most divergent and even contradictory indications are given on the subject. The study of opium has made known successively six principal alkaloids, perfectly definite, possessing either different properties or well marked modifications of action. Claude Bernard has been much occupied with these opium principles, and according to him each of them differs entirely from all the others in respect to its therapeutic action. Thus narceine, morphine, and codeine, are soporifics, whilst thebaine, papaverine, and narcotine, are devoid of hypnotic properties. On the contrary, the last three bodies are the convulsivants of opium in doses in which the first three do not possess that property. As poisons, certain of these alkaloids are dangerous in doses in which the others are only sedative. It is known further, that to narcotine are attributed antiperiodic properties. Here is the explanation of the eccentricities following the therapeutic use of opium, an unreliability depending upon a variability in the proportion of immediate principles impossible to divine *à priori.* By the employment of isolated principles *the doctor would be able to attain the object he proposes without fear of seeing those accidents, sometimes dangerous, and always disagreeable, which are common in the employment of galenical preparations.*

Another inconvenience is, that the inert matters which form the organs of plants can mask or oppose the action of the active principle which Nature has deposited within them. And with what a quantity of these matters it is necessary ordinarily to fill the stomach in order to introduce a milligram of the active principle, even when the plant employed is in the best condition! How often, before the discovery of quinine, did cinchona bark administered in powder derange the stomach of the patient consumed by fever and compel the abandonment of the treatment.

It will suffice to recall these examples; science will furnish many more facts that cannot here be cited. It will be enough to add that these diverse principles, contained together in one plant, are not present always even in constant proportion, which gives rise to many chances of variability in the therapeutic action of the plant. This truth will be developed in a subsequent paragraph.

It is now asked, in presence of these polypharmic compounds, these artificial mixtures of our shops, in presence of these plants, more or less prepared and reduced to galenical medicaments, or even in presence of these pretended "simples," according to the antique expression, "simples," that are now recognized to be compounds, can the medical man see his way clearly in his treatment from a therapeutic point of view? Could he follow and study with certainty the action, so often complex, of the remedy employed? Would it be possible for him to disentangle the effects due to the different immediate agents introduced together into the organism of the patient and of which one often acts contrarily to another? Could he even distinguish the symptoms of the malady from the action or actions of the remedy employed? They are, as Hufeland remarks, weapons with many edges; it is intended to use one, and it is another that wounds, and in a place where it was not desired. It is not astonishing that, with such weapons, ancient medicine should have often appeared hesitating and uncertain in its intervention, and that sometimes it was the remedy that killed rather than the disease.

To go further. In following the labours of Mialhe upon several chemical medicaments and the beautiful researches of Melsens, who traced in the human body the progress of potassium iodide and iodate, and explained their action, their effects, and their passage into the various organs and organic liquids of the body, it may be demanded whether here is not the future of medicine, and whether this precise and nearly mathematical mode of observation, which might be named *réaliste,* is not destined to replace, in part at least, the therapeutic and physiological observations made at the bedside of the sick, and which, numerous as they are, conduct so rarely to a practical and unchallenged conclusion. Now these precise observations, *impracticable with our actual polypharmic medicine,* become possible, if not easy, by the employment of isolated medicinal agents.

The rare specifics recognized in the present day, as created by nature to destroy the germs of certain maladies, are chemically definite bodies, as quinine, mercury, arsenic, etc. Is it not allowable to hope that every morbid species having its peculiar essence, there might be found antagonistic remedies—antidotes in a sense—of the diseases? May it not be that Nature, by the side of every ill, has placed its specific remedy? Finally, is it not probable that these specifics will be found to be substances with characteristic properties, in fact, chemical individualities?

§ 2. *Variability in the Therapeutic Power of Plants, arising from Collection.*—The first quality of a medicament is its therapeutic constancy, its identity of activity always and everywhere. Agents with inconstant action are quickly abandoned. Now the alkaloids and other chemically definite active principles are, above all others, the bodies which, in their chemical, organoleptic, and therapeutic properties, have a complete and permanent identity. Quinine is always quinine, and strychnine is always strychnine. This truth is absolute and indisputable when these bodies are perfectly pure, and it is one of the principal causes that this category of bodies has been received with the greatest favour into the arsenal of medical therapeutics.

If we wish to appreciate from this point of view the vegetable galenical medicaments, simple or compound, what a difference we are obliged to recognize. A plant differs from itself, in a medical point of view, through a multitude of causes. Two specimens of the same species, collected at the same time from beside each other and according to established rules, necessarily vary between themselves, within certain limits, as to their properties and therapeutic action; the one is older, more vigorous, better nourished, less watery; the other is younger, more succulent and softer. What would be the case if these plants had been born and lived in different conditions of soil and climate?

It is not necessary to teach here that a collection made at the wrong time yields inert drugs: such are the leaves, roots, and bulbs collected from plants in flower or in fruit. Neither is it necessary to do more than recall that cultivated plants are less active than wild plants; that plants vary according as the year is dry or wet; that the poisonous umbellifers are more or less so according to the greater or less humidity of the soil in which they are produced, whilst, on the contrary, the aromatic umbellifers gain in essential oil in dry and elevated soils; this is the case with aconite, valerian, etc. Can there be any comparison between the root of *Rheum palmatum* or *Rheum undulatum* cultivated in European countries and that grown in China? The *Cannabis indica*, which furnishes haschish in its native country, is very nearly inert when grown in Europe. The cichoraceæ lose their bitterness by culture, whilst the labiatæ acquire more aroma in our gardens. Now the pharmacist would be much embarassed in selecting his drugs, to say whether a leaf, a root, or a flower had been collected at the proper time or not; whether it had been yielded from a cultivated or a wild plant, whether it had grown in a dry or a humid place.

These common examples need only be recalled in order to establish a truth which is not less important because it is common, to wit, that the therapeutic power of a plant varies according to circumstances of collection, season, weather, climate, cultivation, age, elevation of place of growth, its humidity or dryness, etc.

Every one knows that the crude opium of commerce is so unstable in its alkaloidal strength that attempts have been made to manufacture it artificially of a constant strength. The manufacturers of sulphate of quinine do not purchase their cinchona until after a careful analysis of those barks, so expensive and yet so variable as occurring in our pharmacies. Scammony differs so much, as to the proportion of resin, that medical men, discouraged by the uncertainty of its action, have almost completely renounced it. To how many supposed active medicaments could not the same reproach be applied? But not one of the active principles which gives to these plants their powers and their properties, and which are found in them in different proportions according to the circumstances that have been noticed, can vary in itself, notwithstanding all these causes; it remains always the same whether extracted from a vigorous or a weakly plant. It is unnecessary to dwell upon this advantage offered by chemically definite medicaments.

§ 3. *Variability in the Therapeutic Power of Plants due to the Galenical Preparation.*—From the moment of their collection, the plants which enter into our pharmacies are liable to undergo change, and their instability is so great that they ought to be employed at once and before any ulterior change takes place; this, however, would be quite an exceptional circumstance. But what must it be when they have undergone all kinds of manipulations, from drying to extraction, from pulverization to pulpation, from infusion to distillation? Pharmacy has established the most rational processes of preparation possible, but are these processes perfect? Unfortunately they are far from that. Perfection is not attained by man; and supposing that these processes were always applied by operators in an irreproachable manner the products would still leave much to desire.

The first operation, the fundamental operation of pharmacy, although the most simple, is itself, in this case, namely, desiccation. The best and most successful desiccation profoundly modifies the constitution of the plants. The water of vegetation in evaporating gives place to air, and this exercises upon the immediate constituents of the plant an oxidizing action by which they are partially decomposed.

Such is the state of imperfection into which the simples or primary matters used to prepare our galenical medicines come in pharmacy. What galenical preparation could they supply that would not be marred by inconstancy and variability in its effects? The tinctures differ considerably in composition according to their source, collection, and preservation, so that the sum of the effect cannot be calculated in advance; extracts of digitalis and tinctures of colchicum are met with differing in the proportion of 1 to 100. It is not without reason that Storck has recommended the employment of the juice of the fresh plants in the preparation of narcotic extracts. Neither is it without reason that Beral has introduced into practice the use of *alcoolatures*, so as to avoid the effects of desiccation, and that it has since been proposed to make *alcoolatures* the basis of all the pharmaceutical preparations, such as syrups, extracts, saccharoles, etc. It is well known that our pharmacotechny sins at its basis, and that the primary matters employed at the starting point of its compounds are suspected of therapeutic variability. But the extracts of Storck also would always give evidence of the effects of heat and prolonged evaporation. Besides, these extracts and *alcoolatures* depend for their therapeutic value entirely upon the constancy of the activity of the plants employed, and we have seen what, in reality, this constancy is. As to *alcoolatures* it is necessary not to lose sight of the fact that the menstruum, alcohol, may itself react upon the immediate products of the plant and cause them to undergo new modifications.

We have only spoken of desiccation; but if at the temperature of the atmosphere there is manifested so profound a decomposition, a much more energetic action ought to be expected when heat, and often a prolonged heat, is employed in the preparations of the pharmaceutical laboratory. From this point of view the liquid preparations, the decoction and infusion, have not been specially studied. But it may be assumed *à priori* that they may differ according to the length of treatment and the degree of heat employed, witness the apozeme of the ancient pharmacologists. As to the residues from the evaporation of these liquors, the extracts, these have been the subjects of a number of learned researches, which have all had for their object the perfection of the mode of preparing this important class of medicines. The most competent men are in fact unanimous in recognizing that the action of these products has an unfortunate variability. This variability is due to the complex reactions which are developed during their preparation. These reactions have been affirmed by authors, but no one has yet been able to disentangle the chaos. It will be remembered that after attempting to employ undried plants, evaporation by means of the least possible amount of heat was tried, then evaporation in a vacuum, sheltered from the oxygen of the air. Unfortunately in Belgium the extracts prepared *in vacuo* are not used in medical practice; and more unfortunately still there is a complication of extracts—alcoholic, aqueous, with or without powder, dry or soft—which not rarely are compounded in prescriptions.

It is not necessary here to criticize every process and every preparation of modern practical pharmacy. From this point of view immense progress has been realized. The time is past when medicinal plants were hung to the door to dry, exposed to the wind, sun and rain, or when liquors to be evaporated were left over the fires for weeks without any means being taken to accelerate the evaporation. But the reporter thinks it is necessary not to arrest this progress, and, whenever it is possible, he would substitute for these complex medicines of variable power alkaloids and chemically definite substances of exact composition and with properties always mathematically identical, upon which the physician could reckon with confidence.

§ 4. *Variability in the Power of Galenical Preparations due to Keeping.*—But when the galenical medicaments have passed through all these critical periods of preparation, and arrived in the pharmacy, there to remain under the surveillance of the pharmacist, are they then safe from variability, and will they remain identical with themselves? This is known not to be the case. In spite of all the care and science the pharmacist may bring to their preservation he cannot resist the internal working that modifies slowly the composition of his galenical preparations. Every one knows how much old medicines are worth: the leaves, flowers, seeds, roots, or other plant organs and their powders, lose their colour, odour and taste, and undergo a slow decomposition, as soon as they are no longer under the laws of life. The modification of the numerous elements that they contain results at last in the alteration of the immediate principles occurring in them, which are gradually decomposed in the fermentation by which they are surrounded.

Neither is the preservation of extracts more assured; they become dry or deliquesce, their solubility diminishes, or certain salts escape from them in the shape of crystals. Briefly, their decomposition is slow, but invincible. The tinctures and alcoholates are not much more stable, as the deposits that separate from them testify.

There is nothing unnatural in this slow, but fatal and invincible, alteration of all these organic matters. They were maintained during life in an equilibrium of preservation by the laws of vegetation; but they have been withdrawn from the action of these organic forces, and, re-entering the domain of general laws, have fallen under the empire of an internal decomposing power that induces in them successively new compounds, proceeding from the complex to the more simple.

This constant alteration, inveterately preying in every way, and at all times, upon the agents which for centuries have constituted the sole resources of the art of healing, has certainly been one of the causes of modern medical scepticism, and the therapeutic deceptions that it has occasioned would have led, without doubt, to the complete negation of all remedies.

This state of permanent decomposition of every galenical compound, imposes upon the pharmacist the necessity and duty of renewing his vegetable preparations, an onerous duty that is often neglected, and one that is difficult in respect to the choice and verification of the primary substances. Whatever, in fact, may be the source of these substances, the pharmacist cannot always be sure of their good quality. It is not so with chemically definite products; these have a well characterized individuality that is easily established. To recognize their quality is an easy and trustworthy operation. This facility of examination has also a valuable consequence; it renders illusory all attempts to sophisticate the alkaloids, glucosides, or other definite products, and deception upon this point is practically impossible; but it is easy and habitual to sophisticate extracts, powders, etc.

§ 5. *Facility of Administering Immediate Principles to the Sick.*—Every one will understand how much more easy it will become to administer to a patient the active principle when it has been reduced to its most simple expression, and disengaged from the mass of inert matters in the midst of which it is lost in the plant; matters consisting of organized *débris* or soluble and extractive substances, but always fermentescible and disagreeable to take; matters which it is necessary to incorporate in so large a quantity to absorb a minimum proportion of the active principles.

The example of cinchona has been mentioned before; add to it all the powders—cubebs at their head—the infusions and apozemes, the tinctures and extracts, although in these the active principles are concentrated to the least volume. Of these extracts only boluses can be made, or rather, bullets compared to the granule containing immediate principles. The patient refuses to swallow the galenic drugs prescribed by the physician; what then becomes of the treatment? On the other hand, the smallness of the dose of immediate principles renders their administration extremely easy. The granule, enveloped in a layer of milk sugar and carefully silvered, is an excellent form, which in the present day tends to become general, because it is at once convenient, agreeable, and certain in its effect. *Tuto, cito, et jucunde.* It may be desired to employ one or other of the immediate principles in a liquid form; the most suitable preparation would be the alcoholate of 1 in 50. Every drop would then contain a milligram of active matter, and with good *compte-gouttes* it would be easy to have very equal drops.

The degree of the alcoholic menstruum would naturally vary with the nature of the principle to be held in solution, and according to whether the isolated principle was employed or combined in the state of a salt.

Galenial Medicaments that cannot be replaced by an Immediate Principle.—In treating the question of pharmacology with which he has been charged the reporter feels that on several sides it comes into contact with therapeutics, and that in this respect he is not competent. He claims to have studied it especially from the pharmaceutical point of view and that his provisional conclusions have been drawn up in that sense. They are justified by pharmacology, and also, he thinks, from a therapeutic point of view. But he appeals to the observations of medical men, the competence of whom he recognizes, and desires that they should discuss his conclusions, to support them if legitimate or modify them if necessary. The following are some objections that have been urged against these conclusions as formulated at the end of the report.

There are some plants that practitioners employ either in a natural state or in the form of galenical preparation, in preference to the alkaloid. Digitalis is an example. Experience has proved that amongst the digitalins, so distinct in their essence and which have given rise to many discussions, not one represents really the properties of the plant. In the reporter's opinion that proves one thing, which is, that the study of digitalis has not yet been completed, but he claims that this cannot be applied against his conclusions. There are many active plants that are found in the same case. From this point of view pharmacology and therapeutics are in a state of transition. The conclusions necessarily bear with them a restrictive character, and can only be applied to well studied and well known principles, having a well established utility. It would be overstepping the object sought to impose systematically a general rule. This application would, moreover, be impossible, since many plants endowed with great activity do not act by virtue of a definite chemical principle. Further the possibility is admitted even of artificial or natural mixtures enjoying special properties not found in the components. For instance, cod liver oil, from which it would be impossible to extract an active principle that could really replace the oil.

It has even been claimed that several galenical mixtures possess certain special properties that are far from representing the sum of the constituents or the products of any of them.

In the presence of these facts is it necessary to withdraw from these conclusions? The reporter thinks not, and that it is simply necessary to consider them as exceptions, and to say that in certain cases it is impossible to reduce a medicament to the simple expression of an active principle, and that then naturally the rule is not applicable.

Conclusions.—(1) It is eminently desirable that the employment of chemically definite immediate principles in medicine should be extended, so as, progressively, to establish the practice of substituting for the use of crude vegetable matters that of their isolated active principles.

(2) It would be useful, with this object, to multiply in the Pharmacopœias formulæ suitable for promoting this movement.

(3) The forms which lend themselves best to the employment of immediate principles and to the facility of their administration are—for internal use, the "grain" and the "granule" containing one milligram of active substance, and in default of them the alcoholate, 1 in 50, which would correspond closely to one milligram per measured drop.

MILK OF SULPHUR.

A CHEMIST AND DRUGGIST at Hyde near Manchester has just been fined and condemned to pay the costs of his prosecution for selling "Milk of Sulphur," upon the ground that the article contained only thirty per cent. of sulphur, the remainder consisting of sulphate of lime. The presiding magistrate, Dr. NEWTON, remarked that credit was due to the chief constable of the locality for bringing this case before the Bench because mothers gave sulphur to their children for skin diseases; and he added that if a drachm of this mixture were given to a child the result would in all probability be that the ingredients would become hard, causing congestion and inflammation of the bowels and even death.

Judging from the magistrate's title in this case and the freedom with which he gave his opinions he is probably a medical man, and so far as the majority of persons are concerned it will naturally be supposed that he ought to know when he declared he had no doubt the mortality among children was largely owing to the introduction of mysterious substances into their little bodies, and took the case of the Hyde druggist as an illustration of "how it was done."

After dealing with the case in this manner, it is not to be wondered at that the defendant was informed that the Bench took a lenient view of his case, under the belief that he had no guilty knowledge of what he was selling, and would therefore refrain from imposing on him the penalty of twenty pounds.

Of course a case thus dealt with and commented upon by medical authority would naturally furnish material for the ready scribes of the local penny gushers, and accordingly we have received, from various correspondents, newspaper paragraphs headed "A Cause of Infant Mortality," or otherwise garnished to satisfy the demand for sensation, and editorial articles in which mothers are gravely warned that the infantile constitutions of their little ones, however strong, must almost inevitably succumb to a dose of plaster of paris. Having thus furnished these poor folks with what they regard as an opportunity of realizing the serious nature of the case, and described the presiding magistrate's remarks as being a "revelation," these ingenious writers proceed to descant upon the frightful adulteration of drugs, and the means by which it can be detected; and they may, at least, feel satisfied they have done their best to make some other people uncomfortable besides the unfortunate victim of these misguided proceedings.

In regard, however, to the question whether the sale of the preparation commonly known as milk of sulphur is legitimate or not, it is really time that some mode of deciding the point at issue should be had recourse to. There is no question that precipitated sulphur should always be supplied to those who desire to have it; but there are many who do not approve of this preparation, and prefer the old-fashioned "Milk of Sulphur;" many others, ignorant perhaps of the difference, are at least accustomed to the old preparation, and when they are supplied with it really obtain what they expect. It is monstrous that persons dealing in this article conformably with old established usage should be liable to prosecution and all the detriment attaching thereto simply because it is the whim of some public analyst to assume that "Milk of Sulphur" means the precipitated sulphur of the Pharmacopœia. If the sale of Milk of Sulphur as ordinarily understood is to be treated as offence against the law, some means of warning unsuspecting traders should be adopted, such as an official prohibition. At present the question whether or not it is an offence to sell this article is open to be decided simply by the opinion of one or other local analyst, and that state of things is in our opinion an unmitigated evil.

MORE CORRECTIONS FOR THE BENEFIT OF THE MEDICAL PRESS.

A FORTNIGHT since we had occasion to request a medical contemporary to set us right with its readers in regard to a statement in its editorial columns which was so palpably incorrect that we fully expected an unreserved admission of the error that had been made. That we had good reason for this expectation will be sufficiently apparent when we state that our contemporary's error was the only foundation for the following paragraph:—

"But since that Society [the Pharmaceutical], or at least a majority of its Council, would rather aid and support the druggists in the infringement of the law, it is for our own profession now to consider by what means it may make its voice heard and its authority felt."

We consider this remark by the editor of the *Medical Examiner* calculated to exercise a very mischievous influence in regard to a subject of very considerable difficulty, more especially since it was made upon the erroneous supposition that the Council of the Pharmaceutical Society had resolved to undertake the legal defence of any chemist and druggist threatened with prosecution for prescribing. We regret, therefore, that the explanation now offered by our contemporary that its remarks "were directed more to the discussion on the subject in the Council than to the resolution finally passed by it," is one which we cannot accept as adequate. So far as the formal resolution of the Council is concerned, there is nothing to justify the suspicion that it contemplates the defence of any interference with the functions of medical men, and since the discussion that took place on the subject was, in this respect, perfectly in harmony with the purport of the resolution, we cannot do otherwise than express our opinion that it does not justify the remarks made by the editor of the *Medical Examiner*, but that it still remains for him to furnish a correction of the error into which he has fallen.

While speaking of this subject of illegal prescribing we take the opportunity of pointing out another error in the editorial reference, in last week's *Lancet*, to the case of Mr. WITHERINGTON, who was recently prosecuted by the Apothecaries' Company. It is there stated, upon what authority we know not, that he is a member of the Pharmaceutical Society. The fact is, that Mr. WITHERINGTON is not a member of, or in any way connected with, the Pharmaceutical Society. We are informed however that in 1874 he was placed upon the Register of Chemists and Druggists in virtue of a claim that he was in business before the passing of the Pharmacy Act, and the declaration furnished to support the claim bore the signature of a medical practitionor with the following letters appended, "L.R.C.P. Ed., L.R.C.S. Ed., L.S.A., etc., etc."

If the statement that Mr. WITHERINGTON was a member of the Pharmaceutical Society had appeared in an ordinary newspaper there would have been less need to notice it, but the case is different when such an inaccuracy is published in the *Lancet* without an excuse, so far as we are aware, of being misled by a mere newspaper report.

THE EVENING MEETING.

AN Evening Meeting of the Pharmaceutical Society will be held next Wednesday, December 6th. The papers to be read are:—"A New Mode of Making Grey Powder," by Mr. A BOTTLE; "The Composition and Uses of a New Preparation of Bismuth," by Mr. S. C. BETTY; "Note on Certain Reactions of the Glycerole of Nitrate of Bismuth," by THE PRESIDENT; "Note on Crystallized Hyoscyamine," by Mr. W. MARTINDALE; "Note on Impure Glycerine" and a "Note on a Crystalline Deposit from Tincture of Galls," by Mr. A. W. GERRARD; and a "Note on the Formula of Capsaicin," by Mr. J. C. THRESH. The Chair will be taken at half-past eight precisely.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday Evening, December 7th, at eight o'clock, when a paper will be read by Mr. J. C. SHENSTONE, on "The Microscope," with Illustrations.

WE regret to state that Mr. GEORGE BAGOT KENNET, who was in 1873 elected one of the Annuitants on the Benevolent Fund, died on the 20th of November.

Transactions of the Pharmaceutical Society.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN—NORTH BRITISH BRANCH.

The first meeting of the twenty-third session was held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday evening, 22nd November. The chair was occupied by Mr. William Gilmour, President of the Branch, who opened the session with the following—

INTRODUCTORY REMARKS.

One of the earliest duties which it becomes me to perform on this, the opening night of our scientific meetings for another session, is to thank you most sincerely for the honour done me in electing me for the third time to the honourable position which I now hold. In doing this I am afraid I shall need to crave your forbearance and sympathy even more than in past years, for I feel that with undiminished wish to serve the Pharmaceutical Society in any way in my power, I bring, from recent illness, somewhat diminished ability and strength.

I know, however, from past experience that I shall not ask this from you in vain, and I feel assured further that you will also for the very same cause overlook any imperfections in the short paper which I purpose immediately bringing before you to-night, seeing I have not had the opportunity of overhauling it which I would have required. Before proceeding with my paper, let me call your attention to one or two important matters which have recently come before your Council, and in which you all are more or less deeply interested.

Most of you will probably have noticed hanging on the wall on entering the room, the beautiful and striking portrait of the late Mr. Tait. This handsome memorial has been presented by the firm with which Mr. Tait was so long connected, and a more acceptable or fitting presentation, I venture to say, could not possibly have been made the Society. We do not, I need scarcely remark, require this to keep Mr. Tait's memory green in our hearts, but we accept it, and place it on the walls of our institution as a mark of honour to one who was worthy of all honour, and a memorial of one whose memory will ever be held in esteem by the Pharmaceutical Society. It gives me great pleasure to think that we may soon have a worthy companion to it in a portrait also of the late Mr. Brown. We have many memorials of Mr. Brown in the many handsome donations which he made to the museum and library, but none the less will we value his likeness and hold it in reverence. One of the last donations which Mr. Brown made to the Society was a valuable collection of minerals—a collection which I question if the parent Society in London has the equal. These will shortly be arranged and displayed in cases at present being made for the purpose, and as I am aware from having heard Mr. Brown repeatedly regret, that the collection is not quite complete, I hope we shall all endeavour to show our regard for his wishes and efforts by individually, so far as we are able, supplying those specimens which are wanting.

This probably is not the time, although I may well be excused referring to the late visit of a deputation from the Scotch to the London Examining Board. The importance of such reciprocal visits has long been recognized, and doubtless one of their outcomes is more immediately to secure, as indeed it is intended to do, the harmony of the two boards, and the assimilation of their standards. The report of the Scotch deputation has not yet been published, but I believe it thoroughly bears out what previous deputations, both from the London and Edinburgh boards, have reported, namely, the complete identity of the examinations. Gentlemen, much has been said in some quarters, and more, probably, whispered, about the one board being more lenient than the other in the matter of these examinations, but if the judgment and honesty of the various deputations are at all to be relied upon, they should, I think, set such opinions and whispers for ever at rest. It will, let me add, be an unfortunate day for the best interests of the Society, if outside rumours and statements made in entire ignorance of the facts succeed in disturbing the harmony of the examinations, or induce the two boards to run a competitive race, either as regards the number they pass or reject. And yet such is altogether the tendency, I am afraid, of these assertions and reports.

When upon this question of examinations, let me refer for a moment to an allied subject which has given your Council of late serious matter for consideration. The question of education must always be ultimately associated with examination, especially when, as in the present instance, the latter is compulsory. It has, therefore, been always the endeavour of your Council not only to encourage, but to give every facility to students to attend lectures bearing on the subject matter of their examinations and profession generally. Consequently the application for the use of the rooms for a course of lectures on materia medica and botany, especially by two such lecturers as Dr. Craig and Mr. Sadler, could not fail to be favourably entertained by them, and they therefore transmitted the request to the Council in London with a recommendation. The Council at once generously granted the request, and Dr. Craig's lectures on materia medica, and Mr. Sadler's on botany, have now been instituted, and will, I believe, continue throughout the whole of the winter months. I need scarcely say that I hope both lecturers will be greatly encouraged in this attempt to institute classes in these very important branches of a pharmacist's education. My firm conviction is that we are rapidly approaching a time when every pharmaceutical student will be compelled to undergo a systematic education, just as he is at the present time compelled to undergo a compulsory examination, and certainly nothing will conduce to bring this to pass more speedily than the numbers who, quite apparently from the percentage rejected at each examination, come up unprepared, or superficially prepared, for their examination.

There are undoubtedly other considerations besides this operating upon and forming the minds of pharmaceutical leaders in this direction; but were there no other, I say again, that this of itself would in the course of time be quite sufficient. It would be a hopeful sign for pharmacy were this time anticipated by a voluntary attendance on the part of every young man at, at least, one complete course of lectures on each subject. I see no reason why this should not be the case, for even commercially it would in the end more than repay the trouble, time and money, it would cost. I have said before to young men, and now I repeat that I know of no investment so certain of return as proper books and lectures; but until this is properly understood by them (which I am afraid it is not at present), we may quite expect that a considerable percentage of those who present themselves for examination will be rejected and sent back poorer if not wiser men.

I cannot refrain from here noticing the marked improvement which has taken place during the past year in the arrangement and general conduct of all the different departments under the charge of our assistant secretary. During the year which Mr. Stenhouse has been in office, he has worked with a zeal and ability thoroughly commendable, and the result is that every department is now in a thorough, or in process of being put in a thorough, state of efficiency, which will enhance its value exceedingly. I am sure that every one who is in the habit of using the rooms, and who has felt the pleasure and comfort of the order and neatness which now at all times obtain, will agree with me in according Mr. Stenhouse this recognition of his services.

Of the papers which are to be brought before us during the session, I can scarcely yet speak with any degree of certainty, but I believe that several will bear more immediately on subjects directly pharmaceutical. The interest which such are sure to command will, I think, be sufficient guarantee of a large and appreciative audience, and I therefore feel it quite unnecessary to add one word either in the way of recommendation or inducement to attend the various meetings.

The Chairman then gave a short summary of a lengthened investigation into the reactions of some of the fixed oils, touching on some of the points which have already appeared in the pages of the Journal, and these he illustrated by diagrams shown by the oxyhydrogen light and also by the spectroscope.

Mr. H. C. Baildon, in proposing a vote of thanks to Mr. Gilmour for his instructive and entertaining paper, congratulated him on his recovery, and also expressed the indebtedness of the North British Branch to him for accepting the President's chair for another year.

Mr. David Kemp, Portobello, commented on Mr. Gilmour's paper with reference to the sources of the oils procured for experimenting and also as to the temperature, and following Mr. Baildon, he seconded the vote of thanks, to which the audience very heartily responded.

Mr. Mackay spoke as to the utility of the experiments, and referred to the old process of testing with mercury and nitric acid as being very unsatisfactory.

The Honorary Secretary then intimated the following donations to the Society:—Portrait, in oil, of the late Mr. Tait, presented by the firm of Duncan, Flockhart and Co.

Museum.—"Job's Tears," the seeds of *Coix lachryma*, a species of grass from the Mauritius; flowers and pods of the cotton plant, from St. Helena, presented by Serjeant John Goodrick, Army Hospital Corps.

Library.—'Introduction to Chemical Philosophy,' by Dr. Wm. A. Tilden, from the Author. Six numbers of the *Canadian Pharmaceutical Journal*, from the Ontario College of Pharmacy; four numbers of the *Pharmacist*, from the Chicago College of Pharmacy; five numbers of 'Proceedings of the Royal Society,' and six numbers of the *Journal of the Chemical Society*, from Mr. Mackay.

The attention of the meeting was called to a very interesting collection of articles kindly sent for exhibition by Mr. Herman Drechsel, of Edinburgh, and these consisted of cases of models of crystals, metals, alkaloids, physiological preparations and imitations of precious stones, all of which were much admired.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The first meeting of the session of this Association was held at Britannia Chambers, on Friday, Nov. 17, the chair being occupied by the President, Mr. J. H. Atherton, F.C.S. There was a good attendance of members and Associates. The Hon. Secretary (Mr. R. Jackson) announced some donations, and then proposed the election of two new members and five associates, after which the President presented the prizes, given by the Council, to the successful associates of last session's classes, the first prize in chemistry being awarded to Mr. W. C. Richardson and the second to Mr. J. Cox; the botany prize being won by Mr. J. Clower.

The President then delivered his inaugural address, an able and exhaustive review of pharmaceutical politics, which was listened to with great attention and applauded at the conclusion.

After a short discussion, a hearty vote of thanks to Mr. Atherton closed the proceedings.

Chemical Work done on Board H.M.S. 'Challenger.'

BY J. Y. BUCHANAN.*

(*Continued from p.* 445.)

Observations on the Carbonic Acid contained in Sea-Water.

The carbonic acid when boiled out of the water is received by baryta-water of known strength; its consequent loss of alkalinity is measured by hydrochloric acid of corresponding strength. Having observed that the presence of sulphates in sea-water is one of the potent agents in the retention of the carbonic acid,† I always add 10 cub. centim. of a saturated solution of chloride of barium to the water before commencing the operation. This facilitates greatly the liberation of the carbonic acid, and also causes the water to boil tranquilly, even to dryness, without showing any tendency towards bumping. The quantity of water used has been almost invariably 225 cub. centim., and the property possessed by sea-water of retaining its carbonic acid with great vigour makes it possible to perform the determination of it even a couple of days after its collection. As a proof of this, on the 10th July, 1875, the surface-water was found when freshly drawn to contain 0·0291 gramme carbonic acid per litre. A quantity likewise of the freshly drawn water was boiled *in vacuo* for an hour and fifty minutes in order to collect the oxygen and nitrogen, and then allowed to cool protected from the air. One portion of this water was exposed to the air in a flat dish outside the port for three hours, and in another portion the carbonic acid was at once determined. It contained 0·274 gramme per litre, whilst the water exposed to the air contained 0·6273 gramme. The effect, then, of boiling *in vacuo* was only to remove about 5 per cent. of the whole amount, whilst free exposure to the air had no effect whatever. As the determination of the carbonic acid takes a considerable time, it is only by taking advantage of this property that I have been able to determine it in samples from depths in the same locality; for where boiling *in vacuo* has so little effect, there is no danger of losing carbonic acid when the water is carefully decanted.

As in the great majority of cases, where the carbonic acid has been determined, the oxygen and nitrogen have also been collected, and are being preserved until our return home, when they will be analysed: it would be useless to attempt to discuss the results of the carbonic-acid determinations at present, and before these analyses have been made, especially as there is likely to be some relation between the amounts of oxygen and of carbonic acid. Independently, however, of the relations which may subsist between the two bodies, it may be gathered from the inspection of the accompanying table that, taking surface waters alone, the amount of carbonic acid present is many times greater than would be contained in the same volume of distilled water under the same circumstances. I have again and again exposed distilled water, surcharged with carbonic acid, to the air, and after even a very few minutes the carbonic acid was completely gone; on adding to 225 cub. centims. of it 5 cub. centims. baryta-water, the mixture remained perfectly clear; and on titrating with hydrochloric acid there was no diminution of alkalinity.

The temperature of the water on this occasion was 18°·3 C. On that particular day, namely the 8th July, 1875, when in the middle of the North Pacific, there was no determination made of the carbonic acid in the surface-water; but two days later, when the temperature of the surface-water was 18°·9 C., 225 cub. centims. of it contained 0·0066 gramme carbonic acid. Had there been 0 002 gramme CO_2 in the 225 cub. centims. distilled water, it must have been detected and determined. Hence, under the same circumstances, this particular sea-water, whose specific gravity was 1·02528 (at 15°·56 C., water at 4° = 1), contained at least thirty times as much carbonic acid as an equal bulk of fresh water would have done. Further, as might have been expected from the above observations, the amount of carbonic acid contained by surface-waters of the same temperatures increases with the density, and consequently is greater in the surface-water of the Atlantic than in that of the Pacific, the two oceans being very markedly distinguished from one another by the different densities of their surface-waters. Thus we have a mean of 0·0466 gramme CO_2 per litre in Atlantic surface-water of temperature between 20° and 25° C., and mean density 1·02727; whilst in the Pacific the mean is 0·0268 gramme in water of 1·02594 mean density; and the mean amount of carbonic acid in Atlantic water of temperature above 25° C. and mean density 1·02659 is 0·0409, whilst in the Pacific the corresponding water is of mean density 1·02593, and contains 0·0332 gramme CO_2 per litre. As a rule, other things being equal, the amount of carbonic acid diminishes as the temperature increases; thus the mean amount of carbonic acid in waters whose temperature was between 15° and 20° was found to be 0·0446 gramme per litre, the mean density being 1·02642, whilst we have seen that in the Atlantic the surface-water of temperature above 25° C. and of mean density 1·02659 contains 0·0409 gramme per litre. Also there is usually more carbonic acid in waters taken from the bottom and intermediate depths than in surface-water; but if regard be had to the temperature of the water, it will be seen that there is but little difference in the amount in waters of the same temperature from whatever depth they may have been derived. This seems to indicate that the animal life at the bottom and at great depths cannot be very abundant, otherwise there could hardly fail to be a decided excess of carbonic acid in the deep water, owing to constant production and want of the means of elimination of the gas. On this subject, however, it would be premature to speculate before the determination of the oxygen, from which we may hope for much information.

I have made a number of experiments to detect the presence of carbonates in sea-water. If any were present, they should be found in the residues from the determination of the carbonic acid; and I had been in the habit of testing by adding a little acid to them, and invariably with the same result—that carbonates were not present; at the same time it appeared to me to be very unlikely that such should be the case, when there is plenty of carbonate of lime in the shells of the animals living and dying in it, and also plenty of carbonic acid in the water to dissolve it. It was also not improbable that the very considerable amount of sulphate of baryta in the residues might disguise the effervescence. I therefore evaporated a separate portion (about 150 cub. centims.) of the water in a platinum dish to dryness, removed the soluble salts with a little water, and added a few drops of strong hydrochloric acid, which was allowed to flow slowly over the inner surface of the dish, when even the smallest trace of carbonates could be detected by the appearance of minute bubbles on the platinum surface. In this way I have examined a number of waters between Tahiti and Valparaiso, and with the general result that in ocean-water carbonates are never present except in small quantities, and in many samples they have been absent altogether. They are generally present in waters at or near the surface, disappearing, however, as the depth from which the water has been taken increases. They are generally, though not invariably, absent in waters from greater depths than 400 fathoms. They are present or absent in bottom-water according to their occurrence in the bottom; although here also there appear to be exceptions, as I

* From the 'Proceedings of the Royal Society.'

† 'Proceedings of the Royal Society,' 1874, vol. xxii., pp. 483-495.

have observed water taken from a "*Globigerina*-ooze" bottom which contained no carbonate.

In connection with carbonic acid I may mention that I have frequently tested waters, and especially bottom-waters, for organic matter. None of the methods in use for determining this substance in drinking-water giving satisfaction when applied to sea-water, I had to content myself with endeavouring to detect its presence. If the jelly-like organism which had been seen by some eminent naturalists in specimens of ocean bottom and called *Bathybius* really formed, as was believed, an all-pervading organic covering of the sea-bottom, it could hardly fail to show itself when the bottom-water was evaporated to dryness and the residue heated. In the numerous samples of bottom-water which I have so examined, there never was sufficient organic matter to give more than a just perceptible greyish tinge to the residue, without any other signs of carbonization or burning. Meantime my colleague, Mr. Murray, who had been working according to the directions given by the discoverers of *Bathybius*, had actually observed a substance like "coagulated mucus," which answered in every particular, except the want of motion, to the description of the organism; and he found it in such quantity that, if it were really of the supposed organic nature, it must necessarily render the bottom-water so rich in organic matter that its presence would be abundantly evident when the water was treated as above described. There remained, then, but one conclusion, namely, that the body which Mr. Murray had observed was not an organic body at all; and on examining it and its mode of preparation I determined it to be sulphate of lime, which had been eliminated from the sea-water, always present in the mud, as an amorphous precipitate on the addition of spirit of wine. The substance when analysed consisted of sulphuric acid and lime; and when dissolved in water and the solution allowed to evaporate, it crystallized in the well-known form of gypsum, the crystals being all alike, and there being no amorphous matter amongst them.

These observations were made chiefly on the voyage from Hong Kong to Yokohama in the first quarter of the year 1875; and it subsequently occurred to me that an approximate determination of the organic substance in sea-water might be effected in the following way:—Supposing the amount of carbonic acid in the water to be known, let a little permanganate of potash be added to a sample of it, and let the carbonic acid be determined in the usual way by boiling the solution. If the water contained any easily oxidizable carbon compound, we should obtain more carbonic acid in the second than in the first determination, and the difference would correspond approximately to the amount of organic carbon present. In several waters which I have treated according to this principle, I have found from two to five milligrammes of carbon per litre.

(*To be continued.*)

ROYAL IRISH ACADEMY.

On a New Chemical Test for Alcohol.*

BY EDMUND W. DAVY, A.M., M.D.

Professor of Forensic Medicine, Royal College of Surgeons, Ireland, etc.

Whilst making lately some experiments on molybdic acid, I observed that when a solution of that substance in strong sulphuric acid was brought in contact with alcohol, there is very quickly developed a deep azure blue coloration; and this fact, being (as far as I was able to ascertain) hitherto unrecorded, led me to investigate the reaction to determine the cause of this production of colour.

As I found that the protosulphate of iron, and the protochloride of tin, two powerful deoxidizing salts, produced a similar effect on this solution, there was but little doubt that it was due to the deoxidizing action of alcohol on the molybdic acid. And I afterwards found that the blue substance which was formed in the case of alcohol possessed all the characters of the blue compound which is produced when molybdic acid or its salts are acted on by different reducing agents, whereby a substance consisting of five atoms of the metal molybdenum with fourteen of oxygen is obtained, which is usually regarded as a combination of the binoxide of molybdenum with molybdic acid, the following formula (MoO_2, 4 MoO_3) representing its composition.

With certain precautions which I shall presently point out, I have found that this reaction of alcohol on the molybdic solution stated is extremely sensitive, so that by its indications very minute quantities of alcohol, even when diluted with large proportions of water, may be readily detected. Thus, for example, if one part by volume of commercial rectified spirits be mixed with a hundred parts of distilled water, and one small drop of this mixture be taken, the minute quantity of spirit contained in it can be easily detected by the deep blue coloration which will be immediately developed on bringing it into contact with the molybdic solution, employed in the manner about to be described. But this is not the limit of the delicacy of this test, for I have been able by means of it to detect the spirit in one drop of a mixture of distilled water and anhydrous spirit, in which the latter substance constituted only the one-thousandth part of its volume; and as the drop was found to weigh six-tenths of a grain, the quantity of real or anhydrous alcohol contained in it would be less than the one-sixteen hundred and sixty-sixth part of a grain of that substance.

Though small quantities of spirit, even when considerably diluted with water, will produce with the molybdic solution the blue reaction without the assistance of any external heat, still where very minute quantities, diluted with such large proportions of water as those just stated, are to be detected, it is necessary for the success of the experiment that the reaction should be assisted by a gentle heat, and also that too great a dilution of the test solution with the liquid under examination should be avoided, as the blue coloration will not be developed if water be in excess; and even after it has been produced, the addition of a certain proportion of that substance quickly causes its disappearance. Such being the case, the best way of employing the test, according to my experience, is to place three or four drops of the molybdic solution in a small white porcelain capsule, and having heated them slightly, allow one or two drops of the liquid to be examined to glide or fall gently on the acid solution, when there will be developed, either immediately or after a few moments, the blue coloration. And where the alcohol is very largely diluted with water, it is better to continue the gentle heating of the test solution for some time, to concentrate it or expel as much water from it as possible, before adding the liquid to be tested, for in this way I have succeeded in detecting the spirit in mixtures so dilute as to give no blue reaction when added immediately to the test solution on its being simply warmed. As regards the application of heat, I must observe that the temperature of the acid solution must not be raised too high, for if it be heated till the acid evolves its dense vapours, or begins to boil, the solution will of itself alone, from its partial decomposition, develop a more or less blue coloration, which will become more perceptible on its cooling. But such an occurrence can be easily avoided by employing a water-bath as the heating agent; for I have found that a temperature of 212° F. is incapable of so acting on the test solution—at least an exposure of several hours' duration to that heat failed to produce the slightest blue coloration, and a much lower temperature than that suffices for the application of the test.

I should here state that the molybdic or test solution which I have generally employed was made by dissolving at a gentle heat one part by weight of molybdic acid in

* Read May 22, 1876.

ten parts of strong and pure sulphuric acid, but the exact strength of this solution as regards the amount of molybdic acid it contains seems to be immaterial.

I may observe that the coloration produced in the reaction stated disappears after a variable interval of exposure to the air—a circumstance which is due, as I have ascertained, to the absorption of moisture from the atmosphere, and not to the re-oxidation of the molybdenum compound, as might have been supposed; for amongst other facts in proof of this, I may state that after it has thus disappeared, it may be readily restored either by expelling the water so absorbed by a gentle heat; or, more slowly, by placing the mixture under a desiccator, and thus removing it by spontaneous evaporation at the ordinary temperature. Such being the case, it is evident that, where the test solution has been too much diluted for the immediate development of the coloration described, expelling the excess of water by heating the mixture on a water-bath, it may be made to exhibit itself.

But the necessity for such evaporation should, if possible, be avoided, which in most cases will be so, by using only a drop or two of the liquid under examination, and by employing the strongest sulphuric acid in making the test solution; for it is very probable that much of the spirit contained in the liquid would be lost during its evaporation in the water-bath. Besides there would be some risk that the indications of the test might be more or less interfered with from particles of dust or organic matter getting into the mixture during that process.

The reaction which has been described, I should state, is not peculiar to ordinary or ethylic alcohol, but is, more or less, readily developed by others—at least I found it to be so in the case of methylic, propylic, butylic, and amylic alcohols, those being the only ones I had for my experiments. But it is more than probable that some at least of the other alcohols may act in a similar manner; however, the reaction is much more rapid and striking in the case of ethylic than in that of any of the other alcohols mentioned. I found also that certain salts of the radicles of those alcohols produced a somewhat similar reaction, as well as ethylic ether and aldehyde, and also several organic matters which are readily susceptible of oxidation.

The circumstance that the reaction described is not peculiar to ethylic alcohol will, no doubt, lessen its value as a positive test for that substance; but a similar objection appertains to all the other known tests for that compound, as their indications are not peculiar to that alcohol alone, if we except, perhaps, Berthelot's test, which is founded on the development of benzoic ether by the action of benzoic chloride, along with caustic potash on ethylic alcohol. But, owing to the trouble attendant on the preparation of benzoic chloride, and some other practical inconveniences connected with the application of that test, it is not likely that it will ever come to be one of very general employment.

The test, however, which I have brought before the Academy has this advantage over those already known, that it far exceeds (according to my experiments) any one of them in point of delicacy. And though the circumstance that the blue reaction produced in the case of this test is not peculiar to ethylic spirit lessens, as before observed, its value for the detection of that substance, this is just what renders the test of more general applicability; for by its aid certain impurities or adulterations may be at once detected in different substances or compounds, which in a state of purity should not contain any matter capable of acting on the molybdic solution employed in this test. I may refer to two important substances as examples, viz., chloroform and chloral hydrate, which are now so extensively employed in medicine and surgery for a number of useful purposes; and, being agents of great power, it is of much importance that they should be free from the accidental impurities of imperfect preparation, as well as from the frauds of intentional adulteration, which may either impair their therapeutic value, or even increase the danger of their administration. For there can be but little doubt that in some instances the serious and even fatal effects resulting from their use may, in part at least, have been attributable to the impurities or adulterations of the chloroform, or of the chloral hydrate employed. Now, as I find that neither chloroform nor chloral hydrate, in their pure condition, have any apparent action on the molybdic test, but that many of their usual impurities develop the blue reaction, it affords us a ready means of testing their purity. Thus, as regards chloroform, one of its common impurities is ethylic alcohol, which it may contain either from imperfect preparation, or from fraudulent addition, the very high price of chloroform offering a great temptation to the unscrupulous vendor to increase its bulk or weight by the addition of alcohol, which so readily mixes with it. I have found that the molybdic test at once enables us to detect such an adulteration, even where it occurs in very small proportions in chloroform. Thus, in one experiment, I mixed one part of rectified spirit with a hundred parts by volume of pure chloroform, and one drop of this mixture being brought in contact with three or four drops of the molybdic solution, previously warmed in a water-bath, gave an immediate deep blue coloration from the spirit contained in it; and, in a second experiment, with a mixture of one part of spirit to a thousand parts of chloroform, a single drop of the mixture, being similarly treated, developed a faint blue reaction. Indeed, so searching is this test as regards the purity of chloroform, that I was unable to obtain any sample of that substance in commerce sufficiently pure not to give a blue reaction with the molybdic test, owing to the minute quantities of volatile oils, and other impurities, they contain; and for my experiments I was obliged to repurify the commercially pure chloroform to obtain a sample which would give no coloured reaction with my test.

In the case of chloral hydrate, it is stated that one of its usual impurities is the chloral alcoholate (a compound in which alcohol, instead of water, is combined with anhydrous chloral), and that this substance has somewhat different effects on the system from those produced by the hydrate. This compound, owing to the alcohol it contains, gives the blue reaction with the molybdic test, and I have found that where the chloral hydrate contained even so small a proportion of the alcoholate as one part in a thousand parts, a little of such a sample, being taken, indicated its presence when examined by the molybdic test; and it is probable that some of the other impurities which are met with in this important substance may be similarly detected.

Those two examples are sufficient to indicate the use to which this test may be applied in the determination of the purity of different substances used in medicine, as well as in scientific research.

Finally, I would remark that, as the reaction of molybdic acid on ethylic alcohol is so sensitive and prompt in its action, I entertain the hope that there may yet be found in it, not merely this qualitative test, but likewise a means for the quantitative determination of that important alcohol.

Parliamentary and Law Proceedings.

The Sale of Milk of Sulphur.

At the Hyde petty sessions, Mr. Jonathan Harrison, druggist, Hyde, was summoned by Captain Arrowsmith, chief constable, for selling two ounces of milk of sulphur that was not of the nature, substance or quality demanded by the purchaser. On the 18th of November, the sulphur was purchased for the purpose of analysis, and on being tested by the county analyst was found to contain 61 per cent. of hydrated sulphate of lime, or the elements of plaster of paris, and only 39 per cent. of milk of sulphur.

The Chairman (Dr. Newton) said Captain Arrowsmith deserved credit for bringing this case before the Bench, as mothers gave the drug to their children for skin diseases, and if a drachm of this mixture were given to a child the results in all probability would be that the ingredients would become hard, cause congestion and inflammation of the bowels, and even death. He had no doubt the mortality among children was largely owing to the introduction of mysterious substances into their little bodies. In this case the Bench might have imposed a penalty of £20, but believing the defendant had no guilty knowledge of what he was selling they would only inflict the nominal penalty of 5*s.* and costs.

At the Dukinfield Petty Sessions, on Thursday, November 23, before A. Aspland, G. Newton, and J. F. Cheetham, Esqs., Michael Coffey, provision dealer, Wharf Street, Dukinfield, was summoned at the instance of Captain Arrowsmith, deputy chief constable, for having on the 5th of November sold, to the prejudice of one Joseph Downs, milk of sulphur which was not of the substance and quality demanded by such purchaser.

Defendant said his wife had sold it not knowing but what it was genuine.

Captain Arrowsmith said on the 15th instant he instructed acting-serjeant Joseph Downs to procure from the defendant's shop some milk of sulphur, knowing that the drug was largely used amongst the families of the working classes. The officer went to the defendant's shop and bought two pennyworth of milk of sulphur, and the sample was sealed up and sent to Mr. J. Carter Bell, of Manchester, the county analyst. He had since received a certificate from the analyst stating that the milk of sulphur obtained from the defendant's shop contained 59 per cent. of hydrated sulphate of lime, or the elements of plaster of paris. In these cases of adulteration he would like to reach the manufacturers of such rubbish, because in populous districts such adulterated drugs destroyed more human lives, and especially of infants, than half-a-dozen plagues. The purchase having been proved,

Defendant in explanation said, twenty years ago he became tenant of the shop, and at that time there was a large quantity of milk of sulphur in stock. He had never bought any since, and he believed he was selling the article pure and unadulterated.

Mr. Aspland said the magistrates were of opinion that defendant was guiltless of any intention to defraud. They thought he sold the article in good faith, but at the same time it ought to be known that this stuff with which the drug was mixed was poison and might produce an injurious effect upon the health of children. It was the duty of every tradesman to know that his goods were pure articles, and he ought either to get a warrant to that effect or have the goods analysed. The magistrates thought it best to impose a small fine in the case, and a nominal fine of 1*s.* and costs would be inflicted, but if any more such cases were brought before them the fines would be more substantial.

The next case was one in which Jonathan Radcliffe, shopkeeper, Astley Street, was charged with a similar offence. Defendant said he sold milk of sulphur, but he was not aware that he sold an article contrary to milk of sulphur.

Acting-serjeant Downs said on the 15th instant he called at defendant's shop in Astley Street and asked him for three pennyworth of milk of sulphur. He was served by the defendant, and witness told him he had obtained it for the purpose of analysis, and asked him if he wished to keep a portion of it. He said he did not, and added that he had more of the same sort. Witness sealed up the packet, and it was afterwards sent to the analyst

Captain Arrowsmith said he had received from the county analyst a certificate showing the result of his analysis of two ounces of precipitated sulphur sold by the defendant to Downs. The certificate showed that there was 61 per cent. of hydrated sulphate of lime or elements of plaster of paris in the drug.

Defendant said he did not sell the article as precipitated sulphur.

Captain Arrowsmith replied that it was known throughout the trade as precipitated sulphur.

The Chairman said the two terms meant the same thing. In point of law the customer asked for precipitated sulphur, and defendant gave him a poisonous drug.

Defendant called Mr. W. H. Waterhouse, druggist, of Ashton, as a witness, and he said he wished to say a few words in favour of the trade and in order that justice might be done.

Mr. Aspland: Can you say that this article is milk of sulphur?

Mr. Waterhouse: I know it is milk of sulphur.

Mr. Aspland: How do you know.

Mr. Waterhouse: I have examined it.

Mr. Aspland: Here we have the analysis of an expert, and he says it is precipitated sulphur greatly adulterated.

Mr. Waterhouse: I can quote the opinion of one of the most eminent chemists in the United Kingdom to prove my assertions. I am prepared to say that the article supplied by defendant to the officer was milk of sulphur, and not precipitated sulphur.

Mr. Aspland: We cannot entertain your opinion, because you are not an analyst. Have you anything further to say, Mr. Radcliffe?

Defendant: I sold the article as pure for aught I knew; I never altered it, and it is so long since I bought any that I forget where I bought my present stock.

The Chairman: You are selling an article with only 49 per cent of precipitated sulphur, and 61 per cent. of a poisonous article. If you had gone to a respectable druggist you could have got the pure article. You may have poisoned people by selling this stuff.

Captain Arrowsmith: Mr. Radcliffe keeps a druggist's shop, or rather sells a large quantity of drugs, and it is his duty to ascertain that the drugs are good.

Mr. Aspland: You know very well that if you buy drugs that are not pure you may get protection against the person who sells them, and then you will be safe. If you choose to go and buy cheap drugs which are poisonous you will render yourself liable to all the penalties. As this is the first time, you will only be fined 10*s.* 6*d.* and costs, the cost of the analysis, and the police costs. If you come up again you will probably have the full penalty.

THE SALE OF MUSTARD COMPOUNDS.

At the Ashton-under-Lyne County Police Court, a case of considerable importance to shopkeepers was heard before Messrs. J. R. Coulthart and Abel Buckley.

Mr. William Whitworth, grocer, Hurst, was summoned at the instance of Superintendent Ludlam, on a charge of having sold two ounces of adulterated mustard. The defendant pleaded guilty.

The Clerk: The question is, did you know that this was not real mustard?

Defendant: It is Coleman's mustard, and it said "mixture" on the tin.

The Clerk: But you did not sell the whole tin at once.

Defendant: No, I sold two ounces, but I got it out of Coleman's tin, which was labelled "mixture."

Mr. Ludlam said he did not see the label on the tin, but if it had been labelled, as alleged, it was illegal to sell a portion of it unless every such portion was labelled.

Defendant: I have seen Mr, Coleman's manager about it, and he said it was done by all shopkeepers.

Mr. Ludlam said he purchased two ounces of mustard at the defendant's shop, and it was true, as defendant stated, that the mustard was taken from a tin. The article so bought was forwarded to the public analyst, who stated that it contained 25 per cent. of farina, which was put into it for the purpose of diminishing the strength and improving the appearance. It was not sufficient that the tin should be labelled "mixture" unless it was sold whole. If a milkseller labelled his cans "milk and water" he must, as well, attach a label to every quantity he sold if he wanted to escape the law.

The Clerk: To every gill.

Mr. Buckley: If you had sold the whole tin of mustard you would not have been liable.

Defendant: I can buy it in this way in any shop in Ashton.

The Clerk: Then it is illegal.

Mr. Ludlam said this was the first case in the division that they had had under the Adulteration Act. He had made many attempts to get a case, but all the samples of milk and other things that he had sent to the analyst had, with this exception, been found to be genuine.

The Chairman (to defendant): We consider this a very serious case, but as it is the first one of the kind in the division, we shall not fine you heavily.

The defendant was then fined 1*s.* and costs, the fine to be remitted if the costs were paid. — *Manchester Courier.*

Adulterated Arrowroot.

At Shepton Mallet Petty Sessions, Mrs. Caroline Everett, grocer, of Shepton Mallet, was charged by Mr. Bisgood, deputy chief constable of Somerset, with selling adulterated arrowroot. Police-constable Hoddinott stated that he went to the defendant's shop and asked for an ounce of arrowroot, in order that he might have it analysed. Mr. Bowden, the assistant, brought into the shop a tin box of arrowroot that had not previously been opened, and opened it in the presence of witness, and supplied him with arrowroot therefrom. The box was labelled "warranted genuine," and Mr. Bowden wrote similar words on the packet he produced. Mr. Bisgood proved taking the samples to Mr. W. W. Stoddart, Park Street, the county analyst. He had since received a certificate from Mr. Stoddart, which he handed in. It stated that the arrowroot in question contained 50 per cent. of cassava starch. Mr. Wontner, of London, who appeared for the wholesale house that supplied the arrowroot, said he represented the firm of Keen, Robinson, Bellville, and Company, of London, who had sold the arrowroot to Mrs. Everett, and were also themselves summoned. On the part of Mrs. Everett, he submitted that she had sold the arrowroot in the same condition that she bought it, and had given notice to that effect when she sold it to the constable. She was therefore protected by the 25th section of the Act, and was likewise exempt from paying the costs. The Bench agreed with this opinion, and dismissed the case.—Mr. William John Bellville, trading as Keen, Robinson, Bellville, and Company, spice merchants, of No. 6, Garlick-hill, Cannon-street, London, was next charged with selling fourteen pounds of adulterated arrowroot to Mrs. Everett. Mr. Wontner said the facts were admitted by the firm, who claimed the same protection under the Act as Mrs. Everett, and would prove that they had sold the arrowroot in precisely the same condition as they had bought it, and as it was imported. It was the custom of the firm he represented to submit samples of all goods purchased by them to Mr. Piesse, the public analyst of the Strand, for analysis, before warranting them to their customers; but during last summer Mr. Bellville was out of town for the benefit of his health, and Mr. Swinbourne their spice buyer and salesman, was laid up for six weeks by an accident, and when he returned to business he found a great demand for Natal arrowroot, and he went into the market and bought six cases under warranty from Messrs. Bryant and Wheeler, sworn brokers, and being anxious to supply the customers of the firm he did not wait to have it analysed. He however mixed some with boiling water, and it had the appearance of the best arrowroot. Since these proceedings had been taken they had sent samples to Mr. Piesse, who found the arrowroot was not genuine, and they had accordingly withdrawn all that they had sold from that lot. It contained a mixture of starch of cassava, which was a wild arrowroot. He also thought that as this description of goods was imported and passed through the Custom-house its purity should be guaranteed, as in the case of tea. Mr. Swinbourne, the spice buyer and salesman of the defendant, was then called, and he proved purchasing the arrowroot of Messrs. Bryant and Wheeler as it was imported, and selling the same to Mrs. Everett. The Chairman of the Bench (Capt. Ernst) said the only difference they could see in the two cases was that Mrs. Everett had given notice that she sold the arrowroot in the same condition that she bought it, and the defendants had not; they would therefore have to pay the costs, and the case would be dismissed.—*Grocer.*

Accidental Poisoning by Strychnia.

An inquest was held on Friday the 24th November, by Mr. Malcolm, the Leeds Borough Coroner, into the circumstances of a death which occurred through the mistake of a chemist's assistant. It appeared from the evidence that the deceased, Mrs. Conway, on the previous Tuesday, went to the shop of Mr. Manfield, chemist, 85, Kirkgate, Leeds, and complained to the assistant, Mr. Ward, of indigestion. He said he would make up a bottle of medicine for her, and ask her to call for it in about a quarter of an hour. This she did, but, unfortunately, he gave her in mistake a bottle of strychnine which he had made up for Dr. Burchell, and placed beside the bottle of medicine. An hour or two after returning home she took a spoonful of the contents of the bottle, and died shortly afterwards in great agony.

Maria Adams, daughter of the deceased, said she met the deceased in the Market on Tuesday morning, and went with her to the shop of Mr. Mansfield; deceased complained to Mr. Ward, the assistant, that she felt very weak. He said he thought she was feverish, and that if she called again in a quarter of an hour he would give her a bottle of medicine. They called again, and he handed them a bottle. Deceased asked how the medicine was to be taken. He replied two tablespoonfuls three times a day. They then went home to the residence of the deceased. Witness then unwrapped the bottle, and saw that it had a label on it, with the word "poison." She did not know what it meant, and could not read. Deceased also could not read. Witness soon afterwards left, and was subsequently sent for, and found the deceased stretched on the floor. Deceased said, "Oh, it is too late, that medicine is poison." A doctor was sent for, and soon after his arrival the deceased died.

Cross-examined.—When Ward gave the deceased the bottle it was wrapped up. There were no other customers in the shop at the time, nor was Ward attending any one else when he handed the bottle to deceased. The red label on the bottle did not strike her as noteworthy. She could not spell the word poison or read the letters of the word. Had she been able to make out the word poison, she would have taken it to mean that the stuff would be poisonous if her mother took more than she was ordered.

Margaret Adams, 13 years of age, the granddaughter of the deceased, said she was at her grandmother's when the deceased came home with the other witness. The bottle of medicine was put on the mantelpiece and the deceased went upstairs to lie down. She got up about half-past three, and told her to hold the spoon while she poured the medicine in it. Witness said, "Oh, grandma, it says poison." Deceased replied that the druggist would not give her poison; he knew what he was doing. She took a tablespoonful of the medicine, but as it tasted very bitter she did not take another. Soon afterwards she complained of pains in the head, and began to jump about convulsively. Some neighbours then came in, and the deceased told them she had taken poison. Witness then sent for a surgeon.

A neighbour gave some corroborative evidence, adding that she saw the red label on the bottle, and knew, although she could not read, what it meant.

Mr. Whitwell Manfield, chemist, Kirkgate, said that on Monday an order came to his shop from Dr. Burchell for several drugs, etc., including an order for 8oz. of strychnine. Witness was out of town on Tuesday most of the day. On returning in the evening he was not informed of the mistake that had been made until about seven o'clock, when two police officers came into his shop. They asked him if he had sold any strychnine. He said "No." They asked, "Not to a woman named Conway?" He replied "No." They said that a woman of that name had taken poison, and the bottle had witness's label on it. Ward then said that he made up a bottle of strychnine for Dr. Burchell, and had given it to a woman in mistake. The reason he did not inform witness immediately on his return home was that, knowing that witness had trouble on his mind, he did not like to mention it. Ward had been his assistant for about four years and a-half. Previous to that he had been assistant to a chemist in Norfolk. Hitherto he had given every satisfaction.

In answer to a juryman, witness said he did not use distinctive poison bottles, but he put special labels on, and never sold poison without a caution.

Mr. John J. Pickles, surgeon, said that on Tuesday afternoon he was called to see the deceased. He saw the bottle of strychnine, and found the deceased showing symptoms characteristic of strychnine poisoning. She had convulsions, her jaws were tightly clenched, and she was crying with pain a good deal. He gave her an emetic of sulphate of zinc, but it had no effect. He succeeded with great difficulty in pressing the stomach-pump down the throat, but just as it began to run a convulsion came on and she died from suffocation, as is usually the case with people poisoned by strychnine. Before she died he had withdrawn the pump. There was no doubt that death was due to strychnine poisoning. That opinion was verified by a *post-mortem* examination which he had made.

Albert Halliwell, porter to Mr. Manfield, said that about a quarter past ten o'clock on Tuesday morning Ward, who appeared very confused and agitated at the time, said he would give a thousand pounds if he could call back what he had done. Witness asked what he had done, and he replied that he had given away Dr. Burchell's strychnine in mistake for a bottle of medicine, and asked witness if he could recognize the two women who had been in the shop. Witness said he thought he could, and went into the Market to try and find them, but did not succeed. Ward had no means of tracing them, not knowing where they lived or anything about them. There were only two bottles in the place from which the bottle of strychnine was taken.

The Coroner said he did not intend to call Ward, but if he liked to make a voluntary statement, he would hear him.

Mr. Middleton (solicitor) said Ward had every desire to do so.

The Coroner said he would caution Ward, but that was not intended as any imputation upon him, but simply as a warning that his evidence might be used against him.

Mr. Ward said he made up the bottle of strychnine on Tuesday morning, about half an hour before deceased came into the shop. He wrapped the bottle up after labelling it with a poison label, and put it on a shelf. The bottle of medicine he intended for the deceased he put on a shelf underneath. When the deceased came in the second time he was in a great hurry. About twenty minutes afterwards he found out the mistake he had made, but he had no means of tracing the deceased. He had been in the business about fourteen years. He was very loth to prescribe for the deceased, and told her she ought to consult a medical man.

A Juryman said this case ought to be a severe warning to chemists.

The jury then retired, and, after an absence of five minutes, returned with a verdict "That death was caused by a dose of strychnine taken in mistake, and that the mistake arose from the gross carelessness of Matthew Ward."

The Coroner: You find, then, that the death of the deceased was by misadventure?

Mr. Joseph Walker (foreman of the jury): Yes; and we are also of opinion that it is negligence on the part of the chemist Manfield not to have poison bottles.—*Leeds Mercury.*

Poisoning by Strychnia.

At the Central Criminal Court on Monday last, before Mr. Justice Denman, Silas Barlow, alias Silas Smith, aged 26, and described as a labourer, was indicted for the wilful murder of Ellen Sloper. There was also a second indictment against the prisoner charging him with the murder of an illegitimate child of the deceased woman. Mr. Poland and Mr. Beasley prosecuted, instructed by Mr. Pollard, on behalf of the Treasury; Mr. Fulton and Mr. Grubbe appeared for the prisoner. The prisoner was a platelayer on the Brighton Railway, and he had been on intimate terms with the deceased woman, and a child was born in November, 1875. The prisoner visited the woman at her lodgings on the 3rd of September, and on the following day the deceased was very ill, but she got better. On the 10th of September he again visited her, and after he left she complained of excruciating pain, and her body was bent in the form of an arch. She exhibited all the indications of having been poisoned by strychnine, and died in great agony on the following day. Before her death she stated that her illness was owing to something the prisoner had given her, which he described as sarsaparilla water, but the prisoner in reply said that he had taken some of the sarsaparilla himself. A number of bottles were found at the prisoner's lodgings and traces of strychnine were found in some of them, and it also appeared that the prisoner had access to some Battle's Vermin Destroyer, which contained strychnine. There was no portion of strychnine found in the body upon a *post-mortem* examination, but this was explained by the poison being absorbed during the period that had elapsed from the poison being administered and the *post-mortem* examination. On the part of the prisoner it was contended that all the symptoms exhibited by the deceased were consistent with an attack of epilepsy, and it was admitted by some of the medical witnesses that a portion of the symptoms were such as would appear in an attack of epilepsy.

In the course of the case it was proved that the vermin destroyers that were sold contained flour, Prussian blue, and strychnine, and the learned judge observed that it appeared to him that in the interest of the public it would be very advisable that dangerous articles of this description ought to be made up of materials that could not be used for human food, and in such a shape as to render it impossible for them to be administered without detection.

Dr. Bernays, lecturer on chemistry at St. Thomas's Hospital, the witness who was under examination at the time this observation was made by the learned judge, said he was of opinion that these poisons should not be allowed to be sold at all.

Mr. Justice Denman observed that persons who were pestered with rats and mice might entertain a different opinion.

Dr. Bernays said no doubt that was so, but he should certainly suggest that some restrictions ought to be placed upon the sale of these poisonous articles.

On the part of the prisoner, it was urged that the evidence at most had established a case of suspicion against him, and that the death was as likely to have been caused by natural means as by the administration of poison.

The jury found the prisoner guilty of "Wilful Murder," and sentence of death was passed upon him.—*Standard.*

Review.

REPORT ON THE OIL SEEDS AND OILS IN THE INDIA MUSEUM, OR PRODUCED IN INDIA.

This report was at first intended to include the volatile oils or attars, but it was found that the intricate and extensive character of these would cause so considerable a delay that it would be better to report upon them separately. The reader must not expect to find the report containing the results of original research. It only claims to present, in a useful form, a digest of scattered notes and memoranda, obtained from various sources, so that their accuracy may be tested and further information contributed by competent observers.

The various products treated of are arranged under the following heads:—Waxes, solid and semi-solid fats, and fluid oils. The fluid oils occupy the larger portion of the report, and are divided into four groups, viz., Sweet or Edible Oils, Drying Oils, Lamp Oils, and Medicinal Oils.

In a preliminary chapter, the distinguishing characters of the different kinds of oils are defined, and the principal natural orders yielding oleaginous seeds are enumerated, and a great deal of useful information, including methods of readily ascertaining the physical properties and commercial value of oils and oil seeds, is given. This information applies not only to Indian seeds, but to those of any country, and will be found very useful to those who travel in foreign countries.

Under each plant the botanical synonyms, place of growth, native names, description of the parts yielding oil, and the nature and uses of the oil, so far as is known, and its method of preparation, are given. A very useful addition in the present report is the insertion of wood engravings of many of the seeds and fruits yielding oils. These have been rather heavily printed, but give in most cases a very good idea of the object which they are intended to represent. References to specimens in the India Museum are also appended. The report thus forms a useful descriptive guide to the department of the India Museum containing the products here treated of.

The group of waxes is a very small one, including only three kinds; only one of which, commonly known as Japan wax, is represented in the India Museum. The Petha wax (*Bennicasa cerifera*, Savi) is available for candle making.

The more important solid or semi-solid fats treated of are the following:—Shea butter, obtained from the seeds of *Bassia butyracea*, Roxb., which is white, of the consistence of fine lard, does not readily turn rancid, even in India, makes an excellent soap, and burns without smoke or smell; the greenish fat of *B. latifolia*, Roxb., which might be substituted for Russian tallow in candle making; Cocoa nut oil, the solid fat of the tallow tree (*Excœcaria sebifera*, Müll.); Kokum butter (*Garcinia Indica*, Chois.), which has been recommended as a substitute for spermaceti ointment; and Piney tallow, from *Vateria Indica*, L., a substance intermediate between wax and stearin, and forming excellent candles. Among medicinal fats that of chaulmugra seed (*Gynocardia odorata*, R. Br.), used in rheumatism and cutaneous diseases, and that of the Malabar nutmeg, forming an efficacious application to indolent ulcers, are the most important.

Among the fluid oils of those which form staple articles of commerce, the following receive a tolerably full notice:—Poppy seed, gingelly, linseed, cotton seed and sunflower seed, and castor oils. Several oils possessing valuable properties do not appear to be made to any extent in India. Of these may be noticed walnut oil, ground nut oil, country almond oil (*Terminalia catappa* L.). Chironji oil from the seeds of *Buchanania latifolia*, W. and A., a limpid edible sweet oil, similar to olive oil, not made to any extent because the kernels form an article of food. The oil of the seeds of *Moringa pterygospermæ*, from its keeping properties, seems worthy of attention for use in pomades, and for other purposes in which its tendency to deposit is not an objection, as it is not a drying oil and is almost odourless.

The drying oils include several valuable kinds, among which are prominent tobacco-seed oil, a very fluid colourless oil with peculiar drying properties, used in painting; the oil of *Euphorbia dracunculoides*, Lam., not turning ropy when old; the oil of tamarind seeds, used also for burning; the oil of Niger or Kersanee seed (*Guizotia oleifera*, DC.); and that of the candle-nut tree (*Aleurites moluccana*, Willd), used also as a purgative, and forming an excellent lamp oil. The white linseed appears worthy of especial notice since it is said to yield two per cent. more oil than the dark variety and a sweeter cake. The seed produced in the Nerbudda valley is said to be free from rape seed, which so frequently imparts irritating properties to linseed meal. On this account and from its colour, it would probably yield a very superior linseed meal for medicinal purposes. A large number of the oils are used in medicine by the natives, but comparatively few of them appear to possess decided properties. Chaulmugra oil (*Gynocardia odorata*, R. Br.) and Karunje or Chaulmugra Kunjee oil (*Pongamia glabra*, Vent.), for skin diseases, and the oil of *Celastrus paniculatus* for swellings, hold a high place in the native materia medica.

Among the better known medicinal oils occur croton and castor oils, and the oil of the physic nut (*Jatropha curcas*, L.). It appears from this report, that a great deal has yet to be done in investigating the properties and commercial values of Indian oils, and that the resources of that country in this direction are by no means thoroughly known at present. The deficiencies in the museum appear to be very numerous, and it is quite clear that those interested in the matter in India do not follow the excellent advice of the reporter on Indian products—to send home sufficient quantities of oils or oil seeds, to have their qualities and uses tested by manufacturing firms.

The index of botanical names is a feature in which the present report is an improvement upon the report on the gums and gum resins of India, which we had occasion to notice two years ago. This index would have been still more valuable if the native names had been included in it. The woodcuts will be found very useful to those who are in the habit of receiving seeds, etc., from India, for sale in this country.

Correspondence.

"Apprentice" and H. T.—Glycerine Jelly.—For wood sections Mr. Pocklington recommends to soak good clear gelatine in cold water for three or four hours, then pour off the superfluous water and melt the gelatine at a gentle heat. Add the white of an egg in the proportion of a fluid drachm for each fluid ounce of the gelatine, mix well while the gelatine is fluid, but cool, then boil until the albumen coagulates, and filter through flannel. To the clear product add an equal quantity of the best glycerine, in which a few grains of arsenic have been dissolved, or a few drops of carbolic acid. A good jelly for fine tissues is made with double the quantity of glycerine. For very fine tissues a greater proportion of glycerine still may be used, with or without the addition of gum arabic.

A NEW MODE OF MAKING GREY POWDER.*

BY ALEXANDER BOTTLE.

With a slight alteration in the relative proportion of mercury to chalk, the formula for Hydrargyrum c. Cretâ in the British Pharmacopœia, and the direction for preparing it, remain the same as the formula and *modus operandi* recognized and practised in the first half of the last century. We might from this fact be led to infer that the resulting combination was all that could be hoped for or desired, that it was uniform in its physical condition and reliable in its action, and that from its long and continuous use in medicine there would not be at the present day doubt in the minds of any as to its medicinal value, or difference of opinion regarding the mechanical subdivision or chemical combination of the metal to which its therapeutical action might be more fairly attributed; and yet I venture to assert that there is no preparation in the British Pharmacopœia about which more diversion of opinion has been entertained, and as I believe will, by the discussion that follows, still be shown to exist.

Reference to the observations of writers of good repute who have commented upon this preparation lead us through a chronological labyrinth of contradiction, showing, alternately, mechanical subdivision and oxidation of the metal in the ascendant, and temporarily holding the weather side in the argument. In the first volume of the *Pharmaceutical Journal* is published an elaborate and exhaustive paper on the 'Division of Mercury,' read before this Society by our noble founder and esteemed friend, the late Mr. Jacob Bell, from which I extract the following as the conclusion at which he arrived:—

"The preparations under consideration, *i.e.*, Grey Powder, Blue Pill, and Blue Ointment, are dependent for their efficacy on the impalpably minute division of the mercury, and if any oxide exist in them, the circumstance is accidental, and the quantity so small as to be unimportant."

Professor Attfield, commenting upon the same preparations, writes—"Their therapeutic effects are probably due to the black and red oxide of mercury which occur in them through the action of the oxygen of the air upon the finely divided metal."

Dr. Pereira under the head of Hyd. c. Cretâ, writes —"This preparation is a mechanical mixture. It is an exceedingly mild but valuable mercurial."

Some sixteen years ago Professor Redwood favoured us at one of these evening meetings with the gratification of listening to a paper on "Grey Powder." It was one of those valuable contributions to pharmacy, for which we as pharmacists have been upon very many occasions indebted to him. It is printed in the *Pharmaceutical Journal* [2], vol. i., p. 504. He therein shows, as the result of his examination of six samples of grey powder, that five of them contain oxides in abnormal excess, and suggests the use of sugar of milk as a probable preventive of this tendency to oxidation (a suggestion which appears to have been adopted by our transatlantic cousins), and concludes with a promise to return to this subject hereafter. May I venture to hope that he will deem the opportunity I have now afforded him a fitting occasion to do so?

It has appeared to me that minute subdivision, and not oxidation of the metal, has been the intention of the pharmacopœia process, and that this result is capable of being obtained by a strict adherence thereto; but the process is uninteresting, monotonous and wearisome. I can recall to mind a time when I as an apprentice was first set to make this preparation, and that I looked upon it as a punishment worthy of the inquisition.

In modern times it is, I believe, exceptional to find it made on a comparatively small scale by the pharmacist for the requirements of his own establishment; as a matter of convenience he purchases it from the wholesale houses, by whom it is made in large quantities, and to this I have for a long time past been led to attribute very much of the variation in the condition of the mercury found in different samples of the powder. The quantities directed in the British Pharmacopœia can be prepared with a result containing a very small percentage of mercurous oxide, and a mere trace, if any, of the mercuric; but when made on a large scale by steam power the heat eliminated by the friction and pressure of heavy stones, favours in a marked degree metallic oxidation, and the powder so prepared and afterwards kept for indefinite and comparatively unlimited periods is that in which, more especially, the peroxide in abnormal quantity is found.

Impressed with the conviction that it is alike our duty and to our interest to avoid the use of a powder containing mercury in the higher state of oxidation, and that in every dispensing establishment it is desirable to have Hyd. c. Cretâ prepared at intervals not too far apart, I venture to suggest a slight deviation from the British Pharmacopœia process, to the extent of substituting for the slow process of trituration in a porcelain mortar, active agitation in a wide-mouthed glass bottle, by which means the B. P. quantity may be prepared and the metal minutely subdivided, with an expenditure of very little, if any, more time and labour than is required to be devoted to the preparation of a tincture.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 6, 1876.

THE COMPOSITION AND USES OF A NEW BISMUTHIC COMPOUND—"THE OLEATE OF BISMUTH."*

BY S. C. BETTY.

The use of bismuth in therapeutics has not been unaffected, I believe, by the insolubility—or at least quasi-insolubility—of the greater number of its compounds.

Of late years one notable preparation, the "liquor bismuthi" of Mr. G. F. Schacht, has found great favour with the medical profession, whilst the laminar "ferri citras c. bismutho" is an elegant, and has proved a useful, remedy.

Yet it may not be inexpedient to advert to the fact that owing seemingly to the long, and for a while the exclusive, use of quasi-insoluble bismuth compounds, the hypothesis gained the credence, which it has virtually retained to this day, that their *modus operandi* is essentially mechanical.

We may be permitted, it appears to me, to question this opinion.

For whilst *a priori*, it might be urged that if alone

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 6, 1876.

mechanical, any other substance of similar cohesive properties should act as well; *a posteriori*, the importance of the fact should not be overlooked, that whenever a bismuthic preparation (as the trisnitrate) is administered, the presence of the metal may be detected in the excreta, though, contrary to what may have been anticipated from the preceding evidence, not in the sudatory exhalation.

I have used the words quasi-insoluble on the assumption that in regard to the expression insolubility a merely relative condition has been sometimes mistaken for an absolute one. The term insoluble is meaningless, save when connected with the specification of the proposed solvent.

Because a given compound may be insoluble in water the conclusion by no means follows that it remains insoluble in the gastric juice; and to this latter process of solubility I propound we may without speculation attribute the curative action of bismuth. Thus the liquor bismuthi has been accepted and acknowledged by the medical profession as an efficient medicinal agent, and so fully as to place it in our national Pharmacopœia.

I have ventured to bring before this meeting another preparation of bismuth possessing the characteristic of the liquor bismuthi, solubility. In my experience it is a new compound, or at least so far new that it has not before been introduced to notice publicly. It is an oleate of bismuth containing 20 per cent. of the base.

For the suggestion of such a substance and its first application in medical practice we are indebted to Dr. Louis Lewis, of Albert Street, Regent's Park, who honours us with his presence this evening.

At the commencement of my work I was materially assisted by the advice of Professor Attfield, at one of these gatherings, "that it would prove useful and important for pharmacists not to lose sight of the solvent powers of oleic acid."

Oleic acid and bismuth were brought into contact with such encouraging results that in the end the large proportion of 20 per cent. of bismuth became dissolved.

The oxide of bismuth, B. P. (the trisnitrate and carbonate being useless for this purpose), is ground very fine and the oleic acid gradually incorporated with it. The mixture being placed in a suitable vessel is subjected to a temperature of nearly its boiling point, then allowed to digest, with frequent agitation at a temperature of about 60° during four days or until it solidifies. The result is pharmaceutically a plaster, chemically, an oleate of bismuth.

This process, it should be added, is only mentioned as having effected the purpose of making the preparation now before you. Further experiments will be necessary to prove the easiest or the most reliable mode of its manufacture; as the results of recent operations would demonstrate that under apparently similar conditions results have not hitherto been uniform.

The question of the physiological effects of bismuth generally I leave untouched, as constituting a branch of the subject with which this record does not profess to deal. Yet of its utility as an endermic application I may note that it melts readily in contact with the skin, is bland to an excoriated surface and penetrating by its limpidity.

I grant the employment of the oleate of bismuth would be contraindicated by the proof that the energy of a bismuthic compound became exerted through mechanical contact. We have, however, from Mr. Marshall, the originator of the oleic preparations, a report which places the rapid and specific effects of the oleates of mercury, morphia, and other bases, so far beyond doubt as to justify our entertaining the hope that the "oleate of bismuth," a pharmaceutical product which presents the bismuthic base in the condition most favourable for absorption, will prove a remedy or at least an adjuvant in cutaneous affections of the exanthematous type, certainly superior to those insoluble compounds which have hitherto been employed.

[*The Discussion on this paper is printed at p.* 484].

NOTE ON SOME REACTIONS OF THE GLYCEROLE OF NITRATE OF BISMUTH.*

BY JOHN WILLIAMS.

Chemists and pharmacists generally will feel much interest in the discovery of the so-called "Glycerole of Nitrate of Bismuth," as described in the *Pharmaceutical Journal* of November 11 by Mr. Balmanno Squire. I must say I read the account of the preparation with great pleasure; it is another illustration of the remarkable powers of glycerine as a solvent, and from the fact that the solution is not precipitated when diluted with water, possesses great interest to the chemist. I think we owe our best thanks to Mr. Squire for this important observation.

Having prepared some of the compound, I think that a few notes of the reactions observed may prove of some interest, especially to those who may have occasion to make the preparation hereafter.

I made the glycerole by dissolving 20 per cent. of crystallized nitrate of bismuth in Price's glycerine. I find the solution is best effected in the cold; if much heat is employed in the preparation, the glycerole when diluted does not give a clear solution, but a milky one, at any rate at the end of a few hours.

The property of bearing dilution with water without producing a turbid solution appears to diminish by keeping. Some I have which has been made for three weeks now gives an opaque solution; but a sample made within a couple of days still gives a perfectly bright liquid even when largely diluted.

The diluted solution does not bear boiling, but when so treated deposits a basic salt not afterwards soluble in water.

The most interesting reaction I have observed, and which must be my excuse for bringing this note before the Society, is that caustic potash (or soda), added to the glycerole diluted with water, first causes a white precipitate, which is however perfectly soluble in an excess of the alkali, a bright clear liquid being produced which is perfectly miscible with water in all proportions, and might possibly be employed medicinally as a substitute for the liq. bismuthi ammonio-citratis of the Pharmacopœia. The principal interest of the reaction is, however, from its chemical bearing.

I do not think it had previously been observed that glycerine possessed the property of forming a compound of this nature with bismuth. It would lead us to infer that the glycerole is not a mere solution of the nitrate of bismuth in glycerine, but is really a chemical combination, and that the glyce-

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 6, 1876.

rine is playing a part somewhat similar to that taken by the citric acid in the liquor of the Pharmacopœia.

I find this alkaline solution of the bismuthic glycerole is precipitated white by alcohol, the precipitate not being again soluble in water. Also by boiling, a somewhat coloured precipitate is produced, probably containing some peroxide of bismuth, or perhaps the ordinary oxide in an anhydrous state.

Of course I need hardly remind the Society that solution of nitrate of bismuth in water is readily precipitated by caustic potash and that the precipitate is quite insoluble in excess of the alkali.

It is a curious fact that ammonia cannot be substituted for potash in this reaction, no excess of the former making a clear solution, although a trace of bismuth is held in solution, as can be proved by adding sulphate of ammonium to the filtrate.

In conclusion, I would observe that it is already quite well known that other agents as well as citric acid can be used for producing a miscible liquor of bismuth. I place upon the table a specimen of liquor bismuthi ammonio-tartratis, in which tartrate of bismuth has been substituted for the citrate and dissolved in dilute ammonia. Oxide of bismuth also boiled with cream of tartar forms a solution which is quite miscible, and probably many other organic acids are capable of producing similar solutions.

[*The Discussion on this paper is printed at p.* 484].

CRYSTALLIZED HYOSCYAMINE.*

BY W. MARTINDALE.

It is generally stated in text books of materia medica that a crystalline alkaloid can be obtained from the seeds of *Hyoscyamus niger*, to which the name Hyoscyamia is given; but it is only recently, within the present year, that it has become a commercial article, and notices of its properties having appeared in the medical journals, in one of which it is stated that I supplied the alkaloid,† I have thought it might prove interesting to bring a specimen of it before the Society. The first notice that I have seen of it appeared in the *Practitioner*,‡ and was by Robert Lawson, M.B., of the West Riding Lunatic Asylum. He mentions its having been supplied by Messrs. Harvey and Reynolds, and manufactured by Merck, and also having obtained it from Messrs. Smith, of Edinburgh, and calls it an *amorphous* alkaloid. I have little doubt that he refers to the same preparation which is in the London market, which, however, is not amorphous but very minutely crystalline. As no notice had appeared in our English journals of its chemical properties and mode of preparation, I was anxious to know more about it, and therefore wrote to Mr. E. Merck for a supply, with any information he could give or reference to published accounts of its chemical history. He has sent me his circular which gives some detailed information about its chemical and physiological properties. In the meantime, Mr. Passmore pointed out to me that M. Thibaut published in the *Répertoire de Pharmacie*, tome ii., September, 1874, p. 563, a process for manufacturing crystallized hyoscyamine which appears to yield it readily, and as the alkaloid is now offered by several German chemical manufacturers it is probably with slight modifications the process generally adopted. I abstract the following from the notice o the process in the *Archiv der Pharmacie*, July, 1875 p. 75. M. Thibaut directs the bruised seeds to be deprived of their oil by means of bisulphide of carbon (not ether, as this is said to dissolve some of the alkaloid as well as the oil). They are then reduced to powder and mixed with a 2 to 3 per cent. solution of tartaric acid and digested for two days at a temperature of 10° to 15° C. This is repeated a second time, the fluids are mixed and after filtration precipitated with a solution of iodine and iodide of potassium, which consists of 15 iodide of potassium and 7·5 iodine to 250 of water. Having collected the precipitate on a filter and washed it with distilled water, it is then easily dissolved by aqueous sulphurous acid which decomposes it, forming sulphate of hyoscyamine and hydriodic acid. This solution is treated with calcined magnesia, which even in excess does not decompose the alkaloid. The mixture is dried at 30° to 35° C., and exhausted with alcohol of 95°. When the alcohol has been distilled off in a vacuum a slightly coloured substance remains, which is treated with pure anhydrous chloroform, to get rid of any iodide of magnesium that the alcohol may have taken up. On evaporation of this chloroform solution an adhesive mass remains which only exhibits a few entangled crystals. This is neutralized with diluted sulphuric acid—care being taken to add as little water as possible—and shaken with chloroform to get rid of the remaining impurities. The residue after filtration is treated with potash in slight excess. It is then shaken with chloroform and quickly decanted. This treatment is repeated twice, the chloroform solution is allowed to evaporate and the alkaloid is obtained in colourless silky crystals in stellate groups, while at the bottom of the dish remains a syrupy substance, which is still alkaline, and which possesses the same properties as the crystals. In trying to recrystallize the crystals from an alcoholized ethereal solution M. Thibaut did not succeed, he only got a colourless viscous mass. The crystals obtained from the seed by this method were in no way similar to the hyoscyamine then found in commerce under the same name; their odour was quite distinct from it. On the other hand, M. Thibaut found that by making hyoscyamine from the leaves, he obtained a substance which smelt like that of commerce, so that he thinks himself justified in assuming that two different alkaloids are contained in henbane,—one in the leaves, and one in the seeds. The odour of crystallized hyoscyamine is slight, and the taste sharp and biting. The reaction is alkaline; with acids it forms crystalline salts, which he could not obtain from the hyoscyamine of commerce. It is sufficiently soluble in water to make it alkaline, very freely soluble in alcohol and ether, and more so in chloroform, but in benzine it is not so soluble. Solution of iodine in iodide of potassium gives a chocolate-coloured precipitate; iodohydrargyrate of potassium, on the other hand, gives a greenish white, and the iodide of bismuth and potassium an orange-yellow precipitate from an acid, but not from a spirituous solution. Tannin produces in concentrated solutions a greyish deposit.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 6, 1876.

† *Lancet*, September 2, 1876, p. 319, 'On the Action of Hyoscyamine and its Resemblance to Atropine.' By J. Sydney Pearce, M.R.C.S., etc.

‡ *Practitioner*, July, 1876, p. 18.

Heated on platinum, he states it melts into a brown fluid, which ultimately sublimes without leaving any residue. Its melting point is 90° C. Like atropine it has the effect of dilating the pupil of the eye, and for a considerable length of time—twenty-four hours. The last fact is unfortuuate for the oculists, who have wanted a drug like atropine, but whose effects would not be so prolonged; with hyoscyamine Mr. J. Sydney Pearce found the dilatation lasted from two to twenty-one days.

The crystallized hyoscyamine now sold agrees with the description above given. Mr. E. Merck describes it as consisting of snow-white particles, which under the microscope appear as aggregates of very fine needles, and with high power oblique prisms. He says it is soluble in 120 parts of cold water, and much more soluble in hot. Its aqueous solution, as I have stated, has an alkaline reaction, yet I find that it has only about half the power of neutralizing acids that atropine has. Four grains of it only require two minims of diluted sulphuric acid, carefully added, to form a neutral solution, whereas four grains of atropine require about five minims, and four grains of daturine about 3·5 minims to make neutral solutions. The two latter are generally believed to be identical. I find the commercial daturine always requires less acid to form a neutral solution than the same quantity of atropine does. I am unable to explain this if they are identical, unless it be that it is not so completely dried as atropine. I infer from the above that when a combustion is made of hyoscyamine it will be found to have a higher molecular weight than atropine. As I am not aware that it has up to the present received its "baptism of fire" we have probably no right yet to call it hyoscyamine. When heated carefully in a porcelain capsule it first liquefies and then sublimes, producing a white vapour having a peculiar odour, and leaving scarcely a trace of residue. I had last week to pay the penalty of partial blindness of one eye for twelve hours, through getting the vapour into it whilst noticing its peculiar odour. I noticed also that it was readily inflammable. Mr. Merck states that Dr. Harnack of Strasburg found that the smallest dose which paralysed the terminations of the pneumogastric nerve of the frog is $\frac{1}{200}$ of a milligramme. In this respect it acts like atropine, and is antagonistic to muscarine and pilocarpine. The smallest quantity that produced dilatation of the pupil of the eye of a rabbit was $\frac{1}{250}$ of a milligramme. Given internally in moderate doses it produced, in healthy constitutions, not sleep, but increased restlessness, and in some cases confused talk and delusions of the senses, with dilatation of the pupil and dryness of the throat. In cases of mania, Mr. R. Lawson* gave as large doses as one grain, and even three grains, but he considers one grain as a full dose, producing generally in these cases twelve hours' sleep. He makes this curious statement respecting its keeping properties, that on one occasion "hyoscyamine was tried, but with little effect. This result, however, was explicable by the discovery that the hyoscyamine employed had been kept for some time over a stove in an imperfectly stoppered bottle. When a new bottle of Merck's alkaloid was opened and dispensed, one grain produced the same effect as before and in a very short time the patient was again restored to, and still retains the proper use of his reason." Its further therapeutic uses are on trial. It is said to be useful in allaying cough, in cases of gonorrhœa and stricture of the urethra. It seems that crystallized hyoscyamine is obtained from henbane seed, the only use of which with us is to make an inhalation as a household remedy for toothache.

I stated at the commencement that several chemists had years ago found that henbane seed contained a crystalline alkaloid. The late Mr. Morson informed me that Dr. Anthony Todd Thomson had a specimen in the Museum of Materia Medica at University College, which he considered a great rarity and prized very much, having paid a high price for it, and that he asked Dr. Thomson for a small quantity of it, which on testing proved to be nothing more than a salt of lime, whether he said sulphate or phosphate I am not certain now.

* *Practitioner*, July, 1876, p. 18.

Mr. John Tweedy, F.R.C.S., has kindly supplied me with the following information respecting the action of hyoscyamine on the eye:—

"Respecting the action of hyoscyamine locally applied to the eye I have not noticed that it differs in any appreciable degree from that of atropine. Both cause dilatation of the pupil and both temporarily destroy the power of adjusting the eye for the vision of near objects. The only questions for solution are, whether the intensity and duration of effect are precisely identical. Unfortunately, I do not possess sufficient data to warrant a dogmatical assertion of opinion, but I am disposed to believe, from the evidence before me, that as regards intensity hyoscyamine holds the first place, while the duration of effect is, as nearly as possible, equal. It is manifest, however, that an absolute decision on these matters can only be established by numerously repeated experiments under different conditions.

"If a drop of a solution of hyoscyamine, four grains to the ounce, be placed within the lower eyelid the following effects will be produced:—Within ten minutes the pupil will begin to dilate, and before twenty minutes have elapsed the iris will, in most instances, have expanded to its full extent. Almost simultaneously with the enlargement of the aperture of the pupil the nearest point of distinct vision will begin to recede, the range of accommodation will then rapidly lessen, and before one hour has elapsed it will be almost if not entirely destroyed; the nearest and farthest points of distinct vision having become practically indentical, since the greatest distance of distinct vision remains unaffected throughout. This state will continue without any apparent change for at least forty or fifty hours. A careful examination will then show that a slight power of accommodation has returned, and that objects can now be seen through a limited range. After about seventy to eighty hours the range of accommodation will be about one-third its normal amount; after about ninety hours it will be about one-half, but it will not regain the healthy standard until seven, eight, or nine days have gone by. Even then, the pupil will be somewhat dilated; indeed, it will not recover its former activity for at least ten to fifteen days.

"But in none of these particulars can hyoscyamine be said to differ in any marked degree from atropine."

NOTE ON CAPSAICIN.*

THE ACTIVE PRINCIPLE OF CAYENNE PEPPER.

BY J. C. THRESH.

The difficulty I have experienced in obtaining this principle in a perfectly pure state has been so great that it is only within the last few weeks that I have obtained it sufficiently pure for the purpose of submitting it to an ultimate analysis.

The process of purification consisted in dissolving the crude capsaicin in solution of potash (official strength), and precipitating by carbonic acid; collecting the precipitate, washing, drying, and dissolving in hot petroleum. After several days the principle crystallized out, and was washed, dissolved in alcohol, diluted with water, and left exposed to the air, but excluded from dust, until most of the alcohol had disappeared and the capsaicin had crystallized. This was collected, washed, and placed on the water bath until the weight was constant. When the mass had become solid, I sent it to Professor Flückiger, who was already interested in the subject, and who had kindly offered to undertake its ultimate analysis for me, and the following are the results obtained by Dr. Buri, his assistant.

1. Of the capsaicin dried over concentrated sulphuric acid, 0·2987 grms. gave

CO_2	0·7713
H_2O	0·2486

2. 0·2860 grms. yielded

CO_2	0·7363
H_2O	0·2347

From these results are calculated the following percentages:—

	I.	II.
C	70·42	70·21
H	9·25	9·12
O	20·33	20·67
	100·	100·

The simplest expression of the constitution of capsaicin is therefore most probably $C_9H_{14}O_2$, which form agrees very well with the above results.

9 C	108	70·13
14 H	14	9·09
2 O	32	20·78
		100·

This therefore gives an idea of its empirical composition, but as yet there is no means of establishing a structural formula.

Having now received a large supply of alcoholic extract of cayenne, purchased by aid of the grant generously made to me by the Pharmaceutical Conference, I hope soon to have sufficient of the pure capsaicin to attempt the discovery of its relationship to other organic principles, and its structural formula.

THE BEHAVIOUR OF SOLUTIONS OF SOME SUBSTANCES TO POLARIZED LIGHT.†

(*Continued from p.* 412.)

BY O. HESSE.

c. Starch Sugar.—According to Biot, starch sugar varies very much in its optical behaviour. With a sample prepared according to the older method by the action of sulphuric acid upon starch he obtained $\alpha r = +$ 51·43°, and with a similar sample Péligot obtained $\alpha r = +61{\cdot}54°$; whilst with a sugar prepared by treating starch with 1-500th of oxalic acid Jacquelin obtained $\alpha r = +100{\cdot}57°$. Dubrunfaut looked upon the latter as a mixture of ordinary sugar with his maltose, $C_{12}H_{22}O_{11} + H_2O$. Two varieties were examined by the author.

The first, from Nienhaus and Co., had become yellowish coloured through keeping twelve years. It was, therefore, treated in aqueous solution with animal charcoal, after which upon concentration of the solution it separated in white aggregated crystals similar to those of honey sugar; these melted at 82°. Heated up to 100° they lost altogether 8·91 per cent. of moisture. (1 mol. $H_2O = 9{\cdot}04$ per cent.) After preliminary treatment with 60° to 70° alcohol it dissolved easily in boiling 97° alcohol, from which it crystallized on cooling in small prisms resembling those of anhydrous honey sugar; heated to 110° C. these crystals did not lose weight, and first melted at 144° C. When dissolved in water the hydrated form produced perfectly resembled the hydrated honey sugar. The optical examination of this sugar gave the following results:—

Sugar Used.	Modification.	p	l	$a° +$	$(\alpha)_D +$*
Anhydrous . . .	α	3	200	6·06	101·00
" . . .	β	3	200	3·10	51·67
Hydrated	α	1	220	2·04	92·72
"	β	1	220	1·10	50·00
"	α	3	220	6·23	94·39
"	β	3	220	3·17	48·03
"	α	6	200	10·87	90·58
"	β	6	200	5·64	47·00
"	β	12	100	5·62	46·83

According to these results this starch sugar also agrees with honey sugar.

A fine starch sugar, sold in Stuttgart under the brand "grape sugar, Ia. R. and W.," and which plays an important part in the manufacture of wine and beer in South Germany, was the other examined. With the exception of a trifle, consisting of incombustible substance, the whole sample dissolved easily in alcohol; consequently no dextrin worth mentioning was present. Upon evaporation the sugar separated from the colourless syrup in beautiful clusters of crystals. These were washed upon a filter with dilute alcohol and then dried in the air between blotting paper. The sugar proving to be hygroscopic it was rubbed with dilute alcohol to bring the hygroscopic portion into solution; this object, however, was not completely attained. In this condition, with $p=3$, the α-modification gave $(\alpha)_D = +93{\cdot}78°$, and the β-modification, $(\alpha)_D = +55{\cdot}8°$. The sugar in a finely divided state was now kept for two days in contact with 80 per cent. alcohol, after which it lost 8·93 per cent. of water at 105° C., whilst the α-form gave in aqueous solution $(\alpha)_D = +95°$, and the β-form $(\alpha)_D = +51{\cdot}8°$. The sugar was then kept in contact with a large quantity of 80 per cent. alcohol eight days longer at the ordinary temperature, by which the greater part was dissolved. The undissolved portion, which had the composition $C_6H_{12}O_6 + H_2O$, examined optically gave for the α-form $p=3$, $l=220$, $(\alpha)_D = +96{\cdot}21°$, for the β-form $(\alpha)_D = +48{\cdot}18°$. The sugar obtained from the alcoholic solution was beautifully white and contained 9·48 per cent. of water of crystallization. It gave with $p=3$, $l=200$, the α-form, $(\alpha)_D = +92{\cdot}85°$, for β-form $(\alpha)_D = +52{\cdot}16$. This difference between the two portions disappeared after the latter had been recrystallized from water a few times. After this, more recrystallizations led to no further change in its properties, so that that the author looks upon the variety of sugar, of which this sample of starch-sugar principally consists,

---

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 6, 1876.

† Abstract of a paper in the *Annalen der Chemie*, vol. clxxvi, p. 95.

* In accordance with the author's request the formula $(\alpha)_D$ is from this point substituted for αj in the original paper.

as being chemically distinct. It loses at 70° C. about 7 per cent. of water and from 95° to 100° 2 per cent. more. It melts at 76° C. If heated to a temperature at which it is not baked together, about 60°, and then treated with boiling 97 per cent. alcohol, an anhydrous crystallized sugar is obtained which is identical with the anhydrous grape sugar. When heated to between 60° and 70° it usually passes into the β-form and is baked together and then is not suited for the preparation of the anhydrous crystallized sugar.

d. **Salicin Sugar.**—This sugar was obtained by the action of emulsin upon salicin. Still adhering saligenin and colouring matter were removed by treatment with alcohol and ether and then in aqueous solution with animal charcoal; the solution was concentrated at a gentle heat, when the sugar immediately crystallized out. The crystals lost most of their water at 70° to 80° and up to 100° C. equal to 1 mol. of water. The hydrated salicin sugar melted in a fine tube at 84° The anhydrous sugar boiled in a sufficiency of 97 per cent. alcohol dissolved and crystallized out on cooling in handsome colourless crystalline needles, resembling the anhydrous honey sugar. When the anhydrous salicin sugar is dissolved in water it crystallizes on spontaneous evaporation in the usual hydrated form containing one molecule of water. The optical examination gave the following results:—

Kind of Sugar.	Modification.	p	l	$\alpha+$	$(\alpha)_D+$
Anhydride	α	2·5	200	5·15	103·00
"	β	2·5	200	2·59	51·80
Hydrate	α	1·0	220	2·20	100·00
"	β	1·0	220	1·10	50·00
"	α	3·0	220	6·39	96·82
"	β	3·0	220	3·28	48·48
"	α	6·0	200	11·78	98·17
"	β	6·0	200	5·75	47·91
"	β	6·0	100	2·88	48·00
"	β	12·0	100	5·72	47·66
Hydrate from Anhydride	β	3·0	200	2·84	47·33

Almost throughout salicin sugar shows a greater rotatory power than honey sugar. It also loses its water of crystallization more easily, and, possibly in connection with this property, it melts at a somewhat higher temperature. The author therefore looks upon it as a special kind of sugar.

e. **Amygdalin Sugar.**—A small quantity of this sugar was examined that had become yellowish by keeping. The colour was easily removed by treatment with animal charcoal. The sugar crystallized very easily, and melted in fine tubes at 84° C., appearing to behave like salicin sugar. With $p=2$ and $l=200$ a freshly prepared aqueous solution gave $(\alpha)_D=+94·75°$; after 24 hours it gave $(\alpha)_D=+49·25°$. The anhydrous amygdalin sugar was not examined optically, but it appeared to be identical with the anhydrous grape sugar.

f. **Phlorizin Sugar.**—This sugar was prepared by decomposing phlorizin with sulphuric acid, decolorizing with animal charcoal, and then dissolving in 80 per cent. alcohol to separate a small quantity of white substance (probably mycelium of a fungus), which rendered the solution turbid and interfered with the optical test. Phlorizin sugar is beautifully white, and consists of spherical aggregates of non-hygroscopic crystals. It loses 6 to 7 per cent. of water between 60° and 70° C., and the remainder of one molecule at 103° C. In a hair tube it melts at 74°; but heated in a larger quantity in a crucible it bakes together at a much lower temperature and passes into the β-modification. Probably from this reason the anhydrous sugar cannot be prepared from the hydrated. With $p=3$ and $l=200$ an aqueous solution of the α-form gave $(\alpha)_D=+82·33°$; the β-form, $(\alpha)_D=+40·78°$; with $p=6$ and $l=200$, β-form, $(\alpha)_D=+39·75$. Examined after two recrystallizations from water and washing the crystals each time with alcohol it appeared to have undergone no change in its properties. Phlorizin sugar is, therefore, essentially different from the foregoing sugars, and most nearly approaches the second starch sugar.

Salicin.

An optical examination of salicin yielded the following results:—

$p=1$, $l=220$, in aqueous solution $(\alpha)_D=-64·54$
$p=2$, $l=220$, " " " $=-63·85$
$p=3$, $l=220$, " " " $=-63·28$

These give the formula $\alpha j=-(65·17-0·63\,p)$. A hot solution and a freshly prepared cold solution showed no difference in the rotatory power; the author, therefore, thinks that salicin contains the sugar in the β-modification.

Phlorizin.

Some commercial phlorizin was freed from its yellowish colour by recrystallization from boiling water containing a little sodium sulphate, and was then obtained in handsome colourless needles. The solvent used in the optical examination was 97 per cent. alcohol.

$p=1$, $l=220$, $t=22·5°$, $(\alpha)_D=-51·81$
$p=3$, $l=220$, $t=22·5°$, $(\alpha)_D=-56·50$
$p=5$, $l=220$, $t=22·5°$, $(\alpha)_D=-61·60$

This gives the formula $(\alpha)_D=-(49·40°+2·41\,p)$. Phlorizin also appears to contain the sugar in the β-modification.

Phloretin.

Phloretin was prepared according to Schiff's method, and by recrystallization from dilute hot alcohol obtained perfectly pure. With $p=1$, and $p=3$, in solution in 97 per cent. alcohol, and at a temperature of 22·5, it showed no deviation of polarized light. This result does not agree with the theory respecting sugar compounds and allied substances held by Schutzenberger. For since phlorizin sugar possesses a smaller rotatory power than phlorizin, according to this observation phloretin must be endowed with a tolerably strong rotatory power in order to cover this fall in the rotatory power of the glucoside.

VERATRINE.*

BY ERNST SCHMIDT AND RUD. KÖPPEN.

Crystallized veratrine was prepared by the authors according to the directions of Merck, partly from commercial veratrine and partly from veratrine made by themselves. The general properties of the substance accord with the statements of Merk and Weigelin respecting it. It melts at 205°. The numbers obtained by analysis (64·63 per cent. carbon, 8·68 per cent. hydrogen, 2·66 per cent. nitrogen) lead to the formula $C_{32}H_{50}NO_9$. The hydrochloride forms with gold trichloride the compound $C_{32}H_{50}NO_9HCl+AuCl_3$, which crystallizes in yellow needles; with platinum tetrachloride an indistinctly crystalline compound $(C_{32}H_{50}NO_9HCl)_2+PtCl_4$; and with mercuric chloride a white crystalline precipitate, $C_{32}H_{50}NO_9HCl+HgCl_2$. The sulphate $(C_{32}H_{50}NO_9)_2H_2SO_4$, and hydrochloride are non-crystallizable.

Crystallized veratrine is insoluble in water, but on prolonged washing therewith it becomes transformed into a soluble modification, the solution of which leaves when evaporated a yellowish amorphous mass having the same composition as the crystals. Veratrine dissolved in water is rendered insoluble, and is consequently precipitated, by heating the solution. Acids also appear to convert the soluble into the insoluble modification.

Several samples of commercial veratrine examined by the authors were found to be almost pure.

QUICKSILVER.*

BY SENOR DON R. A. SODA.

Spain for several centuries had exclusive possession of the sources of the supply of quicksilver. The Spanish mines at Almaden,† which, in spite of the important discoveries mentioned further on, are the richest deposit in the world, were worked in the most remote periods. A passage of Pliny shows that the Romans depended on them exclusively for the manufacture of vermilion, and he gives evidence of their immense importance in the ancient world. When the 10,000 *librae* of ore had been extracted from them for the needs of the year, they were shut with solemn ceremonies, and the key of the mines was lodged with the prefect. They could not be opened again without orders direct from Rome. It is generally considered that the Carthaginians, or at least the Phœnicians, preceded the Romans in working the Almaden mines. Historic proof of this fact, it is true, is wanting, but its admissibility seems to me to be possible; firstly, from the great importance attached to their Spanish possessions and their mineral wealth by the Phœnicians; secondly, from the proximity of these mines to the centre of the Phœnician occupation in Spain; thirdly, from the manufacture of vermilion denoting a certain degree of progress in industrial arts, which is more intelligible on the part of a commercial people than on the part of a mere nation of soldiers; fourthly, from the fact that the Romans, who never displayed any marked aptitude for industry, were but the pupils of the peoples who had preceded them in civilization.

Whatever their antecedents, the Almaden mines stood alone in the world during the long period between the rise of the Roman power and the beginning of mineral industry in America.

The separation of silver from its ores, in the amalgamation process, is the principal large use to which mercury is put. The discovery by Spain of the rich silver mines of Mexico and Peru caused a great increase in production, and from that time forward Almaden became important. In Peru the cinnabar mines of Huencavelica had been discovered, and in Austria those of Idria, in the province of Carniola; but the former were closed at the end of last century, the winning having been conducted in a very reckless fashion. The Spanish Government, which retained a monopoly of the trade with the New World, persuaded the Emperor of Austria to an arrangement under which the latter, after retaining sufficient for use in Austria, made over to the Spaniards the whole surplus output of the mines at Idria. The Spaniards carried on a very profitable trade with the mercury which they bought at their own price from Austria, and sold at their own in America. Spain thus remained mistress of the market, although no longer the exclusive producer of the metal. She took from Austria every year 368 tons of mercury, at £240 per ton, reselling it at £360 per ton. At about this time negotiations were entered into with the famous Fugger family by the Spanish Government for ceding to them the right of working the Almaden mines and reducing the cinnabar. This concession was enjoyed by the Fugger family from 1525 to 1645, and enriched it enormously. It members became princes of the Roman Empire, and accumulated one of those colossal fortunes at which history is amazed. Their name, Ibericised into the form Fucar, became a synonym for wealth, and the Spanish proverb, "Richer than a Fucar," is still current.

The mines discovered in Germany and Tuscany being of no great importance, the only apprehenson of the Spaniards was to see China, who was supposed to possess enormous deposits of cinnabar, appear in the market as a seller. The contrary, however, has really happened, China being a buyer in the markets of both Europe and America. Just when no such thing was being thought of by any one, new discoveries were made, on such a scale that the former conditions of the mercury market have entirely passed away.

At the time of the gold fever in California the gold-finders in the Trinidad placers used to come across grains of reddish stone of so high a specific gravity that on washing the sands they always settled at the bottom of the cradles, after lighter matters had been removed. The name of "red stuff" was given to it by the miners, just as that of "blue stuff" was given to other numerous fragments of a bluish colour. The first were cinnabar, the second an extremely rich sulphide of silver.

In a country where science and action are both practical and easily come together for the common good, these indications were speedily utilized. When the importance of the "placers" became less, investigations of a very costly nature were set on foot. At the cost of labours which would have discouraged less energetic and enduring men, the veins were discovered which are now great sources of wealth. At the present time New Almaden, New Idria, Napa, Colusa, Sonoma and Lake Colorado, afford ample field for the energies of that puissant race, which, to its unresting exploration has added unresting winning, and to these an unresting progress in the methods of treatment of the output. Three patents for distilling furnaces are in existence; Randal's, Knox and Osborn's, and Livermore's. These are for treating poor ores, either in cakes or in a pulverulent condition. Ores differ very considerably in richness, the range being from 20 to 2 per cent. All has been the work of less than a quarter of a century, and at the present time more than half the world's consumption of quicksilver is yielded by that privileged country.

The metal is brought to market in iron flasks holding 76 lb. (34·5 kilogrammes) of mercury. Of the total annual production of 100,000 bottles, 60,000 come from California. From the port of San Francisco, where the greater part of this is shipped, there have been forwarded, during the last fifteen years, 400,000 bottles, of the total value, in round numbers, of £2,850,000. New Almaden, which for some years has been the most productive mercury mine in the world, produced 34,765 bottles in 1862, 40,391 in 1863, and 47,191 in 1864. The highest output in any year of the original (Spanish) Almaden Mine was 32,336 bottles; its annual rate at present is restricted to 9600 bottles. The results of the American production have been, in the first place, to arrest the upward tendency of the price of quicksilver, and in the second, to increase the stock, as shown by the contrast between the 23,591 bottles entered at New York in 1874, and the 47,165 entered in 1875. In the third place, the consumption has so increased that China, which in 1873 took 1900 bottles, figures in the statistical accounts of San Francisco in 1875 for 18,190 bottles; while Mexico, which in the first of these two years limited its demands to 3761 bottles, took 5757 in 1875. Lastly, the home consumption has been enabled to rise to 15,000 or 20,000 bottles a year, which is the quantity retained by the States for their own use. The Californian mines produced last year a total of 40,900 bottles, distributed as follows:—Redington, 13,000 bottles; New Almaden, 9000; New Idria, 8800; Guadalupe, 3400; Great Western, 3400; Saint John, 700; Liverdale, 700; Buckeye, 700; Manhattan, 450; Great Eastern, 400; Phœnix, 350. The weight here shown is about 1420 tons. The production of Sulphur Bank, which takes the second rank among American quicksilver mines, and that of several mines of less account, were not included in the documents from which we extracted the foregoing figures.

We can now see to what an extent the market has been modified. Spain has never been in a position to offer more than 40,000 bottles a-year; the Almaden furnaces now producing up to a standard of 25,000 bottles, and the standard consumption being about 100,000 bottles. The difference is furnished by other sources of supply than Spain. The quicksilver market, therefore, it is self-evident, is no longer a monopoly of Spain. It was ours so

* From *Iron*, December 2, 1876.

† Almaden, "The Mine," according to its Arabic name, is situated in La Mancha, at the point where this province joins Andalusia and Estremadura.

long as we were the only producers, but England, for whose custom all producers are desirous, as she consumes on her own account about half the total product, or say 45,000 bottles, has become the field of competition, and the market has been transferred to London. To this change the house of Rothschild has contributed by the share it has taken in quicksilver transactions, the possession of the Spanish mines having been made over to it for a certain number of years.*

Fortunately for ourselves, the heavy cost which the Californian mercury has to defray for carriage before it can make its appearance on the London market, as well as other charges which it has to bear before it leaves its port of exportation, affects it sufficiently to tell very decidedly in our favour, and make our competition possible. The time, however, is come when we should do well to rouse ourselves from any dream of undisturbed possession, and endeavour to get all the profit we can out of conditions which we are not in a position to annihilate. The decided tendency to rise which was marked before the discovery of Californian cinnabar has not only been contradicted, but there has been a considerable decline.

The two principal elements of price are the cost of raising and the cost of purifying.

The first of these elements, the cost of raising, may as well stand out of the discussion; labour is dear at Almaden, as treble pay is given. This cannot be avoided; since the miners cannot work more than three hours a day without being poisoned. But any reduction in the cost of raising would tell very slightly on the cost of the metal, since even the triple pay brings up the first charge to only 2*s.* 6*d.* per cwt. The question is thus limited to one of treatment of ore, and it is in this way that we in Spain have to confess room for improvement.

The furnaces in which distillation is carried on at Almaden are those of Bustamente, invented by that distinguished engineer in 1648 (that is to say, at the time that the Fuggers gave up the mines), and the so-called Idrian, introduced in 1806. This latter year is the latest term of improvement. Idria itself, however, has twice since then reformed its distilling, and in California, as we have already stated, there are three patent systems in use. As it is reasonable to suppose that each and all of these newly-introduced systems have improved on the older ones, this mere recapitulation shows us as very much behindhand.

The treatment of cinnabar is difficult, on account of the volatile nature of mercury, which, if not prevented, escapes with the products of combustion. The damage done by mercury fumes is specified by Dr. Roberts in a remarkable work treating of Berrens' system, by which evaporation is completely avoided.

The ordinary estimate of the loss by evaporation in the Almaden mines is 50 per cent. The result of an experiment by the celebrated engineer Escosura, who obtained a minimum of loss of 4·36 per cent., has sometimes been looked upon as a standard; but the results obtained in a laboratory cannot for a moment be compared with practical furnace-work as carried out at Almaden. Senor Monasterio, director of the Madrid School of Mines, was commissioned some years ago by the Government to report upon the system proposed by M. Pellet, a French engineer, as compared with that followed at the Idria furnaces. He reported unfavourably to Pellet's system, and it is therefore to be supposed that he did the best he could with the San Luis furnace, on the Idria plan. The percentage of loss stated by him was 5·59 per cent.; but the figures are open to question—firstly, for the same reasons as those given in reference to Escosura; and secondly, from the testimony of M. Huyot, who (*Annales des mines*, 1852) states the loss at Idria to be 27 to 29 per cent. Senor Monasterio concludes his report in the following words:—"Can it be supposed that, under normal circumstances, when one has not the same interest (*i.e.*, in the ordinary course of working), the loss rises to twice the amount? Even then it would only be 20·16 per cent., or less than half the amount which has been stated in public documents." It would almost seem as if Senor Monasterio were satisfied with 20·16 per cent. of loss—which, by the way, comes very near to Huyot's estimate of the loss at the Idria furnaces. Letting it, however, stand at this, and supposing that the mines at Almaden have produced to a value of £60,000,000 since the establishment of Bustamente's furnaces, the proportionate loss will be not less than £12,000,000.

The ratio of loss in the patent furnaces used in the United States I am not acquainted with; but I cannot conceive it possible that the Americans would look without concern on the loss of such immense quantities of mercury, discharged uselessly into the atmosphere. It is very possible, therefore, that we are seriously at a disadvantage, relatively to the mines of California.

The advantages which the Almaden mines possess over their rivals beyond sea are very considerable. In the first place, their ores are much richer than those of California; the preliminary costs have been long since defrayed, and the seams are of great thickness, some workings being 12 feet, others 15 feet, and others nearly 30 feet thick. Spanish quicksilver, too, can be put on the English market at only a fraction of the freightage paid by Californian metal. These are conditions which ought to turn the balance in competition, and if the increasing consumption of America absorbs its output, as it tends to do, the market of Europe can and ought to belong to Spain.

Almaden only raises 4 tons of mercury a day, or 25,000 bottles the seven months of working. England wants 45 tons. Since we could let her have them, why do we not?

Fortunately for Spain, an improvement is at hand. A distinguished chemist of Barcelona is now testing at Almaden a furnace of his invention, which is reported to save the whole amount of the mercury distilled, whatever be the quality of the ores. The tests were conducted in the presence of a commission of three mining engineers specially appointed by the Government.

Two experiments were made. In the first, the inventor, Senor Berrens, operating with great care, obtained a quantity of mercury equal to the proportion contained in the ore, less 0·79 per cent. In the second, the inventor, so far from operating with care, seemed to act with studied recklessness, and the commission were surprised to see the ordinary precautions totally abandoned. The inventor hastened the period of roasting; he drove the steam-engine at 126 strokes a minute, he shortened by 25 hours the time taken for roasting in the previous experiment, and raised the temperature of the furnace to a white heat. He did all that could be done to entirely ruin the operation, and yet the loss did not exceed 3·62 per cent. Indeed this loss was apparent only, not real, for the leaf of gold placed at the top of the flue did not show the smallest trace of mercurial change, proving that no loss by evaporation had taken place. This was acknowledged by the commission, which allowed that the mercury thus wanting might be deposited in a part of the apparatus contrived *ad hoc*. The object of the inventor in his second experiment was to show that his system was not easily prejudiced by careless working.

The Berrens furnace has the further advantage of remaining in use all the year round. The two experiments were carried out in August at an exterior temperature of 27° to 33° C., so that, without increasing the proportion of work, the 25,000 bottles produced in seven months could be raised to 43,000 bottles, working all the twelve-month through.

The reality of this important improvement has been testified to by the competent authority of the commission, which presented its report last January.

* The house of Rothschild acquired the right to work the Almaden mines by a cession made in consequence of a contract entered into with the Spanish Government in 1843.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 9, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

EARLY CLOSING AMONG CHEMISTS AND DRUGGISTS.

WE are glad to find that although the subject of earlier closing amongst chemists and druggists has not been so prominently discussed during the present year, this has not been because there has been any general desire to fall back from the ground already won, but rather to give laggards, from one cause or another, opportunity to close up with those in advance. Thus the President of the Halifax Association was recently able to state that although an agreement amongst the chemists and druggists in that town, to put up shutters at 7 p.m. had fallen through in many cases, final closing at 8 p.m. was still general and Sunday business was not only unsought but undesired. A dozen years ago no arrangement on the subject existed, some chemists closing their shops at 9 p.m. and some later. We think this case is typical of what has occurred in many other places; whilst the full extent of the original advance has not always been maintained, there has been sufficient progress to give ample encouragement for fresh efforts.

We are therefore glad to learn that on the 1st inst., a meeting of the chemists and druggists of Notting Hill and Bayswater was held, under the auspices of the Early Closing Association, in the Mall Hall, High Street, Notting Hill. The chair was occupied by Mr. HENRY LONG, Pharmaceutical Chemist, and a very general feeling in favour of the adoption of earlier closing was expressed by the speakers. This feeling was eventually formulated into a resolution to the effect that the business hours observed by the chemists and druggists are unduly prolonged, and might be curtailed without inconvenience to the public or prejudice to trade, whilst conferring great benefit to both employers and employed. A provisional committee was also appointed to carry out the object of the meeting.

We hope that this meeting, in an important suburb of London, may be but the forerunner of many others. Especially we would commend the present season, when many provincial associations are commencing work for a fresh session, as being favourable for taking the matter up. It is an undoubted fact that during the last few years public opinion has undergone a considerable amount of healthy education in respect to the earlier closing of shops, and there does not seem to be any very obvious reason why the customers who have so freely met the wishes of the linen drapers, for instance, should refuse to be as considerate to the chemist and druggist. On the contrary, we believe that the coveted privilege may be obtained by united action, and we would urge that those gentlemen who take an active part in canvassing their brethren on the subject, such as the provisional committee appointed last week, should receive from every chemist and druggist the readiest possible help and co-operation in their work.

A HINT FOR A NEW POMADE.

NOTWITHSTANDING that we owe much to the Baconian philosophy, many discoveries have been the result of pure accident, and the "rule of thumb" has been the predominant feature in their development. When one reads of a Yankee specific for the growth of hair, which when spilt in the neighbourhood of a doorstep over night resulted in a handsome door-mat the next morning, one feels at liberty to exercise the fashionable faculty of scepticism. But when a British Consul tells a "plain unvarnished tale," we presume it must be received with becoming gravity. Still we cannot help remarking that the news conveyed by Mr. Consul STEVENS in his last report to the Government on the trade of Nicolaieff would be indeed a blessing to bald heads, *if true.*

Mr. Consul STEVENS states that a former servant of his, prematurely bald, whose duty it was to trim his lamps, had a habit of wiping his petroleum-besmeared hands in the scanty locks which remained to him, and after three months of lamp trimming experience and practice of his dirty habit he found he had a much finer head of black, glossy hair than he ever possessed before.

Consul STEVENS, therefore, tried the remedy on two retriever spaniels that had become suddenly bald, with wonderful success. During the summer of 1875 his attention was called to several cases of sudden baldness of bullocks, cows, and oxen, and the loss of tails and manes among horses. His previous experience induced him to suggest the use of petroleum to the owners, and it was found that while it stayed the spread of the disease among animals in the same sheds and stables, it effected a quick and radical cure on the animals attacked.

Consul STEVENS says that the petroleum should be of the "most refined American qualities," and should be rubbed in vigorously and quickly with the palm of the hand. It should be applied six or seven times in all, at intervals of three days, except in the case of horses' tails and manes, when more applications may be requisite.

MILK OF SULPHUR.

We have received several letters on the subject of the late prosecutions for the Sale of Milk of Sulphur, in reply to which, we think that a reference to the 12th and 20th sections of the Sale of Food and Drugs Act will enable our correspondents to ascertain the means by which the absurdity of the case they refer to may be effectually demonstrated, and at the same time a service rendered to the trade at large.

The use of a label distinctly indicating that the article sold as Milk of Sulphur is not the Precipitated Sulphur of the British Pharmacopœia would no doubt be a prudent mode of protection, and under existing conditions, we think it should always be used, in accordance with the suggestion made some months since by the solicitors who conducted the defence of a case of the kind at Leeds, a report of which will be found in the *Pharmaceutical Journal*, vol. v., p. 635.

THE NEXT PRELIMINARY EXAMINATION.

We are requested to state that on account of the first Monday in January next being New Year's Day, the Preliminary examination which would in the ordinary course have been held on that day, will take place on the following Monday, January the 8th.

THE PRESERVATION OF COLOUR IN PLANTS FOR THE HERBARIUM.

In a note published in the *Archiv der Pharmacie* for September, Herr Stoelzl indicates a new application of salicylic acid in the preservation of the natural colour in plants dried for the herbarium. It is well known that this, in the case of succulent plants (*Orchideæ, Pinguicula*, etc.), is effected with difficulty, and that during the tedious operation of drying putrid fermentation sets up in the mucus contained in such plants, causing them to become black and indistinguishable. Herr Stoelzl sought to overcome this disadvantage by using alcohol as a coagulant and salicylic acid to prevent putrefaction. A solution of one part of salicylic acid in 600 parts of spirit was heated to boiling in an evaporating dish and the entire plant drawn slowly through (a longer submersion decolorizes violet flowers), then shaken and carefully pressed between blotting paper. Treated thus, the plants dried rapidly, and yielded throughout a favourable result, the red and violet colours especially being preserved exquisitely bright.

The following are the names of a few plants especially liable to become black, which Herr Stoelzl has found can be thus prepared with advantage:— *Orchis moris, O. militaris, Syringa alba, Asperula odorata, Pinguicula vulgaris, Gymnadenia conopsea, Salvia pratensis, Rhinanthus Alectorolophus, Cephalanthera pallens, C. ensifolia, Œnothera biennis, Verbascum Thapsus, Petasites alba, Juglans regia, Pedicularis palustris.*

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, December 6, 1876.

MR. JOHN WILLIAMS, PRESIDENT.

MR WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atherton, Atkins, Betty, Bottle, Cracknell, Frazer, Greenish, Hampson, Hanbury, Hills, Mackay, Owen, Rimmington, Robbins, Sandford, Schacht, Shaw and Stacey.

The minutes of the last meeting were read and confirmed.

The President read a letter from Dr. Fowler thanking the Council and Board of Examiners for affording him the opportunity of being present at the last examination.

Appointment of Examiners.

The following Pharmaceutical Chemists were then appointed Examiners for the ensuing year, subject to the approval of the Privy Council:—

ENGLAND AND WALES.

Alfred Allchin.
James Benjamin Barnes.
Frederick Baden Benger.
Michael Carteighe.
Octavius Corder.
Samuel Gale.
Frederick Janson Hanbury.
Adolphus Frederick Haselden.
John Samuel Linford.
William Martindale.
John Moss.
William Southall.
George Spratt Taylor.
Charles Umney.

SCOTLAND.

William Ainslie.
John Borland.
James Buchanan.
William Gilmour.
David Kemp.
Alexander Kinninmont.
John B. Stephenson.
James Robert Young.

It was resolved that the Board of Examiners for England and Wales should meet in the months of February, April, June, July, October and December, 1877, and the Board of Examiners for Scotland during the months of February, April, July, October and December.

Mr. Shaw said Mr. Greenish had on a previous occasion asked if information could not be afforded as to the subjects in which the students failed in the examinations. Now he found that Dr. Maclagan, in his report on the examinations at the North British Branch, stated that where one failed in pharmacy and materia medica, two failed in reading prescriptions, twenty-two in botany, and twenty-six in chemistry. If the education of candidates and the examinations were practically identical in England and Scotland, it might be inferred that the same proportion would hold good.

Mr. Mackay thought the statistics which had been read were founded on an estimate of the marks obtained by those who had passed. By the system now in force, if a candidate failed originally in one subject he was not examined in the others, and therefore these figures were necessarily incomplete.

Mr. Greenish said he should be glad to have the information even in the case of those who passed, though it was evident from what had been stated that the statistics could not be complete.

Mr. Shaw said the figures he had read referred to those who had failed. It appeared that the candidates were pretty well up in the practical part of their business, but with regard to botany and chemistry they were very deficient.

The PRESIDENT said it was quite within the power of the Council to order that such information should be given. The only question was whether it would tend to a useful purpose or not.

Mr. MACKAY said the report of Dr. Maclagan was framed entirely on that gentleman's own responsibility, without any consultation with the Board of Examiners. He could not himself see what useful purpose would be served by making known the subjects in which the men failed.

Mr. HAMPSON thought the statistics referred to would be useful to the students themselves, in showing them that they must be better prepared in certain subjects.

Mr. MACKAY thought this end would be attained to a great extent under the new regulations with regard to fees which would come into operation in 1877, which would prevent young men coming up totally unprepared, simply as an experiment.

ELECTIONS.

ASSOCIATES IN BUSINESS.

William Daird Williams of Hampstead, having passed the Modified Examination, and being in business on his own account, was elected an "Associate in Business" of the Society.

ASSOCIATES.

The following having passed the Minor Examination and having paid (as Apprentices and Students) or tendered their subscriptions for the current year, were elected "Associates" of the Society.

Ferriday, Edwin Joseph Titchford ..Oakengates.
Mann, Edwin ....Atherstone.
Watson, Lund ....York.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The Registrar was instructed to restore to the Register of Chemists and Druggists the names of the following persons:—

Alfred Faulconbridge ....160, Lambeth Walk.
James Dunkerly ....50, Southgate Rd., Kingsland.
Robert Owen Steed ....189, Wandsworth Rd.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to the widow of a registered chemist and druggist.

£15 to the widow of a late member in very distressed circumstances.

£5 to a former member, not now on the register, having had to give up his business from continued ill health; applicant has a brother in affluent circumstances.

£15 to the wife of a registered chemist and druggist who is at present in a lunatic asylum, owing to the effects of a railway accident.

£10 to the widow of a registered chemist and druggist whose case had stood over from August last, applicant having had two previous grants.

The Committee also recommended that the sum of £200 be invested in Consols, and that the regulations which they had carefully considered, be approved by the Council in an amended form.

Mr. SHAW moved the adoption of the report, and explained the alterations which had been made in the rules.

Mr. HAMPSON, in seconding the motion, asked if any hardship had been found to arise from the operation of rule 8.

The SECRETARY replied that he had not heard of any such instance. Some of the proposed alterations gave rise to discussions, especially a clause discountenancing canvassing.

Mr. SANDFORD moved that the consideration of the amended regulations be deferred to the February meeting, as he thought some of the alterations were too important to be decided upon without further consideration. He saw many objections to the prohibition of canvassing.

Mr. STACEY seconded the amendment.

Mr. BOTTLE said it was very desirable to make the alterations at once, if at all, in order that they might be included in the new Calendar.

Mr. OWEN having had a great deal to do with charitable institutions, objected to any alterations being made. The present regulations had worked well, and he saw no reason to change them.

Mr. ROBBINS spoke in favour of the tenth amended regulation, which had been inserted at his request, and which he thought would lead to a better selection of candidates for annuities.

Mr. FRASER said he was prepared to accept the revised regulations, but he could see that some of them were open to argument, and therefore he was willing to accede to the amendment, or even postpone the subject until next year.

Mr. HAMPSON said the members had had time to consider the regulations; they had been very fully considered in Committee and passed almost unanimously.

The PRESIDENT said the questions were not new, having been discussed over and over again.

Mr. MACKAY said the alterations proposed were not of any great magnitude. The main points were, putting the names of approved candidates for annuities in a book for selection at the October meeting, and the discountenancing of canvassing; and he did not think even Mr. Sandford would, on full consideration, object to either of these changes. He did not think it fair to the Committee to postpone a matter to which they had given so much time and attention.

Mr. SCHACHT said he had previously opposed the proposition to discountenance the use of cards and circulars, and must still do so. He thought the Fund would suffer if anything were done to limit the interest taken by subscribers in the elections. Besides the proposed clause was neither one thing nor the other; it might operate prejudicially on the conscientious candidate who would obey it, but would be disregarded by others.

Mr. SANDFORD said he would, in order to meet the views of some members, make his amendment more general by omitting the date upon which the question should be considered.

Mr. ATKINS thought one of the proposed new rules (clause 11) was a most important addition to the regulations, and it would be necessary to know whether it would have a retrospective operation.

Mr. BETTY supported the original motion. He could not see that the Fund would suffer from the abolition of canvassing.

The amendment of Mr. SANDFORD was then put in the following form:—

"That the consideration of the proposed alterations in the Regulations of the Benevolent Fund be deferred until a future meeting of the Council."

On a division being taken, the Council was found to be equally divided on the question,

The PRESIDENT said that in accordance with a principle which he had always followed, that a casting vote should, as a rule, be in favour of leaving matters as they were, and although his vote would thus be against his own opinion, he would give his casting vote in favour of the amendment for deferring the consideration of the matter.

It was moved by Mr. ATKINS and seconded by Mr. HILLS,

"That clause 11 of the amended regulations should be added to the Rules at present in force."

The motion being objected to was not pressed.

The amendment was then put as a substantive motion and carried.

The report and recommendation of the Committee, with the exception of the amended regulations, was then adopted unanimously, and the Treasurer was requested to purchase £200 Consols on the Benevolent Fund account.

Mr. SHAW then gave notice of motion that he would bring forward the question of the amended regulations at the February meeting of the Council.

LIBRARY, MUSEUM AND LABORATORY.

This Committee had met twice during the month.

The Librarian had reported that the attendance during the preceding month had been as follows:—Day, highest, 30; lowest, 11. Evening, highest, 13; lowest, 4.

The circulation of books had been 149 in town; in the country, 27, to 21 places. The Committee recommended the purchase of the following books for the library:—

'Geological Survey of California: Botany,' vol. 1.
Sutton's 'Volumetric Analysis,' 3rd edition.
Wanklyn's 'Water Analysis,' 4th edition.

The Librarian had also reported that Heaton's 'Experimental Chemistry,' which was missing, had been returned; also that progress was being made with the purchase of the foreign periodicals, and that more shelf-room was required in the library.

Professor Redwood had reported that there were upwards of 40 students attending his class, and that he had not found the increase of fees operate prejudicially on the number of entries.

Professor Bentley had reported 36 entries in his class.

Professor Attfield had reported 49 entries in his class. He also reported that there was no foundation for the report that certain of the Jacob Bell Scholars had been irregular in attendance, only one having absented himself for any length of time since the foundation of the scholarships, and for that absence a good reason could be assigned. The Committee nevertheless considered it desirable that a monthly return should be made of the attendance of the Bell Scholars. It also recommended that an application from Professor Redwood for an electric lamp, etc., for the purpose of illustrating extra lectures that he proposed giving on the spectroscope and its application to polarized light, be acceded to; Professor Redwood having undertaken to give occasional lectures on the subject referred to, that would be open to members and associates, free of charge.

At its first meeting the Committee had considered the subject of the prizes for the lecture classes, and adjourned it, the Professors being requested, in the meanwhile, to prepare detailed information.

The Curator had reported the attendance in the museum to have been, in the day, highest, 44; lowest, 7. Evening, highest, 10; lowest, 0. Also, that the catalogue was in a forward state, the materia medica portion being in print, while the chemical portion would be complete by the end of the year. The catalogue of the "Hanbury Collection," however, would not be ready for some time, and it was recommended that the catalogue of the museum should be issued as soon as possible; that of the Hanbury Collection to be published afterwards as a supplement.

The following letter had been laid before the Committee and ordered to be submitted to the Council:—

"Ashburton House, Croydon, Nov. 15, 1876.

"To the President of
"The Pharmaceutical Society, London.

"Sir,—In accordance with what I yesterday expressed when I had the pleasure of meeting you and other Members of the Pharmaceutical Society, I beg to say I have instructed Messrs. Macmillan and Co. to place at your disposal:—

"30 copies of 'Pharmacographia.'
"30 „ „ 'Science Papers.'

"These books I desire to present in memory of my late brother, Daniel Hanbury, F.R.S., through the Pharmaceutical Society, in the following manner:—

"One copy of each to be presented to the recipients of the proposed "Hanbury Medal," and one copy of each to the first prizemen at the sessional examination in each of the three classes of the Society's School of Pharmacy, but no person to receive in any case more than one copy of each work.

"I am,
"Yours faithfully,
"(Signed) THOMAS HANBURY.

"As I am leaving England for some months I have requested my friend, Mr. T. H. Hills, to arrange on my account for the suitable binding of these volumes."

Professors Redwood and Bentley had presented to the Committee a report containing the statistics with regard to the prizes taken during the last three years. It appeared that the Silver Medal had, in several cases, been taken by students who had attended for more than one session; that honorary distinctions had been obtained at these examinations both by students who had attended more than one session and by those who had attended one session only.

School of Pharmacy Prizes.

The three Professors had presented a joint report, in which they gave as their opinion that it would be undesirable to limit the competition for the Silver Medal to students of one session or two courses of lectures in the School of Pharmacy, unless a prize of a higher value than any now given—a gold medal, for instance—be offered for competition by any student of the School, without limit to the length of time he may have been in the School, except that he should have attended not less than one session in each department, and be at the time of competition actually a student in the School. For the competition for this medal the Professors recommended that there should be a separate examination in each of the three subjects—chemistry and pharmacy, botany and materia medica, and practical chemistry—the prize to be awarded to the competitor who should obtain the highest aggregate number of marks, provided a standard number be reached. There would then be three classes of competitors for prizes, viz.:—

(1) Competitors for a Gold Medal, who must have studied in the School for not less than an entire session in each of the three classes, but not necessarily at the same or at any particular time, except that a competitor must be a student in the School when the competition takes place.

(2) Competitors for a Silver Medal in each class who shall have studied for one, but not more than one, session. Certificates of Honour and Merit also being awarded in connection with this competition.

(3) Competitors for the Bronze Medal, in accordance with the present regulations, but with this addition, that besides the Bronze Medal, Certificates of Merit may be awarded to lecture students of one course.

The Committee having considered the Professors' report, and heard further explanations from them, a proposition was made to recommend the establishment of a Gold Medal. This was negatived, as was also another proposition to restrict the competition for the Silver Medal to students of two courses or one session. A third proposition was also negatived to the effect that the competition for the Silver Medal should be restricted to students who had attended four courses or two sessions. The Committee had finally decided to recommend to the Council that Certificates of Merit should be given at the end of each course in addition to the Bronze Medal; that in the event of a student competing for prizes in more than one session he should not be allowed to take any prize unless he obtain one of a higher value than any which he may have previously taken in the same class; and that no student be allowed to compete for any of the School of Pharmacy prizes unless he be an Apprentice or Associate of the Pharmaceutical Society.

A letter having been read from the College of Pharmacy at New York, asking if certain volumes and numbers of the *Pharmaceutical Journal* could be purchased to complete the set in the library of the College it was recommended that the volumes and numbers required be presented to the New York College of Pharmacy, and that in future a copy be sent regularly as published.

The PRESIDENT explained that the practical result of the report was that the conditions for the Silver Medal competition would remain as at present, but that certificates of merit would be awarded, in addition to bronze medals, to students of one course.

Mr. SCHACHT asked at whose instance the books were recommended for purchase. For instance, he noticed the name of a book on Californian geology.

The PRESIDENT said this book was specially recommended by Professor Bentley as being one of great importance. It was published by the American Government, and was the *botanical* portion of the geological survey of the United States.

Some discussion next took place with regard to the proposed purchase of the electric lamp, but the general feeling was in favour of adopting the recommendation.

The letter of Mr. Thomas Hanbury was next considered, in connection with which—

The PRESIDENT said he had received a letter from Professor Redwood, in his capacity as President of the Pharmaceutical Conference, stating that Mr. Hanbury had presented copies of his late brother's works to that body for distribution.

The prize regulations were next discussed.

The PRESIDENT said he hoped the subject of a gold medal would be again brought forward, and that the Council would see its way to offer one hereafter.

Mr. SHAW thought that this subject was still more important than the proposed alterations in the regulations for the Benevolent Fund, and he therefore suggested that the discussion should be adjourned.

Mr. HILLS remarked that no alteration was now proposed except the addition of certificates of merit to the Bronze Medal competition.

Mr. RIMMINGTON agreed with Mr. Shaw that the members of the Council should have a further opportunity of considering the recommendations of the Professors.

Mr. HAMPSON supported the adjournment of the question He still felt that there was an injustice to the students in allowing those who had attended the school more than one session to compete. He also objected to the proposal that no one should be allowed to compete for prizes who was not connected with the Society, both because it would preclude ladies competing and on general grounds.

Mr. FRAZER objected to the offering of certificates of merit to students of one course only.

Mr. HANBURY thought the suggestions of the Professors ought to carry great weight, and if the Council could not give the gold medal, it should at least give the certificates recommended.

Mr. SANDFORD said many people were of opinion that there were too many prizes already. The Professors, however, were very anxious that the certificates should be given, and to that the Committee had agreed; but he hoped they would not be exactly in the same form as those offered at the end of the session. He also suggested that these certificates, with the Bronze Medals for the first course, should be given to the successful competitors at the April Evening Meeting. He should be happy to second the amendment of Mr. Hampson for negativing the provision that only apprentices and associates of the Society should be allowed to compete for prizes.

Mr. MACKAY opposed the amendment. At the Edinburgh University no one could attend the lectures of any Professor without paying a guinea for a matriculation ticket; and it would be only fair that those who came to the school to study pharmacy, and wished to take prizes, should join the Society.

Mr. FRAZER supported the amendment.

Mr. ROBBINS opposed it. Some of the students who attended the laboratory never intended to join the Society at all; they came to study chemistry, intending to follow some other profession, and giving their attention solely to that one branch, they might stand in the way of other young men, who were studying pharmacy and botany also, from obtaining the prizes of the Society with which they were connected.

After a short reply from Mr. Hampson, the amendment was put and lost by twelve to eight.

Mr. GREENISH said he was still as much convinced as ever that a great injustice was done to the students of one session. He would therefore move that the report of the Professors be printed and circulated amongst the members of Council. After some discussion the motion was withdrawn.

The report and recommendation of the Committee was then received and adopted, and,

On the motion of the President seconded by the Vice-President, a vote of thanks was passed unanimously to Mr. Thomas Hanbury for his liberality in placing copies of his late brother's works at the disposal of the Society; Mr. Hills speaking warmly in favour of the motion.

Mr. SCHACHT also added on behalf of the Pharmaceutical Conference his appreciation of Mr. Hanbury's kindness.

HOUSE.

This Committee had held a meeting at which it instructed the Secretary to obtain plans for providing extra shelf accommodation in the library, and for a mahogany case to receive the Herbarium given by the late Mr. Daniel Hanbury. Other small matters connected with the house arrangements were reported, in particular that the supply of water available in case of fire had, since this matter was last reported, been ample and satisfactory.

The PRESIDENT said the estimates had now been received, and they could either be accepted at once, or referred to the Committee.

The report and recommendations of the Committee were received and adopted, and the estimates were remitted to the Committee, with instructions to carry out the work proposed at a price not exceeding the estimates submitted.

LAW AND PARLIAMENTARY.

The report of this Committee included a communication from the Solicitor stating the progress made with various matters placed in his hands. Other communications had also been received with regard to alleged infringements of the Pharmacy Act, with regard to some of which proceedings were recommended to be taken.

The report and recommendations were received and adopted.

PHARMACEUTICAL MEETING.

Wednesday, December 6, 1876.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting were read and confirmed.

The following donations to the Library, Museum and Herbarium were announced, and the thanks of the Society were awarded to the donors:—

Library.—'Report by Dr. M. C. Cooke, on the Oil Seeds and Oils in the India Museum, or produced in India,' from the India Office, per Dr. J. Forbes Watson; 'Pharmacopœia Officinalis et Extemporanea,' by J. Quincy, M.D., twelfth edition, from Mr. F. W. E. Shrivell; 'The Quinology of the East Indian Plantations,' by J. E. Howard, F.R.S., parts ii. and iii., from the Author; 'Medico-Chirurgical Transactions,' vol. lix., from the Royal Medical and Chirurgical Society; 'Atti del Congresso Internazionale Botanico tenuto in Firenze nel mese di Maggio, 1874,' from the Reale Società Toscana di Orticultura; 'Beiträge zur Chemie des Kaffees,' von O. Levesie, 'Untersuchung des gebrannten Kaffees auf Cichorien,' von A. Franz, and 'Ueber forensisch chemische Nachweisung von Blut in wässrigen Flussigkeiten,' von V. Schwartz, from Professor Dragendorff; 'Transactions and Proceedings of the Botanical Society of Edinburgh,' vol. xii., part 3, from the Society.

Museum.—Specimen of Boracite, from the President; Seventeen specimens of minerals, from Mr. Pound; Specimen of pure Stearic Acid, crystallized from Alcohol, from Price's Patent Candle Company; Specimen of Hydrobromate of Conia, from Mr. Morson; Specimen of Phosphorus, from Mr. Harold Senier; Specimens of English Rhubarb and Biennial Henbane, from Mr. Usher, of Bodicote, near Banbury; Specimens of the Glass Rope Coral (*Hyalonema Sieboldii*) with a sponge (*Carteria*) parasitical upon it, and of the Sponge known as the Venus Flower-basket (*Euplectella aspergillum*), from Mr. H. Cape; Fruit of *Amomum Melagueta*, from Mr. W. Hodgkinson.

In calling attention to the donations to the Museum, the Curator stated that the specimens presented by Mr. Pound possessed an especial interest from their having been collected by the late Mr. J. K. Lord, the well-known naturalist. The hydrobromate of conia was in remarkably perfect crystals, some of which were in the form of six-sided tables, and others in prismatic needles. This salt had been lately recommended in the treatment of whooping-cough and asthma, and in the form of subcutaneous injection in sciatica.* The phosphorus was a particularly interesting specimen. It was stated by Mr. Harold Senier to be some of the first ever made in this country, by Ambrose Godfrey Hanckwitz, about 200 years ago. The Curator said that he had examined the specimen, and found that while a portion of each lump still retained the translucency and horny appearance of ordinary phosphorus, the remainder was of a red colour and friable nature. The red portion treated with bisulphide of carbon was, however, almost entirely soluble in bisulphide of carbon, leaving only traces of amorphous phosphorus. The specimens of English rhubarb were of a very fine quality. Mr. Usher had kindly promised a specimen of the root of *Rheum officinale* for exhibition at the next evening meeting There was also a specimen of a glycerole of saffron, which had been presented by Mr. Samuel Elliott, of Plymouth, now a student in the School of Pharmacy, concerning which he read the following letter:—

"*Glycerinum Croci.*

"Having noticed that glycerine and saffron were frequently ordered in the same prescription, it occurred to me that a preparation of glycerine and saffron would be an useful one; also it appeared probable that the colouring matter would be as well or perhaps better extracted by glycerine than by any other solvent, while the whole of the aroma would be retained, heat not being used.

"I therefore prepared, early last June, the sample of glycerole of saffron, which is now upon the table, and may state that there has been no sediment nor apparent change during the six months which have elapsed since it was made. In this point it has a great advantage over syrup of saffron, which after six months generally shows a copious precipitate of a reddish brown colour. The odour of the glycerole is far stronger than that of any syrupus croci I have ever made. These facts may seem to some hardly worth notice, but as this preparation is being ordered by medical men, it is but right that its formula should be published. I consider it is the duty of each of us to do what we can to further the cause of pharmacy, and this addition, though small, is better than none on my part.

Formula:—

Saffron	1 drachm.
Glycerine	9 fluid ounces.

Mix and macerate for seven days, pour off the bright liquor, press the remainder through calico into another vessel, and again strain it. Mix the two liquors, and make up the whole to 9 fluid ounces with glycerine."

Mr. Andrews said that he also had been making a few experiments upon the action of glycerine on various substances, not only on common bark, but rhubarb and other things. It might be suggested to some of the younger members of the Society that there was a very large field open in that direction. Glycerine had an astonishing power of retaining various substances in solution; they were not thrown down after a time, as from tinctures and other syrups.

Mr. Greenish said that having experienced the difficulty in connection with syrup of saffron which had just been mentioned, he made a syrup of saffron, or a preparation of saffron in glycerine, some eighteen months ago, in the same proportion as the syrup of saffron in the Pharmacopœia. It had kept uncommonly well, without any sediment. It seemed as though it would keep any length of time. It had been his intention to keep it for a considerable period and then bring it before the Society.

The Chairman then called upon Mr. Alexander Bottle to read a Note on—

A New Mode of Making Grey Powder.

The paper is printed on p. 469, and gave rise to the following discussion:—

Professor Redwood said that many years ago his attention was directed on more than one occasion to the subject of grey powder,—hydrargyrum cum creta,—and the opinion which he then formed was very much in accordance with that at which Mr. Bottle had arrived. The great evil that had attached to the employment of grey powder as then met with in commerce had resulted from the substitution of the iron arm of the machine for that of flesh and blood in its preparation. It was made by wholesale manufacturers through the medium of the steam engine, and he had found that the common mode was to put the ingredients into a cask set upon a spindle, with three or four round stones or some other substance, and then to rotate the cask for an indefinite length of time by means of machinery. The operation might go on for a day or for a month, according to circumstances, and this very undue amount of trituration had been accompanied by a very excessive exposure of the mercury to the action of atmospheric air and to undue oxidation. What had been done with a view of remedying this evil, as far as the Pharmacopœia was concerned, was to give a clear indication that grey powder ought to be made by trituration in a wedgewood mortar; but, beyond that, the Pharmacopœia gave an indication of the kind of impurity which it was most important to avoid. Among the tests it indicated that on the addition of diluted hydrochloric acid, whilst the calcium was taken up, mercury ought not to be taken up. That is to say, the solution ought not to give any precipitate of mercury to protochloride of tin. If pharmacists submitted their grey powder to that very simple test they might be secured against the employment of a preparation which was liable to become poisonous. Mr. Bottle had fairly stated that the process for its preparation indicated that it should consist mrely of minutely

* *Pharm. Journ.* [3], vol. iv., p. 23.

divided mercury, mixed with chalk, with, at the most, a small quantity of suboxide of mercury which was the grey oxide. The great point for the pharmacist was that the preparation should not contain the peroxide or red oxide of mercury. If it gave no solution of mercury to dilute hydrochloric acid, which could be precipitated with subchloride of tin, it would be in a perfectly suitable state for use. But suboxide of mercury, present to any considerable extent, became undoubtedly converted into peroxide. The sub-oxide could not be kept for any length of time without splitting up into mercury and peroxide, and that peroxide was quite as poisonous as corrosive sublimate itself. No grey powder ought to be used which would not stand the test which was given in the Pharmacopœia, and which could be applied in two minutes. He had tried the use of sugar of milk as indicated in his original paper, but he did not find sufficient benefit to result from it to indicate that it was worth while to make a change in the process. He believed that Mr. Bottle had done more than anybody else towards securing to pharmacists the means of having the preparation in the state in which it ought to be used. The great object was to facilitate the preparation of the compound in a short space of time without undue labour, and if that could be accomplished by merely shaking the ingredients in a wide-mouthed bottle, that would undoubtedly be the best and the right mode for preparing grey powder. He (Dr. Redwood) saw no other objection to the adoption of that mode than the fact that it a little too nearly approximated to the process of shaking the ingredients up in a cask, and that some people might jump to the conclusion that, if the bottle process was a proper one, the use of the cask might also be allowed. With reference to the condition in which the mercury existed in grey powder, he would call attention to a fact which must be obvious to every one who was in the habit of testing it, namely, that the mercury, after it had been minutely divided, whether it was taken as it existed in grey powder, or in blue pill, or in mercurial ointment, would not run together as it would if it were in a perfectly clean state. It had always appeared to him that the minute globules of mercury as they existed in grey powder, blue pill, and mercurial ointment, were coated with a film, the nature of which he was not prepared to indicate; but his conclusion had been that there was some low state of oxidation existing upon the surface of these minute globules, and that probably that low oxide might give to the mercury a greater amount of activity than it would possess in its bright metallic condition. This oxide might still be a lower oxide than sub oxide of mercury, and it might account for the peculiar efficacy, and at the same time the extreme mildness of the action of these preparations.

Mr. Andrews said that he had his attention drawn to this subject some twenty-five years ago, when he was an assistant in a West-end establishment, at which a large quantity of grey powder was sold. A complaint was made that the preparation caused children to vomit and that it purged them violently. The substance was examined, and it was found to contain, as Professor Redwood had suggested, peroxide of mercury. Since that time he had always been in the habit of making grey powder by a method somewhat similar to that described by Mr. Bottle. He got that hint from a paper by Mr. Stoddart, published in the *Pharmaceutical Journal*. He put the mercury and the chalk together, and shook them till the chalk was reduced to a fine powder. He then put the mixture in a mortar and triturated it in the usual manner. The process was not a long one, and the result seemed to be everything that was desired.

Mr. Umney said that, during the last twelve years, he had made many hundredweights of grey powder by a process certainly the very opposite to that which Professor Redwood had indicated. He had triturated the mercury and chalk under mill-stones, the weight of which was prevented from resting upon the granite bed of the mill by means of a screw. The whole process of manufacturing ninety pounds had been completed in from four to six hours, and the powder so made in no way differed from that which was produced by the ordinary process of trituration with a pestle and mortar. He thought that, perhaps, the presence of mercurous oxide (and upon keeping mercuric oxide) in grey powder was to some extent due to very damp prepared chalk being used; he had always been in the habit of drying the chalk before using it. He was convinced that the age of the grey powder had a very great deal to do with the presence of the mercuric oxide. About twelve or fourteen years since his attention was directed by the late Mr. Thomas Herring to a specimen of grey powder which had caused very serious results in the North of England. Upon examining it, he found a very considerable quantity of mercuric oxide present. Up to that time he had been in the habit of preparing larger quantities of grey powder at once, but since then he had always operated upon smaller quantities in order to avoid excessive age. As to machine-made powder, he could not see why there should be any difference between that made by mill-stones and that prepared with the pestle and mortar, provided the operation was carried on rapidly and completed within four or five hours.

Mr. Greenish inquired what means Mr. Bottle adopted to ascertain the condition of the sub-division of the mercury in his method.

Professor Attfield said that he should like to propound one question, and that was, What is grey powder? Really he did not know, and he had never been able to gather. It might be a mixture of mercury with chalk, and if so, in what exact state of division ought the mercury to be? Or it might be a mixture of chalk and mercury and black oxide of mercury, or a mixture of chalk and mercury and black oxide of mercury and a little red oxide of mercury. If so, what were the maximum and minimum proportions in which either or both of the oxides might be present. His colleague, Professor Redwood, had told them them that it was a mixture of chalk and mercury with a certain "small proportion" of black oxide, but he (Professor Attfield) wanted a definition of a "small proportion" of such extremely powerful medicine. Though he had heard Mr. Bottle's paper with great interest, he thought that pharmacists had now threshed this subject out, and that the next step to be taken was that therapeutists should tell pharmacists exactly what preparations they wanted under the name of grey powder and blue pill, and so on. When that was done there would not be the slightest difficulty in meeting their requirements. For instance, if a mixture of pure mercury and pure chalk without any oxides were required, just for the purposes of that therapeutical research without which pharmacists could not much further move in the direction of improvement of such mercurial preparations, it probably could be prepared by an adaptation of the method described by Mr. Bottle, shaking the substances together in an atmosphere devoid of oxygen. Preparations of such materials as chalk with definite proportions of either oxide of mercury could also be supplied to any therapeutist who would undertake to endeavour to do mankind and his fellow-healers the service of supplying to medicine, pharmacy and the Pharmacopœia formulæ of trustworthy and useful, instead of variable and sometimes harmful mercurial compounds.

Mr. Bland said that there could be no doubt that the greater part of the mercury remained in the metallic state. He had often observed in making up a pill mass with grey powder and some sticky extract, such as extractum lupuli, that the greater part of the mercury had actually separated in the mortar in a bright metallic state, and the globules were very easily united together by agitation.

Professor Attfield said that he wished to draw the attention of the Society to a paper which was read before them last year on pilula hydrargyri, by Mr. Harold Senier.

The author of the paper showed that, of course, by far the greater part of the mercury was in the metallic condition. But still in eight samples, of stated ages, there were proportions of the black oxide, varying from 0·25 up to 4·22 per cent., and associated with the black oxide there was yellow oxide varying from 0·09 up to 1·8 per cent.

Mr. BOTTLE, in reply, said that his attention was called to the existence of peroxide of mercury in grey powder some twenty or twenty-five years ago, in consequence of some grey powder, which had been for some years in a medicine chest in India, having been given, in an ordinary dose of two or three grains, to two little girls, and produced salivation. In reply to Mr. Umney's suggestion as to the oxidation being caused by the chalk being wet, he (Mr. Bottle) must state that, as a matter of convenience, he dried his chalk so as to make it more easily worked. He did not, however, concur in the view that water favoured oxidation, for, if it did, the mercury which was rubbed down with conserve of roses to form blue pill, would, it might be expected, contain more oxide of mercury than grey powder, but such was not found to be the case. In reply to Mr. Greenish, he (Mr. Bottle) would state that, in order to ascertain the state of division to which the mercury was reduced in the grey powder, he adopted the plan which he was taught as an apprentice, and which was to moisten his finger with saliva, and take up a very small portion of the powder and spread it upon a piece of writing paper, and then apply a lens to ascertain whether the mercury had fairly disappeared. In reply to Dr. Attfield, as to what grey powder consisted of, he must really refer him to the Pharmacopœia, for he had nothing beyond that to offer.

A paper was then read on—

"A NEW BISMUTHIC COMPOUND—THE OLEATE OF BISMUTH.

BY S. C. BETTY.

This was followed by a note on—

"SOME REACTIONS OF THE GLYCEROLE OF NITRATE OF BISMUTH."

BY THE PRESIDENT.

The papers are printed on pp. 469 and 470, and gave rise to the following discussion:—

Dr. LEWIS said, with reference to the oleate of bismuth, that Mr. Betty had prepared it at his suggestion, and that he (Dr. Lewis) had used it in the few cases to which he thought it would be applicable, which were principally cases of exanthema, and with favourable results.

Mr. BALMANNO SQUIRE said that he had noticed that the addition of water to the glycerole of bismuth caused a precipitate, and he was very much puzzled by that fact until he had heard the President's explanation. He had, as he stated in his paper, in the first instance obtained a clear mixture, but after a time he found that the addition of water caused a precipitate, and he (Mr. Squire) had thought that he had arrived at a too hasty conclusion.

Mr. GALE said that he had placed on the table a sample of the first glycerole of nitrate of bismuth prepared for Mr. Squire; it had gone quite opaque. The proportion was a drachm to an ounce. It had been prepared by means of heat.

The PRESIDENT said that heat ought not to be applied.

Mr. POSTANS said that his experience enabled him to corroborate what the President had stated, which was that the glycerole ought to be prepared without heat. About a fortnight ago, at the request of Mr. Balmanno Squire, he had tried to find out how much nitrate of bismuth one ounce of glycerine would take up. He ultimately found an ounce of glycerine would dissolve an ounce of nitrate, but the glycerine would only dissolve it slowly. The concentrated solution of one ounce of nitrate in one ounce of glycerine was rather milky, though weaker solutions had been tolerably clear. Thinking that this solution was nearly a saturated one, it occurred to him that the addition of a little warmth might make the solution bright, or enable him to dissolve a larger amount of nitrate. He then took an ounce and a half of nitrate and added it to one ounce of glycerine, putting it in a bottle which was placed in a water-bath and gently heated. Directly the heat was applied a certain amount of effervescence and a whitish froth were produced. The heat was kept up, and ultimately it seemed as though his satanic majesty had got into the bottle. After a short time fumes and a dense smoke came off. A little while afterwards the mixture in the bottle began to rise gradually, and at last it came out of the bottle like what was commonly known as a "Pharaoh's serpent," and reached the length of seven or eight inches. Shortly afterwards the mass gave off sparks from that portion of it which came out first, and ultimately the whole thing became a mass of sparks and gave a brilliant light for about half a minute. That was the end of the whole matter, and there was only the smallest possible trace of anything left behind. With regard to the dilution, his experience was limited, but he had found that on taking a drachm of the concentrated solution which had been made with one ounce of the nitrate to one of glycerine by the cold process, and adding an ounce of water to it, he at first got a bright clear liquid, though at the expiration of about a quarter of an hour there was a whitish crystalline precipitate. A drachm of the solution of the same strength prepared by heat, had been treated in the same way, and gave a dense yellowish bright precipitate, presenting quite a different appearance.

Mr. BLAND suggested that the phenomenon noticed by Mr. Postans when he was making a solution in the water-bath might be due to the formation of nitro-glycerine. If that was the case, and if the stopper of the bottle had been tied down, his satanic majesty might have manifested himself in a much more disagreeable way.

Mr. UMNEY said that he noticed that the specimen which had been handed round the room smelt very strongly of nitrous acid. If they were to have a compound of bismuth with oleic acid or glycerine, there could be no doubt that the oxide of bismuth was preferable to the nitrate, and he fancied that it would be less liable to irritate.

Professor REDWOOD said that it appeared to him that the principal objection to the preparation which had just been recommended by Mr. Betty was the dificulty of getting pure oleic acid. The preparation which had been handed round smelt much more strongly than it would have done if pure oleic acid had been employed. If they always had perfectly pure oleic acid, he should feel much more confidence in such a preparation than in the other. With regard to glycerole of nitrate of bismuth he was disposed to put the very pertinent question which had been put by his colleague with reference to grey powder, which was, "What is this preparation supposed to be, or intended to be?" He was afraid that the glycerole was rarely likely to be uniform in its composition, and it would not be if it was kept for any length of time. This was a natural result considering that the nitrate of bismuth was an acid salt, in which the greater part of the nitric acid was held by an affinity so weak that water itself was capable of removing it, and hence complicated reactions were likely to take place. If the new preparation in question was introduced into medicine they ought to know its nature and have some security that it could be used from time to time without any great alteration.

Mr. LINFORD said that, after hearing the remarks which had been made, and smelling the little bottle which had been handed round, which was then giving off nitrous acid, it was not improbable that nitro-glycerine might be formed, in consequence of age or through the application of heat. He did not, however, think that the effect mentioned by Mr. Postans was due to nitro-glycerine.

A paper was then read on—

CRYSTALLIZED HYOSCYAMINE.

BY W. MARTINDALE.

The paper is printed on p. 471.

IMPURE GLYCERINE.

Mr. A. W. Gerrard reported to the meeting that having been induced to examine a sample of glycerine that had been received as genuine, he obtained results which led him to the conclusion that it was contaminated with lead and butyric acid. Seven other samples were then obtained from various sources and examined. It was found that while four of them might be termed good, the other three upon being burnt gave residues sufficient, he considered, to warrant him in characterizing them as very impure and unfit for medicine or domestic use.

CRYSTALLINE DEPOSIT FROM TINCTURE OF GALLS.

At the request of the Chairman, Mr. Gerrard briefly referred to a crystalline deposit met with in tincture of galls. The tincture was prepared by percolation, and after about ten days a light-brown deposit was noticed on the bottom and sides of the bottle, which increased during the following week, the tincture becoming perceptibly paler. The deposit examined under the microscope proved to be crystalline, and when tested with various reagents it answered completely to the description given in Watt's 'Dictionary' of the characters of ellagic acid, $C_{14}H_8O_9$, a product of decomposition of tannic acid.

The last paper read was a—

NOTE ON CAPSAICIN.

BY J. C. THRESH.

This paper is printed on 473.

The Chairman then announced that the next Evening Meeting would be held on Wednesday, February 7th.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

A General Meeting of the Chemists and Druggists of Sheffield and district, called by the Council of the Sheffield Pharmaceutical and Chemical Association, was held at the society's rooms, Tudor Place, Sheffield, on Wednesday, November the 22nd, at 9 p.m., to meet the Secretary of the Chemists and Druggists' Trade Association and hear from him a statement of the aims and objects of the Association.

There were upwards of forty persons present.

Mr. W. Jervis, President, occupied the chair.

The minutes of the previous meeting of the local society having been read by Mr. Learoyd, the Honorary Secretary, the Chairman said that owing to the important nature of their business he should not trouble them with any remarks, but simply introduce Mr. Haydon who, as they were quite aware, had come to address them.

Mr. Haydon then gave the history of the Association and explained its aims, objects, and contemplated system of organization. In the course of his remarks he said that the Association intended to proceed at once to the prosecution of unregistered vendors of poisons, by collecting the necessary evidence and forwarding the same to the Pharmaceutical Society, as the power to actually take the proceedings is, by the Pharmacy Act, visited in that body. It is in some quarters thought that the Pharmaceutical Society would not accept help of this nature. He did not anticipate any hitch of this kind, as the difficulty the Pharmaceutical Society had hitherto experienced in instituting proceedings had been in obtaining the necessary evidence for dealing with particular cases, as many chemists would give the Secretary information as to certain persons infringing the Act, but would refuse to go into court and prove the purchase of the poison. This difficulty had been acknowledged, and in substance often repeated by the Secretary, as the Pharmaceutical Society has no official authorized to undertake the collection of evidence of this nature.

Respecting co-operative trading he said, that the drug trade was being seriously injured by these large trading companies was an unquestionable fact, and that some means should be taken at once to test the legality of their dealing in poisonous drugs was equally certain, but as the power to take the necessary steps to bring a case into the law courts was in the hands of the Pharmaceutical Society only, and the Council objected to take action in the matter, the situation was very perplexing. That the stores were clubs and only supplied there own members was a hollow sham, as any one taking the trouble to peruse the reports and balance-sheets of any of these so called societies would at once discover. The number of "friends" (who of course were the public) trading at these stores, in some cases, amount to upwards of 15,000 as compared with about 7000 of its members.

It is a fact worthy of note that since the Association has been formed not a single case of prosecution of a member of the trade for an alleged infringement of the Adulteration Act had (as far as he was aware) taken place, whereas in the first six months of this year such prosecutions were increasingly numerous—prevention was better than cure.

Mr. Ellinor moved the following resolution:—

"That this meeting fully approves of the formation of the Chemists and Druggists' Trade Association, and thoroughly agreeing with its objects as expressed by the Secretary, pledges itself to give it its hearty support."

Mr. Radley in seconding the resolution, said he did so with confidence. He had, as they well knew, been connected with the Pharmaceutical Society since its formation, and he believed that the Association now in question was one that would not interfere with the elder society. As they were aware the Council of the Pharmaceutical Society devoted themselves to the work of education and the support of the Pharmacy Act, and he was sure from personal knowledge that the Council had quite enough on their hands already, and if they were ever so desirous of undertaking the duties proposed by the new Association they could not possibly do so. They had for upwards of thirty years tried to raise the status of chemists and druggists and he thought the machinery that had been set at work would do so thoroughly and effectually. The time seemed to have come for them to take steps for the defence of the trade from attacks and encroachments. They must all, every one of them, have found some inconvenience from the various requirements of the Poisons Act and other Acts of Parliament interfering more or less with the free action of their trade. He took it that no chemist and druggist had the right to call himself a medical man; he quite disapproved of "Medical Hall" being put over a chemist's shop window, yet he contended, as a matter of ancient usage and of pharmaceutical rights extending over a great number of years, that members of the trade ought to be at liberty to attend to little ailments over the counter to the benefit of the community at large. It was for them as chemists and druggists to say whether they would submit to that usage and imprescriptible right being taken from them. He was very much gratified that there was now an Association formed to take up the defence of the trade; it was one that they should all support, and he wished to impress on every one present the advantages of joining the Association. It appealed to the personal interest of all, and he thought it was their duty to give it a very free and hearty support.

Mr. Learoyd, in supporting the resolution, referred to the Medical Defence Association, and thought Medical Aggressive Association would be a more appropriate title. He held with Mr. Radley, that they had, and always had, from before the passing of the Apothecaries

Act, the right to prescribe. He was much pleased that the Association proposed to take up the contravention of the Poisons Act; it did away with the individuality in these cases, the onus of local associations having to collect evidence. There had been a great want of something of the kind, and he should give it his hearty support.

Mr. Cubley said the subject had been very lucidly put before them by the secretary. He was very much pleased with the mode of constituting the Association, it was thoroughly representative, as it gave each district the right of sending a representative of its own choice to the general committee, and thereby of acquiring a knowledge of the different customs in each district, with the peculiarities or any particular hardships affecting that part of the country, and the best means of dealing with it. In the constitution of the Pharmaceutical Society it was different. There were other points the Association would find from time to time crop up; for instance, the registration of firms. It seemed a small thing, but they had no means at present of getting correct information as to whether all the parties trading as Diddleum and Co., or any other firm were really registered men. He therefore thought one of the objects of the new Association should be to promote a bill for the registration of firms. He should most heartily support the Association, for so long as the druggist could be caught unprotected, and they could fight him by himself, he would be beaten, because he frequently could not find the time and money to ensure a good defence; that was the way they were beaten one by one, but let them only combine and get, say four or six thousand members, and the case would be very different, he would impress on those present the necessity of joining the Association.

Mr. C. Ibbitt also supported the resolution. He said, although they had not been yet much troubled with co-operative trading, there was a very large co-operative store in course of erection in Trippett Lane.

The Chairman then put the resolution to the meeting, when it was carried unanimously.

Mr. Radley inquired if any members were served with a summons, and in their opinion it was a case in which the Association should defend them, would their proper course be to write direct to Mr. Haydon.

Mr. Haydon replied that should any member receive notice of legal proceedings having been taken against him for an alleged infringement of an existing act, the better course would be to write immediately to their head quarters at Birmingham, as in his (Mr. Haydon's) absence the honorary secretary looked over the correspondence.

Mr. Learoyd asked if the Association intended to support all cases which occurred.

Mr. Haydon said any case which might be brought forward would be submitted to the law committee, and should it meet with their approval, would be defended. He would call their attention to rule 10, which stated the Association retained within their discretion the right of determining what action should be taken in any cases suggested to it. He went on to say some considerable discussion took place when this rule was framed, as to whether they should defend members only. He thought he should be able to make it very clear to all of them that it would in some cases be wise to defend a member of the trade, although he was not a member of the Association, as at any time such a person might become the subject of an unjust prosecution, and that in the absence of a good and sound defence, judgment might go against him. By this means a precedent would be formed which might, and in all probability would, be detrimental to the success of the Association if called upon to defend a similar case for one of its members.

Mr. Ellinor said he should like to suggest that the Association should be well supported. He further asked that all the members of the trade in the town should join their local association; it was to be regretted that so few did so, as it left them with the whole burden.

Mr. Haydon said it gave him great pleasure to support Mr. Ellinor in his last remarks, and he felt quite satisfied that the Association he represented would be materially strengthened and upheld in a variety of ways by the local associations up and down the country. Further than that, local associations did an immense good, they brought members of the same trade, who were perhaps necessarily somewhat jealous of each other, into friendly intercourse, and promoted a better feeling all round; they ceased to regard each other as opponents; when they met together in that room they talked to the persons sitting next them as friends, and the friendly feeling which sprang up at their meetings was, to a great extent, carried into their every day life. He had also great pleasure in proposing a vote of thanks to their chairman; he wished to add his own personal thanks for the very able manner in which he (the chairman) had supported him.

Mr. Appleton seconded the resolution, which was carried with acclamation.

Mr. Jervis, in replying, thanked them exceedingly for the kind manner in which they had received Mr. Haydon's proposition. He might say he had the honour of representing them on the Executive Committee of the Association, and he assured them that should anything go wrong with any who had become members, they need not fear; if they had done nothing illegal they would have his strenuous assistance.

Mr. Wilson proposed a vote of thanks to Mr. Haydon, which was seconded by Mr. Learoyd.

Mr. Haydon having replied, the proceedings were brought to a conclusion.

Parliamentary and Law Proceedings.

The Pharmaceutical Society of Great Britain v. Edward Mickle.

This case was tried on the 6th inst. at the Liverpool County Court, before the Judge, Mr. Perronet Thompson. The defendant was the same person against whom an action was tried on the 12th January last before the same judge and a jury when a verdict was found for the plaintiffs for two penalties of £5 each.

Mr. Lucas from the office of Messrs. Flux and Co. appeared for the plaintiffs, the defendant appeared in person.

Mr. Lucas reminded the Judge of the former trial and and stated that since it, the defendant had twice presented himself for the Modified examination and proved to be unable to pass it, and that notwithstanding the former verdict and his failure to pass the examination he had continued the business of a chemist and druggist, and that the penalty sued for was in respect of a sale of red precipitate or red oxide of mercury on the 30th of October last.

George Tweddle a retired chemist, proved that on the 30th October last he went to the shop No. 48, Stanley Road, Liverpool, and asked for a pennyworth of red precipitate, and was supplied with the same. The packet purchased was taken by him to Mr. Thomas Williams and left with that gentleman. The shop was as he believed kept by the defendant.

On cross-examination by the defendant, the witness expressed his belief that the defendant was not the person who effected the sale.

Mr. Thomas Williams proved that he was a Fellow of the Chemical Society, and practised at No. 23, Lord Street, Liverpool, as an analytical chemist. He received from Mr. Tweddle the packet produced, and subsequently tested the contents and found them to be red oxide of mercury. The packet was labelled poison, and without any name, address, or other words upon it.

The defendant stated that ten days prior to the date of the sale he had sold the business and parted with the possession of it, and that his name did not, at the date of the sale, in any way appear in connection with the business, and he would call the purchaser as a witness.

George Augustus Churchill, called by the defendant, deposed that he was a Member of the Royal College of Surgeons and a Licentiate of the Apothecaries' Company, and, as such, registered as a duly qualified medical practitioner.

The Judge warned the witness that his evidence, if to the purport stated by the defendant, might criminate himself, and that he was not bound to answer any question which would so criminate him, and section 17 of the Pharmacy Act, 1868, was referred to.

The witness in continuation deposed that, on the 20th or 21st October last, he purchased of the defendant, and paid for, and entered into possession of the chemist and druggist's business, which had previously belonged to the defendant, on the premises mentioned, and that from that date the business had been carried on by him alone, and not by the defendant; and that he personally effected the sale of the packet of poison produced.

Mr. Lucas submitted to the Judge that the case was a proper one for an adjournment, on the ground of surprise, for that notwithstanding sundry communications with the defendant on the subject of the sale and the action, no intimation of the facts set up as a defence had previously been made.

The Judge said he was bound to non-suit, but that he would do so without costs if Mr. Lucas would bind the plaintiffs not to bring a further action in respect of the sale in question, and he gave the choice between that and a non-suit with costs, but with leave to bring a further action.

Mr. Lucas elected to take a non-suit in the latter alternative; and 10*s*. in respect of the defendant's attendance, and £1 in respect of the attendance of Mr. George Augustus Churchill as a witness, were paid accordingly.

Review.

CURRENT CHEMICAL LITERATURE.

INTRODUCTION TO THE STUDY OF ORGANIC CHEMISTRY. By HENRY E. ARMSTRONG, Ph.D., F.C.S. London: Longmans, Green and Co. 1874.

INTRODUCTION TO THE STUDY OF CHEMICAL PHILOSOPHY. By WILLIAM A. TILDEN, D.Sc. London, F.C.S. London: Longmans, Green and Co. 1876.

A COURSE OF PRACTICAL CHEMISTRY. Arranged for the Use of Medical Students. By WILLIAM ODLING, M.B., F.R.S., etc. Fifth Edition. London: Longmans, Green and Co. 1876.

So great of late has been the rage for the publication of books on chemical subjects, that it becomes a duty to watch carefully these publications and how far they exert an influence for good or for evil in education. Thus many books have recently appeared which it were better for science had they never been written, while others have been the merest reproductions, not always even in new garbs, of pre-existing manuals. But the more valuable literature may be expected to come from men who are either rising in their science or who have already exerted an influence on scientific teaching. Nevertheless, there are instances of this latter kind in which the work has been badly done, and we, therefore, turn with especial interest to the books whose titles form the heading to this article, in order to ascertain how far they are truthfully representative of the branches of science of which they treat and how far it is reasonable to hope they may effect the objects they profess. As regards organic chemistry so called, or what has been better termed the chemistry of carbon compounds, most of our standard manuals are written in accordance with the old philosophy; in other words, their authors have written them holding as their creed what is known as the type theory in chemistry. This type theory, so much advanced by Laurent and Gerhardt, received in this country great recommendation at the hands of Williamson and Odling, but since then it has been abandoned in Germany in great measure, for what may be termed the theory of structure. That is to say, chemists in these days rather endeavour to express the nature of various organic substances, not merely on a plausible theory, but as far as possible to assert the actual manner and even form in which the component nuclei of larger molecules are combined. With then, the exception of Schorlemmer's book, Dr. Armstrong's treatise is almost the only one in our language which pretends to treat this branch of chemical science in a systematic manner, based upon modern German thought. In doing this the author has adopted, to a large extent, the classification of Kekulé, describing the various series of substances under the divisions of hydrocarbons, alcohols, ethers, aldehydes, acids, ketones, amines, and organo-metallic compounds. After some introductory matter, there is described in excellent manner the general action of reagents on the carbon compounds; and, in short, the author professes to have indicated and has succeeded in indicating a study of the relations existing among substances rather than the enumeration and description of individual bodies.

We are glad that he has not, in doing this, adopted the general division of bodies into two great groups of fatty and aromatic substances. Altogether it must be admitted that Dr. Armstrong has performed the task he set himself well, for while it must be granted that structural chemistry has not yet solved the dark problem of isomerism, it has led to the formation of many new bodies and to the discovery of some relations between them, and it is in this direction that students should be taught thoroughly and clearly. At the same time it would be foolish to adopt what may be called the Kekuléian system to the utter ignoring of others which have led and may still lead to comparable results. For above all things it should be remembered that the primary result to be attained in science is the discovery of general laws, not individual truths, and too often as it is taught, structural chemistry leads to the making of bricks whose positions, however, in the whole structure are left undetermined.

Dr. Armstrong, then, describes briefly the best known substances and others which form connecting links between them; he also describes the general methods of experiment employed in the study of derivatives, and endeavours to group substances into great divisions, explaining their constitution by Kekuléian definition. There is, however, a tendency, as in all such works, to limit the number of possible compounds, and this tendency here and there assumes an assertive nature not perfectly justifiable, and not invariably supported by facts. Moreover it must be borne in mind that Kekulé's benzene ring fails to explain certain facts and is a mere useful hypothesis *pro tem.*; the danger to be anticipated from its use is that it is apt to impress the student with the idea that the figures thus elaborated actually express the constitution of bodies, while in truth they are only images for explaining the existence of a possible number of isomers and derivatives.

The book is to be cordially recommended as a text-book for students.

The second book on our list, by Dr. Tilden, is also a most useful book, for into it has been condensed vast series of facts regarding the properties of bodies and the laws regulating them so far as it is possible to express them. But it is rather a compendium of facts than a system of philosophy in its truest sense. Thus, while the author adopts the molecular theory of matter, and admits the significant influence which physics exert in constructing a philosophy of this kind, he in great measure does not enter into physics as ordinarily understood, and the consequence is that the philosophy is imperfect considered as a system.

In regard to the ultimate constitution of matter he rather neglects the theory of its homogeneity which, held in ages immemorial, has had in more modern times great numbers of adhering supporters.

Our own idea of a system of philosophy would lead us to start first with our system based upon broad facts, and to then demonstrate its various ramifications and show how it was possible that there should exist varieties as regards the forms of matter, and only finally demonstrate the relation of those forms to certain properties and functions. That is to say, matter and force should be sufficient in the mind to admit of the construction of a system, but Dr. Tilden rather takes certain so-called special laws and general properties and then shows certain relations and indicates other probable or possible ones, but fails to band them into a broad system, explanatory of all facts and all functions. Nevertheless, as a compendium of knowledge, and not without originality of conception, as regards its form and comprehensiveness, it is a most useful book, and deserves a good place in educational literature. It is supplemented with a great number of valuable exercises and questions for the student to work out for himself, but as we have said, taking the book according to its title, it is somewhat disappointing. As regards details in such a book, accuracy is guaranteed by the author's name and by the fact that it does not treat of new acquisitions or original views; it would therefore be hypercritical to point out a few doubtful statements and debatable opinions.

We now pass on to the last book on our list, namely, Odling's 'Practical Chemistry,' and we would particularly dwell upon the fact that it is intended for the use of medical students. In reviewing this book, therefore, we must bear in mind that the only practical use to which a medical man can put chemical knowledge is in regard to the chemical identification and treatment of disease. Such knowledge is supposed to be here given. After an introduction, which has reference to general statements regarding matter, chemical reactions, and chemical manipulation, there follows a long chapter on analytical chemistry. Then comes a chapter on toxicological chemistry based upon the analytical knowledge furnished by its predecessor.

The last chapter in the book is on 'Animal Chemistry,' and has been revised in this edition by Dr. T. Stevenson, while the chapter on analysis has undergone the same treatment by Dr. J. Watts. Confining our immediate attention to the chapter on animal chemistry, we find it is, in the first place, very meagre in kind, for the chemistry of many important individual organs is sufficiently known to enable one to write a book fully as large as the whole chapter or indeed the whole book, and, moreover, what information is here given is not free from error, while those general philosophical speculations, which alone have power, when used by those who possess them, to produce good, are neglected. Thus no theory or explanation of the form in which water exists in animal tissues is given. This water, amounting in many cases to 90 per cent. of the total matter, is in true chemical combination, and cannot be squeezed out; in its relation to the tissues it is comparable to the water of crystallization of salts, and may indeed be regarded as water of colloidation. Among other loose statements made in this book, the colouring matter of urine is called Urohæmatine, and the description of it is neither correct nor comprehensive. The name Urohæmatine is based upon an alleged relation or identity of blood and urine colouring matters, which requires substantiation before it can be accepted. Minute traces of sugar are said to exist normally in urine, and Pettenkofer's test is given as the best one adapted for the detection of biliary matter in the urine. Now, not only does this reaction fail to distinguish between biliary and many other matters, but Gmelin's test, employing nitric acid containing nitrous acid, is a far better agent for discovery in this direction. The spectroscopic characters of acid-hæmatine are also incorrectly described. Acid-hæmatine is said to furnish one absorption band in the red; it really gives four, and sometimes a fifth is faintly visible. Reduced hæmatine gives two, and alkaline hæmatine only one broad band. The brain, much less its chemistry, finds no mention. The biliary colouring matters, bilirubine and biliverdine ($C_9H_9NO_2$ and $C_8N_9NO_2$) are also not mentioned. In the face of these facts we are not surprised to find recent investigations ignored. We regret to have to condemn this book, therefore, as regards the purpose it professes to effect. The chapter on Animal Chemistry, so far as it goes, is in the main correct enough, but it does not cover one-tenth of the ground, and that which is surveyed is surveyed in particular parts wrongly.

The human body, consisting as it does of matters which admit of being distinguished and isolated, and subject to changes which elaborate other substances from pre-existing mixtures (these substances being again broken up in their turn with other compounds) is essentially a living laboratory, and has a chemistry more difficult and more profound than any other branch of this science. What is required, therefore, by a medical man before he can make use of chemical knowledge is primarily its possession, and even this he could not secure from the book under notice. In so saying we do not wish so much to criticize the book adversely as to display the glaring short-comings of medical studies. No man is competent to apply his knowledge to the explanation and cure of disease until, beyond his anatomical, histological, and other knowledge, he has a fundamental acquaintance with what is still more important, viz., chemical physiology, and this cannot be obtained without first studying thoroughly the sciences of physics and pure chemistry, general and analytical. And yet the work before us professes to teach the student of medicine all he needs to learn.

Apart from the errors this book contains, it is very good as a general introductory text-book, but considered as a final means of acquiring knowledge for any one of the branches of science it necessarily includes it is a failure, and as regards animal chemistry in this sense, it is a sad failure.

Correspondence.

E. R. Priest.—Our answer does not appear to need explanation; it is simply, as represented, a paraphrase of the 4th section of the Act 9 and 10 Vict. cap. cx., relating to the use of stills. The section is permissive, and provides that the Commissioners of Excise *may* allow a person to keep and use a still for the manufacture of articles other than spirit mixtures, upon complying with regulations laid down by them. The regulation in your case appear to be that you should pay 10s. a year. This is a matter left entirely to the discretion of the Commissioners.

G. F.—(1) Try powdered soap and rectified spirit, using an equivalent quantity of the powder for the compound rhubarb pill. (2) Use powdered tragacanth and mucilage of acacia. (3) No.

"*Nemo.*"—(1) The arsenious acid is itself unchanged, otherwise than by forming an alkaline arsenite as it slowly decomposes the alkaline carbonate. (2) Probably a solution of arsenous acid in dilute hydrochloric acid.

"*Cymro.*"—The use of a 5 per cent. solution of chloral hydrate, rubbing one-half to one ounce of it into the scalp with a sponge every morning has been recommended in the *American Journal of Pharmacy*, but we are unable to say how far it would be beneficial or safe to use. For other remedies see vol. ii., pp. 637 and 878.

S. A.—We are not aware that there is, at present, any law to prevent the title referred to being used by any person wishing to do so.

F. T. Gibson.—The cases are not parallel, Such a case as that you instance from your own experience belongs to a class that requires the exercise of individual discretion.

COMMUNICATIONS, LETTERS, ETC., have been received from Mr. Kersham, Mr. Gilmour, Dr. Hesse, Mr. Alderton, Mr. Ellidge, Mr. Waterhouse, Mr. Nockolds, Country Chemist, Oxfordshire, M. P. S. G. B., G. E., H. S. W.

CHRYSOPHANIC ACID OINTMENT.

BY BALMANNO SQUIRE, M.B.,

Surgeon to the British Hospital for Diseases of the Skin.

A year or two ago a discussion arose in medical and pharmaceutical circles on the subject of a remedy largely used in India in the treatment of skin diseases under the name of Goa powder. This debate resulted in the tracing of that remedy to its botanical and geographical origin, of proving its absolute identity with certain powders used under various names for the same purpose in widely different parts of world, and last but not least, the attention thus directed to the drug led to the determination of its chemical composition in which chrysophanic acid was found to take a prominent part.

The discussion was begun by Sir Joseph (then Dr.) Fayrer.* His paper called forth one from Dr. J. F. Da Silva Lima,† of Bahia, in Brazil, and this occasioned an admirable chemical research into the composition and physical properties of the powder on the part of Professor Attfield.‡ Professor Attfield's paper was followed by one from Mr. E. M. Holmes,§ and thereupon a discussion ensued in which Messrs. Plowman, Moss, and Postans, and Professors Bentley and Attfield took part.

Hence it happened that the powder, which is supplied to the rest of India from the Portuguese settlement of Goa, was clearly traced to its geographical source in Bahia, in Brazil; it was ascertained, moreover, that the powder is a vegetable powder and that it is derived from some kind of leguminous tree, probably from the medulla or pith of the stem and branches of the tree, the tree most likely being a species of Cæsalpinia or of some nearly allied genus.

As the debate progressed it was discovered that the ringworm powder used in Cochin China and in the Malay peninsula under the name of *Poh di Bahia*, the ringworm powder used in Bahia under the name of *Araroba* powder, and the ringworm remedy used in India under the name of *Goa powder*, were all of them one and the same thing, and lastly it was ascertained by Professor Attfield that the Goa or Bahia or Araroba powder consisted almost entirely (namely to the extent of 85 per cent.) of pure chrysophanic acid, a principle common to Goa powder and to some other drugs, for example, to rhubarb, dock-root, etc.

At the time this discussion took place, Goa powder commanded very high rates although its reputation was such that these rates, were by no means prohibitory of a very extensive employment of it. Thus at Saigon in Cochin China a gramme of it cost 2 francs. A quantity of it obtained from Bombay cost £3 12*s*. per pound. Its retail price in London was about 10*s*. an ounce, but rather as a curiosity than as an article of commerce. From the papers I have quoted, it came to light that there was a remedy largely employed in the treatment of skin diseases in many widely distant parts of the world, namely, in South America, in various parts of Asia, and probably also in Africa, but not in Europe. The use of this remedy appeared to be confined to the tropical regions of the world—regions where, as I may mention, skin diseases prevail more commonly even than they do in Europe. It seemed that the reputation of the drug over this very wide geographical area was such as to preserve its popularity in spite of a very high price having to be paid for it. But notwithstanding all these facts in its favour, evidence was at the time adduced that whenever the drug found its way in quantity to England there was no sale for it here, except for the purpose of exportation to India.

I therefore think that a remedy with such a history deserves, as Sir Joseph Fayrer suggested, a trial of its properties in Europe. I think this all the more because I am convinced from some experiments I have recently made with the drug that the popularity it has achieved in the tropics has been won in spite of a very bungling method (speaking pharmaceutically) in the customary manner of employing it.

The favourite mode of applying it in the tropics seems to be to wet the powder with water, or with vinegar or lemon juice, and to smear the thin paste thus produced on the affected skin. I find that the paste thus produced dries up very speedily on the skin, but not into a cake or crust, or paint of any kind, so that it adheres to the skin, but into its original condition of a fine dry powder, the greater part of which may at once be blown away by the breath, and every fraction of which may be easily rubbed off by the slightest touch.

Ointment is unquestionably a much better form of applying the remedy. The form of *ointment* seems occasionally to have been had recourse to; but *wetting* the powder and smearing on the paste is obviously the orthodox custom.

So far as my investigations have yet led me I have every reason to suppose that chrysophanic acid is the *active agent* as well as the chief ingredient of Goa powder. What Goa powder appears to effect therapeutically seems to me to be achieved equally by chrysophanic acid, only in a somewhat more marked degree. I therefore believe that an ointment of chrysophanic acid is the best mode of using the remedy. It is as to the best mode of making that ointment that I have now to speak.

Those who have much to do with the prescribing of ointments, especially if they are in the habit of inspecting what they have prescribed, will probably have noticed, as I have, that ointments even when compounded at the very best houses are rarely quite all that they might be—in short, they are almost invariably somewhat more spotty and gritty than is positively necessary. It is not generally appreciated what a very great quantity of pains and trouble is required for the making of a small quantity of ointment in a really excellent manner.

Now, chrysophanic acid ointment is apt, as I find, to present the more or less gritty quality to which I have alluded, and the object of this paper is to draw attention to a method by which, in the case of chrysophanic acid, this drawback may be effectually prevented, and thereby the activity of the ointment considerably increased.

This latter aim is the more necessary because my experiments show me that the strength in which it has been proposed to use Goa powder in the form of ointment by two of the writers whose papers I have referred to (namely, the strength of a scruple of the powder to the ounce of lard) is a great deal too feeble.

The method I have adopted is suggested by Professor Attfield's researches, which prove that chrysophanic acid is more soluble in hot benzol than in any other of the ordinary menstrua.

Now lard also is soluble in benzol. I accordingly

* *Medical Times and Gazette*, Oct. 24, 1874.
† *Medical Times and Gazette*, March 6, 1875.
‡ *Pharm. Journ.*, March 13, 1875.
§ *Pharm. Journ.*, April 10, 1875.

dissolved two drachms of chrysophanic acid and an ounce of lard in the smallest necessary quantity of boiling benzol, applying heat by means of a water-bath. Then as the brown solution cooled (the vessel containing it being placed in cold water), and the chrysophanic acid, much less soluble in cold than in hot benzol (Attfield), became rapidly deposited, the mixture was briskly stirred in an evaporating basin.

As the mixture speedily became "set" a most perfect ointment was produced in really a very ready manner. After leaving the ointment spread about the dish for a short time, the benzol almost completely evaporated from it, leaving it quite hard.

By this process two desirable results are achieved. In the first place the comparative insolubility of chrysophanic acid in *cold* benzol, and the rapid evaporation of the benzol itself, cause the acid to be deposited not in a crystalline condition, but as a very fine precipitate. In the second place, the evaporation of the benzol causing the lard to be deposited at the same time from the same solution, an intimate and even mixture of the acid with the lard (favoured of course by the constant stirring) is produced. Indeed I have never seen a more perfect ointment; the lard looks as if it had been stained, or rather as if it were some soft sort of yellowish wax.

This, as I take it, is the most efficient sort of preparation that can be used when it is sought to employ Goa powder as a remedy. The ointment of course has more or less of a smell of benzol for some little time, but at last this goes off completely, or it may be concealed by the addition of a little essential oil.

It is now more easy than it recently has been to make trial of Goa powder in Europe, since its price has become very considerably moderated. It can now be obtained for 1*s.* 6*d.* an ounce, or 20*s.* a pound, and if there were to be any general demand for it, no doubt it could be sold for say 2*s.* 6*d.* a pound. Chrysophanic acid, however, is still an expensive commodity, but if it were worth while to manufacture it on a fairly large scale, it would doubtless soon become cheap.

I find that the properties of chrysophanic acid are by no means confined to its being a remedy for ringworm, but that it is likely to prove a valuable addition to the list of drugs as a remedy in many other diseases of the skin. I have, for example, obtained some unquestionably good results with it in the treatment of psoriasis, and it is a serviceable application, as I find, in cases of lupus also. I instance these as two of the most inveterate of the diseases of the skin.

Goa powder ointment has hitherto been advocated as a mere remedy for ringworm, that is to say as a merely indirect therapeutical agent, acting solely or at the least, chiefly, by virtue of its presence being antagonistic to the life and reproduction of such vegetable organisms as are wont to infest the human skin. Now if it were no more than this it would scarcely be worth while to occupy the attention of your readers so much with it. But I find from therapeutical investigations with it in which I have for some time been engaged, that it is much more than this. It is beyond question a valuable remedy also in a large proportion of the *non-parasitic* diseases of the skin.

Chrysophanic acid, as a separate principle, has, so far as I know, never been tried as a remedy in skin diseases. I am, therefore, glad to be able to announce that Professor Attfield's research into the composition of Goa powder, as detailed in this Journal, has not been altogether without fruit.

In showing, as he has, that chrysophanic acid is the chief constituent of Goa powder he had made it possible to construct an agreeable looking and most useful ointment.

I trust it may be thought worth the while of some wholesale house to bring chrysophanic acid within the reach of the general body of prescribers.

In conclusion I ought to say that some special care is necessary in the preparation of the ointment if it is to turn out such as I have described it. In the first place, the acid must be thoroughly dissolved in the hot benzol, and, in the next place, the cooling and evaporation of the benzol must be conducted as rapidly as possible. With this view the process of dissolving may be conducted in a small glass "beaker" placed in a water-bath, and when solution of the acid and the lard has been perfectly accomplished the solution should be promptly turned out into a cold evaporating dish, placed in cold water and immediately briskly stirred with a glass rod until the solution has become fully and firmly "set."

THE DISPENSING OF SALICYLIC ACID.

BY JAS. W. WHITE.

Although much information has reached us from many quarters respecting the chemical history and therapeutic uses of salicylic acid, the prescriber and dispenser have but few data for their guidance in exhibiting the requisite doses of this substance.

As long as a few grains only of the acid were required as an adjunct to a quantity of vegetable infusion, or small doses were ordered in combination with an alkali or an alkaline salt, the dispenser met with little or no difficulty in this matter; but latterly there has been a tendency to prescribe the free acid in increased quantity without indicating suitable means for its administration. This is illustrated by the following prescription—

℞ Acid. Salicylic. ʒij.
Aquæ, ℥vj.
Misce. Sumat cochl. magn. ter die.

An unattractive mess. Continued trituration does not prevent the immediate precipitation to the surface of the liquid of an uneven flocculence, which on agitation does not remain diffused sufficiently long to admit of being accurately divided into doses. It was endeavoured to improve the suspension of the acid by adding an ounce of mucilage of acacia, and with a satisfactory result, which however was greatly improved upon by substituting tragacanth for the acacia. Twenty grains of powdered tragacanth triturated with the acid and water produced an even, emulsion-like mixture, in which the acid remained suspended for many hours before reaching the bottom of the bottle; with this, prescriber and patient were perfectly satisfied.

It may perhaps be useful to give a few memoranda relating to the solubility of this substance in various media.

Boiling water takes up a large quantity of the acid, in fact a solution can be made which will solidify on cooling; but a cold saturated solution does not contain more than 1 in 310. If an aqueous solution be distilled, an appreciable quantity (not a large proportion) of the acid passes over with the vapour of water; loss must therefore be anticipated if such a solution be boiled or concentrated by evaporation.

It is well known that many alkaline salts assist the solution of salicylic acid. I find that a permanent solution of 10 grs. in 1 fl. oz. of water may be effected by the addition of 10 grs. ammonium citrate, 10 grs. potassium citrate, 6 grs. ammonium acetate, or 5 grs. borax.

A fl. oz. of glycerine in the cold takes up about 12 grs., which separate on dilution with water; if however, half its weight of borax be added with the acid, a glycerine solution may be obtained containing 25 per cent. of acid, and this can be diluted to any extent. (*Vide* note by Mr. C. L. Mitchell, *Pharmaceutical Journal*, 3rd series, p. 103.)

Sugar has no apparent influence as a solvent in this case, but oils and fats dissolve the acid readily, especially when heated. A fl. oz. of almond oil will retain 10 grains.

Lastly, if salicylic acid be beaten with $\frac{1}{10}$th its weight of borax, and the same proportion of glycerine and tragacanth, an excellent pill mass is procured, of which 6 grs. represent 5 of acid, and do not form an inconveniently large pill.

It appears, therefore, that except in small doses, this drug is best prescribed in suspension with tragacanth or in the form of pill, more especially as there is little doubt that in soluble combinations with alkalies and alkaline salts the properties of the free acid are more or less modified.

Clifton.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 452.)

RANDIA DUMETORUM.—*Local name*, GHELAPHUL.

A good description of this fruit, with an interesting account of its properties, will be found in Mr. Moodeen Sheriff's 'Appendix' to the Pharmacopœia of India. I may add that the greyish pulp surrounding the seeds is composed of large oval cells containing a little granular matter. The pulp of the pericarp is remarkable for numerous large reddish brown stony cells. The epidermis is formed of tesselated cells of irregular size and shape; the albumen of the seeds is horny and translucent. This drug is much used in native practice, and is well worthy of attention.

BALSAMODENDRON Sp.? PERSIAN MYRRH.

This substance has only recently made its appearance in the Bombay market, occurring in very large masses, the contents of a bale often adhering together. It is of a rich reddish brown colour, and much of it is translucent; very oily; in taste and odour it resembles African myrrh; pieces of papery bark are found adhering to it. I have not been able to ascertain its source, but it is imported from the Persian Gulf ports, and consigned to merchants who deal in Persian goods. I understand that none of it has as yet been sent to England. It readily forms an emulsion with water, and appears to have all the medicinal properties of commercial myrrh.

KALANCHOE PINNATA.—*Local names*, AIRWAN, MAIRWAN, *and* GHAIMARI.

A tall, fleshy, erect, suffruticose plant, having thick ovate-crenated leaves, consisting of one large leaflet and two smaller ones; petiole and margin of leaf purple; blossom a terminal panicle of pendulous, tubular, yellowish red flowers. The fleshy leaves are much used by the natives as an application to boils, wounds, and the bites of venomous insects, etc. They are slightly heated and crushed and applied as a poultice. Their taste is strongly acid and astringent

ARGYREIA SPECIOSA.—*Local name*, SAMUDRA SHOK.

This convolvulus has handsome heart-shaped leaves 9—12 inches long, and 8—10 broad, or even larger; upper surface dark green and smooth, under surface white, and silky from the presence of a felted layer of long simple hairs. Under the microscope these are seen to be simple tubes gradually tapering to a point, and much like the fibre of flax. They are very strong, and not easily removed by pulling, or by scraping; they retain moisture well. Samudra leaf is a kind of natural impermeable piline, and is used in much the same way as that substance. With regard to the alleged blistering properties of the upper surface there must be some mistake, as I find it has no effect when applied to the skin, nor has the leaf any acridity when chewed.

CELASTRUS PANICULATA.—*Local name*, MALKUNGNEE.

The expressed oil of the seeds is not mentioned in the Pharmacopœia of India. It is of a reddish yellow colour, and deposits a quantity of solid fat after in has been kept a short time; the odour is pungent and acrid. Sp. gr. ·951. Treated with sulphuric acid it turns of a dark bistre colour. This oil is used as a stimulant application to relieve local pain in rheumatism and fever. The seeds also crushed are used for the same purpose; they are generally combined with aromatics such as the seeds of *Barringtonia*, and *Ptychotis Ajwan*. Internally the seeds are sometimes administered as a stimulant and aphrodisiac, commencing with a dose of one seed, to be gradually increased to fifty by daily increments of one.

GARDENIA GUMMIFERA AND LUCIDA.—*Local name* DIKAMALI.

The gum of these trees as met with in commerce is described in the Pharmacopœia of India. In the pure state it has a very different appearance, being transparent and of a bright golden yellow; the odour is powerful and like valerian without its camphoraceous aroma. Pure Dikamali dissolves very rapidly in rectified spirit, forming a solution the colour of pale sherry, which when poured into water forms a delicate primrose-coloured emulsion. This after standing for twenty-four hours deposits a portion of the resin in an opaque condition, and of the colour of precipitated sulphur, but not sufficient to visibly affect the colour or opacity of the emulsion. Besides the external uses generally mentioned in books on Indian Materia Medica, Dikamali is in Bombay much prescribed by Hakeems in dyspepsia attended with flatulence. I have heard it spoken very favourably of by those who have taken it.

MORINGA PTERYGOSPERMA.—*Local name*, SHEGUA.

The root of this tree is universally accepted in this part of India as a substitute for horseradish, The oil of the seeds is not expressed, the pods being always gathered in an unripe state for use as a vegetable; they may be boiled and served with melted butter, or cut in pieces and mixed with curries. The flowers are eaten in curries, and also fried with butter. The leaves boiled with onions and spices are used in the same manner. A decoction of the bark is used as a fomentation to relieve spasmodic pain arising from various causes. The gum when it first exudes is opaque and white; from exposure to the sun it soon becomes pink, and finally of a dull red colour on the surface, the interior remaining white. It occurs in pieces of considerable size, and generally more or less vermicular in form. Placed in water it swells up and forms a salmon-coloured, firm, bulky jelly. The taste is mildly astringent. Shegua gum is said to be used to produce abortion, but it is difficult to obtain any reliable evidence upon a point of this nature; it would be quite possible to use it as a tent to dilate the os uteri, as it is very tough and swells rapidly when moistened.

JATROPHA GLANDULIFERA.—*Local name*, JUNGLI ERENDI.

A small shrub, remarkable for the shining reddish brown colour of its young foliage. The leaves are palmate, 3—5 cleft; panicles terminal, short, few flowered; flowers reddish brown in the monsoon, in the dry season both flowers and leaves lose much of their red colour. The young branches and petioles of the leaves are thickly studded with sticky red glandular hairs. The capsules are three celled and three seeded, with an outer adherent fleshy epicarp, which dries up as the fruit ripens; when this takes place the three triangular woody cells of which it is composed divides into six pieces suddenly with a sharp report, and the seeds are projected to a considerable distance; it is, therefore, necessary to gather the fruit before it is quite ripe and dry it in a covered place. The seeds, including the strophiole, are three-tenths of an inch long, and two-tenths broad; they are of a grey colour with two brown stripes on the dorsum, which is convex, the under side has two flat surfaces, divided by a central ridge. The kernel is without smell, and very oily, it has a sweet nutty taste. Under the microscope it is seen to consist of a delicate stroma, completely filled with small oil cells; when these are crushed large oil globules make their appearance. In this part of India the juice of the plant is used as a counter-irritant, to remove opacities of the cornea, or thickening of the conjunctiva, and the oil of the seeds as a stimulant embrocation in chronic rheumatism. The shrub is very common on waste ground in the Island of Bombay; it appears to have been introduced from the Deccan.

JATROPHA NANA.—*Local name*, KIRKUNDI.

It much resembles the above mentioned plant, and has the same medicinal properties.

ADHATODA VASICA.—*Local name*, ADULSA.

The leaves of this shrub are elliptic oblong, attenuated at both ends, glabrous, upper surface dark green, under surface much lighter, margins waved, petioles half an inch long, length of leaf 4—5 inches, breadth one and a half to one and three-quarters inch, venation reticulated, taste bitter. Adulsa has a very considerable reputation an an expectorant amongst native practitioners in this neighbourhood. From the remarks in the Pharmacopœia of India it will be seen that this drug is very generally esteemed in other parts of the country. It would be interesting if further experiments could be made with a reliable preparation; a succus might answer very well.

ECLIPTA PROSTRATA.—*Local name*, MAKA.

A small prostrate or ascending plant; stem reddish; leaves lanceolate, attenuated at the base, with waved edges, one to one and a half inch long. The whole plant is rough to the touch, from the presence of numerous adpressed white hairs. The flower heads are in pairs, one having a peduncle twice as long as the other; flowers numerous; corolla white; root much branched, woody, fibrous rootlets, about four inches in length. The whole plant is used; it has a strong disagreeable smell when bruised. The structure of the hairs is peculiar: the base is red and turned upwards, upon it is attached a conical white glandular structure. The seeds are wedge-shaped, about the size of lettuce seed, and marked with rough irregular prominences on both sides. Maka has been very favourably mentioned as a substitute for Taraxacum in the Pharmacopœia of India. In Bombay it is used by the natives as a tonic in combination with aromatics, such as *Ptychotis*, *Ajwan*, etc. The bruised leaves are also applied to wounds and sores. It is a very common weed.

ASTERACANTHA LONGIFOLIA.—*Local name*, TALMAKHARA.

The seeds of this plant are not mentioned in the Pharmacopœia of India; they are very generally used, and are to be found in every druggist's shop. they are small and flattish, of irregular form and brown colour; the largest one-tenth of an inch long, one-sixteenth broad. When placed in the mouth they immediately become coated with a large quantity of extremely tenacious mucilage which adheres to the tongue and palate, and is of rather agreeable flavour. When a section of the seed is placed under the microscope with a drop of water the development of the mucus may be observed. It appears to spring in filaments from the columnar cells of the testa; these spread rapidly in every direction, and form a network which resembles the growth of some of the lower forms of algæ; it does not dissolve when much water is added. Talmakhara (vulg. Talimkhana) seed is considered to be very efficacious in promoting the concoction and increasing the quantity of the seminal fluid; it is diuretic. The powdered seed is administered with sugar or milk in doses of from one to three drachms.

ZANTHOXYLON TRIPHYLLUM.—*Local name*, TRIPHALI.

The fruit is a small, roundish-ovate, somewhat flattened capsule about the size of a large pea; it has a fleshy dotted pericarp, which in the dry drug forms a rough dark brown aromatic covering to the tough woody shell enclosing the seed. The small peduncles of the fruit often remain attached. The seed is single of the shape of a lentil, black and shining. The capsules when ripe dehisce, and the seeds fall out and are thrown away as useless. Upon pressing the pericarp with the nail the essential oil exudes; it has an agreeable lemon odour, and tastes hot and aromatic. Sections of the capsule placed under the microscope show that the outer portion of the pericarp is thickly studded with cells containing the essential oil, and that the elasticity of the capsules is due to the presence of strong bands of spiral fibre. The dry open capsules when soaked in water close and resume the shape which they had before dehiscence. Triphali is an agreeable aromatic and stimulant; it grows abundantly in the Goa territory.

BARRINGTONIA ACUTANGULA.—*Local name*, SAMUNDAR PHAL.

The seed of this tree resembles a nutmeg in size and shape; externally it is somewhat rough, brown, and marked with longitudinal striæ; internally it is of a chocolate colour, hard and brittle when dry, but easily softened by immersion in water, when a section for microscopic examination can readily be made. A small central cavity of an oval form contains the germ; the rest of the seed consists of starch. The granules are small, and their natural form, which appears to be oval, is much modified by compression; they are contained in a delicate cellular stroma. Samundar Phal is considered by the natives to be warm and stimulating; it has a starchy taste; in Bombay it is generally prescribed in combination with other and more active medicines.

(*To be continued.*)

SERUM SANGUINIS EXSICCATUM*.

BY FRANCIS VACHER,

Medical Officer of Health, Birkenhead.

In a recent paper "On Serum Sanguinis as a Therapeutic,"† I gave the particulars of some experiments I undertook for the purpose of discovering any agent or agents by means of which this most unstable liquor might be prevented from decomposition. The conclusion I arrived at was that *serum* might be preserved for a period of eight days, "in four ways, viz., (1) by the weak solution of chloride of aluminium known as chloralum, in the proportion of 1 to 16; (2) by spirit of chloroform in the proportion of 1 to 32; (3) by chlorate of potash, 15 grains to the fluid ounce; and (4) by a scarcely appreciable quantity of camphor." Of these methods I stated the first appeared a little uncertain, and was open to objection from the mixture of *serum* and chloralum having a disgreeable smell and taste. The use of spirit of chloroform as a preservative, or chlorate of potash, was also seen to be not altogether unexceptional, as circumstances might arise when it would not be expedient to combine the *serum* with either of these drugs; so that the *serum* I supplied to the practitioners who kindly offered to make trial of its therapeutical properties, and that which I myself prescribed, was always, when not quite fresh, kept sound by the camphor dissolved from a small floating fragment. Even when the *serum* was protected with camphor, I dared not use it after the eighth day, reckoning from the date of the shedding of the blood from which it was obtained.

The results of my investigations in this respect were therefore far from satisfactory, and I could not but be conscious that in advocating a remedy which, besides being bulky in form, was difficult to preserve for a week, I was little likely to receive attention. The preparation I desired to introduce to notice, and whose claims to a place among recognized therapeutical agents I wished to have fairly tested, was of so unstable a nature as to be practically only within reach of a few. Druggists could not be expected to procure it, butchers would not take the trouble to learn how to prepare it, and thick unfiltered samples discredited it. The fate of a therapeutic agent difficult to obtain, bulky in form, exceedingly susceptible of change, and when changed noisome and poisonous, was a foregone conclusion. No remedial agent, however manifest its uses, could contend against such odds. The conviction forced itself upon me, that if *serum* was to struggle into favour, and be of real service to the public and the profession, all these conditions must be reversed —it must be presented in a convenient portable form, insusceptible of change; and I set myself to solve the problem how this was to be accomplished.

Receiving advice from a correspondent that glycerine possessed the property of preserving *serum* (his statement was that the addition of about one per cent. of this kept *serum* sweet for a month), it occurred to me that a mixture of *serum* and glycerine might be reduced in evaporating dishes to the consistence of condensed milk, and put up in hermetically sealed tins. This, however, could only have been attempted on a large scale, and would have entailed considerable outlay, so the experiment was not made. It was next suggested to me that if the *serum*, instead of being reduced to the consistence of honey or an ordinary extract, were simply evaporated to dryness, it would then be light, portable, and practically immutable without the addition of any preservative or foreign substance whatever. All that was necessary was to be careful that the *serum* was, in the first instance, perfectly sound, that it was dried without loss of time, and that in drying the temperature did not approach too closely a height liable to coagulate the albumen, about 145° F. A preparation of dried *serum* was accordingly made, the drying chamber being maintained at a temperature of from 130° to 140° F., and the process of manufacture in no respect differing from that observed in producing albumen mordant. Whereas, however, the latter, as I explained in my previous paper, is often made from stale *serum* which has been acidulated and "corrected," and always from the whole of the *serum* that can be separated, the dried *serum* made for me has been derived from selected samples of fresh *liquor sanguinis*, having only a trace of colouring matter, but retaining the alkali and soluble salts normal to it. Removed from the evaporating dishes it occurs as thin yellow flakes, bright on the surface and more or less curved. After being ground, the yellow colour is nearly lost, and it appears as a fine light almost white powder, with a peculiar faint odour, and a salt, somewhat fishy, taste. It dissolves in cold water, but more readily in water slightly warmed.

The *serum* has been obtained indiscriminately from the blood of sheep and oxen, but the yield of *serum* sufficiently pure to be suitable for medicinal purposes is as regards either very small. The average quantity of blood collected from a slaughtered ox is about 3½ gallons, or 35 lbs., but the clot holds so much *serum* that the whole quantity separable is often not more than 7½ lbs., and under the most favourable circumstances rarely exceeds 12½ lbs. So the average yield of an ox may be estimated at 10 lbs., and only from a third of this will clear enough to make a neat preparation. The average quantity of blood collected from a slaughtered sheep is about 4 lbs. In Watts's 'Dictionary of Chemistry' the percentage of water in the serum of ox-blood is stated to be from 90·8 to 91·5, in the *serum* of sheep from 91·6 to 91·8. An ounce of the preparation made for me may therefore be considered equal to ten ounces of fresh *serum*.

As regards the uses of *serum sanguinis exsiccatum*, I

* From the *Practitioner*, December, 1876.

† *Liverpool and Manchester Medical and Surgical Reports*, 1876.

submit that any specific properties which *serum* may possess as an anthelmintic (evidence on this point is still wanting) can hardly be affected by drying, while now that *erum* is presented in a light portable form, which will keep sound as long as it is free from moisture, it may serve many purposes for which fresh *serum* is not adapted. Proteic substances are not largely represented in the Pharmacopœia. They putrefy readily when not dry, and putrefying act as ferments, so that part of the process of manufacture of many pharmaceutical preparations has for its object the removal from them of protein compounds. Thus the practitioner who wishes to prescribe an animal or vegetable "flesh-former" is exceedingly limited in his choice of materials.

One of the most important uses to which *serum exsiccatum* can be applied would, therefore, appear to be in the treatment of the subjects of emaciation, whether from phthisis pulmonalis, struma, or diabetes, especially adult patients. If, for instance, the dried *serum* be made into a thick mucilage with a little water, and then added to an equal quantity of cod-liver oil, a compound is obtained somewhat resembling the yolk of an egg, and exceedingly nutritious. When cod-liver oil is ill borne, sweet oil might be substituted for it. Secondly, inasmuch as *serum* in a dry condition may be combined with water to any required spissitude, its value as an emollient or demulcent is obvious. I would suggest a trial of it in diseases of the alimentary mucous membrane and of the urinary organs. Then it might occasionally be at hand when the usual antidote for poisoning with perchloride of mercury, soluble salts of copper, etc., was not. Thirdly, this form of *serum* cannot but prove convenient for suspending camphor, oils, resins, copaiba, etc., in aqueous vehicles. Turpentine also, especially when exhibited as an anthelmintic, might be fitly combined with a strong solution of this preparation.

Externally it occurs to me that *serum exsiccatum* may be of use in three ways. Mixed sparingly with water and made into an emulsion with oil, it forms a suitable dressing for burns and scalds, etc.; mixed with a little water and an equal volume of rectified spirit, it may be used as collodion for painting over the skin when red or excoriated from pressure, or in cases of erysipelas, or to prevent or diminish pitting in small-pox; and the precipitate produced by agitating the dry serum with alum-water (after the water had been strained off through muslin) forms an excellent astringent poultice—alum-curd, a similar preparation, used to be a favourite application in ophthalmia.

In conclusion I would advise that the dried *serum* be only mixed with water just before being used. If introduced into a mixture the mixture may not be finished before decomposition begins, and calculations as to the time it will continue sound are liable to be falsified by patients incautiously exposing it to the sun. When kept carefully corked, *serum exsiccatum* may be preserved unchanged for any length of time. The presence of water being in all cases necessary to decomposition, so long as *serum* remains dry, exposure to the sun will not alter its properties.

REACTIONS FOR CARBOLIC ACID.

The following list of reactions for carbolic acid is quoted in *New Remedies*, from a lengthy article, by Dr. Richard Godeffroy on the "Modes of Formation, Methods of Preparation, Properties and Reactions of Carbolic, Benzoic, Salicylic, Oxybenzoic and Parabenzoic Acids," which has appeared in the *Zeitschrift* of the Austrian Apothecaries' Society :—

1. Solutions of *caustic alkalies* dissolve phenol readily, with formation of *phenates* (carbolates) of alkali metals.

2. On treating phenol with an excess of fused *caustic potassa*, a copious disengagement of hydrogen gas occurs after a short time, while at the same time there are formed oxybenzoic and salicylic and diphenol.

3. *Potassium* or *Sodium* dissolves in melted phenol, with disengagement of hydrogen and formation of *phenate* of the alkali metal.

4. On passing dry *carbonic acid* into phenol containing *sodium* in solution, sodium *salicylate* is formed, together with paraoxybenzoic acid.

5. Pieces of *caustic potassa* brought into a solution of phenol in *chloroform* became covered with a rose-red shell, but the mixture soon became very hot, dark-coloured, and thick.

On adding to an aqueous solution of phenol a little *potassa*, evaporating to dryness, and, after the residue has become cold, pouring over it some *chloroform*, a magnificent purple colour makes its appearance, which is ascribed to the formation of rosolic acid. (J. Guareschi.*)

6. A watery solution of phenol immediately discolours *potassium permanganate.* If the latter be added until the colour ceases to disappear, the products of oxidation are only carbonic and oxalic acids ; if, however, the oxidation remains incomplete, the products are a resin, closely allied in composition to phenol, a small quantity of oxalic acid, and a few other bodies.

7. Strong *hydrochloric acid* is poured upon *potassium chlorate* in a test-tube, so that the fluid stands a few centimetres over the salt; after the subsidence of the first reaction, and the removal of the chlorine vapours from the upper portion of the test-tube by blowing, the liquid is diluted with $1\frac{1}{2}$ volumes of water ; *water of ammonia* is now poured into the test-tube, so that the latter forms a separate layer over the other. On adding to this test-liquid a watery solution of phenol, the *ammoniacal layer assumes a tint*, varying with the quantity of phenol, from rose-red, through blood-red, reddish, or dark-brown. One part of phenol may be easily recognised in 12,000 parts of liquid. (Ch. Rice.†)

8. On passing the vapor of phenol over *zinc* in powder, *benzole* and zinc oxide are formed : $2C_6H_5OH + Zn_2 = 2ZnO + 2C_6H_6$.

9. On adding an excess of *bromine water* to a dilute aqueous solution of phenol, there is immediately formed a yellowish-white flocculent precipitate of *tribromphenol*, $C_6H_2Br_3OH$. This reaction is said to be distinguishable in a dilution of 1: 43,700, and by waiting for a few hours, even in one of 1 : 54,600 parts.

10. On shaking a watery solution of phenol with *aqueous ammonia*, and exposing the liquid to the vapour of bromine, the liquid assumes a distinct blue colour, even in presence of only $\frac{1}{20000}$th part of phenol. (F. A. Flückiger.‡)

11. On mixing a solution of a *hypochlorite* with *ammonia* and a liquid containing phenol, an intense blue colour is developed. Very small quantities of phenol may be detected by this reaction.

12. Dilute solutions of phenol are coloured violet by *neutral aqueous ferric chloride* solution. *Alcoholic* ferric chloride solution produces a blue colour with alcoholic phenol solution. Free acids prevent the reaction.

13. A watery solution of phenol reduces *metallic mercury* from a solution of *mercurous nitrate*, and the liquid assumes a red colour, which is said to be visible still if only $\frac{1}{30000}$ phenol is present.

14. By united action of *iodine* and *mercuric oxide* upon phenol, substitution products of the latter, containing iodine, are formed. (P. Weselsky.§)

15. *Albumen* is immediately coagulated by phenol.

16. Concentrated *sulphuric acid* dissolves phenol without colour, and produces *phenol-sulphuric* (sulphocarbolic, sulphophenic) acids. Warmed with *fuming sulphuric acid*, phenol yields phenol-disulphuric acid,

* *Gaz. Chim. Ital.*, 3,402.
† *Am. Journ. Pharm.*, 1873, 98.
‡ *Arch. d. Pharm.*, [3] 3, 30.
§ *Wien Ber.*, 69, II., 832.

which latter imparts a *ruby* colour to ferric chloride solution.

17. On heating phenol with *oxalic* and *sulphuric acids*, a beautifully red mass is obtained, which assumes a magnificent purple shade with *alkalies*. This is owing to the formation of *coralline*.

18. On heating phenol with sublimed (and, therefore, dehydrated) oxalic acid to 110-120° C., rosolic acid is formed. (Prud'homme.*)

19. Nitric acid acts upon phenol with more or less violence, depending upon its concentration, and produces either mononitrophenol $C_6H_4(NO_2)OH$, or dinitrophenol $C_6H_3(NO_2)_2OH$, or trinitrophenol, $C_6H_2(NO_2)_3OH$. This latter is commonly known as picric acid.

COTO BARK AND ITS CRYSTALLIZABLE CONSTITUENTS.†

BY JULIUS JOBST.

The author reports that the crystallizable body some months since separated by him from Bolivian coto bark, and named by him "cotoin,"‡ has since, on account of its excellent anti-diarrhœic action, been used to a considerable extent, but unfortunately the importation of the crude material has not kept pace with the demand. After a long interval a larger parcel of coto bark came into his possession, but the new bark showed marked differences in its exterior which were also manifest in the taste and smell. Upon the extraction of the bark by the process given for cotoin, a body similar to cotoin crystallizing in yellow flakes was obtained, which, however, was not cotoin, and differed from it essentially in its reactions.

In the first place the new body wants the biting taste of cotoin; further it is much more difficultly soluble in water, alcohol, ether, ammonia and potash solution. Concentrated sulphuric acid does not give with it the characteristic reaction of cotoin, but only a yellow solution; lead acetate causes no precipitate.

The author proposes for this substance the name "paracotoin," and states that in the last imported coto bark several other crystallizable bodies are contained in smaller quantities.

Upon making complaint respecting the varying quality of the bark, the author was told that the parcel in question came from the banks of the river Mapiri, in Bolivia, and represented the best coto that it furnished. No further information could be obtained.

The author's stock of cotoin, prepared from the original coto bark, being almost exhausted, he was induced by the undoubted similarity of the two barks and their principal products to seek to ascertain the therapeutic action of the new body. The experiment was made by Herr Burkart. He found that paracotoin exercises the same anti-diarrhœic action as cotoin, the difference between the two preparations being only one of degree; paracotoin, in accordance with its inferior solubility, showing a somewhat weaker action than cotoin, consequently the dose slightly varies. In his therapeutic experiments, Herr Burkart administered it either in the powder form, 0·1 gram with 0·2 gram of saccharum album every three hours, or in emulsion, 0·5 gram. On account of its insolubility, the powder form, in the above doses, was preferred, the patients taking the powder more readily on account of its complete tastelessness.

A relation appears, therefore, to exist between the two coto barks similar to that observed in the case of the cinchonas; where barks have been found within narrow limits in which alternately quinine or cinchonidine or cinchonine predominate.

The author is engaged in an investigation of the relation in which cotoin, paracotoin and the other crystalline constituents of the coto bark stand to each other in respect to their chemical composition.

EXAMINATION OF SPURIOUS BEESWAX.*

Not long ago some yellow beeswax was offered for sale in a German city, which, on account of its cheapness, found a ready market at first, but was afterwards ascertained to be a gross fraud. As the method of examination adopted presents a few novel features, we reproduce it here.

In appearance, colour, fracture, brittleness, pliability, and odour (on the outside portions) this pseudo-wax could scarcely be distinguished from the genuine. But the freshly-cut surfaces had a lustre different from that of true wax, and on breaking the mass into pieces, a distinct odour of resin was perceptible. On melting it with a gentle heat, the honey odour disappeared entirely, but the pitchy odour became gradually more intense and oppressive. These simple means having already pointed out the probable composition, the melting point and the specific gravity were determined in the following manner: A wide-necked glass flask was filled three-fourths with water and into the middle of this was immersed a thermometer and a test-tube containing some fragments of the wax; the mouth having been loosely stoppered, heat was carefully applied, until about one third of the wax had melted. The temperature at this point was 70° C. (158° F.). To determine the specific gravity, two equally large pieces were dropped into a beaker containing dilute alcohol, in which they sank; distilled water was now gradually added, until after stirring, the pieces floated a little below the level of the liquid. The specific gravity of the latter, being found to be 0·962, corresponds to that of the wax.

One gramme of the substance was warmed in a small flask with 10 gm. of chloroform. The solution was clear and yellow, but on cooling became opaque, and deposited on the sides an almost transparent and colourless mass. Another gramme was dissolved by heat in 15 gm. of 70 per cent. alcohol, and set aside to cool. This caused the deposition of globular colourless masses, leaving the liquid of a clear yellow colour. The globules having been separated by filtration, they were dried and weighed. They amounted to 0·6 gm., and had a specific gravity of 0·910. The filtrate, on evaporation, left behind a brittle, yellow resin, weighing nearly 0·4 gm. One gramme of shavings was next boiled in a solution of 1·4 gm. of borax in 20 gm. of distilled water, whereby a colourless mass was obtained, floating on top of the liquid, which latter was cloudy, but did not become either milky or gelatinous on cooling. Japan wax was therefore not present.

Another portion, in fine shavings, was shaken with dilute ammonia, but the liquid remained clear and transparent and the substance unaltered, which proved the absence of stearine as well as turmeric and orleans. The above mentioned globular masses, free from resin, were now examined for paraffin. They had a lustrous, alabaster-like appearance, became soft on kneading without getting adhesive, and dissolved easily and completely in oil of turpentine and benzine, but were entirely insoluble in five parts of hot absolute alcohol. They were hence pure paraffin. The composition of the substance was therefore 60 parts of paraffin and 40 parts of yellow resin, covered with a thin coating of genuine beeswax. The specific gravity in this case was identical with that of many samples of genuine beeswax.

PILOCARPUS PINNATUS (JABORANDI).*

BY ERNEST HARDY.

America has been a privileged land for therapeutics. It has yielded most active and valuable medicines, and although it has been explored by naturalists and travellers for three centuries it is not yet exhausted. In the present day observers still describe plants from these prolific lands, the origin and properties of which are unknown. Others rescue from oblivion plants already described, but only partially made known by an imperfect description; so that a definite introduction of one of these species into scientific classification becomes equal to a new discovery.

Pilocarpus pinnatus has had this fortune. Formerly described and imported into Europe under the name "jaborandi," given to it by the natives of South America, it had been forgotten and confounded with other plants designated under the same popular name, when a happy chance recalled attention to its properties.

Two years since, a Brazilian physician, Dr. Coutinho, visiting France, brought with him for his personal use some jaborandi leaves, a popular remedy in his own country, the efficacy of which he had frequently tested in various affections. Ignorant whether this plant was known in Europe he attended a lecture by M. Gubler. The learned Professor of Therapeutics to the Paris Faculty of Medicine spoke of sudorifics, and regretfully remarked that no medicine was truly worthy of that name. At the close of the sitting Dr. Coutinho made known to him the properties of jaborandi, and to demonstrate its efficacy he immediately instituted an experiment; the next day M. Gubler and his pupils were able to testify to its astonishing effects as a sudorific and sialogogue. After repeated experiments MM. Gubler and Coutinho published their researches, which have since been verified by a large number of observers.

Very soon jaborandis were imported in large quantity and delivered to the public. Then commenced an era of deception. These jaborandis possessed different properties, whilst some were nearly inert. Serious doubts were raised in the minds even of the least prejudiced. It was possible that they had to do with various plants, but the absence of flowers and fruits prevented them from being distinguished. However, by the simple examination of a leaf, M. Baillon, Professor of Botany to the Paris Faculty of Medicine, succeeded in tracing the history of the plants designated under the name "jaborandi," and in distinguishing them one from another.

About the middle of the seventeenth century, Pison and Margraff, in their celebrated work 'De Medicina Brasiliense,' described three ligneous frutescent jaborandis. One of them, better studied than the others, has been since described by Gaudichaud under the name *Serronia Jaborandi.* Pison's second frutescent jaborandi is described as having seeds that are powerfully burning. The third, analogous in its exterior characters to long pepper, has acuminate linguiform leaves, and is employed in Brazil in the preparation of baths and fomentations. All these jaborandis have roots that taste rather insipidly at first; but after having been chewed some time burn the tongue and palate like the pyrethrums. They are employed as odontalgics and cephalics; also in cases of poisoning, suppression of urine, and affections produced by chills.

There are some jaborandis that belong to the Scrophulariaceae. The *Herpestes gratioloides*, a South American herb, has a sudorific antirheumatic action; *H. colobrina* is an alexipharmic employed by the Peruvians; *H. Monnieria*, Kunth (*Gratiola Monnieria*, Linn.), has a root that is aperient, diuretic and sudorific; it is used also in cases of fever and poisoning, and as an antidote to the bites of venomous serpents.

A fourth jaborandi of Pison and Magraff was, according to the custom of the time, separated as a herb from the others, which were ligneous plants. The description which those authors have given of it agrees completely with *Monnieria trifoliata*, a rutaceous plant of the Cuspariæ tribe, which grows in all the warm eastern region of South America. It is especially common on certain portions of the littoral of Brazil, where it is known as *Alfocava de cobra.* Like most of the plants of the same group it is a kind of aromatic stimulant; the odorous root is as strong as that of pyrethrum.

This classification of the plants designated under the name "jaborandi," illustrates the errors that the employment of a popular name may introduce into science; moreover, it does not include the plant upon which public attention has been fixed for some time.

This jaborandi, the only one to which the subsequent remarks apply, is a *Pilocarpus*, recognized by M. Baillon as *P. pinnatus* or *pennatus.* It grows in the north of Brazil, in the provinces of Céara and Piauhy, the warmest in the empire, in the neighbourhood of Pernambuco; it is found especially upon the sides of mountains in the Sierra de Biapaba. In these provinces there reigns an eternal spring and a soft climate; the winter is marked by torrents of rain; in the summer the land is refreshed by numberless streams and springs that break forth in every part; forests cover the tops of the mountains and descend into the plains in the midst of the most luxurious vegetation. The *Pilocarpus pinnatus* is met with on the hill slopes, upon the borders or in the clearings of the forest.

Bonpland found this jaborandi in the province of Corrientes. The first plants sent to Europe were collected by Lebon in 1847, in the province of St. Paul, near Villafranca. They flowered soon afterwards in the conservatories of the Duke de Croy, at Dulmen, in Westphalia, and afterwards in Belgium and in Paris. MM. Baillon and Planchon describe *Pilocarpus pinnatus* as a very beautiful shrub, eight or ten feet high, completely glabrous when full grown. Its cylindrical branches are covered with a pale bark, sprinkled all over with whitish projecting lenticular spots. This bark is easily detached from the ligneous portion; its internal surface is white and finely striated longitudinally. Examined microscopically it presents below the suberous layer a circle of well characterized glands, analogous to the oil glands of *Citrus;* in the liber layers are sclerogenous cells, each containing a drop of resinous matter; and further in the interior are resiniferous cells. These same cells are found disseminated in all the layers of the roots, except in the thin epidermic flakes which exfoliate on the surface of that organ. The taste of the root bark is very strong.

The leaves are compound, alternate, without stipules, imparipinnate, with 9 (sometimes 7, rarely 11) leaflets, and sometimes attain a length of 18 inches. The leaflets are in oposite pairs, borne on a short petiole, articulated at the base, varying in form with the individual and with the position of the leaf; they are sometimes 6 inches long and 2 inches broad. The mid-rib is very prominent on the under surface, less so on the upper. Under a microscope numerous oil glands can be seen on the leaves, the glands being constituted like those of the exterior parts of the bark and the stem.

The flowers are disposed in a long flexible raceme, sometimes nearly 20 inches long, and bearing upwards of a hundred flowers. Some of the inflorescence is terminal, but the greater part occurs upon the stems and branches. The flowers have a short peduncle, a small calyx with five slightly marked teeth; the corolla before opening forms

* *Bulletin de la Société d'Acclimatation* for October, 876, p. 671.

In this paper the author, following M. Baillon, calls this species "*pinnatus*," or, alternately, "*pennatus.*" But the original name given to it by Lemaire was "*pennatifolius*," as may be seen by referring to Lemaire's paper in the *Jardin Fleuriste*, vol. iii., tab. 253, July, 1852.

an ovoid, nearly globular, bud; the petals are thick, tawny grey, marked with numerous oil glands, $\frac{1}{10}$ to $\frac{1}{8}$ inch long. There are five stamens, alternate with the petals. The pistil is short, surmounted by five stigmata. The shell-like fruit usually contains a single seed.

Animals avoid touching the leaves and shoots of this shrub; but according to popular opinion it loses the greater part of its active properties after the rainy season, recovering them afterwards. The leaves and buds have their maximum effect in the spring, at which time it is preferable to collect them.

The botanical study of *P. pinnatus* indicates especially the presence of an essential oil, which is easily obtained by distillation. This oil possesses peculiar characters, but it is not the active principle of the plant. That is an alkaloid* met with in the leaves and existing also in the branches. MM. Bochefontaine and Galippe, and afterwards Guido Tezzoni and Chiacconi, have shown that it was seated in the bark. According to their researches the wood of the branches deprived of bark is devoid of all physiological action. The experiments that have been made with *Pilocarpus pinnatus* may be grouped as follows:—(1) Study of the action of infusions or extracts of the leaves or stems; (2) The examination of their chemical composition; (3) Study of the various bodies that enter into the composition of the plant.

1. *Physiological Action of Infusions of P. pinnatus.*—The leaves and stems of this plant have a remarkable action upon the system. An infusion, of the strength of 3 to 4 grams to 100 or 150 c.c. of water, has an agreeable odour, recalling that of camomile; it has a sweet taste, and its physiological effects are very energetic and prompt upon most subjects. It is rarely necessary to exceed this dose; frequently it is rather too strong and leads to symptoms of intolerance that are not serious.

Soon after the infusion has been introduced into the system, often after only a few minutes, an abundant sweating is produced, and generally prolonged during several hours. The sweat runs over the face and all parts of the body, without causing either lassitude or fatigue. A method has been employed to give an idea of the amount of transpiration, which, however, is only approximative. The trunk and limbs of a patient were enveloped in an impermeable covering, and after several hours the quantity of sweat collected amounted to a litre, and even more in some cases.

To ascertain whether the liquids secreted under the influence of jaborandi have been modified in their composition, MM. Hardy and Ball† examined the urine, saliva, and sweat. They found that the quantity of urea excreted in the urine was diminished, that the saliva contained only a trace of urea, and that the sweat showed the presence of a large proportion of urea. But the amount of urea excreted in the sweat added to that eliminated in the urine did not equal the quantity of urea present in the urine before the experiment.

Pilocarpus pinnatus produces other effects also which, without being so constant or remarkable, are worthy of note. It provokes hypersecretion of the nasal and bronchial mucus, and that of the lachrymal passages; sometimes its administration is followed by nausea and vomiting, and it causes diarrhœa. It has been employed by Messrs. Sydney Ringer and Gould to increase the secretion of milk. It decreases the power of accommodation of the eye at certain distances. These results are most striking when operating on animals. When the infusion is injected into the femoral vein of an animal, tubes being previously fixed in the Steno's and Wharton's ducts, the quantity of saliva secreted is fifteen to twenty times greater than that secreted by the animal in the normal state. But not only the salivary glands are influenced by this medicine. Upon fixing the tubes in the biliary and pancreatic ducts, or in one of the ureters, it is found that the secretion of the liver, pancreas, or kidney is five times greater than the normal quantity. These phenomena are accompanied by a considerable slackening in the beats of the heart.

* Hardy, *Comptes Rendus de la Société de Biologie*, March, 1876.

† *Comptes Rendus Soc. Biologie*, 1874, p. 342.

One of the most remarkable of the properties of *Pilocarpus pinnatus* is its action antagonistic to the salts of atropine. MM. Vulpian and Carville found that when infusion of jaborandi leaves was injected into the leg of a dog having a tube fixed in Wharton's passage, the salivary secretion was increased after a few minutes and the number of heart beats diminished. The injection of a solution of atropine under the skin of the animal was sufficient to arrest the hypersecretion and to cause the beats of the heart to recover their normal rhythm.

2. *Chemical Composition.*—The leaves and stems of *Pilocarpus pinnatus* have a complex chemical composition. They contain an essential oil, a peculiar alkaloid (pilocarpine), and various salts.*

Submitted to distillation with water, the leaves yield an essential oil which is easily collected. Ten kilograms of the leaves gave 56 grams of crude essence; this essence, fractionally distilled, yielded a hydrocarbon boiling at 178° C., a substance passing over at 250° C., and a third product which distilled at a still higher temperature and after a time formed a solid transparent mass.

Pilocarpene, the hydrocarbon boiling at 178°, is a colourless, transparent, mobile liquid, having a peculiar and rather agreeable odour, and is lighter than water. Its sp. gr. at 18° C. is 0·852. It rotates the plane of polarized light to the right, its rotatory power for the D ray being $\alpha_D = + 1{\cdot}21$. Its composition corresponds to the formula $C_{10}H_{16}$. It forms with hydrochloric acid a solid and a liquid bihydrochlorate, both corresponding to the formula $C_{10}H_{16}2HCl$. They are obtained by passing a current of dry hydrochloric acid into the pilocarpine or a mixture of it with ether.

The solid hydrochlorate is a crystallizable colourless transparent body, melting at 49·5°. It crystallizes immediately when a crystal of hydrochlorate of terebinthine is added to its saturated solutions. With solution of perchloride of iron it gives the successively rose, red, and blue colours characteristic of the bihydrochlorate. The author is certain that there is no monohydrochlorate or artifical camphor produced during the reaction.

In its boiling point, and some of its characters, the essential oil of *Pilocarpus* appears to approach the isoterebenthenes, and on the whole it presents a great analogy with oil of citron.

The active principle of *Pilocarpus pinnatus*, or "pilocarpine," has been obtained by various methods.† One way is to make from the leaves and stems an aqueous and an alcoholic extract successively; these are treated with water and then precipitated with ammoniacal acetate of lead. After filtering, excess of lead is removed by sulphuretted hydrogen, leaving an uncrystallizable acetate of pilocarpine. Bichloride of mercury is added to the solution, which precipitates a double salt of mercury and pilocarpine, and by decomposing the precipitate with sulphuretted hydrogen a solution of hydrochlorate of pilocarpine is obtained. To set free the base the salt is decomposed by ammonia in the presence of an excess of chloroform. Upon evaporation of the chloroform the free pilocarpine is left behind.

A more simple method of obtaining the pilocarpine is to make an infusion of the leaves of the plant, reduce it to a syrupy consistence, mix it with an excess of magnesia, evaporate to dryness, treat the mixture with

* Hardy, *Comptes Rendus de la Soc. Biologie*, 1875, p. 109.

† Hardy, *Bull. de la Soc. Chim*, vol. xxiv., p. 497.

chloroform, evaporate the chloroform and take up the residue with water.

Upon placing the solution in a vacuum, the water is disengaged and the base remains in the free state as a colourless viscous mass, soluble in water and alcohol.

With hydrochloric, sulphuric, and nitric acids pilocarpine gives crystalline salts; with acetic and oxalic acids it forms compounds that do not appear to be crystallizable. Hydrochlorate of pilocarpine gives with chloride of platinum a precipitate soluble in water, which is deposited upon evaporation in perfectly crystallized golden yellow plates.

Since the publication of these methods of extraction, M. Duquesnel, in France, and Mr. Gerrard, in England, have proposed other methods by which they obtain also a semi-liquid alkaloid and crystalline salts.

3. *Physiological Action of Pilocarpine.*—Numerous experiments made by MM. Hardy and Bochefontaine have shown that pilocarpine has a physiological action upon the heart and the glands similar to that of the infusion of jaborandi. The injection of a solution of pilocarpine into the foot of a frog, the heart of which had been exposed, arrested the movements of the heart, and when they were nearly stayed the introduction of sulphate of atropine into the other foot was sufficient to re-establish the action. Injected into the veins of a dog, a tube being introduced into Wharton's duct, pilocarpine induced in a few minutes a flow of saliva that continued during several hours. The injection of a salt of atropine under the skin of the animal arrested in a few moments this morbid secretion. In another dog, curarized and subjected to artificial respiration, tubes were placed in Wharton's duct, the biliary duct, Wirsung's duct and one of the ureters, then the number of drops of liquid running from the first three passages was noted, and the cardiac contractions. 0·06 gram of hydrochlorate of pilocarpine was then injected. Twenty seconds afterwards the secretion augmented considerably, the submaxillary glands secreting thirty drops of saliva per minute; the contractions of the ureter were nearly doubled, the beats of the heart were diminished by one-third.

With man, according to P. Dumas, the temperature decreases during the administration of hydrochlorate of pilocarpine; on the day following or the evening of the day on which the medicine has been taken it is always below that of the commencement. It decreases especially during the first hour; during the two or three hours in which the medicine is most active it remains stationary, but it never increases. Five or ten minutes—fifteen minutes at most—after the injection of the hydrochlorate salivation becomes manifest; it continues to increase and attains its maximum after about half an hour; it then diminishes and ceases after about another half hour. The sudation generally manifests itself when the salivation begins to decrease; in half an hour it attains its greatest intensity, and diminishes in three or four hours. Sometimes the salivation has been observed to reappear upon the stoppage of the sweating.

The mixed saliva secreted under the influence of hydrochlorate of pilocarpine has a greater density than normal saliva, from 1004 to 1015; it becomes also more stringy and viscous. This change in the composition of the saliva is explained by supposing that the hydrochlorate acts specially upon the submaxillary and sublingual glands, which produce a thick and ropy saliva, and has no action upon the parotid gland, the secretion of which is clear and limpid.

The employment of *Pilocarpus* is extending and increasing quantities of it are being imported from America. But the question arises whether the material consists of the leaves and stems of a single species, or of those of several varieties possessing analogous, or perhaps slightly varying properties. Several species of *Pilocarpus* grow in our conservatories, and among the most interesting are *P. pinnatus* and *P. simplex*. The physiological study of these two plants has shown that they possess properties similar to those of the leaves and stems actually imported from Brazil.

A first experiment was made with a single leaf of *P. pinnatus*, gathered in the conservatory of the Jardin des Plantes. An infusion of this leaf contained an alkaloid which was easily detected by the use of proper reagents. The solution was reduced to a small volume and injected into the femoral vein of dog, previously chloralized; five minutes afterwards the salivary liquid appeared and the flow continued upwards of an hour.

Another experiment was made with an infusion of the leaves of *P. simplex*. The presence of an alkaloid in the aqueous infusion was shown by reagents, and two minutes after injection into the femoral vein saliva appeared at the end of a tube fixed in Wharton's duct.

It was previously ascertained that the injection of a small quantity of water by itself had almost no influence.

So far as the action upon the salivary secretion these results are analogous to those obtained with the *P. pinnatus* from Brazil. The sudorific effects could only be tested upon man; but, unfortunately, it was then impossible to deprive the young shrubs of any more leaves. The author, however, thinks the preceding facts justify him in affirming that the *Pilocarpus* plants raised in conservatories preserve the same physiological properties as those which grow in tropical countries.

The acclimatization of these shrubs in Europe presents great interest; the author thinks their efficacy as a medicine would not be modified. The species of *Pilocarpus* possess a botanical character and chemical composition which bring them near to species of *Citrus*, and favour the belief that they would grow in the same soils. Moreover, a knowledge of the place of their origin facilitates the placing of them in similar conditions. The *Pilocarpus pinnatus* grows in the equatorial regions of Brazil, remote from places exposed to burning heats; it seeks a soft climate, modified by vegetation, gentle breezes, and elevation of the soil. The surrounding temperature never rises above 36° C.; the difference between day and night is about twelve degrees; that between winter and summer is only a few degrees. The rains commence in autumn and last until June; humidity stimulates its vegetation. Other species of *Pilocarpus* grow in Brazil in colder regions, and resist better the inclemency of the seasons. *P. simplex* is more robust; other species seem still more so, and very probably their physiological action would not be less efficacious. When the *Pilocarpus* is raised in conservatories a temperature of 25° C. is considered necessary for their development; perhaps a lower temperature, if constant, would suffice. Their multiplication would appear to be facilitated by their being reproduced easily by either cuttings or by seeds. The cuttings should be placed under a layer and covered with a bell-glass until they have struck. The sowings should be made at the bottom of drained pots and put under a layer. The seeds only require to be one-half to one inch under a friable and sufficiently moist earth—peat is preferable—and the watering should be rather frequent. No difficulty is met with in the growth of these shrubs in conservatories, and it is believed that acclimatization experiments made at a similar altitude and temperature, and in a soil of the same nature as that in their native country, would meet with full success. They climatic conditions can be met with in the south of France upon spots sufficiently sheltered and humid. They occur more numerously still in certain parts of Algeria, the latitude of which approaches that of the equatorial regions. The author, therefore, brings the subject before the Société d'Acclimatation in the hope that by the acclimatization of the *Pilocarpus pinnatus*, or neighbouring species, France may be enriched by the possession of this valuable medicine.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 16, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

INDIAN QUININE.

ACCORDING to the last reports we published respecting the cultivation of cinchona in India, a very glowing account was given of the results that had been obtained at the plantations at Darjeeling, and great anticipations were held out as to the probable value of the mixed alkaloids that were prepared from the bark grown in that district.

As we then stated a considerable quantity of this mixed alkaloid was sent to medical officers in various parts of India for the purpose of having the preparation practically tried in the treatment of fever, and the results reported upon. We have now received a copy of the *Neilgherry Courier* of the 7th November, containing a report addressed to the Chief Secretary of the Indian Government, by Surgeon-General G. SMITH, of the Indian Medical Department, in which a summary is given of the reports which have been sent regarding the effects of the Darjeeling preparations of mixed cinchona alkaloids in the treatment of fever. It appears that two pounds of the drug were sent to twelve hospitals and that reports have come in from ten of them. The drug is described as being a fine brownish powder, somewhat gritty and astringent in the mouth and having a strong bitter taste, insoluble in water, but completely soluble in about four times its weight of dilute sulphuric acid.

The doses in which this preparation has been administered ranged from five to twenty-five grains, and the total quantity given in each case in which a cure was effected varied from 30 to 120 grains. In large doses it was found to produce the usual symptoms of cinchonism, and in various instances it produced, even in moderate doses, vomiting and other signs of considerable gastric irritation. In referring to these disagreeable effects, the Civil Surgeon at Cochin, an officer of long experience, says that "if the patient can *tolerate* the medicine, I believe it will probably stop the fever, but I found it to produce so much sickness, giddiness, and prostration, that, as far as my experience goes, I would not recommend it for general use, as long as quinine and the other febrifuge preparations of bark can be procured." It is suggested in the reports of Surgeon-General SMITH that the insolubility of the drug is probably the main cause of the marked gastric disturbance which it induces and that although it may be dissolved by acid, the large quantity that is requisite for this purpose makes the administration of the drug, in many instances, highly objectionable. In an experiment made in his presence three drachms of dilute hydrochloric acid failed to make one drachm of the powder dissolve in two ounces of water. This character of sparing solubility he considers to be very objectionable, and, together with the tendency to cause gastric irritation, sufficient to prevent the general use of the preparation in India as a febrifuge. It is also deserving of notice that of sixteen cases of fever treated with this preparation at Salene and thirteen cases treated at Cochin five and four of the patients absconded after getting one or more doses, the inference being that they were alarmed at the effects produced. With few exceptions, the whole of the trials were made in cases of mild uncomplicated intermittent fever, the paroxysms of which are easily arrested by the ordinary preparations of bark. In a more complicated case the powder induced diarrhœa, but a cure was effected by resorting to quinine. On the whole, therefore, Surgeon-General SMITH comes to the conclusion that the results obtained in the trial of the new preparation have not been satisfactory, and consequently he is not able to recommend a continuance of its use.

The following is a summary of the remarks in the reports of the several medical officers upon which bases the foregoing conclusion was arrived at:—

General Hospital.—Was used solely in such cases as are usually treated with quinine in doses of from 15 to 25 grains in solution with acid. Has every reason to be satisfied with its power as antiperiodic. It was also given, with benefit, in large doses in low continued fever. Found at times to disagree with the patient. The first dose may induce vomiting, but not subsequent doses, which are retained on the stomach: no action on the bowels.

Monegar Choultry.—Reports thirteen cases of fever in which the drug was used, and in eleven of these, of a mild intermittent type, it affected a cure. Two of the cases were complicated with enlargement of the spleen, and in these the powder had no effect. Quinine was then resorted to with marked benefit. In two cases it appeared to bring on diarrhœa, the passing of the motions being attended with severe gripping pain. Produces decided cinchonism.

Royapettah Hospital.—Tried in several cases and not found superior to any of the cinchona alkaloids given separately.

Rajahmundry.—Treated mild and uncomplicated cases of ague with the febrifuge. Results on the whole favourable, but doubts its efficacy in severe cases, compared with quinine. The average quantity of the drug required to completely subdue an attack was 85·27 grains, and the average number of days under treatment 5·77.

Guntoor.—In slight cases of fever seems to act fairly well, but in severe and urgent cases it altogether failed, having, when given frequently in five grain doses, caused incessant vomiting. Used hypodermically had no effect on fever, and seemed to disagree.

Under these circumstances it is likely that the three tons of mixed alkaloids intended to be manufactured during the present year will be too literally a drug in the market, and that we have thus an additional reason for congratulating Mr. WOOD on his recent appointment as Professor of Chemistry at the Calcutta Medical College.

GLASGOW CHEMISTS' RETAIL PRICE LIST.

WE are glad to notice numerous indications that chemists and druggists in different parts of the country are showing an increased disposition to come to an understanding as to the charges that should be made in their respective localities, for drugs, prescriptions, etc. Pharmacists have too long trusted alone to their customers for information as to the prices charged by their neighbours; the customers have sometimes been, perhaps, not so exact as they might have been in their statements, and the result has been considerable heartburning and dissatisfaction, which has manifested itself frequently in strongly worded epistles, sent to this and other journals. The work performed by the committees that have been entrusted with the task of drawing up "price lists" has generally met with acceptance. In fact, we have this week been favoured with a copy of the fourth edition of the price list compiled by a committee appointed at a general meeting of chemists and druggists of Glasgow and its neighbourhood. The Manchester price list, issued by the council of the local association, has reached a second edition, and one which resembles it in many respects was a short time since issued by the newly formed association at Plymouth. It is satisfactory to find that although, as might be expected, the prices vary in these lists, there is considerable similarity in the general rules laid down in them, and the adoption of the same private trade price mark will much advance the object in view.

We believe that copies of the new edition of the Glasgow price list may be obtained from Mr. J. A. CLARKE, Convenor of the Committee, 132, London Street, Glasgow.

PROPOSED ACCLIMATIZATION EXPERIMENTS IN PERU.

M. MARTINET, writing from Lima, in Peru, to the Paris Acclimatization Society, calls attention to the advantages that might result from an attempt to acclimatize in the Lima district the better kinds of Bolivian and Carabayan barks, giving to the plants the same care in cultivation as the English give to those in their stations in the Himalaya, Ootacamund, etc. It appears that the proposition has been made to the Peruvian Government, and actually accepted in principle, but the financial crisis through which the country is passing has prevented any attempt to carry out the experiment.

M. MARTINET says that the rich cinchona forests in Bolivia and Southern Peru, where the Calisaya is found, are becoming further and further removed from the coast. No attempt is ever made to restock the nearer forests in the cinchoniferous zone with these valuable trees, and now the nearest forests are upwards of ten days' march from inhabited districts. The convex portion of the arc described by the cinchoniferous zone is, it is true, scarcely sixty leagues from Lima, and will soon be connected with it by the trans-andean railway, but in this district only cinchonas poor in alkaloids at present grow.

M. MARTINET also describes an unsuccessful attempt that has been made in Lima to acclimatize the coca plant (*Erythroxylon Coca*). The change from the warm and humid climate of the interior of Peru was too great; the nights, even in the hot season, being far too cold. Of one hundred plants planted in the open air one-half died during the first winter, and the remainder disappeared during the next two years. Some plants kept in conservatories flowered when four years and a half old; they were then about four feet high, but not robust.

COCHINEAL FROM THE CANARIES.

THE evil of making haste to be rich appears to have received a fresh illustration in the Canaries. Mr. Vice-Consul WETHERELL says that the prosperity of the Island of Grand Canary has undergone a serious decline, principally in consequence of the depreciation of cochineal, now the principal product of the country. Between July 1, 1874, and June 30, 1875, the quantity exported was nearly 3,000,000 pounds, valued at nearly £300,000 sterling. The large profits realized from cochineal in former years led to the exclusive cultivation of the cactus wherever it would grow. The profits were as a rule squandered before even they were realized. Soon the value of cochineal declined; but, although at last yielding little or no profit, the growers cannot realize the necessity for cutting down the cactuses, which to them represent so much capital, and replacing them with other crops. The production therefore continues to increase in the face of falling prices.

In the palmy days of cochineal, it was an object of competition amongst shippers as furnishing almost the only return cargo available in the island. Sometimes therefore they were induced to bid a higher price for it than it was actually worth. But some of them were equal to the occasion; by paying for their cochineal in coin made of platinum coated with gold, which was purchased in Barcelona for 28 per cent. of its nominal value, they got their cochineal at a low price and added largely to the ruin of the island.

THE CHRISTMAS HOLIDAYS.

WE are requested to state that the Library and Museum will be closed from Saturday, December 23rd, to Monday, January 1st, both days inclusive. The School of Pharmacy will be closed during the same period.

ERRATA.—We are informed by the Solicitors to the Pharmaceutical Society that the medical man, who in the recent case of the *Pharmaceutical Society* v. *Mickle* deposed that he had purchased the defendant's business, stated that his name was AUGUSTUS HENRY CHURCHILL, not GEORGE AUGUSTUS CHURCHILL, as reported.

On p. 479, in the list of Associates elected, the first name should have been, "FERRIDAY EDWIN JOSEPH PITCHFORD, Oakengates.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting of this Association was held at Britannia Chambers, Pelham Street, on Monday, the 11th inst. The President, Mr. J. H. Atherton, F.C.S., occupied the chair, and there was a large attendance of members and associates. The Hon. Secretary (Mr. R. Jackson), read the minutes of the last meeting (which were confirmed), and announced that the *Pharmaceutical Journal* had been received regularly, and on the motion of the President a vote of thanks was awarded to the donors.

Mr. H. Major, B.A., B.Sc., then delivered a lecture on "The Senses." In commencing, the lecturer said the great difference between the higher and lower animals lay in their senses, the lower animals not having distinct organs for the different senses as in the higher. Man, the highest and noblest animal, has six senses, which he placed in the following order:—muscular consciousness, touch, taste, smell, hearing, and sight. He remarked that there are no sharp contrasts in Nature, that she abhors sudden jumps, consequently the senses merged almost imperceptibly into one another. He placed muscular consciousness lowest, because it is not confined to any particular member, but is diffused through the whole system; next he placed the sense of touch which is confined to the outward part of the body, and is not felt inwardly; taste, the next sense, is more localized being only felt at the back part of the mouth, and the lecturer showed that nothing can be tasted which is not capable of being dissolved and so passed through the membranous covering of the mouth and tongue. Of smell, the next sense treated, he remarked it is more limited and localized still, being confined to the nostril, and only such subjects are smelt as can be oxidized. He called attention to the intimate connection existing between touch and taste and smell, saying that the two latter had been called sentinels to the passage of the body, because they gave instant warning of the approach of injurious things, such as foul air for instance. The next sense is that of hearing, the organ of which is very complicated and very localized, the sensation which affects it being a vibration of the atmosphere which strikes on the drum of the ear and is thence carried to the brain. The last and highest sense being sight, which he described as being the nearest approach of physical to vital force. The lecturer showed how very inferior man is to some of the lower animals in his senses, being only superior in his sense, and gave as instances the acute sense of sight possessed by the vulture and scent by the bloodhound, and concluded a most eloquent and able lecture amid loud applause.

A hearty vote of thanks to Mr. Major, proposed by Mr. Rayner, seconded by Mr. T. B. Fletcher, and supported by the President, brought an agreeable and instructive evening to a close.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday 7th December, 1876, Dr. J. H. Gladstone, F.R.S., Vice-President, in the chair. After the names of the visitors had been announced and the minutes of the previous meeting read and confirmed, the following names were read for the first time:—Messrs. W. Hampton, J. Napier, D. W. Vadle, J. C. Leach, and W. V. Ellis. Messrs. Walter Charles Davis, John Clark, Frank Herbert Marshall, John Wood, Griffith Jones, B.A., John Falconer King, and Charles Cecil Capel, were elected fellows of the Society by ballot after their names had been read for the third time.

The first communication was by Professor A. H. Church, "On Colein." This, the red colouring matter existing in the stems and leaves of the *Coleus Verschaffellii*, was prepared from the bruised stems by exhausting them with cold alcohol, slightly acidulated with sulphuric acid, removing the acid by barium carbonate, and concentrating by distillation. Various processes were tried for the purification of the red colouring matter, the best being to dissolve it in alcohol, precipitate with ether, again dissolve in alcohol, and pour the solution into water, repeatedly washing the precipitate with water at 50°–60° C. On analysis it gave numbers corresponding with the formula $C_{10}H_{10}O_3$; this was confirmed by the results obtained from the lead compound, $C_{20}H_{18}PbO_4$. This was prepared by precipitating the colein with excess of lead acetate, both in alcoholic solution. It is of a dull indigo blue colour. Colein is insoluble in ether, only slightly soluble in water, but readily in alcohol, yielding a solution, which is at first crimson, but fades rapidly, owing to a combination taking place between the alcohol and the colouring matter. On evaporating the nearly colourless solution, or on adding an acid, the crimson colour is restored however. By gradually adding ammonia to a solution of colein, the colour is changed successively to purple, violet, indigo, chrome green, and finally to greyish-yellow. Stannic chloride gives a precipitate of a beautiful violet colour, when added to a strong alcoholic solution of colein. The author also described and exhibited the spectra of colein, both in a pure state and also when submitted to the action of various reagents.

The Chairman having thanked Professor Church for his interesting paper, a member said that when working with ivy he had extracted a colouring matter from the pericarps of the fruit, which appeared to be analagous if not identical with the colein of Professor Church. Its colour was intensified by the addition of acids, whilst alkalies on the contrary change it.

Mr. Prosjean, in reference to the author's remark as to the close resemblance between the colouring matter of the grape and colein, stated that when determining the value of red argol, he had noticed that the colouring matter present gave a very sharp reaction with alkalies, almost as distinct in fact as litmus. In this case, however, the yellowish tint produced by a slight excess of soda was again changed to red on the addition of an acid, whilst colein appears to be decomposed, as the colour when once changed by an alkali does not come back.

Dr. Otto Webb made a short verbal communication on "Phenylene Diamine." This was prepared by the action of reducing agents on dinitrobenzene, and is employed in the manufacture of the brown dye known as "Vesuvine." It may be obtained from the solution as a crystalline hydrochloride, after the removal of the lime by oxalic acid. On distilling the hydrochloride with lime the phenylene diamine passes over. It is a colourless crystalline substance which, however, rapidly becomes dark coloured on exposure to the air. The author has obtained the diacetyl compound, and also several brominated derivatives of the latter. He hoped soon to lay before the Society a detailed account of the manner of preparation and the properties of these compounds.

Dr. Gladstone, having thanked the author in the name of the Fellows, the Secretary read a paper by Mr. J. B. Hannay, "On Calcium Sulphate." The paper contains a description of various double and triple salts containing $CaSO_4$, which were deposited in the interior of pipes in a manufactory. Solutions circulated through these pipes containing simultaneously, potassium sulphate, sodium sulphate, magnesium sulphate, and yellow chromate of potassium, the last being in by far the largest proportion. The temperature of the liquids varied from 40° to 80° C. In one instance most of the incrustation consisted of $CaK_2(SO_4)_2+H_2O$, but there were also present two other compounds, $CaSO_4$, $K_2CrO_4+H_2O$, and $CaSO_4$, $2K_2CrO_4$. They were both of a bright golden colour, resembling lead iodide, and very similar in appearance. By the action of water they were decomposed, the potassium dissolving out, and leaving calcium sulphate, but without any change in the form of the crystal. In another pipe where there were large quantities of the salt $CaNa_2(SO_4)_2$, a salt having the formula $CaSO_4$, Na_2SO_4, $K_2CrO_4+H_2O$ or some multiple of this was found. The author has also made several experiments to ascertain if the following series of compounds existed:—

$$2\,CaSO_4+4\,H_2O$$
$$2\,CaSO_4+3\,H_2O$$
$$2\,CaSO_4+2\,H_2O$$
$$2\,CaSO_4+\ \ H_2O$$

The first of these is deposited when a solution of calcium sulphate is evaporated at 100° C. under the ordinary pressure, and the last by evaporatiou under a pressure of 90 lbs. to the square inch. No definite results could be obtained at intermediate pressures. On heating $CaSO_4+4\,H_2O$ (pure selenite) to 118° it begins to lose water at 150°. The loss indicated the formation of $2CaSO_4+H_2O$; at 190° the last molecule of water is driven off. By heating the selenite, first at 118° to start the dissociation, and then at 100° for a long time, indications were obtained of the existence of $2\,CaSO_4+3\,H_2O$, but none of the compound $2\,CaSO_4+2\,H_2O$.

Dr. H. E. Armstrong said he had made some experiments with a view to ascertain if there was any relation between the loss of water experienced by certain isomorphous salts under precisely similar circumstances. He had found that at the ordinary temperature over sulphuric acid the sulphate of zinc, magnesium, nickel, and iron, parted with their water of crystallization in ratios represented by the numbers Zn ·7460; Mg 2686; Ni ·1570; and Fe ·4013. With potash and chrome alums the ratios were K ·0865 and Ca ·4625, the nitrates of cobalt, nickel, and manganese gave Co ·272, Ni ·032 and Mn ·210.

The Chairman having thanked the author for his paper and Dr. Armstrong for his interesting observations, Mr. G. S. Johnson read some "Additional Notes on Potassium Triodide," consisting of a corrected determination of the specific gravity of the crystals, which was found to be 3·498, and the atomic volume, which is 120·2. The theoretical number calculated on the supposition that an atom of potassium unites with three of iodine without condensation is 122 2.

The meeting was then adjourned until Thursday 21st December, when Mr. W. N. Hartley will give a paper entitled "A Further Study of Fluid Cavities."

ROYAL SOCIETY.

CHEMICAL WORK DONE ON BOARD H.M.S. 'CHALLENGER.'

BY J. Y. BUCHANAN.*

(Concluded from p. 463.)

Observations on the occurrence of Manganese Nodules on the Sea-bottom.

Occasionally pieces of stone of a black colour have been brought up, and been found to consist of peroxide of manganese mainly. Several interesting specimens were obtained between Bermuda and the Azores, which were apparently steps in the formation of the black substance out of concretions of the bottom at the place in question. They were obtained on the 17th and 27th June, and may be divided into four classes:—1st, those which contain no manganese at all; 2nd, those where the manganese formation has commenced; 3rd, those where it is well advanced; and 4th, those where the bulk of the substance is peroxide of manganese. Those of the first class are, as far as can be learned from qualitative analysis and microscopical examination, merely mechanical aggregations of the bottom existing at the place in question. Of a white colour, and generally the same appearance, are those of the second class; they contain, however, numerous perforations, whose walls are lined with a very thin black film peculiarly striped. On treating with dilute hydrochloric acid, the mass is found to consist chiefly of carbonate of lime with a considerable quantity of clay. Strong hydrochloric acid decomposes the latter, when a certain amount of chlorine is given off. In another concretion, belonging to the same class, the manganese is seen forming in minute mammillary concretions on the outside surface, as well as on the tube linings. Belonging to the third class is one (also brought up on the 27th June) where the outside is wholly covered with oxide of manganese; and in cutting through the substance of the stone, the layer is seen to be of a sensible thickness; also all the worm-holes are seen to be completely coated; and numerous more minute holes are found, all of which are coated in the same way. A very considerable percentage of the whole mass has thus become manganese. On the face of a fresh cutting the interior of the mass may be seen to preserve its white colour. From the edge of the black layer inwards, however, the mass is stained of a brownish colour, which gradually disappears towards the centre. Blackish brown veins are also seen to traverse the whole mass. Pulverized, it effervesces strongly with dilute hydrochloric acid. The residue is easily decomposed by strong acid, evolving large quantities of chlorine; silica is left undissolved with a little sand. In the hydrochloric acid solution there was found, besides alumina, manganese, and a little iron, a certain quantity of nickel and cobalt. A concretion of the fourth class came up on the 17th June. It is an irregular nodule, about 1½ inch long, of a brownish-black colour, having its outside surface mammillated all over. This mammillated surface is so peculiar that, by its means, the manganese may be at once recognized. When broken it is found to consist of irregularly concentric layers of peroxide of manganese, alternating with fine seams of calcareous and earthy matter. It contains a small, white, earthy nucleus. The broken surface resembles the figuring of polished walnut wood. It consists of peroxide of manganese, alumina, iron, silica, small quantity of lime, magnesia, cobalt, and phosphoric acid. Heated in the tube it gives out, like all these concretions, water with a strong alkaline reaction.

The most remarkable occurrence of peroxide of manganese on the bottom was met with on the 18th February, in latitude 35° 45′ N. and longitude 20° 12′ W. The dredge was put over in 1500 fathoms, and came up full of dead coral of a jet-black colour on the surface. Some of the sticks adhered to large black masses, and on breaking them the inside was seen to be perfectly white, the black substance forming merely a very thin rind which cracked off easily on receiving a smart blow. This black rind, as well as the masses to which some of the sticks were attached, consisted of peroxide of manganese, the white part or inside having the composition of ordinary coral (chiefly carbonate of lime). The black masses to which some of the sticks were attached present, like the concretions already described, a minutely mammillated appearance on the outside, and when broken across are seen to consist of concentric layers, blacker and more compact towards the outside, and browner and more earthy towards the inside. The layers are separated from each other by numerous very fine layers of mud, chiefly carbonate of lime. They increase in number towards the inside, and in some instances can be seen to be composed in part of fragments of foraminiferous shells. The black mass was found on analysis to consist of peroxide of manganese, alumina, oxide of iron, silica, small quantities of lime and magnesia, and traces of copper, cobalt, and phosphate of lime. Compared with the manganese concretions already described, they appear to have the same chemical composition, and their internal structure in layers points to a similar mechanical origin; in fact they

* From the 'Proceedings of the Royal Society,'

differ from the others only in being fragments of much larger concretions. Where the coral sticks adhere, they do not penetrate into the mass at all, but their flat roots are as sharply divided from the black mass as the black rind is from the inside coral.

On the 27th June, amongst the concretions, a fragment of slate, coated on the outside with mammillated peroxide of manganese, was brought up.

The preceding notes on the occurrence of the manganese nodules was written at the Cape of Good Hope, and sums up our knowledge of the subject at the close of the Atlantic cruise. In the Antarctic Ocean the soundings obtained showed in a remarkable manner the general comparative shallowness, the depth being in general under 2000 fathoms. Whenever the dredge or trawl was used in that ocean it brought up large quantities of stones; but they were invariably fragments, more or less rounded, of granitic and igneous rocks, and I did not notice any manganese. On the 13th of March, however, when approaching Australia, the depth increased to 2600 fathoms; a very large haul of manganese nodules was obtained, presenting the same general characteristics as those in the Atlantic. In the Pacific the amount of manganese found has been immense, there being hardly a sounding where it could not be detected in small particles amongst the mud; and, indeed, in many parts the nodules occur in such quantity that the sounding-tube has brought them up in considerable numbers at one time; they have also frequently come up sticking to the bottom of the water-bottle. Here, however, they have chiefly come under the observation of my colleague, Mr. Murray, and will be treated of in his report. Chemically they are very much alike, as far as qualitative analysis can supply information. They all contain one of the higher oxides of manganese in preponderating amount, cobalt and nickel in notable quantity, and copper in traces, besides argillaceous and often sandy matter. I hope, when the cruise is over, to be able, by means of quantitative analysis, to render a detailed account of their nature, from which it may perhaps be possible to obtain some hints as to their origin and development.

Since the discovery of this most remarkable and unexpected occurrence of a mineral, having much resemblance to psilomelate, evidently forming at the bottom of the sea, I have taken every opportunity of examining specimens of peroxide of manganese from terrestrial sources; and in many cases I have found them to resemble the marine mineral in several points, especially in nodular structure and in giving off alkaline water when heated. Some peroxide of manganese which I got from the mines near Paarl, about thirty miles from Cape Town, had most perfectly nodular structure, but was extremely hard, whereas our nodules, when freshly brought up, can generally, although not invariably, be easily cut with a knife; but they increase very markedly in hardness when exposed to tke air, even for only a few weeks. I do not attach very much importance to the fact of its giving out alkaline water, for this is a property which I have found to be very generally possessed by rocks and minerals. Of the zeolites, for instance, which were found in Kerguelen, there was not one which did not give out alkaline water with a very perceptible empyreumatic smell when heated.

It has been mentioned above that the dredge frequently brought up large quantities of stones in the Antarctic Ocean. Amongst them were almost invariably fragments of granite or syenite, as well as of both basalt and trachyte. On the 2nd February, 1874, when between Kerguelen and Heard Islands, a very large quantity of stones was brought up in the dredge from a depth of 150 fathoms. Amongst them were a piece of granite, also two varieties of basalt, one coarse-grained with porphyritic olivine, and the other exceedingly fine-grained and compact, without any separate crystals being visible to the naked eye. It was chiefly remarkable from the fact that the stones, though fresh from the bottom and still quite wet outside, were, when broken, perfectly dry inside, the moisture not having penetrated beyond the thickness of a sheet of paper. The edges of these stones were less rounded than those of the other species which accompanied them. In order to be perfectly sure that there was no mistake, I broke about a dozen of them, the species being easily recognized by the edges of the stones being less rounded than those of the others and always with the same result; while those of the other species were not only wet inside, but, especially in the trachytic ones, decomposition in concentric shells had made considerable advances. As a drop of water applied to the fractured face was readily and quickly absorbed I can only account for the dryness inside by considering that the stones in question had passed but a very short time under water. As they were found in latitude 52° S., and the first iceberg was only met with in 60° S., it would be difficult to imagine that they had come ice-borne from the Antartic land; at the same time it was equally difficult to imagine any other adequate means of conveyance than ice. I believe that they come from Heard Island, whose ice-bound shores are constantly despatching miniature bergs into the sea, which, from their insignificant size, would suffer rapid destruction alike from the violence of the seas and from the temperature of the water, which, on the occasion in question, was between 3° and 4° C. Many small ice-masses, such as I have supposed, were floating off the southern shore of Corinthian Bay, which on this side had a continuous icy coast line formed by a glacier descending from the central high grounds which culminate in Kaiser Wilhelm Peak, and reaching the sea both on the west and on the east side of the inhabited isthmus, as I have described in my short note on the island. The position where the stones were dredged is within 100 miles of Heard Island, and through the above mentioned agency there must be a constant conveyance of the *débris* of the island out to sea, which would account for the very stony character of the bottom found.

Observations on Sea-water Ice.

Many different opinions have been expressed as to the nature of ice resulting from the freezing of sea-water, all agreeing, however, in one point, that when melted the water is unfit to drink. During the Antarctic cruise I took an opportunity of examining some of the broken pack-ice, into which the ship made an excursion on the morning of the 25th of February, and also some ice which had formed over night in a bucket of sea-water left outside the laboratory port.

The piece of pack-ice which I examined was in substance clear, with many air-bells, most of them irregularly shaped. Two portions of this ice were allowed to melt at the temperature of the laboratory, which ranged from 2° to 7° C. The melting thus took place very slowly, and made it possible to examine the water fractionally. My experiments consisted in determining the chlorine in the water by means of tenth-normal nitrate of silver solution, and observing the temperature of the ice when melting.

A lump, which when melted was found to measure 625 cub. centims., was allowed to melt gradually in a porcelain dish. When about 100 cub. centims. had melted, 50 cub. centims. were taken for the determination of the chlorine; they required 13·6 cub. centims. silver solution, corresponding to 0·0483 gramme chlorine. When 560 cub. centims. had melted, 50 cub. centims. were titrated, and required 1·6 cub. centim. silver solution, corresponding to 0·0057 gramme chlorine. The remainder (65 cub. centims.) of the ice was then melted and 60 cub. centims. titrated; they required 0·39 cub. centim. silver solution, corresponding to 0·0014 gramme chlorine. We have, then, in the first 50 cub. centims. 0·0483 gramme chlorine, in the next 510 cub. centims. 0·0579 gramme chlorine, and in the last 65 cub. centims. 0·0015 gramme. Hence the whole lump (615 cub. centims.) contained 0·1077 gramme chlorine, or, on an average, 0·1723 gramme chlorine per litre. A qualitative analysis of the water showed lime, magnesia, and sulphuric acid to be present.

Another piece of the ice was pounded and allowed to melt in a beaker. When about half was melted, the water was poured off and found to measure 95 cub. centims.; 75 cub. centims. were titrated with silver solution, and required 1·9 cub. centim. The remainder, when melted, measured 130 cub. centims., and required 0·9 cub. centim. silver solution. Hence the first fraction of 95 cub. centims. contained 0·0085 gramme chlorine, and the second of 130 cub. centims. 0·0032 gramme chlorine. The whole quantity (225 cub. centims.) of ice, therefore, contained 0·0117 gramme chlorine, or, on an average, 0·0520 gramme per litre.

From these results it is evident that the ice under examination was very far from being an homogeneous body; and, indeed, nothing else could be expected, when it is borne in mind that the ice in question owes its existence, not only to the *bonâ fide* freezing of sea-water, but also the snow which falls on its surface and is congealed into a compact mass by the salt-water spray freezing amongst it.

The ice formed by freezing sea-water in a bucket was found to have formed all round the bottom and sides of the bucket, and forming a pellicle on the surface, from which, and from the sides and bottom, the ice had formed in hexagonal planes, projecting edgewise into the water. The water was poured off, the crystals collected, washed with distilled water, pressed between filtering-paper, and one portion melted. It measured 9 cub. centims., and required 4 cub. centims. silver solution, corresponding to 0·0142 gramme chlorine, or 1·5780 gramme per litre. The other portion was used for determining the melting-point. The thermometer used was one of Geissler's normal ones, divided into tenths of a degree Centigrade, whose zero had been verified the day before in melting snow. The melting-point of the ice-crystals was found to be —1°·3. The temperature of the melting mass was observed to remain constant for twenty minutes, after which no further observations were made.

In the same way the melting-point of the pack-ice was determined. The fresh ice began to melt at —1°; after twenty minutes the thermometer had risen to —0°·9, and two hours and a half afterwards it stood at —0°·3, having remained constant for about an hour at —0°·4. Another portion of the ice rose more rapidly; and when three-fourths of the ice was melted, the thermometer stood at 0°.

These determinations of the temperature of melting sea-water ice show that the salt is not contained in it in the form of mechanically enclosed brine only, but exists in the solid form, either as a single crystalline substance, or as a mixture of ice and salt crystals. Common salt, when separating from solutions at temperatures below 0°, crystallizes in hexagonal planes; sea-water ice, therefore, may possibly have some analogy to the isomorphous mixtures occurring amongst minerals.

A very important practical consequence follows from these observations, namely, that pack-ice, though unfit to drink when a lump of it is melted as a whole, may serve as a source of fresh water if melted fractionally. As the melting-point of the salt ice is lower than that of pure ice, it melts first, and at the same time, by keeping down the temperature of the mass to its own melting-point, it prevents any of the fresh ice being wasted. When the salt ice has all been melted the brine may be thrown away, and the remainder of the ice will supply fresh water. If a thermometer be kept in the ice during the process of melting, it will indicate by its reading when drinkable water is being formed.

Parliamentary and Law Proceedings.

Poisoning by Carbolic Acid.

Dr. Hardwicke held an inquiry on Saturday, December 9, in the Board Room of the Hampstead Smallpox Hospital relative to the death of William Smith, aged 43, one of the inmates. Dr. Brewer, Chairman of the Metropolitan Asylums Board, was present on behalf of the managers, and expressed his great regret as to what had occurred. Deceased, who had been an inmate for a fortnight, came from Gifford Street, Islington, where he had a wife and five children, having been sent to the hospital under a parochial order while suffering from smallpox. Dr. Henry Case, resident medical superintendent, said deceased was a convalescent from the worst case of smallpox he ever saw when the accident occurred. On Wednesday morning he asked for his allowance of 1oz. of port wine, but in mistake Sister Rachel, one of the Protestant sisters from East Grinstead, having charge of the ward, gave 1oz. of carbolic acid instead, which, being the same colour as the wine, he drank off before perceiving the error. In 20 minutes deceased became insensible, but by the aid of artificial respiration he lived for an hour and a half. The doctor said death arose from carbolic poisoning, the mistake occurring in consequence of the wine and carbolic acid being in gallon stone bottles, exactly alike in size and appearance, although properly labelled. The carbolic acid had just been used for disinfecting purposes, and the Sister quite inadvertently took up the wrong bottle. Usually the wine was sent to the ward in proper wine bottles, but owing to the large quantity used in the convalescent ward, the steward had sent it in the large bottle. Dr. Case gave Sister Rachel a very high character as a nurse, and said this was a pure accident. Dr. Brewer also eulogized the services rendered by Sister Rachel. There was 300 smallpox patients, and they were scarcely got into order. Sister Rachel elected to make a statement. Her explanatory remarks were quite satisfactory to the Coroner and jury, who desired it to go forth that they exonerated her from all blame, and sympathized with her in the circumstances. The Coroner referred to the frequency of death from carbolic acid poisoning, and expressed his belief that the fluid was not one of the most safe disinfectants, after which the jury agreed to a verdict of "Death from accident or misadventure."—*Times.*

Poisoning by Vermin Killer.

On Monday, December 9, an inquest was held by Mr. Phillips, at Brierley Hill, respecting the death of a servant girl named Eliza Round, aged 16. The employer of deceased stated that hearing screams proceeding from the kitchen, on going there he found deceased lying upon the floor. He asked her what was the matter, and she first exclaimed "cut," and afterwards uttered the word "poison." She was apparently undergoing much suffering, and he immediately sent for medical assistance.

Mr. Chapman, surgeon, said he was called in to see the deceased, and she was apparently suffering from the effects of poison. He administered an emetic, but this had no effect, and he then administered a strong dose of mustard and water. He found some stains upon the front of deceased's dress of a corresponding colour to Battle's "Vermin Killer." The girl died, no doubt, from strychnine poison.

Mr. John Rawlings, chemist, Brierley Hill, deposed that he sold a packet of "Battle's Vermin Killer," and a pennyworth of ammonia to a girl who called at his shop on the evening of the 1st inst., about nine o'clock, but he could not identify the body of deceased. The girl, however, told him that she came from Mrs. Emery's.

Mrs. J. A. Emery said that upon the return of the deceased after being out she was carrying a white packet, which she said contained ammonia, with which she intended to make a hair wash.

The jury found that the deceased committed suicide whilst in a state of temporary insanity, and added the following recommendation:—That some more stringent restrictions be placed on the sale of such a deadly poison as Battle's "Vermin Killer," so as to prevent an unknown person getting such on a simple application.—*County Express.*

INFRINGEMENT OF THE LICENSING ACT.

On Thursday, December 7, George Herbert, grocer, attended at the Leeds Town Hall to answer two summonses charging him with selling certain liquors and allowing them to be consumed upon his premises without a licence. The alleged offence arose from the carrying out of an advertised promise to give a glass of wine to every purchaser of a quarter of a pound of tea. The defendant pleaded that there was no sale of the wine, it being given, and therefore that there had been no offence committed. The magistrate ruled, however, that there was a contract to supply the wine which was part of the inducement to part with the purchase money, and he inflicted a penalty of £5 and costs. The defendant said he would appeal against the decision.

Reviews.

CURRENT CHEMICAL LITERATURE.

A MANUAL OF INORGANIC CHEMISTRY. THE NON-METALS. By T. E. THORPE, Ph.D., F.R.S.E., etc. 1874. William Collins, Sons and Co., London and Glasgow.

CHEMIA COARTATA, OR THE KEY TO MODERN CHEMISTRY. By A. H. KOLLMYER, A.M., Ph.D., etc. J. and A. Churchill, London. 1876.

MANUEL DE CHIMIE PRATIQUE (Analytique, Toxicologique, Zoochimique a l'usage des étudiants en médecine et en pharmacie). Par E. RITTER, Docteur des Sciences, Professeur agrégé de l'ancienne Faculté de Médecine de Strasbourg, etc. Paris: Librairie, F. Savy. 1874.

PROCÉDÉS PRATIQUES POUR L'ANALYSE DES URINES, DES DÉPOTS ET DES CALCULS URINAIRES. Par E. DOLEFOSSE, Docteur en Médecine, Professeur particulier des Maladies des Voies urinaires et d'Urologie. Paris: Librairie, J. B. Baillière et Fils. 1877.

There is a well known story of an Eastern King, who employed a squeezer to condense the learning contained in his whole library into a few volumes. Such a functionary would find plenty of work requiring to be done if the same process were applied to chemical treatises. The only excuse that can be advanced by many authors for ever having written books, is the inordinate vanity which causes their souls to rejoice at the sight of their names printed on the title page. Such a sight has a marvellous fascination and exerts its baneful influence alike on the professor, the quack, and the student. It is the "my novel" rage which pervades society.

But to pass on to our immediate subject; namely, the review of the books in the above-given list.

We may commence our remarks by admitting that Professor Thorpe's book is of a superior order to those in common use, because it is constructed on a more philosophical basis. Instead of going through the various non-metallic elements and compounds in the ordinary routine manner, the author takes advantage from time to time of certain stated facts to impress on the mind of his readers the truth of a law or a theory.

To instance our meaning; from explaining the action of admixed metallic oxides on potassic chlorate when heated, Professor Thorpe passes on to review briefly those general actions known in chemistry as catalytic or contract actions.

Again, in treating of the solvent power of water, he seizes the opportunity of presenting some observations and speculations on the absorption of gases by water and the conditions upon which the amount absorbed depends. These considerations lead to remarks on the solubility of solid substances, then to the phenomena of liquid diffusion, and finally to a study of water of crystallization.

In like manner, in describing the properties of carbonic anhydride, a brief summary is given of Andrews' famous researches on the continuity of the gaseous and liquid states.

Professor Thorpe also includes in his book short accounts of various manufacturing processes, and generally speaking, these attempts are well sustained. But in treating of the manufacture of bleaching powder, he says the chlorine "is generated from a mixture of manganese dioxide and hydrochloric acid, or from manganese dioxide, sulphuric acid and common salt." In the first of these modifications no mention is made of Weldon's process for the regeneration of the manganese, and we may remark that the second method has not been used for many years.

En passant we may remind the reader that the constitution of bleaching powder has been elucidated by the isolation of calcic hypochlorite from it, as produced by the action of water (Kingzett). This discovery shows that the substance is properly formulated $Ca\left\{\begin{matrix}Cl\\OCl\end{matrix}\right.$

Certain small errors may be pointed out in the work under review. Thus on page 84 we are told that ozone is produced by the action of strong sulphuric acid upon peroxide of barium. But no proof has yet been furnished that the active agent thus set free is not simply nascent oxygen or peroxide of hydrogen. The old story regarding the formation of ozone from ether vapour and air is also repeated. It is peroxide of hydrogen which is formed. We are surprised further, to find Professor Thorpe (p. 178) expressing it as highly probable "that the salubrity of country air and the depressing effect of the air of towns is intimately related to the presence or absence of ozone, and to its action in organic matter." Yet, according to Houzean, country air contains as a maximum only 1 part of ozone in 450,000 parts of air by weight. Further this determination would also include peroxide of hydrogen, and there are those who believe ozone does not occur at all in air.

We had hoped that Professor Thorpe would have directed special attention to the similarity in the chemistry of silicon and carbon compounds. Lastly we would point out that the author opines that the blue compound produced by the action of iodine upon starch is not a definite chemical compound. We think it a compound which is definite enough, but it has not yet been sufficiently well studied to ascertain its exact nature.

Altogether, however, the book, which reminds us of the late Dr. Wilson's excellent little manual, is an extremely good one; in fact we know none better.

The next book on our list is by Dr. Kollmyer and is an American production. The author's professed object in writing it has been "to compress into as small a space as possible everything connected with the study (of modern chemistry) that deserves attention." If he seriously meant this in its full signification, he has signally failed. But we are persuaded he has not expressed his meaning clearly. The author first gives some general considerations on matter, symbols, atomic weights, quantivalence, nomenclature, synthesis, analysis, and formulæ, etc. Then in tabular form are presented the names of the best know substances in chemical science, together with their synonyms and historical notes, sources, equations referring to their production, and their chief properties including the symbol, combining weight and specific gravity, etc; finally follow a few characteristic tests or reactions of each substance.

In this way Dr. Kollmyer goes first through the nonmetals and their compounds, then he takes organic chemistry, while in the last division is given a synopsis of poisons together with a list of antidotes and general treatment.

This last chapter is extremely useful, but taken as a whole we cannot recommend the book to students. It is rather useful to persons who are cramming facts preparatory to undergoing examination, but, like all such productions, is not calculated to develop those powers of mind in the student which connect effects with causes. To men, read in their science and practising their profession, the book forms a useful index for reference.

We now pass on to the volume by Dr. E. Ritter. This book is a kind of *Gradus ad Parnassum* for medical students; and indeed, between it and the work by Professor Odling, there is a remarkable similarity of arrangement and matter.

It consists firstly of a methodic series of analytical exercises in qualitative inorganic chemistry, extending over 114 pages out of a total of 430. After this there follows an elaborate attempt at a general system of qualitative analysis of organic matters in which a few well-known substances are arranged according to their solubility in water, alcohol, and ether. This chapter is very useful so far as it goes, but it is imperfect in scope. Then follows a section devoted to toxicology, and afterwards one on volumetric analysis. There are also divisions devoted to the analysis of some more usual medicines, foods, and drinks. Finally is given the methods of estimating the inorganic substances in animal fluids and tissues; analyses of the blood, the chemistry of the digestive and respiratory organs; and lastly, that of the urine. Much of the matter and the engravings relative to volumetric analysis are evidently taken from Mohr's "Titrir methode."

There are several matters worthy of attention in this book. Thus the author gives on the last page the atomic weights with the whole of the decimals cut off.

On page 17 the student is directed to filter a solution of Nessler's test, consisting of two volumes mixed with three of strong potash.

On page 361 there are given drawings of crystals of hematoidine (hemine), and bilirubine, and the statement of their identity is also made. This assertion is one without foundation in truth. There are no facts on record, and not a single analysis throughout chemical literature, which proves this identity. Bilirubine, indeed, has the formula $C_9H_9NO_2$, whereas hemine, as made from the blood, consists of hematine $C_{32}H_{32}Fe\,N_4O_6$, its hydrochloride, and a phosphorized substance. Acid hematine is said to present one band when its absorptive spectrum is examined, whereas it really presents four or five.

The brain and its chemistry receive in this book the barest mention.

We could point out many other errors and omissions, but those we have alluded to are sufficient to demonstrate that this work is a mere compilation (like many others), from pre-existing works, and constructed without reference to original memoirs, while it neglects in great measure recent scientific research.

Now according to Dr. E. Ritter his students are passed the whole of the course indicated in his book in a single year. In reference to this matter we only express our regret, but we are more sorry for the students, because throughout the course they are not made acquainted with the methods of elementary organic analysis, and while men devote themselves to test-tube chemistry only, physiological chemistry will most certainly stand still.

We cannot say in fairness, that the book is without use; indeed to a certain class of students it must prove extremely useful, owing to its comprehensiveness, but we cannot recommend it as heartily as we could wish.

The last book on our list is by Dr. E. Delefosse. In reference to it we would first observe that its stated date of publication is 1877, and this together with an advertisement opposite the title page, renders it too evident that the whole book is simply a puff for its author's particular pursuit. We reproduce the advertisement:—"Dispensaire pour l'enseignement et le traitement des maladies des voies urinaires, 2 rue des Poitevins. Consultations gratuites les mardis, jeudis et samedis, à midi et demi. Les samedis, après la consultation, les élèves sont exercés gratuitement aux manipulations micro-chemiques pour l'analyse des urines." In a plate on p. 90 referring to urinary deposits we have represented, among other microscopical objects, hair, cat's whiskers, linen fibre, cotton fibre, tea leaf, fragments of feathers, etc., etc. In fact nearly all the plates are as sensational in character as most of them are valueless.

The strongest condemnation of the book is to be found, perhaps, in the fact that not a single chemical formula occurs once in the whole treatise. The subject matter proves that the author is not acquainted with the true chemistry of his subject, for it abounds with errors, while it is also incomplete. In dismissing the book without further notice, we must also condemn its use.

Les Richesses de la Nature.—Le Regne Animal.—Etude de ses Matières Premières et des Procédés industriels modernes qui en permittent l'Exploitation. Par P. L. Simmonds. Traduit de l'Anglais sur la 2e Edition, refondu et considerablement augmenté par le Dr. Jul. Morel. Ghent: A. Hoste. 1877.

Upon the occasion of noticing in these columns Mr. P. L. Simmond's little volume, 'Waste Products and Undeveloped Substances,' it was pointed out how much the wealth of materials suffered in appearance from the want of method and judgment in setting them out. In this respect Dr. Morel's edition is a great improvement upon its original, for as he himself says, "l'ouvrage, rédigé suivant une méthode plus rationelle, est devenu plus conforme a l'esprit du lecteur française," and, it may be added, of the English reader likewise.

The subjects are in this book confined to the animal kingdom, and are now arranged so systematically as almost to dispense with the necessity for an index, the place of which is supplied by a "Table des Matières," containing suitable divisions and subdivisions. The following are the principal divisions and will indicate the nature of the arrangement now adopted:—Skins, including furs, feathers, hides, hair, wool, horns and hoofs; Flesh, Bones, Blood, Milk, Eggs, Animal Fats, Useful Insects, Crustaceæ, Molluscs and Zoophytes, and Animal Manures.

There is so much that is curious in this book that selection is difficult, but we translate the following instance of "*exploitation*" of the animal kingdom, which may be new to some of our readers.

"In Paris there exists a public pound,* upwards of ten acres in extent and surrounded by stone walls, to which are carried the bodies of dead animals in order to obtain the bones for sale. These bones have a certain value, but it is necessary that they should be cleaned and deprived of adherent and sometimes putrid flesh. To carry out this operation by hand would have been tiresome and costly; but the authorities, remembering the greediness of rats for horseflesh, have stocked the pound with thousands of rats from the catacombs of Paris. These little creatures achieve admirably the desired work, so that animals placed in the enclosure over night are found on the morrow in the proper and polished skeleton state.

"But one result is that, in consequence of this excellent feeding the rats grow and multiply in a prodigious manner and it is necessary to have recourse to some

* The word in the French edition is *étang*, but this is probably a mistranslation of the English "pound," the French "*fourrière*."

means to control this multiplication. Every three months, therefore, there is a general battue made in this colony of rats and all the rats found above the soil are trapped. This operation is excessively curious. Horizontal cylindrical troughs are drilled in the lower part of the walls surrounding the pound, the depth and diameter of these openings corresponding to the length and size of the body of a rat. On the day of the battue men armed with saucepans, kettles, drums, etc., pass into the inclosure and treat with rough music the poor rats, who, seized with a mortal fear, push their heads into the first openings that present themselves. But every rat that attempts to save itself in one of these holes has a tail that it leaves outside. The man charged with the collection of the rats then makes his rounds, sack on shoulder, and adroitly seizes the rats by the tails and throws them into his sack. These rats, fat and provided with beautiful sleek skins, are a source of great profit, for the whole of them is utilized, fur, skin and flesh."

The proximity of the following lines in the same pages is rather suggestive of one method of utilization:—"In China the soup prepared from the tails of rats is as much esteemed as is that made with ox-tails by us; a dozen rats are there worth a couple of dollars."

THE CHEMISTS AND DRUGGISTS' DIARY. 1877. London 44A, Cannon Street, 1876.

Everybody who keeps a Diary, and the name of such is now "Legion" will soon be on the look out for the form which will best adapt itself to the wants of the coming year. To those chemists and druggists who have hitherto used the Diary issued in connection with our contemporary the *Chemist and Druggist* advice will probably be superfluous; to those who have not, but who wish for a good desk book, specially adapted for the memoranda of the chemist and druggist's business, we can conscientiously recommend it. Besides the Diary itself, and various almanack and other information, there is a collection of about three hundred recipes. We agree with the editor that it would be indeed curious if out of this large number thus brought together, a purchaser failed to discover something of value and service to himself.

Obituary.

Notice has been received of the deaths of the following:—

On the 14th of October, 1876, Mr. John Rowntree, Chemist and Druggist, Copenhagen Street, Islington.

On the 24th of October, 1876, Mr. William Gardner Hill, Pharmaceutical Chemist, George Street, Edinburgh. Aged 36 years. Mr. Hill had been a Member of the Pharmaceutical Society since 1869.

On the 15th of November, 1876, Mr. John Alexander Carrington, Chemist and Druggist, Bakewell, Derbyshire.

On the 18th of November, 1876, Mr. Henry Bard, Chemist and Druggist, St. Thomas, Exeter. Mr. Bard had been a Member of the Pharmaceutical Society since 1875.

On the 22nd of November, 1876, Mr. James William Read, Chemist and Druggist, Chelsea.

On the 25th of November, 1876, Mr. Samuel Penrose Kernick, Pharmaceutical Chemist, Duke Street, Cardiff. Mr. Kernick had been a Member of the Pharmaceutical Society since 1858.

On the 25th of November, 1876, Mr. David Viney, Chemist and Druggist, South Street, Isleworth.

On the 27th of November, 1876, Mr. Samuel Aldred Darby, Chemist and Druggist, St. Botolph Street, Colchester.

On the 30th of November, 1876, Mr. William Morton Coombes, Chemist and Druggist, Old Kent Road.

On the 30th of November, 1876, Mr. John William Taylor, Pharmaceutical Chemist, Lincoln. Mr. Taylor had been a Member of the Pharmaceutical Society since 1873.

Correspondence.

HYOSCYAMINE.

Sir,—My attention has twice to-day been directed to your report of Mr. Martindale's paper on Crystallized Hyoscyamine. Mr. Martindale seems to have made a mis-statement which calls for immediate correction. He says that in one of my papers on Hyoscyamine I speak of the drug as an amorphous alkaloid and states that he has little doubt that I refer "to the same preparation which is in the London market, which, however, is not amorphous but very minutely crystalline."

Acting on this assumption he subsequently states that I have given "as large doses as one grain and even three grains," but that I consider one grain as a full dose.

Now it should be very definitely understood that what has been called "the amorphous alkaloid" is not identical with the crystalline principle. The latter is very much more powerful than the former. As Harley had already written about this distinction, as far at least as concerned the amorphous drug as different from the sulphate of the alkaloid, I did not consider it necessary to comment on the subject. There seem to be in reality three forms of the principle: the first is an extractive, that which has been called the amorphous alkaloid and which I have employed in all observations the result of which I have as yet published; the second is the sulphate of hyoscyamine, a specimen of which Harley prepared for himself and employed in numerous observations (see *Old Vegetable Neurotics*); the third form is offered by chemists under the name of crystalline hyoscyamine, and appears to be the form to which Mr. Martindale refers.

The dose of the amorphous or extractive form which I have found necessary to produce full physiological action in man is three-quarters of a grain. The dose of the sulphate to correspond to this seems to be about one-twelfth of a grain and Mr. Sydney Pearse appears to have got a similar action from one-sixtieth of a grain of "crystalline hyoscyamine."

It will be at once seen, therefore, how grave the consequences might be if I were to allow Mr. Martindale's statement that the drug used by me and that supplied by him to Mr. Sydney Pearse are identical, to escape without contradiction.

I had intended to write to Mr. Martindale to give him the opportunity of correcting his own statement, but the desire to ensure the insertion of this letter in this week's issue of your Journal caused me to change my intention. I am sure, however, that he will appreciate my motive and exempt me from any suspicion of discourtesy.

Both Mr. Martindale and Mr. Sydney Pearse appear to be unaware that I published a long account of the actions of the drug in the fifth volume of the West Riding Asylum Medical Reports. May I add that a new series of observations on the therapeutic actions of the extractive principle will appear in the forthcoming volume of the same Reports?

ROBERT LAWSON.

West Riding Asylum, Wakefield,
December 12, 1876.

GREY POWDER.

Sir,—From the report in last week's Journal, the preparation and composition of blue pill and grey powder does not appear very satisfactory. Have the goodness to allow me space in your next to give the result of my experience in the matter, which may lead to other observations.

From 1830 to 1837, I was in the habit during my apprenticeship of making large quantities of both preparations, the whole of which were made by hand with an ordinary mortar and pestle. Finding the process very tedious and unsatisfactory, I frequently thought if mechanical power could be applied to the pestle it would be a great advantage, both in saving labour and producing a more uniform action.

In course of time I was led to accomplish that object, which has been a great advantage to me in my business, and I think the following experiment may be interesting to some of your readers.

A chemist in the town said he could not procure a satisfactory sample of blue pill and wished me to make him four pounds. I put the mercury into the mortar with the confection of roses and applied the pestle without any weight at a gentle speed. In about two hours it appeared finished, but, being anxious to make it perfect, the process was continued until the evening, when a sample was sent to him; he said the mercury was almost killed.

The same process was continued through the next day, with the same result. I then applied a weight on the pestle and drove it at a greater speed, and in about two hours the mercury was separated and visible at the bottom of the mortar. The weight was then removed and the pestle driven at a gentle speed, and in about two hours the mercury was again obliterated. I then applied the weight and increased the speed, which again separated the mercury. This alternate process was continued for a week, with the same result, thus proving that the mercury in fresh-made blue pill is merely a mechanical division of the mercury.

Some time afterwards the person for whom I tried the experiment told me he had recently examined with a powerful microscope the sample I sent him, but could not discover the slightest trace of metallic mercury.

H. GOODALL.

Derby, December 12, 1876.

GLYCEROLE OF NITRATE OF BISMUTH.

Sir,—With your permission I will reply in your columns to the questions that were put to me by two of the speakers at the discussion on the President's paper on December 6th. I did not think that I ought to venture on any reply at the time although the President had courteously invited me to speak, for I saw that the time of the Society was already fully occupied.

Mr. Umney and Mr. Linford noticed that the specimen handed round smelt of nitrous acid. As I was sitting next to them I had opportunity for observing that the specimen they referred to was the one prepared for me by Mr. Gale. As Mr. Gale had just stated, this was prepared by means of heat, which the President's researches had enabled him to say ought not to be applied. Mr. Umney stated if we are to have a compound of bismuth with oleic acid or glycerine there could be no doubt that the oxide was preferable to the nitrate, and he requested me to give an opinion as to the therapeutical bearing of such an option. To this I reply that we are not compelled to choose the one and leave the other, we may have both of them at our disposal if we please, but I fancy any choice between the two can only apply to outward use. I tasted some of the oleate as it was handed round, and feel convinced that the extremely nauseating quality of it as well as its chemical composition quite unfits it for internal uses; whereas one of the chief uses of the nitrate would be for inward administration.

It is hardly fair on Mr. Umney's part to put the difference as oxide *versus* nitrate, for it properly stands thus, namely, as oleate *plus* a large excess of oleic acid as against nitrate *plus* glycerine. Professor Redwood objected to the oleate on account of the difficulty of obtaining pure oleic acid, but then the oleates have by the balance of convenience become an article of wholesale instead of retail manufacture, and the difficulty here put has not interfered with our having always at our disposal in any part of the kingdom the best possible oleate of mercury. The professor's inquiry "What is glycerole of nitrate of bismuth supposed to be or intended to be?" may be thus answered. It is, or rather *was*, intended by me to be a simple solution of the salt in glycerine; the President, however, has shown that it is not so, but Professor Redwood is himself the very man who is best able to discover by means of a chemical analysis what reply ought now to be properly given to his question. "If the new preparation is to be introduced," said Professor Redwood, "we ought to know its nature and have some security that it will not undergo any great alteration." To this I reply we by all means ought *if we can*, but then was not opium a valuable drug long before we knew that it contained morphia, and did not Jesuits' bark do good service to mankind before quinine had been dreamt of. Let me take a later instance. Goa powder was a favourite and efficient remedy in the tropics long before it was discovered in the laboratory of the Pharmaceutical Society that it contained 85 per cent. of chrysophanic acid. Then again if the preparation will not keep for many weeks unchanged, no more will any of the infusions which are so largely prescribed and no more will sulphurous acid solution.

Lastly, as to the professor's objection that the nitric acid of the nitrate is held by an affinity so weak that water itself is capable of removing it, it must be remembered that my own experiments, confirmed by the more careful researches of the President, have shown that this remark does not apply to the nitrate when recently dissolved in *cold* glycerine, inasmuch as water under those those conditions has no effect on the nitrate in whatever quantity it may be added to it.

BALMANNO SQUIRE.

THE HYGIENE OF PINE PRODUCTS.

Sir,—I have read with interest the paper in your last issue by Mr. C. T. Kingzett, on the Hygienic Influences of the Pine and Eucalyptus, and am somewhat surprised that in the elaborate recapitulation which the author has given in it of both the literary and practical contributions which have been made to this subject, he should have omitted any reference to terebene, a derivative from oil of turpentine, to the valuable properties of which, as a deodorant and disinfectant, I first called public attention nearly two years ago. I am unable to attribute this omission on Mr. Kingzett's part to ignorance, first, because his own important researches on the terpenes must have made him quite familiar with this body itself; and, secondly, because at the Pharmaceutical Conference at Bristol in 1875 he specially referred to it in some remarks which he made.

I abstain at present from entering into any discussion on the point which is raised in Mr. Kingzett's paper, whether the volatilization of the aromatic hydrocarbons is accompanied by the production of ozone, as some authorities allege, or of peroxide of hydrogen, as he asserts, or of both of these bodies as appears to me the more probable assumption, since the whole subject is beset with considerable difficulty. My object here is to call attention to the practical point; that if, as Mr. Kingzett states, and as is, I think, highly probable, the admitted hygienic influence of the emanations from pine wood are due to the oxidation of turpentine, and to the production of a volatile body or bodies, whose presence is indicated by the characteristic odour which pine wood exhales, we have in terebene the exact body by which these exhalations are produced, since the aroma of this liquid, when diffused through the air, is so nearly identical with that of pine wood that it immediately suggests the comparison.

Of the practical value of terebene for disinfecting and deodorizing purposes it is unnecessary for me to speak, as its large use by the medical profession and the public, not only in this country, but abroad, has already amply established it. I refrain also from criticizing the new disinfectant for which Mr. Kingzett bespeaks attention until it is open to precise examination; but from Mr. Kingzett's own description of his method of producing it, and from my own researches on the subject, I shall be somewhat surprised to find it anything else than terebene under a new name.

FRANCIS T. BOND, M.D., B.A. Lond., F.C.S.
Medical Officer of Health to the Gloucestershire Combined Sanitary District.

Gloucester, December 6, 1876.

J. Kershaw.—You are recommended to apply to Messrs. Williams and Norgate, Henrietta Street, or Messrs. Dulau, Soho, for a catalogue of such works.

J. E.—The quinine is incompatible with the other ingredients of the mixture. Probably rubbing the three salts together with about one drachm of powdered gum arabic, adding a little water, and continuing the trituration for a few minutes, afterwards adding the other ingredients—spirits last—will produce the best result.

"Assistant."—The formulæ of a series of elixirs, including a "simple elixir," have been issued by a committee of the American Pharmaceutical Association. See vol. iv. of this series, p. 682.

COMMUNICATIONS, LETTERS, ETC., have been received from Mr. A. E. Ekins, Mr. Rimmington, Mr. Stevens, Mr. Gilmour, Mr. Nicols, Mr. Davenport, Mr. J. B. Austin, Inquirer, Bonus Puer.

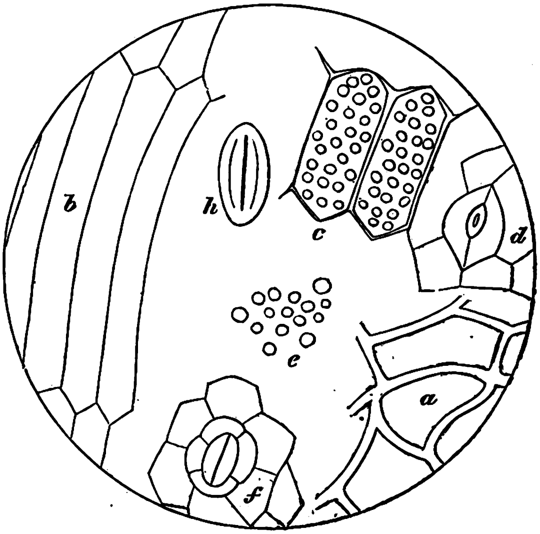
THE MICROSCOPY AND ADULTERATIONS OF COLOCYNTH POWDER.*

BY WILLIAM INGLIS CLARK.

At a time such as the present, anything bearing on adulterations, whether intentional or accidental, must be interesting to pharmacists in general, but, as the physician to be useful should be able not only to detect the disease, but also to point out the cure, so it is desirable that not only should an adulteration be pointed out, but also some easily applicable method of detection be at hand.

It is under this apprehension that I shall endeavour in this paper to place on record my investigations on colocynth. The *Citrullus Colocynthis* belongs to the natural order Cucurbitaceae, and like many of the other plants in this order, as for instance *Momordia elaterium*, the pulp of its fruit contains an active cathartic principle, colocynthin, much used in medicine as a trustworthy purgative in the form of extract of colocynth. The fruit of this plant (as may be seen from the transverse section of it) is a pepo, globose, smooth, and yellow when ripe, and divided internally primarily into three loculi or chambers, and finally into six by spurious septa. It will be noticed in the pepo that the septa have attached to them a cellular portion termed the pith or pulp, and it will be remembered that it is in this pulp alone, and in no other part of the fruit, that the active principle resides. The seeds, on the contrary, are oily and albuminous, and perfectly bland, the albuminous matter present being actually made into cakes in some parts of Africa, and used as an article of food. It is with a view to the exclusion of the inert rind, and also of these inert seeds, that the Pharmacopœia directs the use of the pulp, freed from the rind and seeds, in the preparation of the extract; and it will be apparent that if the seeds be not removed, a powder made from the whole pulp containing all the seeds will be much less active than one prepared from the pulp alone, the proportion of seed to pulp being as 1 to 2., *i.e.* the seed weighs fully one third of the whole fruit. Now any such admixture must be regarded as an adulteration, and it is to be regretted that the greater part of the commercial powdered colocynth contains more or less of the seeds. Indeed it may be safely stated that the colocynth powder sold in shops invariably contains some seed, and this, even although very considerable care be taken in removing the seeds. As in many other cases, the microscope is here a useful servant, pointing out readily the presence of even a very few seeds in a large bulk of the powder.

In order to facilitate a comprehension of the method of detection, it will be necessary before going further to describe briefly the various tissues which are present in the pulp itself, the rind, and also in the seed. Beginning with the seed, we find that it consists of a hard outer layer or episperm, and a soft part inside, the embryo, which in this case is exalbuminous, that is to say, it consists of the radicle, plumule and two large leafy cotyledons only, without any extra supply of albuminous matters for the young plants' nourishment. On making a very thin section through the outer layer of the seed, we find that there is a superficial layer of epidermis, below which are stellate cells, shaped much like a jelly mould, and consisting of a raised up central portion, having ridges on folds of the cell wall radiating out from the centre. This structure is at once shown by an examination of the transverse section, from the lower or inner side. If a section be made of any spherical body, it is evident that at the margin of the circular slice obtained, the section will be very thin, while in the centre it will be thickest. If therefore we look from below (*i.e.* from the flat side) at such a section, through the stellate cells above referred to, we shall see at the margin only the outline of the cells themselves, hexagonal or otherwise, as the case may be, while as we gradually approach the



470 Diameters.

a, inner layer of embryo sac; *b*, outer layer of ditto; *c*, cells of palisaded layer with granules; *d*, stomata from cotyledon; *e*, granules from cotyledons; *f*, epidermis of rind; *h*, starch granule (side view.)

centre, the ridges will appear at first as mere dots finally developing into well marked rays. Such corresponding exactly with what we see in the section represented in the diagram, we conclude that the cells have the shape indicated. This is even more fully borne out by the isolation of individual cells by means of potash solution, when the structure is well seen, and the rays stand out prominently. As we proceed deeper into the seed, we come upon several layers of dotted cells, more or less hexagonal in section, and having very thick, striped cell-walls. These constitute the hard part of the seed, and are thickened by deposits of ligneous matter in them. Closely investing the inner side of this hard layer is a very thin layer of tissue, the cells of which are much flattened, and nearly resemble figure *a* in the diagram. This layer is not truly separable from the episperm. If a seed, after being steeped in water for some time, or better still, in solution of potash, be opened, and the embryo removed, a very thin walled sac will be readily separated from the included cotyledons. On examination, this will be found really to consist of two tissues, not readily separable, each consisting of a single layer of cells. The outer, represented by fig. *b* consists of elongated

* Read at an evening meeting of the North British Branch, Edinburgh, December 13th, 1876.

narrow hexagonal cells, and is often met with in the commercial powder. The inner, in like manner, is also to be found, and in structure (fig. *a*) much resembles the inner layer of the episperm, previously referred to. Between these, however, and the episperm are to be found spiral vessels, forming a kind of sheath round the embryo and its coverings. We now come to the cotyledons, the structure of which can be seen in the transverse section. This is specially interesting, as showing us, not only what the structure of a cotyledon really is, but also its complete homology to an ordinary leaf. In fact, small though these cotyledons are, they present to us exactly the same layers of cells as we find in the fully developed leaf. First of all, then, there is an epidermal layer of irregular, flattened cells, shown in fig. *d*, covering both the inner or upper side, and the outer or lower side, and even at this comparatively early stage, stomata, well developed, and capable of contraction and dilatation, are to be found leading into loose spaces among the cells, and, no doubt, to some limited extent carrying on the functions of transpiration and respiration. This epidermal layer with the stomata, is exceedingly difficult to separate, or even to examine *in situ*; for, it being of extreme tenuity, the cells below are readily visible through it, in most cases rendering it impossible to detect such a tissue. If the albuminous cells, however, be very carefully removed, we get such a structure as we have referred to above. Immediately below the stomata there are two layers of small cells, measuring about $\frac{1}{1800}$ inch in diameter, and underneath these are one or two palisaded layers, viz., layers of very regular elongated cells, hexagonal in section.

Now come a considerable number of rounded cells, followed by three palisaded layers and a single row of small cells, covered by the epidermis. Besides this general structure, I would, however, specially direct attention to the fact, that all the cells of the cotyledons are filled with a very large number of small, oily, albuminous granules, about $\frac{1}{8000}$ inch in diameter, represented as fig. *e* in the diagram. These must not be mistaken for starch, as has been done, for the form is much more rounded than we usually find in starch grains, and the absence of blue colour with iodine, as well as the behaviour with polarized light, at once shows the difference. The grains above mentioned constitute the nutritive portion of the seed, and are able to withstand the action of solution of potash. By gently pressing the cells containing them with a little water the cell walls are ruptured, and the little granules as they float about are so characteristic as to be an infallible proof of the presence of the seed in a sample of the powder.

Having now run over the chief tissues to be found in the seed, I have still to describe those of the rind and pulp, before referring to the adulterations. The rind is of a light yellow colour, and is comparatively thin. The epidermis (see diagram *f*) when carefully removed is rather a pretty microscopic object, exhibiting as it does irregular flattened cells with thickish cell walls, and numerous stomata. If examined by a transverse section, it will be seen that the stomata are raised above the general surface, and open into loose spaces among the cells. These cells, underneath the epidermis, resemble much in appearance the thickened cells of the episperm, previously described, but are larger, looser, and with narrow cell walls. The pulp, on the other hand, consists of the most irregular cellular tissue, the cells, which are easily separable by means of potash, being oval or elliptical in form, and lying together in no very definite order. This pulp is traversed by vessels of various kinds, the most important of which for us to remember are the spiral vessels, which are of large size, larger as a rule than the corresponding structures in the seed, but as the size is no criterion, it is necessary for us to remember that the same structures are present in both parts, and that therefore the presence of spiral vessels in the powder is no proof of the presence of seed.

We are now in a position to recognize an admixture of seed or rind, with the true pulp. The most general and characteristic test for the former, as was before mentioned, is to be found in the small albuminous granules contained in the cells of the cotyledons. If a small portion of the suspected powder be placed on a glass slip, a drop of water added, and the cover glass gently rubbed on it, so as to extend the drop, these granules will be readily noticed. In the true powder, no granules are to be seen, or at the most but one or two, but in proportion as more or less seed is present, so are the granules more or less numerous. Unless these constitute a considerable bulk of the powder, their presence should only be considered accidental, and the powder not be condemned on this account. With most pharmacists, I believe, this will be considered a perfectly satisfactory test, but confirmatory proofs are easily pointed out. It will be evident that when the seed is powdered, the tissues will be also broken up, and fragments of these may be noticed. The commonest and most easy of detection is the double walled sac enveloping the embryo (see figs. *b* and *a*), showing on the outer side, elongated, more or less hexagonal cells, and on its inner side, the structure shown in figure *a*. Besides this, the spiral vessels are sometimes present, but these cannot be with certainty distinguished from those of the pulp. Stomata may and do occur, but their presence is so difficult of detection that they cannot be depended on. The episperm again, although it shows a characteristic structure on section, yet, in the state of powder, cannot be recognized. The rind, on the other hand, is still less frequently met with, but the characteristic stomata, in this case easily seen, would furnish a ready means of detection. In none of the samples I have examined have I detected any of the rind. Besides the admixture of the seed, powdered colocynth is liable to contain other substances, foreign to it, and these, fortunately, are easy of detection. As in most cases of adulterated powder, so here, starch is the most common adulterant. When I say adulterant, I do not mean that perhaps a few grains are to be found scattered through a large bulk of the powder, because such can hardly be avoided if the colocynth be ground at any ordinary mill; but if the starch bulk largely, so as to constitute a reasonable proportion of the whole, then it may be safely concluded that its presence is intentional. If the powder contain very much starch, the readiest method of detection would be the use of iodine, without the aid of the microscope, but unless a large proportion be present, this could not be relied upon. With the microscope, however, each individual grain coloured blue is visible, and therefore this test is perfectly satisfactory. By the use of polarized light, also, we are able readily to decide on the identity of a starch granule, independently of the use of iodine. When polarized light is passed through a cereal starch grain, a more or less well marked black cross will be noticed. The only exception to this rule is the oat starch, which does not present a cross, but in this case the granules are polygonal. I have examined about one dozen samples of the commercial powder, obtained from different parts of the country, and of these three contained starch. In one of these, about 75 per cent. or more of the powder consisted of wheat starch, while only occasionally was a fragment of pulp to be seen. In the other two the quantity was smaller, but in one, starch granules with a three or four-rayed star in the centre, greatly resembling rye starch, were detected. These, however, were evidently stragglers, and not intentional adulterants. They may have been simply wheat grains with folds of the cell wall giving the appearance described, for it must be remembered that the wheaten starch granule is not of invariable shape, and when viewed from the side it presents an oval shape (see fig. *h*), with a longitudinal furrow, described by some authors as the hilum, but really only a fold of the cell-wall.

In concluding, it may be satisfactory to remark that although in none of the samples which I have obtained is the seed absolutely separated, still the proportion present in more than half of them is not so large as to prevent our believing them to have been honestly prepared. In bringing forward these investigations I shall be fully repaid for my labour if I have succeeded in demonstrating how easy it is for every chemist who possesses a microscope to ensure the genuineness of his colocynth, and to guard against the rapacity of dealers.

[*The Discussion on this paper is printed at p.* 517].

A DEPOSIT IN SOLUTION OF BICARBONATE OF SODA.*

BY WILLIAM INGLIS CLARK.

Some time ago my attention was drawn to a deposit in a bottle in which bicarbonate of soda had been dissolved in water. There appeared to be a white film obscuring the glass; but as it occurred that probably there was some simple explanation of it, the subject was passed over, and no steps were taken to examine the nature of the film. Some time after this, however, some hard, apparently sandy matter was found lying at the bottom of a block-tin cistern containing a solution of the above salt. Under the impression that this had entered accidentally, I examined the cistern, and found an incrustation on the sides and bottom, some of which I removed and analysed, the result showing it to be pure carbonate of lime, with a trace of colouring matter. An examination with the microscope revealed the presence of very minute hexagonal prisms, the form in which carbonate of lime usually crystallizes, measuring from $\frac{1}{1000}$ to $\frac{1}{4000}$ inch in diameter. Besides these, I recognized three species of diatoms, namely:—gomphonema, pleurosigma, and a discoidal form, the name of which was not determined. These were of very minute size, and had passed through the carbon filter along with the water.

The composition of the deposit being settled, the question as to how its presence could be accounted for remained. It was suggested that perhaps the crystals were present in the soda before solution. This being shown not to be the case, and a chemical examination indicating the absence of lime and the purity of the salts, the only possible cause seemed to be the Edinburgh water. From an analysis of it, the number of grains of carbonate of lime per gallon was 6·286, whilst of sulphate of lime there were only 1·0214 grs. present. The carbonate present would then account for the deposit. But how came it to deposit? The cistern was very cold, and Edinburgh water is not known to deposit carbonate of lime in the cold. To determine more carefully, and for myself, the conditions under which the precipitate falls, I treated 90 gallons of water with 5¼ lbs. of subcarbonate of soda ($Na_2CO_3 10H_2O$), and weighed the deposit, which amounted to about 300 grains. In like manner, with bicarbonate of soda, $NaHCO_3$, the deposit weighed 200 grains, while with the corresponding salts of potash the weights were 40 and 9 grains respectively. Now to account for this the action of the carbonates on the sulphate of lime seemed competent, but the largest deposit obtainable in this way could be no more than 75 grains, and even this would not fall, as carbonate of lime is sufficiently soluble in water to prevent this. I have found that even with more sulphate of lime than one grain per gallon of distilled water no precipitate was thrown down by an alkaline carbonate. The tendency of sodic carbonate to become bicarbonate by removing carbonic acid when in a loose state of combination seemed a plausible explanation, as in the case before us the carbonate of lime, 6·286 grains per gallon, was chiefly retained in solution by the carbonic acid dissolved in the water.

The equation representing the change would be—

$$Na_2CO_3 + CaCO_3, CO_2 + H_2O = 2NaHCO_3 + CaCO_3.$$

Of course the bicarbonate could have no action on such a water; but, in practice, as we have seen, there is a deposit of 200 grains. On testing with mercuric chloride, the copious red precipitate showed the presence of carbonate, and when absolutely pure bicarbonate was used no precipitate was thrown down from the water. This then, is sufficient to explain the greater deposit with the carbonates than with the bicarbonates; but why the soda salts should show more action than the potash salts remains a question. Although potash has undoubtedly a greater affinity for most acids than soda, yet, with carbonic acid the case is different, the bicarbonate of potash being even more readily changed to carbonate than with the salts of soda, so that, in like manner, it seems unable to remove the carbonic acid from the bicarbonate of lime so perfectly as the soda.

It is evident then that the deposit is due to the carbonate alone, and that, in proportion as the bicarbonate contains more of the carbonate so is the precipitate increased.

As has been brought recently before the public, little of the soda water of commerce contains carbonate of soda, so this deposit can have no interest to those makers to whose waters this statement applies. To those, however, who adhere to the Pharmacopœia strength, it may be an interesting point. In practice, at least in my own experience, the deposit has occurred, not only in the cistern, but also in the taps and

* Read at an Evening Meeting of the North British Branch, Edinburgh, December 13th, 1876.

pipes leading to the aerating machine, so much so, that several times the pipes have been filled solid with this deposit, which in a week's time will weigh from 7 to 24 oz., and if the crystals referred to pass into the machine and bottles the carbonic acid may be, and actually in cases on record has been, unable to effect solution of them. If the solution be made in small quantity, and immediately bottled, no doubt the deposit will not fall, the carbonate of lime being retained in solution. Those waters which contain little or no lime, such as distilled rain, or Loch Katrine water, would be free from the objection, as also boiled water, but where these are not to be had, some device must be resorted to. The best and simplest way of dealing with the matter is to allow the deposit to settle in some special vessel before using the water. In the absence of this, the saturation of the bicarbonate with carbonic acid before use is an effectual preventive. Whether the deposit can be accounted for in the way I have proposed, or whether some other explanation is the right one, I leave be to decided, trusting that in the discussion which may follow, some facts may be elicited which shall throw light on this point, interesting alike from a theoretical and a practical point of view.

[*The Discussion on this paper is printed at p.* 517].

FOURTEENTH ANNUAL REPORT OF THE GOVERNMENT CINCHONA PLANTATION IN BRITISH SIKHIM.

BY GEORGE KING, M.B., F.L.S.,

Superintendent of the Royal Botanical Garden, Calcutta, and of Cinchona Cultivation in Bengal.

The record of work done on the cinchona plantation during the year 1875-76 is, unlike that of any former year, more one of harvest than of planting. After thirteen years of expenditure, at first on experiments and latterly on *bonâ fide* planting, during which period but little return was received, the scale has now begun to turn, and for the first time in its history the plantation has yielded a tangible result in the way of crop, 211,931 pounds of dry bark having been collected since last annual report. This amount considerably exceeds the forecast made by the Government of India in the seventh paragraph of Mr. Hume's letters reviewing the plantation report for 1873-74, in which it is estimated that, by the year 1877, the plantation should begin to yield at the rate of 150,000 pounds of dry bark per annum. The collection, within a year short of the date fixed by the Government of India, of a quantity of bark exceeding the estimate by nearly 62,000 pounds, may therefore, I hope, be regarded as satisfactory.

2. *Details of the year's crop.*—The bark collected during the past year was taken from different parts of the plantation, and in a variety of ways. The taking of the crop divided itself into eight operations, which I shall now proceed to sketch briefly, premising that the first three of these were cultural, having been undertaken primarily in the interest of the piece of plantation worked on, while the remaining five were undertaken with the double object of getting bark and of adding as much as possible to that practical experience of the various modes of harvesting it which is the only sure basis on which a regular working plan for the plantation can be founded. The crop consists entirely of red-bark (the produce of *Cinchona succirubra*), and the eight operations by which it was harvested were as follows:—

(1) The whole of the plantation of 1867 (with the exception of eight acres, to be subsequently accounted for), extending to about 180 acres and situated on Rungbee, was carefully gone over and thinned where necessary. From this there were obtained 8017 pounds of dry stem and 12,388 pounds of dry branch-bark.

(2) The upper part of the Rishap spur, planted in 1869 at 6 by 6 feet, was thinned and pruned,—an operation which yielded about 74,000 pounds of dry bark, of which about one-fifth was stem-bark and four-fifths were branch-bark.

(3) In like manner the whole *succirubra* plantation of 1872 (with the exception of eleven acres, to be afterwards mentioned) was subjected to a moderate thinning and pruning. The year 1872 was the first in which close planting was adopted. The trees in this piece of plantation stand only four feet apart, giving 2722 trees to the acre, against 1210 trees to the acre in the older planting at 6 by 5 feet apart. As these trees stand in very good soil, and as their growth has all along been luxuriant, a certain amount of thinning had become absolutely necessary for their general welfare. About 16,153 pounds of dry bark were thus obtained, which was composed in round numbers of one-fourth root-bark, and rather less than a fourth of stem-bark, the remainder being branch-bark.

(4) About eight acres of trees on Rungbee, planted in 1867, were cut down close to the ground, only a small proportion of trees being left standing. This operation will give further experience as to the result of nearly complete coppicing of nine-year old red-barks. I say *nearly* complete coppicing, because a few trees are left standing, but not enough to afford any material amount of shade to the shoots that will rise from the stools of the felled trees. The trees cut on these eight acres yielded 6400 pounds dry stem-bark and 3781 pounds of dry branch-bark, or a total equal to 1272·5 pounds of dry bark per acre. These figures do not, however, by any means show all the bark which has been collected from these trees since they were planted, for they have from time to time been thinned and pruned in years past; but of the bark thus obtained, unfortunately no separate record has been kept. This patch of eight acres lies contiguous to a one-acre patch (also planted in 1867), which, on being coppiced in a like fashion in December, 1874, yielded about 2000 pounds of dry bark; but from this patch also bark had been, previously to 1874, taken by thinning. The young shoots that have risen from the stools on the one-acre piece now promise very fairly indeed, as also do those which are beginning to spring from the stools on the eight-acre piece. The future history of the coppice on these nine acres will be of much value and interest, therefore have I entered into so much detail regarding it.

(5) A patch of thirty-five acres of trees near the site of the old Rishap hut, planted in 1866 and 1867, and therefore about nine years old, was entirely uprooted. The yield of bark was as follows:—

	Pounds.
Dry root-bark	41,374·28
„ stem-bark.	19,677·48
„ branch-bark	21,576·00
Total. . . .	82,627·76

This is equal to 2360·8 pounds of dry bark per acre, of which about half is root-bark containing 8 per cent. of alkaloids, and nearly a fourth is stem-bark containing at least 6 per cent. of alkaloids. The present is not the first occasion on which this thirty-five-acre plot has formed the subject of report: it will, therefore, I think, be instructive to trace briefly its past history. Originally planted at distances of 6 by 6 feet apart, the trees, when two and a half years old, were thinned, and 1600 pounds of dry bark were thus obtained. Shortly before the sitting of the Commission appointed to consider the subject of a disease which then (in the opinion of some) threatened the plantation with destruction, and when the plants were about three and a half years old, each alternate row of them was cut down, and dry bark was thus obtained to the extent of 3200 pounds. One of the witnesses who appeared before the Commission was the late Mr. W. G. McIvor, Superintendent of the Government Cinchona Plantation on the Nilgiris, and in April, 1872, or shortly after his examination by the Commission, Mr. McIvor put on record his opinion that, if cut down then (*i.e.*, in April, 1872), these thirty-five acres might (including the 4800 pounds already taken from them) yield a total of about 273 pounds of dry bark per acre, but that, if allowed to remain uncut, a large proportion of the trees would be dead before a year should elapse. Mr. McIvor even went so far as to say that in his opinion more good bark would be got by cutting the trees then than could ever again be taken, bark from dead and dying trees being worthless. Some time after this opinion had been given, a further thinning (the third) of these trees was undertaken, which yielded 8000 pounds of dry bark. Prior to uprootal, these thirty-five acres had therefore yielded 12,800 pounds of dry bark, or at the rate of about 365½ pounds per acre: at uprootal, as we have just seen, they yielded at the rate of 2360½ pounds, bringing their total yield per acre up to 2726 pounds of dry bark, or about ten times the quantity estimated by Mr. McIvor. Mr. McIvor was the most experienced cinchona cultivator of his day, and his opinion carried much weight. These thirty-five acres were about as much affected by the disease of which Mr. McIvor took so gloomy a view as any part of the plantation: it is therefore satisfactory to find that the ravages of any disease that has hitherto appeared amongst cinchonas need after all be but little dreadful.

(*To be continued.*)

HULL CHEMISTS' ASSOCIATION.

The annual supper of the members of the above Association took place at the Cross Keys Hotel, on Wednesday evening, December 13. The President, Mr. C. B. Bell, occupied the chair, the honours of the vice-chair being sustained by Mr. J. F. Smith. There were also present the Mayor (Dr. King), Councillors Chapman and Smith, Mr. B. Stoakes (Secretary), Mr. A. Smith, Mr. H. J. Parsons, Mr. G. Wokes, Mr. E. Allison, Mr. Oldham, Mr. Grindell, and other prominent members of the Association.

The Secretary announced that he had received several letters of apology from gentlemen unable to be present.

The usual loyal toasts having been given and duly acknowledged, Mr. A. Smith proposed the "Mayor and Corporation of Hull," remarking that when Dr. King resigned the mantle which the Corporation had unanimously placed upon his shoulders he would do so with credit to himself and the Town Council.

The Mayor, who was warmly received, observed that this was the first occasion upon which he had had to respond to this toast since he had been for the second time elected to the mayoralty, and he might say that he could not have chosen an assembly to which to respond more congenial to his feelings than was this Association. He had heard it said, again and again, that medical men could scarcely be good sanitarians, because it was a means of reducing their own revenues and cutting their own throats, as some people vulgarly put it. Underneath this assertion there is a fallacy, because it was natural that no man wished to devote a portion of his revenue to burying his family. It was said that enough had been done in these matters, and that our bills of mortality were not increasing; but it must be borne in mind that there was much disease which did not affect the bills of mortality. He knew for a fact, by comparing his practice and those of other gentlemen, that during the short epidemic of scarlet fever which occurred in Hull about two years ago, no less than 800 persons suffered from it. After alluding to the proposed appointment of a public analyst, the Mayor remarked that he hoped there would, eventually, be several medical officers in the town, and that they would divide the town into sections. The trade was well represented in the council chamber by his friends Mr. Councillor Chapman and Mr. Councillor Smith. In conclusion, the Mayor expressed his great acknowledgments for the toast.

Mr. E. Allison briefly proposed the "Town and Trade of Hull," and Councillor Smith, in responding, observed that he thought there must be some benevolence agitating the members of the chemists' trade, because it was not a business to which much profit was attached. The members of the profession were very inadequately paid for their labours, and for the great responsibility which rested upon them. Mr. Smith then alluded to the office of public analyst, and the duties which he considered that officer should fulfil, and, in conclusion, expressed the hope that the Corporation would long maintain the position and credit of the town.

The Mayor then proposed "Success to the Hull Chemists' Association," remarking that he could not help thinking that this Association had done a great deal of good in the town, and that it had it in its power to do a great deal of good in the future. He understood that a much severer test had been established for those who wished to enter the trade. He believed that these examinations had a beneficial effect upon the trade, and he thought this was a wise piece of legislation, and would tend to elevate and educate the minds of the people engaged in it, and thus would be so much the better for the whole trade. He believed the chemists of the future would deserve, and would obtain, a higher recognition than they had done in the past, and would eventually attain an improvement in standing, in social position, and in the profits of the trade.

The Chairman returned his hearty thanks to Dr. King for the kind and handsome manner in which that gentleman had proposed the toast, and he also thanked the members of the Association for the honour they had conferred upon him in re-electing him to the dignity of president. This Association, he believed, had made its mark not only in this country, but throughout the world, because one particular case in which they were interested had been published and circulated all over the world. He was alluding to the celebrated "pick-me-up case." During the past year they had not had any more "pick-me-up" cases to deal with, and he hoped they would have no more. The Excise had looked after them, and they had not to go again before the magistrates. He was glad the Executive Committee had been allowed a little rest, and he was also glad to find that the number of members had not fallen off, but had increased. There had been a slight change in the executive, their friend, Mr. Oldham, finding that he could not now spare the time necessary to devote to the office of secretary. This was a subject of regret, because that gentleman had been a very able and painstaking officer; but the present secretary, Mr. Stoakes, would, he felt sure, be an able substitute for Mr. Oldham, and would render every assistance in his power.

Councillor Chapman briefly proposed "The Officers of the Association," to which toast Mr. J. F. Smith, Mr. B. Stoakes (Secretary), and Mr. Oldham responded.

Mr. Thyer proposed "The Medical Profession," and Dr. Sawden responded.

"The Pharmaceutica Society" was proposed by Mr. G. Wokes, and acknowledged by the Chairman, as Local Secretary of that Society.

The Vice-Chairman gave "The Visitors," who found a respondent in Mr. Lane, the representative of Messrs. Maw, Son, and Thompson.

"The Press," "The Ladies," and other toasts followed.

THE SUNDERLAND CHEMISTS' ASSOCIATION.

The annual dinner of the Sunderland Chemists' Association was held on Wednesday, December 13, at the Palatine Hotel. Alderman Thompson, President of the Society, occupied the chair, supported by Lieutenant-Colonel Gourley, M.P., Councillor Sidgwick, Dr. Yeld, medical officer of health for the borough, Mr. J. J. Nicholson, Mr. R. T. Nicholson, and Mr. Alfred Thompson; Mr. B. Robinson filled the vice-chair.

The company having drunk to "the Health of the Queen and Royal Family," the Vice-Chairman briefly proposed "The Army, Navy, and Volunteers," coupled with the name of Colonel Gourley.

Colonel Gourley, M.P., in the course of his remarks in acknowledgment of the toast, said that, he would like to see all the young men in Sunderland bearing arms, and he was sure that if they were to form in connection with their Society a Pharmaceutical Company they would prove not only a credit to themselves but to the town in which they resided. To persons daily engaged as the gentlemen he saw around him were, the physical exercise involved in the military training would be advantageous in preserving their health and maintaining their mental activity. As commanding officer, he would only be too glad to witness the addition of a pharmaceutical company to the corps. If the chemists took such a step, they would not only be doing themselves good, but they would have the satisfaction of knowing that they were doing something for their country.

The Chairman next proposed "The Borough and County Members," and Colonel Gourley, M.P., who was heartily received, responded in appropriate language. In the course of his speech he asked whether, as an association, the chemists of Sunderland were doing anything for the education of the members of the profession? They represented a branch of one of the most important professions and interests in the whole world—a profession which had its representatives even among the savage races, who, like civilized races in this respect, were obliged to have recourse to the science of medicine. Seeing Sunderland was so deeply dependent upon them, it was important that they should endeavour to raise the educational status of the members of the profession to the highest point. He was not aware whether they were doing anything in this direction, but he suggested that the society should provide a laboratory for the use of students, engage lecturers on professional subjects, and take other steps with the object he had mentioned. Such facilities ought to be accepted as extremely valuable aids to further knowledge by the rising intelligent young men in the profession in this town who ought to occupy a high educational position amongst their fellow men. On the Tyne they found large chemical works, and even the small town of Seaham had got chemical works; but he looked in vain for such works at Sunderland. The attainment of the highest professional position was possible to the young men he saw around them, if they gave themselves to the study of their profession; and he hoped that at some future time they would be able to congratulate themselves on having chemical works established at Sunderland Proceeding to advert to the desirability of the Association forming a class for the study of botany, the hon. speaker urged that for the benefit of the people at large, the names of various plants and flowers in the Park should be placed on labels. When he first occupied the position of Mayor of the borough, Mr. Hartley offered to give glass, Mr. Backhouse £500, and the speaker £250, to build a glass house on the Park, for the protection of rare plants, etc., so that the pleasure of the people might be increased; but the offer was neglected by the "powers that be" at the time.

The Chairman said the promotion of education amongst the young members of the profession had not been lost sight of by the active members of the Association. He had recently suggested that the Corporation should provide in the proposed Library and Museum Buildings rooms in which lectures could be given to classes on various subjects, amongst others chemistry, materia medica, etc. If the Corporation were to provide such a room, the chemists would be prepared to furnish it, and provide lectures, etc.

Mr. Harrison proposed "The Mayor and Corporation of Sunderland."

The Chairman responded, as also did Councillor Sidgwick.

Mr. Alfred Thompson proposed "Success to the Sunderland Chemists' Association." The number of chemists in the town, he said, is 47; while there are 42 or 43 in the Association. They had every reason to congratulate themselves on the position of the Association. He hoped to see the day when they would possess a laboratory, etc., but he would not have them be under obligation to the Corporation for it. He coupled with the toast the name of Mr. J. J. Nicholson, who, he said, had shown very great interest in the Association, and had done all he possibly could to promote its interests.

Mr. J. J. Nicholson responded. He said the report he had to give concerning the society was a most favourable one. Circumstances had occurred which had caused them to draw more closely together in unity, and there had been a considerable accession to their number. There was inaugurated at the beginning of the year a national society, having something like the same objects as were professed by the local society, namely, the protection of their trade interests. The chemists in Sunderland approved of the society, and they sent delegates to the meeting. With two or three exceptions they all joined it, and he believed the national society was going to be a very strong society. It had been objected that its objects were hostile to those of the Pharmaceutical Society, but it should be remembered that while they desired through the Pharmaceutical Society to attain to the dignity of a profession, it was important that at the same time they should not forget to protect themselves as a trade, which they could do through the new society. There was a separate work for each society to do, and he had every hope concerning them. Referring to Colonel Gourley's remarks, Mr. Nicholson said they had aimed in the direction the hon. member had advised ever since the commencement of the Association eight years ago. They had rented rooms and engaged teachers; but there had been inertia in their own body—they could not get the young men to avail themselves of the facilities afforded them. As the funds which were available at the beginning were, he believed, still available for such a purpose, he trusted they would now see a desire manifested to take advantage of the facilities suggested.

Mr. Sharp proposed "The Medical Profession," to which Dr. Yeld responded. The doctor referred to the benefits which were likely to accrue from the new sanitary scheme of the Corporation, and said in the Mayor he found one of his best helpers in carrying out this scheme. The speaker intimated that he had not concurred in the getting of drugs from chemists in the town for analysis, because from his experience of them he knew they did not adulterate the articles they sold. He also commented on the fact that when cases of milk adulterations had been brought before the magistrates, the justices had in some cases inflicted only a fine of 2*s.* 6*d.* and costs, and in others dismissed the persons summoned. In London, the other day, an offender was fined £10 and £3 13*s.* 6*d.* costs. Farmers would rather pay the small fine of a retail dealer than that their names should be published. The magisterial decisions he had alluded to were very little encouragement to the Health Committee and the officers of the Corporation to direct their attention to a most valuable article of food.

"The Officers of the Society" (proposed by Mr. Turnbull) and other toasts having been drunk, the company separated.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 23, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MILITARY PHARMACEUTICAL SERVICE IN RUSSIA AND TURKEY.

THE possible outbreak of war between Russia and Turkey may give interest to a few particulars respecting the military pharmaceutical service in those countries.

In Russia, the mobilization of the army, by which the number of troops under arms has been considerably increased, naturally required also a corresponding strengthening of the medical *personnel.* It is estimated by the military authorities that in case of war, besides the ordinary number on the peace establishment, there will be required 1140 additional medical men, 324 pharmacists and 60 veterinarians. We learn from the *Pharmaceutische Zeitung* that in order to obtain this increased number in the event of an outbreak of war, a plan has been drawn up and sanctioned by the military medical department. In this it is provided that the time of discharging the students from the Medico-Chirurgical School shall be hastened; that all persons serving in the military medical reserve shall be called into active service, and that their places shall be supplied by others in the civil service or in independent practice, and that medical men living in districts where military operations are being carried on should be induced to join the service.

The pay of physicians on active service is to range from 994 to 2291 roubles, or from about £156 to £350 sterling. The pay of pharmacists on active service ranges from 994 to 1411 roubles, or £156 to £220. The independent and retired practitioners entering the military medical service temporarily are to be paid from 150 to 250 roubles, or £23 10*s.* to £39, monthly. Pharmaceutists of this class are to be paid from £23 10*s.* to £30 monthly.

Concerning the Turkish apothecaries, Professor LANDERER writes that those specially available in the military service are trained in a school in Constantinople. In this pharmaceutical school the French language is used by the professors, though few among their auditory are conversant with it. Their pupils are Turkish apprentices, who at some time have had the fortune to serve with some of the French and Italian immigrant pharmacists who are scattered by hundreds over the kingdom, from whom they have acquired such an amount of knowledge as a respectable German apprentice would pick up in six months. In the school they are taught botany, pharmaceutical chemistry (with practical examples, limited, however, to the preparation of plasters, ointments and similar preparations) and the elements of physics. These pupils are remunerated by the Government, and after a theoretical pupilage of twelve to eighteen months they are drafted into the military service.

The Greeks who settle in the Turkish empire as physicians or apothecaries are required to undergo an examination at the Medical College in Constantinople. But, says Professor LANDERER, with true *amor patriæ*, those who have received a pharmaceutical training in the University of Athens are admitted to the distinction of apothecaries, although their experience in practical chemistry may be imperfect, as they would know more than the examining members of the Medical College. What the native pharmacists lack in knowledge, however, they appear to make up in show, for according to the same authority there are in Constantinople, Smyrna and Alexandria pharmacies as handsome as any in Europe, in which prescriptions are made up without a laboratory and with only the assistance of a few pans for the preparation of decoctions, plasters and extracts. Apparatus for filtration and distillation, and other similar vessels, kept only for show and to delude the public, are stored like jewels in a cabinet. A set of reagents for chemical analysis or the testing of the medicines imported from the outside world would be looked upon as a superfluity. Indeed, what use would they be? Preparations imported at fancy prices, especially chemical products, are enclosed in handsome bottles with splendid labels. In fact it would be a pity to examine them, since they bear on their exterior the stamp of genuineness. At least, so says the Turkish apothecary. "These medicines are all very good, for they come from the land of the Franks!" What childlike faith!

THE COLOURING OF CHEESE.

A WELL known public analyst, while giving his evidence before the last Committee of the House of Commons on Adulteration, expressed his opinion that the public had as much right to be supplied with green tea, if it preferred tea of that colour, as to be supplied with brown coats. But the present standards of purity being somewhat personal are also local, and the circumstances which now make it penal in some districts to sell as milk of sulphur the compound known under that name for a couple of centuries, whilst it can be freely sold in others, would probably make it risky for a grocer to sell an artificially coloured tea until he has studied the idiosyncrasy of the public analyst who might be called upon to examine it. But how is it that coloured cheese has been tolerated so long, and that it has been left to the cheesemakers to initiate a movement for its abolition?

The subject was mooted at the last meeting of the Cheshire Agricultural Society, in the shape of a proposition that in future all cheese exhibited at the Society's shows should be free from "colouring adulteration." The speaker enforced his argument by describing the colouring matter as nasty to look upon, nasty to smell, and unpleasant to taste, whilst at the price of 3*s.* to 4*s.* a hundredweight it was estimated to cost the farmers of the county at least £10,000 per annum, for which they received no return. Another speaker, while admitting that the colouring was of no benefit, but rather injurious to the cheese—"in fact, a sham, a delusion, and a snare"—objected to the prohibition unless it could be shown that the colour was detrimental to the health of the consumer. The chairman seemed to express the opinion of the meeting in saying that the question lay between the producers and the consumers, for everybody knew what coloured cheese was; some people liked coloured cheese, and some did not. Such reasonable arguments, however, as shown by previous experience, would have as much effect upon the stern purism of some public analysts as the pouring of water upon a duck's back.

THE COPAIBA TREE.

MR. ROBERT CROSS, who has just returned to England from South America with a large number of india rubber plants (*Hevea brasiliensis*), has also brought with him, we learn from the *Gardeners' Chronicle*, a small quantity of well ripened seeds of the Copaiba tree, which gives the balsam of capivi of commerce. The seeds were collected, after much searching, in the forests of Pará. The balsam obtained from the Pará tree is reported to be more transparent than that from other districts, and is called *copaiba blanca*. A large quantity of it is sent annually to the French market, where it commands the highest price. In the Pará forests the trunks of the trees are seen rising to a height of about eighty feet without a branch. Such trees, if tapped at the proper time,—which has yet, however, to be determined,—will often yield 4 "potos," or about 84 pints, each. Mr. CROSS describes the life of the balsam collector as being a very wretched one.

THE ROYAL INSTITUTION ARRANGEMENTS.

IT is announced that the probable arrangements for the Friday evening meetings of the Royal Institution before Easter will include lectures by Professor TYNDALL, Professor HUXLEY, Professor OSBORNE REYNOLDS, Mr. FRANCIS GALTON, Professor F. GUTHRIE, Mr. J. F. MOULTON, Sir JOHN LUBBOCK, Mr. F. J. BRAMWELL, and Professor GLADSTONE. The Christmas lectures, adapted to a juvenile auditory, are to be delivered by Professor GLADSTONE, the subject being 'The Chemistry of Fire.'

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

December 13, 1876.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Three* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Andrews, William Leatham ...Scarborough.
Gostling, William Ayton.........Diss.
Hart, Philip ....Bolton.
Wilkinson-Newsholme, Geo. Thos. Huddersfield.

MINOR EXAMINATION.

Sixteen candidates were examined. *Eight* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Asher, James ....Derby.
Barrow, Frank Arthur ....Newmarket.
Cæsar, Julius.......................Cosham.
Colling, Herbert ....Brighton.
Hume, John Wm. David ......Stokesley.
Ottey, Thomas ....High Wycombe.
Saunders, James Edwin ....Stamford.
Wilmer, Frederick Joseph ......Newport Pagnell.

December 14, 1876.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor and Umney.

MAJOR EXAMINATION.

Six candidates were examined. *Four* failed. The following *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Frank, John ....Whitby.
Hatch, James Oliver ....Lancaster.

MINOR EXAMINATION.

Eighteen candidates were examined. *Nine* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Curtis, Frederic George ....Dorchester.
Dester, Joseph ....Warton.
Dixon, Richard Dobson ....Sharow.
Greenish, Henry George.........London.
Hogg, James Edmund............Worcester.
Jenkins, Thomas ....London.
Newton, Arthur James ....Dudley.
Wells, Albert Charles ....Leamington.
Wright, Watkin Valentine......Wrexham.

December 15, 1876.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Eleven* failed. The following *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Alcock, Henry ....Coventry.
Anderson, James Johnstone ...Epworth.
Aves, Arthur Kerner ....Mansfield.
Burrows, Charles Wm. Grimes...Ironville.
Cluett, Benjamin...... ....Kingston-on-Thames.
Davies, Thomas William.........Cardigan.

Gibson, John Chambers .... Manchester.
Ives, Robert Hanworth .... Norwich.
Jenkins, Thomas .... Swansea.
Palmer, George Smith............ Lincoln.
Parkinson, Frederic William ... Peterborough.
Wheeler, Frederick Ebenezer... Manchester.

December 20, 1876.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Southall, Taylor and Umney.

MAJOR EXAMINATION.

Six candidates presented themselves. *Four* failed. The following *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Davidson, Alexander .... Insch.
Robinson, Thomas Dexter ...... Bedford.

MINOR EXAMINATION.

Nine candidates presented themselves. *Seven* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bate, Joseph William .... Walsall.
Blackbourn, Arthur .... Birmingham.

MODIFIED EXAMINATION.

Seven candidates presented themselves and passed, and were declared qualified to be registered as Chemists and Druggists:—

Bannister, Sam...................... Bewdley.
Coates, George .... York.
Evans, David .... Croydon.
Judge, James .... Kilburn.
Morton, Samuel Edward......... Newington, Surrey.
North, Thomas Henry............ Hull.
Spurgeon, Frederick John ...... Chelmsford.

October 21, 1876.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Southall, Taylor and Umney.

MINOR EXAMINATION.

Twenty-two candidates presented themselves. *Eleven* failed. The following *Eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Beall, Samuel Smart .... Cambridge.
Biddiscombe, Charles .... London.
Bond, Alfred......................... Fallowfield.
Brayne, John William Ward ... New Mills.
Colegrove, John Thos. Faulkner. Liverpool.
Jones, George Henry .... Hanley.
Kent, James Stephen .... London.
Marshall, Charles William ...... Devonport.
Mayne, James .... Chertsey.
Thornber, William .... Preston.
Webb, William James............ Melbourn.

PRELIMINARY EXAMINATION.

The undermentioned Certificates have been received in lieu of the Society's examination:—

Certificate of the College of Preceptors.

Sherwood, Joseph.................. Stockton.

Certificate of the Royal College of Surgeons of England.

Bellingham, Timothy Barney... Dudley.

Certificate of the Society of Apothecaries of London.

Bell, Charles T. .... Retford.

Certificates of the University of Cambridge.

Kemp, Herbert William .... Horncastle.
Sergent, William Thomas ...... Croydon.

Certificates of the University of Oxford.

Carter, Joseph Montague ...... Manchester.
Hart, William .... Bolton.
Shephard, William Arthur ...... Spalding.

NORTH BRITISH BRANCH.

The second meeting of the present session was held in the Society's rooms, 119A, George Street, Edinburgh, on the evening of Wednesday, 13th December, 1876, Mr. William Gilmour, President of the North British Branch, in the chair.

Mr. William Inglis Clark, Edinburgh, read a paper on the Microscopy and Adulterations of Colocynth Powder, which is printed on page 509 of the present number.

Mr. Clark also read a short paper "On a Deposit in Solution of Bicarbonate of Soda," which will be found on page 511.

Mr. Clark illustrated his paper on colocynth powder by numerous diagrams and microscopic specimens; and the one on Bicarbonate of Soda by chemical experiments in proof of the different points alluded to.

On the conclusion of the paper on colocynth powder, Mr. Gilmour, in proposing a vote of thanks to Mr. Clark, remarked that the subject of adulteration of colocynth was one that would come home to each one present, and he felt more and more convinced of the great benefits to be derived from the use of the microscope in practical pharmacy. He had no doubt Mr. Clark could mention many other powders, drugs, etc., which might be as easily and as certainly examined as powdered colocynth; the great point necessary in such an examination being the thorough acquaintance with the microscopic structure of all the tissues to be met with. He felt sure that the subject had been made more interesting and more easy to be followed by the numerous diagrams which Mr. Clark had prepared in illustration to the parts referred to.

Mr. J. R. Young said that he was astonished to hear of the large proportion of starch present in a sample of the powder, but he hoped that this was an exceptional case, and that the exposure of this instance, drawing attention to the adulteration, would prevent a continuance of the practice. He felt sure that each one who had a microscope would be able and anxious to examine the purity of his colocynth.

In reference to Mr. Clark's paper on bicarbonate of soda, Mr. Gilmour remarked, that although it did not come home to each one as the paper on colocynth, yet it was a thoroughly practical paper, and showed how many little points often overlooked, when properly investigated, could be made very instructive and interesting. The deposit referred to, he said, had annoyed several soda-water makers for a long time, and he believed in order to remedy it, they added some acid or chemical which would be able to dissolve it, and yet not act on the soda-water. He said that it was difficult to follow such a paper fully without going over it in detail, but it appeared to him that the theory suggested by Mr. Clark was the true one as it certainly was a possible one. Referring to a large glass jar of Edinburgh water which had been treated with solution of carbonate of soda, and which had turned almost milk-white with the deposit, he expressed his astonishment not only at the copious deposit but also at the rapidity of its formation—the experiment taking about half an hour. Mr. Gilmour in pointing to some pieces of soda-water apparatus exhibited, which were incrusted with carbonate of lime, said that the subject was one of considerable importance to soda-water makers and worthy of further investigation.

Mr. Mackay in referring to the experiment with the Edinburgh water, before mentioned, asked what was the strength of the solution of carbonate of soda used. In reply, Mr. Clark stated that it was equivalent to a little less than 30 grains of bicarbonate of soda per pint, while in another experiment with carbonate of potash, instead of the soda salt, little or no precipitate was thrown down, the solution of potash being of an equivalent strength.

In speaking to Mr. Clark's statement that this deposit does not fall with Loch Katrine water, Mr. Mackay pointed out the great advantages some makers have over others, and mentioned the case of a famous soda-water maker, who had long drawn very pure water from an artesian well, when suddenly and without warning the water smelt strongly of sulphuretted hydrogen, and the result was for a time, he believed, very damaging to the maker. No chemical explanation had as yet been offered for the occurrence, unless a discharge of gas from the interior of the earth had happened. He then said that it was interesting to learn that the sole cause of the deposit, as had been demonstrated by experiment, was the presence of the carbonate in the bicarbonate of soda, and that the passing of carbonic acid through the bicarbonate would effectually remove it, as had, he believed, been already demonstrated.

Mr. J. R. Young asked if the deposit of 200 grains per gallon occurred with Howard's bicarbonate, and was answered in the affirmative.

At the request of Mr. Gilmour, Mr. Clark made a few remarks supplementary to his paper on perchloride of iron, read before the Society last February. Referring to the decomposition of perchloride of iron, he reminded them that if it had been prepared from a basic liquor, it would contain a large quantity of ferric oxide which would be deposited, and that if the tincture again was heated in a closed bottle, a similar result would be obtained and ferric oxide thrown down, but that in this latter case, if the tincture was then exposed to light for some months, the precipitated ferric oxide would be re-dissolved, a very brown tincture resulting. On further exposure, chlorine is abstracted from the ferric chloride and partially used up in forming chlorine compounds, and partially in converting the alcohol into aldehyde, leaving a tincture, having a pure green colour due to ferrous chloride. The decomposition proceeds still further however, for in a sample exhibited the ferrous chloride itself had been entirely decomposed, ferric oxide being thrown down, and the clear liquid left containing but very little iron. Samples of the tincture in all stages of decomposition were exhibited and presented to the museum.

Mr. Gilmour stated that he had been investigating the decompositions of tinctures by heat and light, and that although not analogous to the one in question, he had found even an hour's exposure to sunlight sufficient to induce decomposition in most of them. He asked if the samples exhibited and described had been openly exposed to the air, or contained in a stoppered bottle.

Mr. Clark said that they had been kept in stoppered bottles and exposed to light, in some cases, for more than a year.

Mr. Young asked if anything could be done to restore a sample of tincture which had decomposed to the extent described.

Mr. Clark considered such a tincture as incorrigible.

Mr. Mackay then read the following note:—

"5, Lorne Terrace,
"December 12, 1876.

"John Mackay, Esq.,

"Dear Sir,—Mr. T. Knott having now finished the portrait of my late father, I have much pleasure in handing it to you for presentation to the North British Branch of the Pharmaceutical Society.

"I am, dear Sir, yours truly,
"DAVID BROWN."

Mr. Mackay said it was not often as honorary secretary to the Society he was privileged to ask the acceptance of such a gift as the portrait now before them. In doing so he could not refrain from reminding those present of the high position which his late much-esteemed friend Mr. David Rennie Brown had occupied as a member of the Society. His whole career pointed to a man of great natural ability, combined with an amount of energy and indomitable perseverance which had resulted in placing him in the foremost rank of British pharmacists. He had a very quiet and unpresuming manner, and to those privileged to know him it was frequent matter of regret that from this cause he was so unwilling to come to the surface, for had he done so, much valuable information might have been gained on pharmaceutical and chemical subjects. A more honest, upright man never lived, and this was more especially shown in connection with his position as a member of the Board of Examiners for Scotland, where, with a calm genial mode of questioning, he soon put the candidate at ease; but in the results he was most particular and unflinching. Making every allowance for the nervous trepidation of many young men coming before him, he yet felt how important it was for those about to be placed on the register to possess a fair knowledge of chemistry in all its details, and when he found real deficiency no one was more firm in denouncing and recognizing such a state of matters. By many his memory will be long cherished, while his contributions to the library and museum will form a lasting memorial of the strong desire he had that both these departments should be worthy of this branch. He (Mr. Mackay) therefore hailed the presentation of this portrait not only as an adornment to their walls, but as a remembrance of one much respected and esteemed, while a glance at the likeness could not fail to act as an incentive to those of their young friends who were already acquainted with the name, if not with the efforts of him who had so recently left them.

Mr. Mackay then moved that a special vote of thanks be accorded to Mr. David Brown for his kind presentation; and further, that the same be expressed in writing and sent to the donor, who in honouring the memory of his father had also honoured the Society in asking it to accept the excellent portrait.

Mr. Gilmour, in seconding the vote of thanks proposed by Mr. Mackay, could endorse all that had been said regarding the late Mr. Brown. It so happened that he had been examined by Mr. Brown in chemistry, and it would be difficult to express how much he had benefited by having been thus brought in contact with the deceased gentleman. He cordially seconded the vote of thanks proposed, to which the meeting heartily responded.

Mr. J. R. Young briefly, and with much feeling, endorsed the sentiments expressed by Mr. Mackay in reference to his late partner in business.

The following contributions to the library were announced:—'The Chemists and Druggists' Diary for 1877,' from the publishers; the *Canadian Pharmaceutical Journal* for November, from the Ontario College of Pharmacy.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fourth general meeting was held at the Royal Institution, November 23rd 1876. The President, Mr. A. H. Mason, F.C.S., in the chair.

Mr. J. F. Raimes was elected a member, and Mr. G. Oldershaw an associate.

The inquiries in the question box were answered.

Mr. T. Garside, F.C.S., detailed the results of some experiments on sulphuric acid, stating that he had found lime present in some samples. On diluting the acid with distilled water and letting it stand, a white deposit subsided, which upon treatment with sulphuretted hydrogen was not blackened. He believed that it was often taken for granted that the deposit formed when testing sulphuric acid by the Pharmacopœia process was sulphate of lead, but he found it to be lime, and the only way he could account for its presence was from the plaster of paris used to cover the stoppers of the vessels containing the acid.

Mr. E. F. Morton read the following paper:—

Notes on some Organic Substances Produced in Certain Saline Solutions.

BY E. FORBES MORTON.

The production of some organic substances in certain saline solutions at the Queens' College Laboratory, was noticed by Professor Hamilton, and afterwards by myself; more especially in those solutions which were exposed to the direct light of the sun.

At his suggestion that I should try some experiments on the subject, I performed the following, of which I will give an account after naming the solutions in which we found the development taking place, and describing the appearance of the substance produced.

Magnesium Sulphate. In solution of this salt the organic substance forms as a layer, somewhat similar in appearance to mould, on the bottom of the bottle, and is at first white; it then gradually changes in colour, becoming pale green. This pale green substance changes slowly to dark green, and is slightly altered in character, until it resembles miniature foliage. It chiefly confines itself to the bottom of the solution, but after a considerable development has taken place, it is produced on the surface and on the sides of the bottle.

Sodium Phosphate (common). The organic substance is produced in a similar manner in solution of this salt, the above description therefore will apply to its formation, with the exceptions that it is developed on the sides of the bottle at an earlier period than in the magnesium sulphate solution and the green colour makes its appearance more slowly.

Calcium Sulphate. The formation of the organic substance in solution of this salt takes place slowly, and the colour of it seldom becomes more than pale green.

Water. A very slight development takes place in distilled water.

The solutions were kept in glass stoppered bottles, they were moved frequently during the winter, but in the summer remained almost untouched.

The organic substances produced became dark green only in those bottles on the side of the laboratory which is exposed to the direct light of the sun, those on the other side becoming light green, but not dark green. Similar solutions kept in the dark showed no such organic products.

When shaken, the green substance was broken into small portions, which floated about in the liquid; some having the appearance of flexible laminæ then subsided and continued to flourish, ultimately uniting together again.

When examined with the microscope the substance was seen to consist of cells, some of which were very slightly developed, others contained nuclei and others again occurred in groups of three or four. Mr. G. F. Chantrell, Honorary Secretary of the Microscopical Society of Liverpool, has been kind enough to examine them for me, and is of opinion that most probably they will develop into fungi.

The green substance formed in the solution of magnesium sulphate, also that occurring in the solution of sodium phosphate, as well as the white primary deposit produced in the latter solution, each when washed, dried, and then ignited, charred and gave off a disagreeable odour. On adding potassium chlorate to the residue, and heating again, deflagration took place; proving the black residue to be carbon.

At the commencement of last March I made the following solutions, and introduced them into wide mouthed bottles fitted with loose corks.

Consisted of	Together with
No. 1. 100 c.c. Distilled Water	
No. 2. 100 c.c. Distilled Water	1·0 gram Magnesium Sulphate
No. 3. 100 c.c. Distilled Water	0·5 gram Magnesium Sulphate
No. 4. 100 c.c. Distilled Water	1·0 gram Zinc Sulphate
No. 5. 100 c.c. Distilled Water	1·0 gram Alum (Common)
No. 6. 100 c.c. Distilled Water	1·0 gram Sodium Phosphate
No. 7. 100 c.c. Distilled Water	1·0 gram Sodium Chloride
No. 8. 100 c.c. Distilled Water	1·0 gram Microcosmic Salt
No. 9. 100 c.c. Distilled Water	0·5 gram Magnesium Sulphate and 0·5 gram Sodium Chloride
No. 10. 100 c.c. Solution of Calcium Sulphate (Saturated)	0·5 gram Magnesium Sulphate and 0·5 gram Sodium Phosphate
No. 11. 100 c.c. Solution of Calcium Sulphate (Saturated)	
No. 12. 100 c.c. Solution of Calcium Sulphate (Saturated)	0·5 gram Magnesium Sulphate 0·5 gram Sodium Phosphate 0·5 gram Sodium Chloride 0·5 gram Sodium Silicate and 0·5 gram Microcosmic Salt.

I then placed these bottles in that part of the laboratory where they would be most exposed to the sun's rays.

In numbers 10 and 12 it will be observed that precipitates must have formed; these I allowed to settle down to the bottom and remain there.

The results obtained up to the present time have been as follows:—

Nos. 1, 2, 3, 5, and 12. In these no visible change has occurred.

No 4. Early in April a yellow sediment formed at the bottom; probably owing to some impurity in the salt used.

Nos. 7, 8, and 9. A slight white sediment was produced in each of these during April, and has since remained unchanged.

No. 6. About the 23rd March white specks appeared on the bottom of the bottle; by the 30th March these had developed into white tufts. which formed at the surface of the liquid, as well as on the sides and bottom of the bottle. These tufts continued to increase in size and number, varying slightly in appearance, but still all having a radiated structure. On the 8th May one of the tufts had become brown towards the centre, but since this date no marked change has been observed.

No. 10. No visible change took place until about the 20th July, when small patches of a green colour formed on the precipitate. Probably the substance had been already produced, and owing to its colour being white had escaped observation. The substance has since become darker in colour, and increased in amount, though it continues to form irregularly.

No. 11. About the 20th April a white sediment appeared, which gradually changed to yellowish green, and by the 12th May had become green. On the 20th June it had commenced to form on the sides of the bottle, round about the surface of the liquid, and since this date has slowly increased in amount, and darkened in colour.

From the facts observed it would appear that the substance formed is a vegetable organism; that the direct light of the sun, acting for a considerable time (many weeks) is essential for its full development and the production of its green colour; and that of all the solutions employed, magnesium sulphate, calcium sulphate, and sodium phosphate, are most favourable to its growth.

A discussion followed in which several members took part, and on the motion of Mr. Garside, seconded by the Honorary Secretary, the President conveyed the thanks of the meeting to Mr. Morton, hoping that he would lay before the Association the results of his further investigations on the subject.

The fifth general meeting was held at the Royal Institution, December 7th, 1876, the President, Mr. A. H. Mason, F.C.S., in the chair.

Several donations to the library were announced, and the thanks of the meeting passed to the donors.

The President spoke of the loss which the Association had sustained by the death of Mr. J. H. Johnson, who was one of its oldest members.

The following inquiries were found in the question box:—

"Does sodium carbonate become decomposed by intense heat?"

"What is hyocholic acid?"

and were answered by Mr. Davies and the President.

Mr. E. Davies, F.C.S., called attention to an important trial that had recently taken place respecting the shipment of some zinc powder, the ruling of the court certifying that it was of a combustible and dangerous nature. Mr. Davies explained that the zinc powder is metallic zinc in a very finely divided state, being produced in the process of zinc smelting. He had noticed in operating on small quantities with addition of water that a considerable elevation of temperature takes place, but not actual fire.

Mr. Thomas Williams, F.C.S., said that during long experience which he had had in the management of zinc works he frequently had noticed a spontaneous combustion of zinc powder. The usual circumstances under which this happened were—1st. When newly produced powder was inadvertently deposited in a damp situation. 2nd. The zinc powder, which is collected in sheet iron pipe-condensers attached to the mouths of the retorts, on being emptied undergoes active combustion. When the best zinc ores are under operation the zinc sublimate is of remarkable purity. The condensation of zinc powder takes place in an atmosphere of carbonous oxide gas.

The President read a paper, "Notes on Glycerole of Subacetate of Lead." Alluding to the paper published by Mr. Balmanno Squire, M.B., in this Journal, in which he gives the formula for preparation as follows:—"Acetate of Lead, 5, Litharge, 3½, Glycerine, 20 parts: heat for half an hour in a boiling glycerine bath, constantly stirring, and filter in a gas oven or other kind of heated compartment; the result is a perfectly clear and colourless liquid, etc.;" the author alluded to other methods for the preparation, and exhibited various specimens of glycerole of lead. In the *Pharmaceutical Journal*, May 6th, Mr. Squire publishes a communication for pharmacists, in which he summarizes his pamphlet for their consideration and modifies his previous suggestions for manufacture. The President considered Squire's process most unsatisfactory and recommended the suggestion made by Mr. Parry (*Pharmaceutical Journal*, May 27th), that equal parts of liq. plumbi subacetatis and glycerine be gently heated until the water is evaporated, by which method a very satisfactory and elegant preparation was produced.

In the absence of Mr. Michael Conroy, through indisposition, the President read the following paper—

Summary of a few Laboratory Notes on Glycerole of Nitrate of Bismuth.

Mr. Balmanno Squire, M.B. Lond., in his very interesting paper on the above subject, published in the *Pharmaceutical Journal* of the 11th ult., states that he found nitrate of bismuth to be readily soluble in glycerine without decomposition. As my experience is to the contrary I beg to put before the meeting the results of experiments. In the first experiment one part of nitrate of bismuth and nineteen parts of Price's pure glycerine were shaken together for three hours, and occasionally afterwards for a couple of days, without the salt becoming entirely dissolved, showing that it is most difficult to dissolve this salt in cold glycerine. In the second experiment the same proportions were placed in a water-bath and warmed up to 140° Fahr., when the nitrate of bismuth became slowly dissolved; the operation taking altogether about fifteen minutes. By this latter process I noticed that before solution the crystals became considerably effloresced, owing, undoubtedly, to the dehydrating property of glycerine, while the glycerine itself became slightly tinged brown, owing to the action of free nitric acid. From these observations I am inclined to believe that a decomposition occurs, part of the water of crystallization with part of nitric acid being taken up by the glycerine, converting the normal nitrate into a basic salt; probably it is the salt mentioned by Graham, which he obtained by heating the nitrate to 78° C., viz., $2BiNO_4H_2O$ (Watts's 'Dictionary of Chemistry,' vol. iv.). Be this as it may, the preparation is the result of a very happy idea, and destined, in my opinion, to come into very general use.

An interesting discussion followed, in which Dr. Symes, Messrs. Tanner, Abraham, Davies, Haddock, Williams, and the President took part.

Mr. Arthur Haddock made the following communication:—

Notes on Dr. Davy's Molybdic Acid Test for Alcohol.

I have had occasion to try Dr. Davy's molybdic acid test for alcohol,* and found it to succeed admirably. I prepared a solution of molybdic acid by digesting it on the water-bath with ten parts by weight of pure sulphuric acid until a clear solution was obtained. I then made two solutions: one containing 1 per cent. by volume of absolute alcohol and the other 0·1 per cent. Three drops of the molybdic acid solution were then placed in a porcelain dish and heated for a short time in the water-bath and a single drop of the alcohol solution allowed to fall into them. With the 1 per cent. solution streaks of blue immediately appeared which gradually spread through the whole of the solution and an intense blue coloration was the result. With the 0·1 per cent. solution the colour was much fainter but still quite distinct. With amylic alcohol and with the ordinary chloroform I also obtained the reaction, although with pure chloroform no colour is produced, alcohol being generally added to chloroform for the purpose of preserving it. It is necessary in applying the test that the liquid to be tested should be gently dropped into the molybdic acid solution, as the least agitation destroys the colour. It reappears in the 1 per cent. solution after heating on the water-bath for ten minutes, but shortly after finally disappears. In the 0·1 per cent. solution the colour does not reappear after agitation.

The President took exception to Dr. Davy's statement that chloroform which was affected by this test was necessarily adulterated with alcohol; the addition of alcohol to pure chloroform being necessary to preserve the chloroform.

Mr. Abraham said it was the first time he had heard an official statement that spirit was added by the manufacturers to chloroform, and he should be inclined to dispute it, for although this article was labelled by the manufacturers sp. gr. 1497, he believed in reality it would be found 1501. He alluded to Dr. Gregory's method of the manufacture of chloroform and to some investigations he had made several years ago, which resulted in Dr. Gregory's method being condemned.

The President said he agreed with Mr. Abraham that pure chloroform had a specific gravity of 1500, but he considered that the fact of the British Pharmacopœia giving the specific gravity as 1497 justified, and was purposely so given to allow the addition of 1 per cent. of alcohol. He would feel obliged if Mr. Abraham would examine the specific gravity of Duncan and Flockhart's chloroform and report at the next meeting.

---

* See before, p. 463.

Some discussion took place upon the application of the molybdic acid test for the detection of alcohol in urine.

The thanks of the meeting being given to the authors of the various communications, the members adjourned.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The usual monthly meeting of this Association was held in Anderson's University, on Wednesday evening, the 13th inst., Mr. Kinninmont, the Vice-President, presiding. The minutes of former meeting having been read and confirmed, the Chairman stated that it had been thought advisable to give the members of the Association an opportunity of expressing their opinion as to the necessity for a Trade Protection Association, and this meeting had been called for the purpose of discussing the question,—Is the Pharmaceutical Society, as at present constituted, capable of protecting the interests of the entire trade, or is the existence of a special Trade Association necessary? A letter had been received from the President, as follows:—

"113, Buchanan Street, Glasgow,
"December 13, 1876.

"My dear Mr. Fairlie,

"I hope you will excuse my absence from the meeting of the Society to-night.

"I think it quite right to ascertain—now that the question on both sides of it is fairly before them—the feeling of our members as to the Trade Association, but as I have said my say on the subject and have nothing to add to it, I think my presence may be spared. I just hope that every one present will give as full and frank an expression of their views on the subject as I myself ventured to do, and that should there be a divided vote, that whichever view prevails the minority will loyally fall in with the majority, so that we shall henceforth have, as in the past, a united society with which to confront any or all foes who may seek to molest us in the *lawful* pursuit of our anxious and irksome calling.

"I am very truly yours,
"DANIEL FRAZER."

Mr. Kinninmont said he regretted the President's absence, but he had no doubt but that they would act upon his advice; he had now to call upon the Secretary, who had kindly consented to open the discussion.

Mr. James M. Fairlie (Hon. Sec.), then read the following paper:—

Mr. Chairman and Gentlemen,—In introducing the subject that has been placed upon the programme for discussion this evening, I feel that I have undertaken a somewhat delicate if not a difficult, task, as it may be necessary for me, at least indirectly, to refer to the objections our much esteemed President made against the necessity for a Trade Protection Association in his inaugural address last month; and this I believe in ordinary circumstances is a breach of etiquette, but as the subject of the unwillingness or the inability of the Pharmaceutical Society's representatives at London to cope with all the little matters which crop up from time to time to worry and annoy members of our trade, and the apparent necessity there is for a special Trade Defence Association has been engaging the minds of pharmacists throughout the country for some months, and as this Association has had no opportunity hitherto of considering the matter, there appears a reason why we should discuss the subject, and if possible come to some decision upon it. I place two points therefore before you. First,—The Pharmaceutical Society is not able to protect the interests of the entire trade. This is denied by not a few of the leading members of the Society. But there are such performances as going up in a balloon, and we are told by people who have made such an ascent that when they reach a certain altitude they see trees like men, and men like insects on the ground; with all due respect, however, to those parties, and no one can deny their disinterested labours and enthusiasm in trying to advance the common interests of the trade, I venture to suggest that they go up in a balloon when they make the assertion, "That the Pharmaceutical Society is able and ready to do all that is required in the interests of the whole trade." What I mean is that their position in business prevents them from understanding the exact position of those who happen to be in a smaller way of business than themselves. Their own statements prove this; they say, "let every member of the trade join the Pharmaceutical Society, and they have the power to change the membership of the Council in their own hands; in two years the whole of the present Council could be turned out, and a new council substituted." There are two reasons, however, why a change of this kind could not produce such a complete alteration in the composition of the Council as might be necessary or expedient, even though every chemist in the kingdom joined the Society tomorrow; in the first place, the constitution of the Council is in one respect definite, the majority *must* be pharmaceutical chemists; and second, it is only the few that can afford the time to attend to Council business, although they had the qualification in every other respect. Now the number of pharmaceutical chemists are very few in comparison to the number of registered chemists and druggists, and such being the case it can hardly be possible to get a Pharmaceutical Council that could fairly be said to represent the bulk of the trade. Bear in mind I do not find fault with this arrangement in the composition of the Council at present, I bring it forward only as an illustration of the absurdity of such a line of argument. But they say the Council as representing the Society is prepared to defend the interest of any chemist that is harassed unnecessarily. To prove that this is not the case, need we go back so far as 1871, when a Poisons Bill was before Parliament, and which but for the existence of the Defence Associations which were then formed in three parts of the country would in all probability have been in one form or another forced upon us as a trade, and with the consent too of the majority of the then Pharmaceutical Council? Need we refer to the numerous prosecutions under the Adulteration Acts, most of which I am certain that had the Council the power as well as the will to bring their authority to bear upon the cases in question the law would be so laid down that no druggist would have the shadow of an excuse to be entrapped by inspectors either of one class or another? If it is wrong to sell precipitated sulphur for milk of sulphur, or the effervescent saline for citrate of magnesia, and the Council have the power, let a circular be issued to every member of the trade making a declaration to that effect; such would leave individual members of the trade in no doubt as to their duty in the matter. If on the other hand, it is right and proper to sell these articles according to "use and wont," then let the Society's law agent or his representative defend the cases, and let us not have in one case a conviction and in another a verdict of "not proven," with one section of the trade thinking it is all right and another that it is all wrong. Or need we refer to the action of the Medical Defence Association in its raid against prescribing druggists. Those of us who read the trade journals know that by a narrow majority the Council decided to defend any unjust case of prosecution in this respect, but the bulk of the trade know nothing about it, and we know well that very many druggists do prescribe, and are probably ignorant of the fact that they are liable to prosecution; here again is a case where a circular might do a world of good. The question of expense comes in here, however, when a matter of this kind is suggested. It is possible that the Council have no money to spend in this way; if not, then my argument holds good that they cannot protect the interests of the whole trade aright. If, however, they have the power, but withhold it on the ground of the expenditure, then, I say, it is short-sighted policy. One of the reasons I believe why so few become connected with the Society is just because they know little or nothing about it; they seldom see a trade journal; they scarcely ever receive a circular from the Society that governs them, and unless some national movement takes place—such as a fight over a poisons bill—they hardly remember such a body exists, and then they imagine it is not fulfilling its province, and when the agitation is over they go back to their old habits, and continue to nurse their old grumbles about the existence of a society that is not doing its duty. A body such as the Pharmaceutical Society must keep itself prominently before those who ought to be its constituents, if it is to exercise that power and influence it ought; and I feel warranted in asserting that if but once a year a circular were issued to every person on the register, touching on some of those points I have indicated, accompanied by a leaflet explaining the object of the Society, an annual addition would be made to the membership which would more than repay the outlay; and though the Society did lose financially, it would gain in the respect with which it would be looked up to by all sections of the trade. There are other reasons than these why the Society does not and cannot represent the entire trade; one of these I would instance is the publication of its Journal. The great mass of the matter that is contained in its pages is far beyond the reach of the great majority of the trade to comprehend—it is, in fact, at least a dozen years in advance of the trade it represents; and while speaking of the Journal I cannot but refer to the conduct of present and past Councils in conducting their business with closed doors, serving up to its constituents month after month a "cooked" report, which in every case I am satisfied gives but a poor account of the amount of business they get through. If the Society could adopt with propriety some such action as I have indicated, then I would acknowledge at once that there was no need of a Trade Association. But is it advisable that it should take upon itself the *rôle* of a trade protection society? If so, it must do much more even than I have here indicated; there must be a disposition to regulate the retail prices for medicines and hours of closing, together with a more active interest in provincial matters; the doors of the Society itself must also be made a little wider by doing away with the entrance fee, if not reducing the annual subscription under certain circumstances—as well as a Council drawn from a wider area. But is this advisable? I think not, and I would not be in favour of it if it were proposed. Unless, however, the opponents of the Trade Association are prepared to grant all this and a great deal more, they are tied down to the other alternative, and that is my *second* point, that the formation of a Trade Protection Association has become absolutely necessary. But the opponents ask what good can it do? It can have no legal status! As a prosecuting agent I acknowledge it cannot; but as has been before argued, it can do work in the way of preparing evidence, defending and getting up cases, which the Pharmaceutical Society is quite unable to do with its present machinery. The Trade Association requires no legal status to defend cases of unjust prosecution on the part of the Excise, the Medical Defence Association, or Adulteration Act inspectors. But, say our opponents, "these cases are few and far between, and when they do arise there are always other members of the trade ready to help to overturn any unjust proceeding." Very true, but we have no guarantee that the cases will continue to be few and far between; already they are thickening, and is it business-like to trust to haphazard in a matter of this kind? I think not. We will take a case in point; a dozen men are summoned for some assumed offence, and from some slight error on the part of a local law agent, who perhaps does not understand the case, a conviction is made, and as one case is taken as a type of the whole, each are fined; the fines and expenses of the whole, we shall say, amount to £30, the amount is subscribed among the local friends; but is there any guarantee that another batch may not be taken up the following week? None whatever. But looking at it from another standpoint, this case is perhaps a test case, the whole trade are interested in the decision one way or the other. If it is unfavourable they will know to comply with the laws. In this way the whole trade benefits, but the few in one district have to pay the piper. Why should the money to defend such a case not come out of a common fund? and why should any withhold from aiding such a fund? Another objection presents itself for our consideration, namely, it is a species of trades' unionism. If trades' unions are conducted on right principles there is not much objection to them, it is only when ignorance and spleen cause men to go beyond the bounds of law and justice that such organizations become obnoxious. But there are trades' unions and trades' unions, we have them more or less in all grades of society. Medical men combine, lawyers combine, and why not pharmacists? It appears to me that want of unity is one of the hindrances to progress. We have an instance of what union has done in our own city. When I commenced business it was everyone trying to undersell his neighbour; now a common cause has bound us together, and we now get better prices, we understand each other better, and we feel that we do not live for ourselves alone, but that each depends upon one another. What the local association has done for the West of Scotland so the Trade Association will benefit the whole trade. The Pharmaceutical Society in all these years has only brought in a tithe of the trade;* the Trade Association, however, from its liberal constitution, nominal fee, and the good work it is bound to accomplish as time progresses, will, I anticipate, break down barriers which at present exist, preventing good men from joining the Pharmaceutical Society, and induce them to come within its fold also. But another objection presents itself. The objects of the Trade Association are futile, as instanced by its failure to take up the co-operative store question, one of the grand aims it had when first instituted. My answer is, that expediency can only be a makeshift; it may be inexpedient to prosecute openly at present, but surely if a powerful organization presented a case to the proper authorities, showing clearly there was hardship, I hardly think that any government would decline giving redress. The patent medicine question is another of a similar nature to that of the co-operative stores, and it is my opinion that very little would convince the government to amend the law in this respect. In this matter at all events we have the medical profession at our backs; it is their desire that the sale of quack medicines should be greatly diminished; and the intelligent portion of the community are becoming alive to the fact that the great majority of them are not what they are represented to be. We have a strong case at all events in endeavouring to keep within ourselves the sale of all poisonous patents, and combined and determined effort on the part of the Pharmaceutical Society, the Trade Association and the local associations will have a wonderful effect in bringing about an approximation to the desired change.

And now the question arises will the Trade Association affect our own special grievance—the surgeon-druggist? Had we been as united in 1869 as we are approaching to now, we might have amended the Pharmacy (Amendment) Act of 1869 more in our favour than it was done in that of the medical profession. We have still, however, a good case. In the first place, I believe I am correct when I say that it is only those who receive the diploma of L.F.P.S.G. that have the power granted them to practise pharmacy. The university, I understand, gives no such authority, and as the great bulk of the surgeon-druggists in and around Glasgow hold university degrees they are carrying on an illegal business in keeping

* If Mr. Fairlie will turn to page 687 of the Journal for February 26 last, he will see that at the commencement of the present year 33 per cent., or nearly one-third, of all the chemists and druggists on the Register were connected with the Pharmaceutical Society as Members or Associates. This is a matter of fact, not of opinion.—ED. PH. J.

open shop. Then many of the medical men have abused their privileges by giving their names to protect unqualified men. All this gives us a hold on the General Medical Council, which has the regulating of affairs under the Medical Acts, and one of their duties is to see that the interest of the pharmacist is not in any way interfered with. The Trade Association can approach that body and if within their province, the General Medical Council are bound to remedy what is at fault. We can never for a moment hope to shut up the surgeon's shops altogether. They must have the privilege of supplying their own patients with medicines if they desire to do so, which will cover the case of small country districts entirely, but in all cases where the surgeon engages in a general drug business, it seems but fair and reasonable that they should be made to place a qualified dispenser in charge in their absence. The chief objection to the Trade Association is probably that it may at some future time clash with the interests of the Pharmaceutical Society. This is a contingency as likely to occur without the existence of a special organization as with it, as instanced in the formation of the defence associations five years ago. If there is anything that will engender such a possibility it is by leading members of the Pharmaceutical Society either holding aloof from the Trade Association, or engaging themselves in active hostility to it. Such conduct will not check the progress of the Trade Association; it is now an accomplished fact, and if those who fear collision will do their duty to the Pharmaceutical Society as well as to the trade generally, they will give the defence association their hearty support, and thus by their weight and influence help to guide its destinies, and at the same time aid in drafting an occasional contingent from the Trade "Light Foot" into the Pharmaceutical "Artillery." And now it only remains for me to refer to one other objection, viz., "It is a reactionary policy." But I have to ask is reaction always wrong? I think not; at the same time I fail to see wherein the reaction lies, in so far as the Trade Association is concerned. I look upon it from the opposite standpoint, and I say it is the very essence of true progress. Ask any merchant if he is not a member of some society for the protection of trade. I know I have subscribed a guinea a year to what is known as "The Guardian Society" for many years, and I look upon it as the best spent guinea I make in the whole year. It was only the other day I had an application for goods from a firm, and in the ordinary course of business I made inquiry respecting them through the Guardian Society, and got back a reply shortly advising, "No Sales." I acted on their advice, and a few days afterwards I was informed that this firm had turned out to be what is known as a "long firm," and that the parties had been apprehended with a great quantity of goods got from all quarters, for which they were unable, and had no intention, of paying. Had I written for references simply, I would have got them, and probably to some extent, satisfactorily, which might have induced me to send off the goods. I saved, however, a ten-pound note by it; and it is just such aid I expect from this Chemists' Trade Association. I quite believe that had it been in existence when the liquid extract of meat was first introduced we would all have been put on our guard respecting the nature of that substance before recent prosecutions took place. They had known of it in England for eighteen months previous, and it would have been the duty of the executive of the Association to warn at least all its members of the danger, because, with the Trade Association, nothing is to be taken for granted; it will not be assumed that every member reads the trade journals and keeps himself posted up in small matters; but the executive will always be on the alert. What I consider the best feature in the Trade Association is, that while it will have its head-quarters in a central part of the country, it will also have attached to it a great number of local centres. It will have something more than a local secretary in each district. Already much good has been done in this way. In small towns, such as Chesterfield, the trade has been drawn together such as it never was before. Men of one trade or profession come by frequent contact to see that they have a common interest and a common cause; that jealousy and distrust of each other is a great hindrance to their own advancement, and that by united and harmonious action they can advance themselves and their fellow-tradesmen at the same time. And when we are thus united, and have managed to shunt aside many, if not all, of those petty and vexatious annoyances, let us hope we may have time left us to look into the many attractions and wonders which lie within our reach in our mixtures and potions, and by diligent study and careful research may we then show to the world that we are a disinterested body, aiming at a greater knowledge of nature and nature's laws, that we may have them with us and not against us, for we believe there is not an atom but contains volumes of contemplation.

At the close of the reading of Mr. Fairlie's paper, which was heartily applauded, the chairman invited the members to express their opinion individually.

Mr. John W. Pettigrew said, that at first he had a doubt as to the propriety of the Trade Association, but after carefully reading and hearing the views on both sides he had come to the conclusion that there was a need in the country for some such organization as the Trade Association was likely to occupy. He had always thought that the Pharmaceutical Council was composed of gentlemen whose knowledge of the requirements of the great majority of the trade was very meagre, and it was natural to suppose that such would be the case as long as the present system of election continued. The gentlemen of whom the Council had been composed of late years were elected to office chiefly because they were known and respected by the members, and not because they held certain views on pharmaceutical politics, because there was no opportunity of judging what their opinions were until the reports of their speeches appeared in the Journal. Mr. Pettigrew thought that the members of the Society ought to have some means of judging of the various candidates' fitness to hold the office of councillor; as it was at present, a list of names were sent down, and one had either to pitch the paper aside or vote at random. Regarding the Trade Association, he did not see why any jealousy should exist, as the two bodies ought to work to each others hands and help each other.

Mr. J. A. Clarke coincided with much of what Mr. Pettigrew had said. He was surprised at the statements some of the members of Council had made when in Glasgow in September last, in regard to the position of the Glasgow Druggists and the competition they had to contend against with surgeons' shops. It showed that they could not understand the position of their less fortunate brethren unless they visited the different parts of the country and saw for themselves what work they ought to take in hand. He believed in the Trade Association because he could now carry on his business with some peace of mind. He took every precaution he could with respect to the purity and genuineness of his medicines, but even with these precautions, he felt that he might be pounced upon for keeping some such article as rhubarb or scammony over which he had little control. He had been once visited by an inspector, and for some days, until he learned that the result of the analysis was favourable, and although he was convinced in his own mind the article was all right, yet he felt anxious for fear of a prosecution and an unjust conviction. He now felt, however, that being a member of the Trade Association he had some one to appeal to for help, and if help was needed he would get it.

Mr. McGill Murdoch could only say "ditto" to the remarks of the other speakers, he could not see how any gentleman having the interest of his profession at heart could say a word against the Trade Association.

It was a body which with judicious management could effect much good apart from the Pharmaceutical Society. There was work to be done which it was very evident the Pharmaceutical Council either could or would not do, and as it was necessary it should be done he thought the Trade Association was the body to do it.

Mr. R. Brodie referred to the milk of sulphur cases and said he thought the Pharmaceutical Society should have appealed against the adverse decisions that were given by some magistrates, and with the decision of the Court of Queen's Bench before it, both the trade and the analysts would have known whether they were right or wrong, and an end would have been put to such fighting as has taken place over what seemed to him a mere quirk. If the Trade Association made this matter alone quite clear to the trade, it deserved the support and countenance of every pharmacist.

A few remarks were then made by Mr. McCann, who referred to the surgeons' open shops, but expressed his neutrality regarding the question under discussion; after which several other members spoke in favour of the Trade Association.

Mr. Thomas Davison said that he had from the first thought highly of the Trade Association, and he further thought it would be a help rather than a drawback to the Pharmaceutical Society. He noticed that the leading members of the Trade Association were members of the Pharmaceutical Society, and he thought the Pharmaceutical Council ought to trust its own members that nothing would be done derogatory to the parent society. He had faith in the members of the Pharmaceutical Society having always sufficient influence and weight in the executive of the Trade Association to prevent any unnecessary collision or clashing of interests. He had much pleasure therefore, in asking the Glasgow Association to adopt the following resolution, viz.:—"That this Association cordially approves of the formation of the Chemists and Druggists' Trade Association, and urges its members to give it their hearty support."

Mr. Pettigrew seconded the resolution.

The Chairman said he believed they were all but unanimous, and he might be excused also expressing his opinion on the subject. He believed there was a great deal of apathy in the trade generally. It was most difficult to get them aroused at all unless it was a question of warlike importance, such as the poisons agitation in 1871. He felt that the prosecutions under the Adulteration Act were the things they had most to fear, and where the Trade Association would stand them in good stead. They are under this act practically prosecuted by scientific men, and it required that law agents and others who understood their position should be pitted against such men, so as to enable the magistrate—who generally in such cases has no mind of his own—to come to a proper conclusion. With regard to the Pharmacy Act, he thought there was a grave error in it, as no one in reading it would think for a moment that medical men had anything to do with the sale of drugs. A clause ought to have been added making it imperative that every separate drug-shop, whether possessed by a surgeon or a druggist, should have a qualified and responsible person in charge of it. He was not anxious for a prosecution of co-operative stores, as he believed that if they did succeed the same men would engage a registered person, put up his name, and carry on the trade in the same way as at present. He did not put much faith in counsels' opinions, as they differ so that you might not get two to give the same opinion. He thought, however, that the class who were supporting the co-operative store system at present were showing an example to those beneath them in station, which might ultimately come back upon themselves.

The motion was then put to the meeting, and carried unanimously. Several new members were then proposed, and after the announcement of some donations by the Treasurer, the proceedings were brought to a close.

LEEDS CHEMISTS' ASSOCIATION.

The third general meeting of this Association for the present session was held in the Library, on Wednesday evening, the 13th inst., at 8·30 p.m. The President, Mr. Yewdall, in the chair. The Honorary Secretary, Mr. S. Taylor, read the minutes of the last meeting, which were confirmed. It was announced that two books of the value of 15*s.* and 7*s.* 6*d.* each were offered as prizes for the students in Mr. Abbott's botany class, and two books of a similar value to those students who were attending Mr. Ward's chemistry classes and were associates of this society.

The remainder of the meeting was occupied in a discussion upon the position of chemists and druggists under the Apothecaries and Medical Acts, the subject being introduced by the President as follows:—

About the year 1618 a charter was granted to a certain class of individuals calling themselves apothecaries, by virtue of which all such persons were formed into one body under the name of the Master, Wardens and Society of the Art and Mystery of Apothecaries of the City of London.

This corporate body seems to have enjoyed the privileges of their charter and to have rested satisfied with it until the year 1815, when "An Act for the better regulation the practice of apothecaries throughout England and Wales" was passed and became law. It is the provisions of this and subsequent medical acts which I propose to bring before you to-night. It seems necessary that we should in the first place clearly understand the meaning of the term apothecary.

According to the 5th section of the Act previously referred to the duty of every person using or exercising the art and mystery of an apothecary is "to prepare with exactness and to dispense such medicines as may be directed for the sick by any physician;" and it is further enacted that if such a person (that is, the apothecary) here referred to shall refuse to make such medicines or to sell to any person any medicines or medicinal compounds, or negligently, falsely or unfaithfully mix or make any medicines, he shall be liable to certain penalties mentioned in the section. It appears, therefore, that an apothecary was formerly a tradesman dependent upon the physician for his occupation, and having by study advanced his position nearer to the physician than the chemist and druggist, it was thought desirable to incorporate all such persons into a separate body. According to the provisions of the Act, it does not seem, however, that they gained any legal right to visit or prescribe for the sick, and although no person (unless in business prior to the passing of the Act) can carry on trade under the title of an apothecary unless he has passed the examinations therein referred to, yet it is evident that it was not intended that they should interfere in any way with those who preferred to carry on the business of chemists and druggists, as by the 28th section it is provided "that nothing in this Act shall extend or be construed to extend to prejudice or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing and vending drugs, medicines or medicinal compounds, wholesale and retail, but all persons using or exercising the said trade or business or who shall or may hereafter use or exercise the same shall and may use, exercise and carry on the same trade or business in such manner, and as fully and amply to all intents and purposes as the same trade or business was exercised and carried on by chemists and druggists before the passing of the Act."

The character of the examinations of the Society of Apothecaries was evidently changed from time to time until the knowledge required fitted the apothecary to occupy a higher sphere and to undertake the treatment of some if not all the diseases to which we are liable. Yet they possessed no powers to recover any charges for attendance, and, therefore, in the year 1858, another act was obtained, entitled "The Medical Act," in the preamble of which it is stated "it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners," to which end it is directed that a register of all persons holding certain qualifications, of which a list is given in a schedule appended, and in which Licentiates of the Apothecaries' Society are included, shall be made and continued from year to year.

The advantage gained by being upon this register is the right to practise medicine either with or without surgery and to be able to demand and recover reasonable charges for professional aid, advice and visits, also for the cost of any medicines and medical or surgical appliances rendered or supplied by the medical practitioner.

By the 32nd section of this Act "No person shall be entitled to recover for any medical or surgical advice, or attendance or for the performance of any operation or for any medicine which he shall have both prescribed and supplied unless he shall prove upon the trial that he is registered under this Act."

The word prescribe is here used for the first and only time in any of the medical acts, and whilst it clearly indicates that you may not recover for any medicine the formula for which you have devised, yet there is no clause throughout any of the acts which makes it unlawful to construct formulæ or treat any disease; and further by the 53rd section it is enacted that "nothing in this act contained shall extend or be construed to extend to prejudice or in any way affect the lawful occupation, trade or business of chemists and druggists."

The business of the retail chemist and druggist being that of a dealer in drugs and chemicals used as medicines or for the preparation of medicinal compounds, if a person desires to purchase a draught for indigestion, a cough mixture, or any other similar preparation, the order given indicates that they have formed an opinion of their ailment; and in such a case we are justified in supplying them with the remedy which we think is best for the purpose. Let it not be understood that I am in favour of the course adopted by some of visiting sick people in their own homes; although there is no law to prevent such a course providing it is distinctly understood by the patient that he is under the treatment of a person who does not pretend to be a properly qualified person according to the Medical Act, yet it is assuming a position which we have no right to occupy, not having received the education necessary to fit us for such an important work.

It must be remembered also that any error of judgment, want of skill or improper treatment on the part of the unregistered practitioners, whereby a person loses his or her life, not only renders the person so practising liable to be charged with manslaughter, but also to a civil action for damages. He was indebted to Mr. F. Reynolds for an extract from the 'Chemists and Druggists' Diary,' which he read, and in which the legal aspect of the case had been treated by Messrs. R. G. Glen and Tompson Chitty, Barristers-at-Law, who, whilst expressing slightly different views, were each of opinion that unless a person, chemist and druggist or any one else, assumed the title of a properly registered medical practitioner he was not prevented from supplying any medicine.

An interesting discussion was carried on by Messrs. Freshfield Reynolds, E. Brown, W. Child, E. S. Payne and Thomas Iredale, in the course of which it was incidentally mentioned that the character of the trade carried on in the premises was indicated by the facia, and was a sufficient guide to the public as to the pretensions of the tradesman conducting the business.

There was a unanimous expression of opinion that from the digest of the acts bearing upon the question now laid before the meeting, there appeared to be no law to prevent anyone prescribing; and further, that in the event of any retail chemist and druggist being prosecuted and convicted it would be the bounden duty of the Council of the Pharmaceutical Society or the Chemists and Druggists' Trade Association to carry the case to the highest Court of Appeal.

A vote of thanks to Mr. Yewdall for his paper was carried on the motion of Mr. E. Brown, seconded by Mr. Iredale.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The first ordinary monthly meeting of the session was held on Friday evening, December 15th, in the Memorial Hall, the President, Mr. W. S. Brown, occupying the chair.

A communication was read from the Manchester Chemists' Assistants' Association to the following effect:—

"That owing to the indifference with which every endeavour to further the objects of the Association had been met by the assistants of Manchester, it had been decided to wind up the affairs of the Association, and to transfer the balance in hand to the library fund of the Manchester Chemists and Druggists' Association, to which thanks were tendered for the use of its rooms, etc."

After the election of associates and other business, Mr. John Wallace exhibited a series of gas burners of the Bunsen or atmospheric type, by which he demonstrated that very high temperatures could be obtained from coal gas without the aid of either blowpipe or chimney draught. The chief feature of the Wallace burner is a cylindrical cap of finely perforated metal fitting over the top of the tube, and made adjustable to various heights, so as to regulate by back pressure the quantity of air drawn in by the jet of gas to be mixed with it previous to combustion. As the preforations in the cap are too small to allow the passage of a flame downwards, a much more inflammable mixture of air and gas may be burned than would be possible with another form of burner. The result of this arrangement is that a flame may be obtained which is perfectly solid, containing no hollow conical space within as is usual with all other round flames; it burns with a temperature of over 3000° F., and its peculiarities involve a new theory in the structure of flames. Instead of a dull blue colour within, it presents to the eye a spectrum of the most intensely brilliant green at that part of the flame where combustion commences. Above this the flame is of an amber colour, and combustion is so complete that it makes no stain if played upon a white porcelain plate.

The tubes of the burners exhibited varied in diameter from $\frac{3}{8}$ in. to 2 in., the largest burning 30 to 35 cubic feet of gas per hour in a manner as completely as did the smallest.

One of the $\frac{3}{4}$ in. burners was perforated with half-inch air holes for its whole length, and yet burned gas above the cap with a heat which rendered a twisted mass of platina wire immediately incandescent. A link of $\frac{1}{8}$ in. wire was added to a chain of copper and the joint of the link fused together by simply suspending it over the flame. The gas in all experiments was taken direct from the chandelier of the room. By careful experiments made with the test apparatus of the Newcastle-on-Tyne Gas Company, Mr. Wallace found he could mix previous to combustion 4 $\frac{6}{10}$ volumes of air in his burner with gas whose total combining quantity was 6$\frac{1}{2}$ volumes. The experiments concluded by the exhibition of a singing flame.

A one-inch burner was made to burn within the end of a piece of 3 in. stove pipe 4 feet long. The loud monotonous roar which followed, although it crowned the experiment with success showed that the title was a complete misnomer. A few remarks followed, on the application of gas heat so as to obtain the most effective and economical results.

Mr. Siebold, in proposing a vote of thanks to the lecturer, remarked that Mr. Wallaces improvements in gas burners would be most acceptable to analysts. The motion was seconded by Mr. Slugg and heartily carried.

Parliamentary and Law Proceedings.

Prosecution for the Illegal Sale of Poisons.

At the Chatteris Petty Sessions, on Tuesday, December 12th, before Messrs. J. Fryer and A. S. Ruston, William Crussell, shopkeeper, Benwick, was charged with selling a packet of Battle's vermin killer containing strychnine, without attaching his name to the same; also with selling half-a-pound of arsenic without a label; also with selling the same unadulterated with soot.

A police constable named Green was called to prove the purchase of a packet of Battle's Vermin Killer on the 20th of November last, which he handed to Inspector Mitchell, who took it to Mr. Langman, chemist, Chatteris, for analysis. Witness said he wanted the powder for killing crickets, and afterwards told Mrs. Crussell it did not destroy the beetles so well as he thought it would. He was not directed by anyone to obtain the poison, and got it for killing crickets. He had heard that Crussell sold arsenic, and on the 28th witness asked him if he could have some for the same purpose, and Crussell replied, "No, Mr. Green, I do not keep such a thing." Witness then went to a public-house opposite and asked the landlady, Mrs. Shaw, to get him some. Witness stood in her house and watched defendant fetch the arsenic from a warehouse and saw him doing it up in paper as he returned to the shop. Mrs. Shaw brought witness the arsenic; it was not labelled; but was sent just as witness now produced it. He took the arsenic to his house and gave it to Superintendent Collins, who was there at that time. As soon as he delivered the arsenic into Mr. Collins' hand, Mr. Crussell came running with the label and said he hoped they would not do anything in the matter. He knew he had no business to sell it, and if they prosecuted, it would ruin him.

Mary Shaw proved purchasing the arsenic.—Cross-examined: She was sure she asked for arsenic, the stuff they dress wheat with. Some call it mercury. Green sent her for it. After she had got it in the house Mr. Crussell came running after her and brought a label to put on.—Cross-examined: Mr. Crussell said at the time that it did not matter about the label, and yet he brought it directly afterwards.

Green in cross-examination stated that he was aware another shopkeeper had a very bad feeling against Crussell.

Mr. Atter for the defence said he should ask the Bench to dismiss the two charges respecting the strychnine, and made a technical objection to the non-production of the *London Gazette*, by the prosecution, such procedure being legally necessary to prove the cases.—The Clerk advised the magistrates to convict in these cases, but the Bench was of a different opinion, and allowed the objection, but fined defendant £5 and costs in the arsenic case.

Prosecution under the Medical Act.

At Marlborough Street, Dr. John Hamilton, of 404, Oxford Street, was recently summoned before Mr. Knox, by Dr. Robert Spencer Carpenter, on behalf of the East London Medical Defence Association, for pretending to be and using the name and title of doctor of medicine. Mr. Pridham appeared for the prosecution; and Mr. Besley defended. On the previous hearing Mr. Besley, for the defendant, stated that his client had undergone the proper examinations, and had obtained a diploma from the Metropolitan College of New York. The diploma from that college was displayed in the window of his house, and he contended that as long as Dr. Hamilton stated what he was there could be no intention to deceive the public. At the time the defendant received his diploma he was qualified to register, but, registration not being imperative, he failed to register, and could not do so now. Mr. Knox said the case would mainly turn on the *bona fides* of the diploma, and he would adjourn the matter for a fortnight.

The case was resumed on December 13, when, after hearing further evidence Mr. Knox said, that according to his judgment, a good deal of misconception appeared to exist as to the Medical Act of 1858. The meaning of that Act for present purposes was, not only that a man should not wilfully and falsely pretend to be what he was not—that was not sufficient; a man must not pretend to have a right to any of the titles and qualifications recited in the 40th section of the Act. He must not pretend to be or take or use the name or title of a physician, doctor of medicine, and so on. Neither must he use any name, title, addition, or description implying that he was registered under the Act, or that he was recognized by law as a physician, surgeon, licentiate in medicine, and so forth. Such pretence apart, any private person might, without peril from the Act, prescribe for and treat any person who might be so unwise as to trust his health and life to such untrained minds and unskillful hands. So far of laymen; but with regard to *bonâ fide* medical men, a surgeon need not be registered. The penalty for non-registration was that a man could not recover his fees and could not hold certain offices. But he must not pretend to be registered if he was not on the Register. So with regard to the title of physician, doctor, and so on. It would be found in the reported case of *Andrews* v. *Stysop* that Baron Martin—the other Judges agreeing with him—laid it down as law that a man must not pretend to be on equal footing with any regularly bred and registered physician in England. The offence here was the assumption of the title of M.D., without mention of the University of Philadelphia, from which the degree proceeded. The words of the 34th section were very express. The words "duly or legally qualified medical practitioner," or any words importing a person "recognised by law"—mark the term, for it was used again in the 40th section, the penal one,—when used in any Act of Parliament, should be taken to mean a person registered under the Medical Act. By the use of this simple test two-thirds of the section were got rid of, for no one surely would argue that a man who wrote M.D. of Berlin, St. Petersburg, etc., after his name assumed to be registered under the Medical Act of 1858. It was only the first part of the 40th section which would give one a moment's pause. Persons must not pretend to be a physician, surgeon, general practitioner, or apothecary if they were not such, or use any name or title implying that they were registered. Surely that must apply to British medical titles? The whole scope and meaning of the 55 sections of the Act were the protection of the medical profession here, and, therefore, the protection of the British public, by distinguishing qualified from unqualified practitioners, and by a carefully-devised system of guarantees, conceived on British forms only. That being so, from the preamble to the schedule only British arrangements are dsscussed. It was hard to think that when a man held himself out as a graduate of a foreign University, and trumpeted the fact forth to the world, he could in reason be said to offend against the 40th section. That brought Mr. Knox to the second point. If there was nothing illegal so far as this was concerned in the use of a foreign medical title, what right had the magistrate to inquire whether it was a genuine one, or whether it had been obtained by the merest trickery and imposture? It might be worn by a man who was an ornament to his noble profession, or by the most pitiful quack whose name was entitled to registration only in the annals of the criminal courts. Such a one might escape free under the Act, but he might be reached by the law of manslaughter or false pretences. That was one of the cases in which he might say he had strained such faculties as he possessed to see his way to a conviction, but he could not. The defendant had called himself a New York doctor, and nothing else. The summons, he regretted to say, must be dismissed.

Counterfeit Chlorodyne.

It having been found that certain frauds were being committed in Japan, both on the revenue of this country and on the proprietors of Dr. J. Collis Browne's Chlorodyne, Sir H. Parkes was instructed to lay the matter before the Japanese Government, with a request that the offenders might be brought to justice and a repetition of the offence prevented. Shortly afterwards he was verbally informed that the guilty parties had been discovered and arrested. Their trial, however, proceeded but slowly, and it was not until the 14th of September that Sir H. Parkes was informed that sentence had that day been pronounced, seventy days' penal servitude having been adjudged to the manufacturers of the spurious medicine, and sixty and fifty days respectively to the engraver and the printer of the forged labels, the profits of the fraud and the stock of counterfeit chlorodyne on hand having also been forfeited as well as the money received for the engraving and printing.

Sir H. Parkes adds that within a month after he had made his complaint, certain "Regulations for the issue of Licences for Medicine" were published by the Japanese authorities, containing provisions for the analysis of all prepared medicines manufactured in Japan, and for the issue of licence stamps to be attached to them, and these regulations, he trusts, coupled with the deterrent effect likely to be produced by the penalties imposed in the present case, will go far to prevent the repetition of offences of this class in the future.

The Sale of Milk of Sulphur.

At the Runcorn Petty Sessions, on Monday, December 18, Mr. George Marshall, Mr. Andrew Brown, and Mr. Isaac Speakman, chemists and druggists, were summoned for selling adulterated milk of sulphur. Mr. Henry Glaisyer, of Birmingham, the legal adviser of the Chemists' Defence Association, defended, and said he intended to call scientific evidence from London and Birmingham to show that the defendants were not guilty. There had been various prosecutions under the Act, with various results; but he thought the height of absurdity was reached when, in a case before the Hyde bench, in which there was a conviction, the chairman, who held a diploma from the Royal College of Surgeons, was fined the week following for selling adulterated milk of sulphur himself. As the circumstances of the present case were somewhat peculiar, he would ask the bench to adjourn it for a week, to enable him to procure the requisite scientific evidence. The cases were then adjourned until the next petty session.—*Liverpool Daily Post.*

Supposed Poisoning by Opium.

Dr. Diplock, coroner, opened an inquest on Wednesday, at the Wellesley Tavern, Chelsea, on the body of Henry Randall, aged 23, potman, who is alleged to have died from poison acidentally administered to him by one of the servants at a women and children's hospital in the King's Road.

Jeannett Outten deposed that she was 18 years of age, and housemaid at the hospital in question. She had known the deceased for a fortnight and he was always trying to be after her. She saw him on Sunday afternoon, when he said that he had a very bad cough, and she gave him some pills the next afternoon. She obtained the pills from a box in a lower room of the hospital. The box produced was the one she took them from. There were several other boxes in the room, but being unable to read the labels upon them she took the small pills. She had had small pills given her for her own cough by the nurse, and therefore took small pills for deceased, not knowing that they were poison.

Mr. John Leonard, of King's Road Chelsea, surgeon, deposed that he saw the deceased on Monday night, and found his pulse slow and laboured, countenance livid, pupils unequally contracted and insensible to light. He died early the next morning. Witness was next day handed the pills produced, and he found they contained opium, and were the same as those deceased had in his pocket.

The inquest was adjourned in order that a *post-mortem* examination might be made.—*Standard.*

Poisoning by Vermin Killer.

On Thursday, December 14, Mr. Humphreys held an inquiry in Banner Street, St. Luke's, respecting the death of Mary Ann Hill, aged 39. Thomas Hill, a tent maker, stated that on the previous Monday morning he left deceased, his wife, in bed, apparently in her usual health. He was afterwards fetched, when he found her dead. On the table and strewed about the floor were several labels of Battle's vermin killer. Deceased drank heavily. Since her death he had found out that she had been pawning many things, and was now of opinion that she had taken her own life for fear that he should discover it. A lodger in the same house deposed that on Monday morning deceased exclaimed, "Will any one fetch my husband?" and then fell to the ground, striking her head against the drawers. A doctor was sent for, who pronounced life extinct. Deceased had swallowed as much strychnine as might kill half-a-dozen people. The jury returned a verdict of "Suicide while in a state of unsound mind."—*Times.*

Poisoning by Chloral Hydrate.

On Tuesday last Dr. Hardwicke held an inquest at the King's Head, Longford Street, Munster Square, as to the death of Randle Jackson Waters, telegraph engineer, who was found dead in bed on Sunday morning by his wife, there being a bottle that had contained hydrate of chloral on the dressing-table. Deceased was very restless at night, and found it necessary to occupy a separate bedroom from his wife and children. The widow believed her husband had taken an overdose of the chloral, which he had been in the habit of using to procure sleep. Dr. Mason, of Osnaburgh Street, said the cause of death was failure of the heart's action, caused by an overdose of chloral. The jury agreed to a verdict of "Death from misadventure."—*Times.*

Attempt to Murder by a Druggist's Assistant.

At Woolwich, on Thursday, December 14, Thomas William Christian, 22, a druggist, was charged on remand before Mr. Balguy with wilfully attempting to administer poison to Mrs. Susannah Bayley, his landlady, of 6, Kingston Terrace, Charlton. The prosecutrix, said that she left the prisoner alone in her kitchen after supper on the night of Monday, the 4th, and met him going to his room as she returned. Her daughter handed her a glass partly full of beer, which she had left at supper, and she was about to drink it when she was alarmed at the overpowering smell, and set it down untasted. She afterwards poured it into a glass pickle dish containing a little vinegar, and then went up to bed. At four o'clock in the morning she was suddenly awakened by the prisoner grasping her throat with one hand and trying to pour something from a bottle into her mouth. She set her lips fast and struggled, causing the contents of the bottle to be spilt over the bed. The prisoner then ran out of the house.

At the adjourned hearing on Tuesday, Mr. G. W. Wigner gave his evidence. He said the beer when he received it contained prussic acid, but an amount insufficient to cause the death of an adult person, though a large quantity must have evaporated by exposure in the pickle dish, into which the liquid was thrown. He had made an experiment to prove this, and found that seven-eighths of the poison would evaporate by exposure for six hours. He had at first suspected the presence of some ingredient other than prussic acid, but had found only some drug, not poison, which he presumed had been used to adulterate the beer. The small phial supposed to have been taken into the bedroom by the prisoner had only two or three drops of prussic acid remaining in it, but there were evident traces of the poison having been spilled over the complainant's night dress. The handkerchiefs found in the bedroom had also prussic acid upon them, and one of them appeared to have been wetted with it all over. All the handkerchiefs were heavily scented with some strong perfume. Mr. Balguy committed the prisoner to Newgate for trial.

Correspondence.

Chrysophanic Acid Ointment.

Sir,—I observe in this week's issue of your Journal, an article by Mr. Balmanno Squire on Chrysophanic Acid Ointment, in which he states that he believes it has not been used before. I therefore write to inform you that I used it in the skin department of this hospital about nine months ago for ringworm. The acid was obtained from araroba powder by Mr. A. W. Gerrard, the dispenser to the hospital, and was employed by me in the form of a saturated solution in benzol, which retains about 10 grs. to the ℥ when cold, and also as ointment made with simple lard, the strength varying from 10 to 40 grs. to the ounce. Twenty grains of Goa powder often creates considerable irritation, as I can testify by my own feelings; for having as an experiment applied a small quantity of the ointment to my own skin on two consecutive nights, much redness was induced, and the irritation was so great that after enduring it for three or four days I had to resort to soothing applications to allay it. The results of my experiments with this substance, which were, however, limited to parasitic diseases, are already in the hands of the Editor of the *Lancet*, and will be published shortly, and it will then be seen that it is by no means deserving of unqualified praise.

H. Radcliffe Crocker, M.D.

University College Hospital,
December 19, 1876.

Sir,—As during the past nine months I have prepared large quantities of ointment, both from araroba powder and chrysophanic acid, the following note may be of value. The araroba used was of two varieties, one, the Goa powder of English commerce, the other known as Poh de Bahia, obtained from the Pharmacia Dias Limas, Bahia, and presented to Dr. Sydney Ringer by Dr. Paterson, of Pernambuco. Soon after they came into my hands I examined them for their percentages of chrysophanic acid, according to the method indicated by Professor Attfield, in the *Pharmaceutical Journal*, March 13, 1875, viz., exhaustion with hot benzol; from the Goa variety I obtained 84 per cent., and from the Bahia variety 82 per cent. of chrysophanic acid, in minute microscopic crystals.

The ointments were prepared (for some experiments which have been carried on by Dr. Radcliffe Crocker) of a variety of strengths, by simple admixture of the fine powder of the different substances with lard. The result was a perfectly smooth application, giving every satisfaction.

In the course of some experiments to obtain a strong cold solution of chrysophanic acid, in which I may say I failed, I observed that it was soluble in boiling fats and oils in almost any proportion, from which on cooling a large portion separated in a very fine state of division. I have since found that vaseline is even a superior solvent of this body than fats; the use, therefore, of benzol in the preparation of chrysophanic acid ointment, as recommended by Mr. Balmanno Squire, is not necessary.

A. W. Gerrard.

Hyoscyamine.

Sir,—I am sorry I made a mis-statement in my paper on the above subject with regard to Mr. Robert Lawson having used crystallized hyoscyamine. I was under the impression that in one part of his paper in the *Practitioner* he called the preparation he used an amorphous powder, which term could not apply to the hyoscyamine until recently generally met with in commerce, and as Mr. Lawson's paper, in which he stated he had used Merck's alkaloid, did not appear in the *Practitioner* till July this year, whereas Mr. Merck was supplying crystallized hyoscyamine as early as the 1st of January, I concluded they must be the same.

But to allay any unnecessary alarm which Mr. Lawson's letter may have caused, I beg to inform your readers that I was quite aware when I read my paper that one-grain doses of crystallized hyoscyamine had been administered in London in cases similar to those of Mr. Lawson, the detailed account of which will shortly be published.

Dr. Ringer now authorizes me to state that he has repeatedly given one-grain doses of crystallized hyoscyamine to different patients at University College Hospital.

Wm. Martindale.

10, New Cavendish Street,
December 20, 1876.

W. R. Smith and J. A. Saunders.—The advertisements have been forwarded to Messrs. Churchill.

H. W.—The leaves of *Chimaphila corymbosa* were official in the London Pharmacopœia, which included a formula for a decoction (1 in 8), but not an infusion.

S. W. F.—The conditions of the solidification of glycerine by cold have not yet been clearly made out. According to Roos, after it has been once crystallized and melted it may be restored to the solid state by exposing to a temperature of 30° F., provided a crystal be placed in the liquid as a nucleus; otherwise, a temperature of 24° F. and vibration of the liquor is necessary.

"Tr. Opii."—See the British Pharmacopœia under Resina Podophylli.

"Glycerinum."—Recipes for glycerine preparations for chapped hands have already been given; but we do not know of one that is also suitable "for all cutaneous eruptions of the skin."

"Tr. Camph. Co."—There is no relation between passing the Minor and Major examinations and becoming a Fellow of the Chemical Society.

"Mist. Tuss."—We do not understand your question. The so-called "patent medicines" do not require to be entered anywhere.

J. M. Fairlie.—We should be happy to correct the statement referred to if furnished with the means of doing so. Would it not be advisable to write to the author of the article, through the journal in which the statement appears, and ask him for a more definite explanation of what he means?

"Pharmaceutist."—The Rotten Stone of Derbyshire is an aluminous silicate, containing a little carbonaceous matter. It is also found in Carmarthenshire and Breconshire. Another "rotten stone," known as "tripoli," having been first imported from that country, consists almost entirely of silica, in the form of skeletons of infusoria. Tripoli is found in Saxony, France, Bohemia, Tuscany, Mauritius, and other places. See Watts's or Ure's 'Dictionary,' for further information. "Bath brick" is made from a calcareous and silicious earth, a deposit of which is found in the estuary at Bridgewater; also at Cumwick and Highbridge.

"Bonus Puer."—A recipe for solution for soap bubbles will be found in vol. v., p. 78, of the present series.

F. Stevens.—The fact has not been lost sight of.

"Inquirer."—Two tablespoonfuls.

A. C. Ekins.—We would suggest that the lecture should be on a subject with which you are yourself well acquainted, and that you should be better able to judge than we are what that might be.

H. S. W.—(1) We cannot tell you. (2) Your request has been handed to the Secretary.

"Nemo."—Sibson's 'Medical Anatomy' is published by Messrs. Churchill, price, in cloth, £2 2s.

Communications, Letters, etc., have been received from Mr. Vawser, Mr. Stephens, Mr. Nottingham, Mr. Shaw, H. M. W.

THE SPECTROSCOPE IN PHARMACY.

BY WILLIAM GILMOUR.

It will, I think, be admitted that the spectroscope has not, so far as pharmacy in general is concerned, as yet occupied the place which might have been expected from it, when we consider its achievements in other and even allied departments of investigation. It has become, for example, indispensable to the chemist; to it the astronomer is indebted for his knowledge of the nature and constitution of the heavenly bodies; the physiologist and pathologist have alike drawn largely on its capabilities, and even the mineralogist and geologist are not without their obligations to its powers. The pharmacist alone, with even, if possible, a wider sphere, seeing it embraces the character, collection, preservation, qualities, preparation, purity, etc., of almost every substance which comes into his hands (and from the very fact of its being thus more comprehensive, coming more we should say under its cognizance than any of the foregoing)—he alone has failed to avail himself duly of its power, and in consequence has let many of the discoveries in this, as in other departments peculiarly his own, slip from his grasp. Without stopping to inquire too minutely into all the various causes which doubtless have tended to produce this indifference on the part of the representatives of pharmacy to the uses and capabilities of the spectroscope in their own immediate sphere, it seems to me that one cause at least should be referred to as probably exerting, more than any other, a pernicious and deterrent influence. I refer to the fact that, whilst in other departments its discoveries have been both primary in their nature and application, here they have been nearly altogether of secondary importance as well as of a subsidiary character entirely. Anything which it has hitherto done for pharmacy has been more interesting than practical, more a matter of curiosity than of direct usefulness. Take any of the known substances yielding absorption spectra and it will be found, first, that the spectra give as a rule no indication whatever of purity; and, second, that they fail to give a more certain indication of the nature of the substance examined than may be obtained, probably, by simpler and readier means at the command of the investigator. The absorption spectra, for example, of some of the potassium, manganese, and didymium salts are extremely interesting and beautiful. They are individually both delicate and distinctive in their reaction, showing bands peculiar to the substance, and capable of being detected in many combinations, and yet they have never hitherto served any higher purpose in pharmacognostics than becoming mere test objects in the hands of the experimentalist. In the same way many solutions and tinctures yield very beautiful and characteristic spectra, though, unfortunately, they also give no better indication of the nature of the substance, nor of its strength and purity, than would in most cases be acquired by a rough and ready examination from general appearance or by taste, smell, and so on. This element of weakness is, moreover, much more apparent still if we take another class of solutions yielding no absorption bands whatever, and whose general characteristics some have in consequence sought to obtain or discover in the amount of absorption at the extremes of the spectrum. Such substances possess an absorptive power on white light when it passes through them similar to a piece of coloured glass, and it is quite apparent that the amount of light transmitted in an individual case will depend principally on these three conditions, namely, the depth of colour, the thickness of the medium, and the intensity of the light infringing on the medium through which it is being transmitted. There are other sources of error still, even were the foregoing conditions adjusted and an attempt made to create a standard. Principally this, however, that in no case is there a hard and fast line of demarcation betwixt the light transmitted and the light absorbed. In other words, in every spectrum there is a greater or less amount of shading which renders it peculiarly difficult, and even in most cases almost impossible, to detect the precise moment at which complete absorption takes place. Under these circumstances, if we would elevate such spectra out of mere test objects or matters of curiosity, and place the spectroscope at the same time on a proper basis towards pharmacy, it is quite apparent the first thing to be done is to cease attempting to put a construction upon them which manifestly they will not bear, or which are, to say the least, open to such grave objections. Keeping this in view it has often struck the writer that there is one important class of pharmaceutical preparations to which the spectroscope may advantageously be applied, if not directly as a test or to detect their strength and purity, at least in the no less important work of revealing something of their constitution, history, and therapeutic value. The class of substances referred to is derived entirely from the vegetable kingdom, and the following, as being possessed of some considerable medicinal activity, may be considered representative, so that to them, together with their officinal preparations, reference will be more immediately confined at present—

Aconite.	Hops.
Belladonna.	Hyoscyamus.
Bearberry.	Lettuce.
Buchu.	Lobelia.
Cannabis Indica.	Matico.
Conium.	Senna.
Digitalis.	etc., etc.

The only officinal preparations of the foregoing which require notice are extracts and tinctures, and they all yield or should yield when placed in the spectroscope a characteristic series of absorption bands which, for convenience, may at present be called the chlorophyll group. This group, as we are to consider it when complete, consists of five bands of various degrees of intensity, and the different preparations may contain one or more of these, according to their nature or other modifying circumstance which exert upon them a decomposing influence. The very fact, however, that they are not permanent is sufficient to excite inquiry into some of the probable causes which operate in producing this variation in the character of the spectra. In doing this we may be enabled, as already stated, to arrive at some definite conclusion both as regards their history and therapeutic value. Chlorophyll, it need scarcely be said, is the green colouring-matter found most abundantly in leaves, but existing also in other parts of plants. Its precise functions in the vegetable economy are not as yet well understood; nor can it be said that very much is known regarding it, either chemically or optically. The chlorophyll, for example, derived from fresh green leaves differs in several important respects from that derived from dried or old leaves, whilst the extreme susceptibility of all the bands of both old as well as fresh chlorophyll to change and decay, with the single exception of band 1, has probably operated in causing some investigators to overlook in several respects their importance. M. J. Chautard,* who has investigated and classified these bands, says, "that as to bands recognized in the other colours of the spectrum (*i.e.*, bands 2, 3 and 4), they are liable to modification by so many different causes that their study would not lead to uniform results. Mr. Stokes, again,† finds that modified chlorophyll—chlorophyll acted on by light—undergoes no further change when precipitated, and again redissolved by ether, on exposure to diffused light; but that chlorophyll thus modified has a somewhat different spectrum from the fresh, the dark band 3 being lighter and displaced towards the more refrangible end of the spectrum, and another band appearing in the spectrum, so that in the modified chlorophyll there are five dark bands, whilst in the fresh there are only four. Gerland, to investigate this change,‡ took an alcoholic solution of chlorophyll obtained from the fresh leaves of *Urtica dioica*, and on exposure to sunshine found it changed colour perceptibly in five minutes; in ten it was olive-green; in fifteen brown, and after the lapse of an hour it had become bright yellow, and no longer showed any signs of fluorescence. During the change the absorption bands gradually became more indistinct, and disappeared in their order, band 1 being most stable. The same change took place in diffused light, but more slowly. Mr. Sorby, again, who probably has investigated more than any other individual the colouring matter existing in leaves, classifies all the numerous colouring principles which he has discovered into five groups, according to their action under certain chemical reagents. These groups he has distinguished by the names—chlorophyll, xanthophyll, erythrophyll, chrysophyll and phaiophyll, and each yield spectra distinct and characteristic. Leaves he finds, generally speaking, contain colours belonging to several groups, and frequently more than one of the same group, so that it will be understood from this and all the foregoing, as a matter of scientific investigation, that both chlorophyll and its spectra are sufficiently complicated. It is not, however, strictly speaking, so much in their scientific aspect which we wish to consider them at present, nor in their relation to each other as convertible spectra (if we may be allowed the use of such an expression), as simply in the relation which certain phenomena, which we may conveniently call chlorophyll spectra, stand to the therapeutic activity of certain medicinal substances and their preparations. It is sufficient for our purpose that certain substances yield, or rather should yield, uniform spectra; that these spectra are very susceptible to change; that the changes are not erratic in their nature, but may be assigned or traced to certain definite causes; and, lastly, that they bear significantly on the medicinal history and activity of the substance.

Leaves.—Take the leaves, for example, of any of the foregoing officinal substances, and it will be found that there are at least three circumstances which primarily exert a very powerful influence upon the chlorophyll absorption bands, namely—1st, the time at which the leaves are collected; 2nd, the mode in which they are dried; and, 3rd, the mode in which they are preserved. Leaves, it is now well known, should only be collected when the flowering stage has somewhat advanced, as they then contain their active principle in greatest quantity; they should next be rapidly dried at a low temperature, in a darkened oven, and afterwards preserved in closely stoppered opaque bottles. On these conditions being strictly observed depends very much the therapeutic activity of the plant, but as they are conditions beyond the sphere, or at least the cognizance of most pharmacists, and as under ordinary circumstances it is impossible to tell whether they have been observed or not, the importance of the chlorophyll spectra will readily be recognized. Not, let it be understood, that any medicinal activity is here ascribed to the chlorophyll itself; but undoubtedly it is of the greatest importance to preserve the colouring matter contained in the leaves as, if it is destroyed, much of their active principle is lost with it. There is the highest authority for asserting that the leaves of all the more active medicinal plants, such as belladonna, digitalis, and others, contain less of their peculiar active principles when badly, than when carefully, dried. The readiness with which chlorophyll fades may be very interestingly shown by removing the epidermis of a leaf of the officinal *Digitalis purpurea*, and exposing the cells to sunlight. In a very short time—in proportion to the intensity of the light as well as the temperature—it will become quite colourless, in which state, so far as its medicinal activity is concerned, the leaf will be found practically inert. On the other hand, as showing their stability when dried and preserved with care, the leaves may be found to exhibit the whole five bands very distinctly, even after being kept for several years, and this, too, contrary to general belief, without impairing their medicinal activity in the least.

Extracts.—The sometime disputed question as to the admission or rejection of the colouring matter into fresh or green extracts, has been finally set at rest by the Pharmacopœia directing the juice obtained from the fresh leaves and young branches to be heated gradually to 130°, and the green colouring matter then separated by means of a calico filter, to be afterwards added at a future stage of the evaporation. This nursing of the chlorophyll necessarily leads us to expect its absorption bands in the spectra of all these extracts, and their presence is, therefore, no indication of the quality of the preparation. But, on the contrary, if their presence thus gives no certain proof of their medicinal activity, their absence, it must be admitted, indicates with double assurance that the preparation has become bad, and is worse than useless. The danger to which they are exposed, and which would affect the chlorophyll spectra are chiefly these—excessive heat on the one hand, or on the other, undue delay in the process of inspissation after the colouring matter has been added, both of which lead to injurious chemical decomposition; or preserving in places exposed to too high a temperature which tends to promote fermentation; or preserving in damp places, promoting the development of fungi and other changes. Probably, however, the greatest source of danger, espe-

* *Pharm. Journ.*, June 21, 1873.
† 'Pogg. Ann. Eng.,' iv., 128.
‡ 'Pogg. Ann.,' CXL., iii., 585.

cially in those extracts whose consumption is limited, is after they have reached the hands of the pharmacist, in the length of time they are frequently kept, and the careless way it is to be feared they are too often protected from atmospheric influence. The best prepared extracts, it is needless to say, under these circumstances, would soon deteriorate, and ultimately become altogether bad.

Tinctures.—Little need be said as regards tinctures, for if in the process of maceration and percolation, by which most of them are prepared, the whole of the active principles be eliminated, and if they afterwards be carefully stored, the only further risk they will run will be from exposure to light. Still it must be confessed that the way in which they are kept by pharmacists in general, namely, in clear glass bottles exposed to the full sunlight from window and door, does not conduce to their preservation. The consequence is that few of the tinctures will be found to present complete chlorophyll spectra, some of them, it may be, having only band 1, others, and more than probably the majority, having no bands whatever. Now, without asserting that in every case the decomposition of the chlorophyll is indicative of a change in the medicinal activity of the tincture, similar to that which has just been indicated as taking place in the leaf as well as in the extract, it is undoubted that certain tinctures, such as conium, belladonna, and others, suffer very materially in their activity by the deposition which accompanies the modification of the chlorophyll, whilst they all suffer from the change which takes place in their appearance, taste, and so on. Without claiming more then, in the meantime, from an examination of the spectra of the various tinctures, than that it gives us some indication of the medicinal value of the plant from which they have been prepared, or that some change, more or less important, has taken place from exposure in the tincture itself, it will be admitted that even this is not unimportant, and the possibility is that further investigation may lead us to still more important results.

With these general observations we will now be prepared to consider the spectra of some of the officinal preparations more in detail.

(*To be continued.*)

COMPARATIVE EXAMINATION OF THE MORE IMPORTANT COMMERCIAL VARIETIES OF GALBANUM AND AMMONIACUM GUMS.*

I. GALBANUM.

BY EDWARD HIRSCHSOHN.

(*Continued from page* 431.)

10. *Treatment with Petroleum Spirit.*—As it was difficult to effect the complete distillation of the oil, especially from the Levant sorts, and as a portion of the oil remained dissolved in the water, exact results could not be obtained in this way. The author, therefore, adopted Dragendorff's method of estimating essential oils, which is based upon the fact that when the finely divided drug is treated with petroleum spirit (boiling point between 30° and 40° C.) nothing of importance except essential oil is extracted.

To facilitate the solvent action and to prevent the gum resin agglutinating, a quantity was rubbed up with pure sand that had been boiled with hydrochloric acid, washed, heated to redness and kept over lime. According as the resin was soft or hard, four to ten times its weight of sand was used. A quantity corresponding with 2 to 4 grams of resin was then put into a well corked bottle with an exactly measured quantity of petroleum spirit (10 to 20 c.c.) sufficient not only to penetrate the mixture but also to slightly cover it. The mixture was allowed to remain in contact, being frequently shaken, for twenty-four hours, this time having been found sufficient for complete solution of the oil. A portion of the solution was then removed and filtered through a funnel covered with a glass plate to prevent loss by evaporation, and a carefully measured quantity of the filtrate (2 to 3 c.c.) was placed in a watch-glass standing in a larger one and left at the ordinary temperature as long as the odour of petroleum spirit was perceptible. It was then weighed between two well closed watch glasses and afterwards again exposed, and the operation was repeated at intervals of 30 seconds until the weighing showed only a difference represented by the fourth decimal place. The author gives some figures obtained by experimenting with known quantities of the essential oil dissolved in petroleum spirit, which show, that operating in this way the loss of oil by evaporation is very slight. The quantities obtained are shown in the following tabular summary.

Results obtained by Treatment of Samples of Galbanum with Petroleum Spirit, Ether, Alcohol and Water successively.

The petroleum spirit extracts were, with the exception of Nos. 6, 11 and 22, which were more or less yellow, all colourless, and left an oily residue that was either quite colourless or slightly yellow. All these residues possessed a strong odour of galbanum, which, in Nos. 2, 3, 4, 15, 17 and 24, was mixed with that of turpentine, in No. 1 with that of assafœtida, and in No. 23 with that of cumin. When heated to 120° C. these oily residues almost completely disappeared, with the exception of Nos. 6 and 22, from which the author concludes that from galbanums of good quality petroleum takes up almost exclusively the essential oil. From Nos. 6 and 22 resin also was removed. Further experi-

* From a memoir for which the gold "Suworow" medal has been awarded by the Medical Faculty of the University of Dorpat. (*Pharmaceutische Zeitschrift für Russland*, April 15, 1875, p. 225.)

ments showed that the samples from which the resin as extracted were mixed with olibanum and sagapenum.

The small residue, originating in the resinification of essential oil, was in some cases weighed; mostly it amounted to less than 0·47 per cent. of the whole drug. The Hamburg "galbanum in granis," No. 8, was an exception, its residue amounting to 1·04 per cent. These residues did not dissolve in petroleum spirit and were coloured yellowish red or violet by hydrochloric acid, which the freshly distilled oil was not, but an oil kept exposed for some time to the air probably would be. In the adulterated "galbanum in granis," No. 6, the residue amounted to 4·81 per cent.; it dissolved only partially in alcohol, but completely in ether, and when deflagrated with saltpetre gave a clear sulphur reaction (sagapenum). The "galbanum artificiale," No. 22, left behind 16·21 per cent. of a very brittle resin, which was not dissolved by 95 per cent. alcohol, but was completely dissolved by ether and petroleum spirit.

Upon treating the petroleum extracts with some drops of a solution of bromine in double its volume of ether, in the Persian sorts, Nos. 1 to 4, 15 and 24, a red, passing into violet, turbid mixture was produced, from which, after standing, a small quantity of a violet body separated, that gradually became blue, and was soluble in alcohol, ether and chloroform; after this the liquid was perfectly clear. The Levant specimens, Nos. 5 to 14, 16, and 18 to 21 gave no colour, but probably there was a precipitation of a very small quantity of the violet body. The adulterated galbanum gave neither colour nor separation, whilst No. 23 gave no colour, but a yellow precipitate. The author considers that this test furnishes a method of distinguishing between Persian and Levant galbanum.

The residues from the evaporation of the petroleum spirit exposed to bromine vapour was coloured violet, changing into blue very intensely; in Nos. 3, 4, 15 and 24, and in Nos. 1 and 2 less so; whilst in the others only a yellowish green colour was produced. A small quantity of Frohde's reagent, applied carefully with a glass rod, gave a yellow solution which quickly became blue; except in Nos. 5, 6, 7, and 19, where the colour was first a beautiful red, gradually passing to violet and finally to blue.

Upon treatment of the residue with hydrochloric acid (sp. gr. 1·12) Nos. 1 to 4, 15, 17, and 24 gave a yellow red solution, gradually becoming red; Nos. 5 to 9, 12, 13, and 16, a red violet solution; Nos. 11, 14, 18, 20, 21, blue violet; No. 19, blue, No. 10 only after a long time became faintly violet; similarly No. 22 became a faint rose colour. No. 23 showed no change.

When treated with nitric acid (sp. gr. 1·25) the residue from Nos. 1 to 4, 15, 17, and 24 gave a rose colour; Nos. 5 to 9, 11 to 14, 16 and 21, a violet or more or less red violet; Nos. 10, 22, and 23 no change. Some drops of a mixture of chloral and chloral hydrate applied with a glass rod produced after some minutes with the residues from the Persian sorts, Nos. 1 to 4, 15, 17 and 24, a solution of an intense green colour. The residues from the older Levant sorts, Nos. 5, 6, 7 and 19, became rose coloured, gradually passing into violet; whilst with the residues from the Levant sorts at present met with in commerce, Nos. 8 to 18, 20 to 21, there were produced ~~solved. that~~ were of a faint yellowish red, passing into undecided green, and faintly rose-coloured at the edges. In No. 23 scarcely any characteristic colour could be observed. The false galbanum, No. 22 gave a yellow-brown solution.

By deflagration of the residues with saltpetre and reagents for sulphur, the sulphur could be detected only in the adulterated specimen No. 6.

11. *Behaviour with Ether.*—The residue from the exhaustion with petroleum spirit, was treated with ether for the estimation of the resin. After being well shaken with ether, it was allowed to stand and then filtered through a weighed and dried filter; the residue upon the filter was treated with ether until a few drops of the filtrate evaporated upon a glass plate left no resin. The ether was then distilled off from the ethereal extract; as the ether adhered persistently and the last portion was difficult to remove, the residue was allowed to stand five or six days at a temperature of 80° to 100° C. and finally heated at 110° and weighed. The quantities obtained are shown in the table on p. 531.

The resins from No. 1, 2, and 22 were light yellow; these from the other sorts were more or less dark red brown. They were very brittle, and had a conchoidal fracture. The melting point of Nos. 1, 2, 3, 15, 17, 24, was 40° C.; that of Nos. 10 to 14 and 18 to 20 was 42° C.; that of Nos. 4, 21, 24 was 45° C.; and that of No. 22, the false galbanum, 75° C. They dissolved completely in ether, alcohol, chloroform, amylic alcohol, glacial acetic acid; and nearly so in benzine and carbon bisulphide. Solution of ammonia (sp. gr. 0·96) exercised no action, either when cold or hot. Boiling caustic soda solution dissolved them almost completely, as also did warm spirit of turpentine.

Upon boiling the resin with water, in every case, with the exception of that from the false galbanum, No. 22, a faintly acid, strongly fluorescent, colourless solution was obtained, which became turbid upon cooling. This turbidity disappeared upon the addition of a few drops of caustic potash, or soda solution, giving place to a very strong fluorescence, a property characteristic of umbelliferon. It appears therefore that some umbelliferon occurs already formed in galbanum.

Alcoholic solutions of the resins treated with alcoholic solution of lead, zinc, or copper acetate, underwent no change. Upon deflagration of the resins with pure nitre and afterwards testing for sulphuric acid, only negative results were obtained, except in the case of that from the adulterated galbanum, No. 6; in this respect they differ essentially from sagapenum and asafœtida.

Submitted to dry distillation the resins from Nos. 1 to 4 yielded a very small quantity of blue oil, but much more umbelliferon; thus from No. 2, 3 per cent. of umbelliferon was obtained. Nos. 5, 11, and 12 yielded considerably more blue oil, No. 11 yielding 33·3 per cent. Treated under pressure, with alcohol containing hydrochloric acid, they all gave umbelliferon with the exception of that from the artificial galbanum, No. 22.

Three or four grams of the resin from No. 2 were digested with soda ley, and barium chloride added as long as a precipitate was formed; a considerable quantity of a strongly coloured dark yellow precipitate was obtained, which was separated from the yellowish alkaline liquid, washed and dried. Upon boiling the baryta precipitate with 95 per cent. alcohol, the greater part was dissolved, the solution being strongly coloured yellow. Upon cooling this solution a yellow body separated, which under the microscope exhibited no crystals; it was not soluble in cold alcohol, but was dissolved by ether. Treated with concentrated sulphuric acid it formed a yellow solution. A baryta estimation of this body gave only 1·07 per cent. of barium. The portion not dissolved by boiling alcohol was brown, amorphous, and gave with strong sulphuric acid a yellow solution. The quantity was too small to make a barium estimation. This body was insoluble in ether.

Into the liquor separated from the baryta precipitate carbonic acid was passed as long as a precipitate was formed. This precipitate washed and dried, gave up when boiled in 95 per cent. alcohol, a small quantity of a body, which upon adding to the alcohol sufficient water to produce turbidity was deposited upon the glass in an asbestos-like mass, which under the microscope appeared as beautiful acicular crystals. Heated upon platinum foil the crystals melted and took fire and left but a very small residue; they dissolved in alcohol and ether. With concentrated sulphuric acid they formed a yellow solution; they were not changed by concentrated hydrochloric acid. The quantity obtained was too small to allow further experiments to be made.

To the liquor separated from the precipitate obtained with carbonic acid hydrochloric acid was added until it showed an acid reaction, when a considerable quantity of white flocks were deposited. These were washed and dried at a gentle heat (as they were easily melted to a yellow resinous mass), and under the microscope showed no crystals. This body burned without residue, and dissolved in alcohol and ether with a yellow colour. Treated with concentrated sulphuric acid it formed a yellow solution; whilst with concentrated hydrochloric acid, especially when heated, it gave a violet solution, a resinous body being separated. The resin purified by repeated solution in soda ley and precipitation by hydrochloric acid gave no colour with that acid and partially dissolved in ammonia.

After the separation of the body precipitated by hydrochloric acid the liquor gradually assumed a faint rose colour, and when heated and more hydrochloric acid added gave a splendid violet solution, which after a time passed into a dirty grey. Petroleum spirit shaken with the liquid took up a very small quantity of a colourless body, which gave the reaction with hydrochloric acid very intensely. It is therefore apparent that this resin, like most resins, was a mixture of at least four bodies, which might be named α, β, γ, and δ resins. Besides the two barium compounds, as shown, baryta precipitated free resin from the alkaline solution; by treatment of the filtrate with carbonic acid another resinous compound was thrown down; after this had been separated and the filtrate acidulated with hydrochloric acid another precipitate of resin was obtained, which may be considered the principal constituent of the ether extract. The proportion of resin contained in the two drugs not showing any distinctive character the investigation was not carried further.

(*To be continued.*)

A METHOD OF DETECTING AND ESTIMATING CASTOR AND OTHER FIXED OILS IN BALSAM COPAIBA.*

BY DR. MUTER.

This oleo-resin, commonly but wrongly termed a balsam, has been said in books for many years back to be subject to admixture with fixed oils, especially castor oil. The *British Pharmacopœia* furnishes a qualitative method of examination, but the tests are, in practice, totally insufficient, as the exact degree of rectification of the benzol (an important point) is not stated, and the difference between a pure balsam stain and that with a small percentage of oil is very slight, unless the two are observed side by side. The other methods which have been proposed may be summarised as follows:—

1. Pure balsam gives a translucent and not an opaque emulsion, with strong solution of ammonia.

2. Pure balsam, if boiled with water for some hours, leaves a tenacious resin.

3. The specific gravity.

The latter test is entirely fallacious, owing to the great variation in commercial samples, and the others, though possibly characteristic with large admixtures, fail with anything under 20 per cent.

Observing the close affinity between copaivic and pinic acids, it struck me that advantage might be taken of the difference of solubility of the sodium soaps in certain menstrua. A very good solvent for sodium pinate has been discovered by M. Barfoëd to be a mixture of five parts by volume of *absolute* ether, and one part *absolute* alcohol, which, moreover, only dissolves sodium oleate to an exact extent corresponding to 1 in 1000 of oleic acid. I will not occupy space by detailing at length the numerous experiments on a great number of samples of balsam, varying in age and colour from every known commercial scource, but the whole thing ended in the certain conclusion that besides the essential oil (which is dissipated in the process of analysis) good commercial balsam contains only copaivic acid, which forms a sodium salt, instantly soluble in the ether-alcohol mixture, and a little altered resin not so readily saponifiable, forming a salt only slowly soluble. The amount of this second resin I have found to vary slightly, and, in very old samples, especially of Maranham balsam may sometimes amount to five per cent., although usually really less. Going upon the principle that performing any official analysis the lowest commercial standard should be taken, I have adopted six per cent. as the highest possible quantity of the second resin ever existing in any sample of balsam still having a trace of odour remaining. This wide standard may sometimes lead to an under estimation of the oil by two or three per cent., but renders any over estimation impossible.

The actual process I employ is as follows: 3 to 4 grammes of the sample are weighed into a clean dry flask, and saponified on the water bath with 50 c.c. of alcohol and a lump of caustic soda, weighing not less than 5 grammes. When all is dissolved water is added, and the whole washed into a half-pint basin so as to nearly fill it, and evaporated to 100 c.c. over a low gas flame. Dilute sulphuric acid is then added till the whole just becomes permanently turbid, and then solution of caustic soda is dropped in till it *just clears* again. By this means a solution is obtained with the least possible excess of alkali, and with a good amount of sodium sulphate. The whole is now evaporated to *perfect dryness*† on the water bath, stirring towards the end, so that the sulphate may mix with the soaps and produce an easily pulverulent residue. The residue is removed from the basin into a small wide-mouthed stoppered bottle, and treated with 70 c.c. of

* Read before the Society of Public Analyists, November 15th, 1876. From *The Analyst*, November 30, 1876.

† The best way to ensure absolute dryness is to moisten the apparently dry residue with a few drops of absolute alcohol and again dry.

ether-alcohol, and well shaken up. As soon as it is fairly settled the fluid is filtered off through a *quick* filter, and this is repeated with two successive quantities of 70 c.c., making 210 c.c. in all of the solvent used. The residue in the bottle and on the filter now consists of sodium oleate and sulphate if the balsam be impure, and of the latter only if pure, with a little trace of the insoluble resin soap already referred to. The contents of the bottle and filter are then dissolved in warm water, and after heating until all smell of ether is gone, the whole is boiled, freely acidulated with hydrochloric acid, and set to cool. If, when cold, nothing but a few specks of brown resin should rise to the surface, the balsam is pure, but if an oily layer be formed, it is adulterated, and the smell of the separated oleic acid will at once determine whether it is actually castor oil or not. In the case of the presence of oil, two grammes of pure and dry white wax are added, and the whole heated till the wax melts with the oleic acid. On cooling, a solid cake is formed, which is detached from the side of the beaker, and the fluid below passed through a filter. The cake is once more melted in boiling water, cooled, detached, dried by gentle pressure in blotting paper, put into the water oven in a weighed platinum dish till dry, and then weighed, and the weight of the wax used deducted. The beaker, filter and rod, etc., used are, if at all dirty, dried, extracted with ether, and the residue left after evaporation, weighed and added to the total.

The calculation is then performed as follows:—

1. To the weight in grammes found, add ·20 for loss of oleic acid in solvent, and then say as

95 : 100 :: total oleic acid.

2. Calculate to per cent. from the quantity taken, and from the total percentage deduct six per cent. for possible altered resin in the balsam.

Out of the whole number of samples I have done, I have selected the following twelve, as being fair representations of the degree of accuracy obtainable by the process. The error, owing to the correction, of course increases with the amount of oil present, but it is always an error in the direction of under estimation, which is the great point for public analysts.

Nature of Sample.	Calculated.	Found.
Para (pale)	Pure	No oil drops.
Para (pale)	23·60 per cent. castor	23·50
Old Para (dark)	Pure	No oil drops.
Old Para (dark)	51·0 per cent. castor	50·0 per cent.
Carthage (medium)	Pure	No oil drops.
Carthage (medium)	21·5 per cent. castor	21·20
Maranham (pale).	Pure	No oil drops.
Maranham (pale).	26·5 per cent. castor	26·27
Old Maranham (darkish very little odour)	Pure	No oil drops.
Old Maranham (darkish very little odour)	47·3 per cent. castor	46·4
Para (fine pale)	Pure	No oil drops.
Para (fine pale)	21·4 per cent. lard oil.	20·9

In conclusion, I may say, that the process, although it looks formidable, is in practice very simple, and for all ordinary purposes, if the beaker be well scraped out, the weight of the main cake may be taken as sufficient to give an analysis true within 3 per cent. *below* the real amount, which is accurate enough for public purposes, and saves time and the expense of the extra ether. Unless oil actually floats and *remains on cooling in fluid drops*, after adding the hydrochloric acid, the sample may be passed as good.

When working on three to four grammes, with an admixture of not over 25 per cent., the errors due to loss of oleic acid and insoluble resin soap respectively so nearly balance each other, that any correction is unnecessary, and the actual amount of oleic acid found may be taken as correct within a per cent.

FOURTEENTH ANNUAL REPORT OF THE GOVERNMENT CINCHONA PLANTATION IN BRITISH SIKHIM.

BY GEORGE KING, M.B., F.L.S.,

Superintendent of the Royal Botanical Garden, Calcutta, and of Cinchona Cultivation in Bengal.

(*Concluded from page* 513.)

(6 and 7).—With the view of testing at once the results of a shorter rotation than one of eight or nine years, and of the respective merits of coppicing and uprooting as modes of harvesting bark, a six-acre patch of three and a half years old *succirubra* trees, standing four feet apart, was selected on Mungpoo ridge. On three acres of this the whole of the trees were cut over close to the ground (*i.e.*, were entirely coppiced), and on the other three acres all the trees were dug out by their roots. For the sake of comparison, I shall consider the results of these two experiments in the present paragraph.

The yield of dry bark from these two pieces was as follows:—

	Root.	Stem.	Branch.	Total bark.	Total per acre.
Three acres uprooted	1,155·53	1,365·80	1,565·10	4,086·43	1,362·14
Three acres coppiced	...	1,550·07	1,568·65	3,118·72	1,029·60

For plants standing 4 by 4 feet apart and three and a half years old, these figures show a yield at the rate of 389 pounds of dry bark per annum, as against a yield of 302 pounds per annum in the case of the thirty-five acres of nine-year old plants standing 6 by 6 feet apart, and which had undergone three thinnings and prunings prior to uprootal. This evidence therefore is, so far as it goes, in favour of close planting and early cropping. The three-acre uprooted piece has been replanted with red-bark seedlings equal in number to the plants removed, and the new plants have been put down in the spaces between the sites occupied by their predecessors. The three-acre coppiced piece has yielded at the rate of 294 pounds of dry bark per acre per annum. All death vacancies in the latter piece have been filled up by young plants; the stools of the cut trees will receive careful treatment, and both the uprooted and coppiced patches will get an equal amount of care and cultivation. At the end of a given time both patches will be again harvested, and definite comparative results will thus be obtained.

(8) A five-acre patch, similar in every respect to the two three-acre pieces just mentioned and adjoining them, was severely thinned by coppicing and by uprooting a proportion of the trees on it and by pruning the remainder. Dry bark to the extent of about 270 pounds per acre has been thus obtained from it. This five-acre patch will be cultivated like the two adjoining three-acre patches above mentioned, and its future yield will be duly chronicled. The results of these eight operations will be found in a tabular form as an appendix to this report.

3. *Various modes of harvesting compared.*—The past year has thus added considerably to our experience on several matters of importance connected with the bark harvest. Experience has been got for the first time of the results of uprooting the trees—a mode of working suggested by Mr. Gammie in imitation of the well-known practice of the *cascarillados* in the natural cinchona forests of South America. The root-bark of this plantation contains, according to Mr. Wood's analysis, about 8 per cent. of total alkaloids, and is therefore richer than the finest of our stem bark, which rarely yields more than 7 per cent. It has, moreover, all along been found that in the operation of coppicing a certain proportion of the stools fail to shoot—in other words, they die, and as the bark of every part of a dead cinchona tree is perfectly destitute of alkaloid, there is always in coppicing a certain amount of bark lost. It appeared, therefore, well worth while to give a trial to a method which would make sure of the entire bark of every tree touched. From the two experiments in uprooting which have been above recorded

we have learnt that this is by no means a difficult or expensive process, bark so taken having cost for collection about two and a fourth pies per pound when green, as against one and three-fourth pies per pound for green bark taken by coppicing. During the process of uprooting, a very thorough upturning cannot fail to be given to the soil, and I am hopeful that it may be found to answer to replant such ground at once with cinchona, and thus to secure gratuitously the advantage of a very complete kind of digging. With this view a certain proportion of the uprooted area will, during the earliest good planting weather that occurs, be replanted with red-barks, care being taken to avoid as far as possible the exact spots occupied by the uprooted trees. The great objection to immediate replanting with the same species is of course the obvious one that the soil is possibly to some extent exhausted for red-bark. But, after all, the only part of the former trees which has been removed is the bark; the leaves, branches, and (as far as the coolies can be prevented from appropriating it as fuel) the wood also, being allowed to decay on the ground. If experience should show that immediate replanting does not answer, a period of rest can be allowed to the soil. As regards the proportion of root to stem and branch-bark, the uprooted three-acre patch gives for healthy succirubra trees planted 4×4 feet, three and a-half years old, and from which no bark had previously been taken, the following percentages of green bark:—root 26·5, stem 30·2, and branch 43·3 per cent. These percentages are, be it observed, for *green* bark. But in the process of drying these three sorts of bark lose weight in different proportions. The loss of weight in drying varies, moreover, with the season. In wet seasons green bark naturally contains more moisture than in dry seasons. The past cold season having been an exceptionally dry one, the loss of weight by drying was correspondingly small. The actual figures may thus be tabulated:—

	Pounds.
100 pounds green root-bark dried to .	32·94
100 ditto stem-bark ditto . .	34·06
100 ditto branch-bark ditto .	27·30

The thirty-five acres of uprooted nine-year old trees at Rishap yielded an exceptionally large amount of root-bark (nearly 50 per cent.), a result which is accounted for by the very large proportion of coppice-bearing stools to standard trees at the time of uprootal. The brief history of this patch, which has been already given, explains why there were so many coppice stools.

With regard to coppicing as a mode of harvesting bark, some experience has been gained during the year, and the basis has been laid down for a good deal more to be gathered hereafter. The progress during the year of the shoots from the stools of a number of trees coppiced under a variety of circumstances in 1874 confirms my belief that an almost complete coppicing, by which a minimum of standard trees is left (and that means a minimum of shade and of drip), is more likely to yield good results than a partial coppicing, by which only alternate plants or alternate rows of plants are cut. The shoots which follow a complete or nearly complete coppicing are in every case more healthy and vigorous, and in many cases more numerous also, than any which I have seen to rise from stools standing in shade. If the precaution of earthing up the stools be taken, the damage done to the young shoots by wind does not appear to be great. The cost of weeding and cultivating complete, or nearly complete, coppice will be about the same as for seedlings planted from the nursery. Experience alone can show whether coppicing or uprooting will pay best; and it would be premature as yet to form an opinion as to their respective merits as modes of harvesting. With regard to the third method of harvesting which has been proposed, viz., decortication of living trees, former experience having shown that renewal of bark under moss is a failure in Sikhim owing to the attacks of ants, no further experiments have been made by that method. Some trees which were partially stripped of their bark during the year 1874 have partially renewed it without the application of moss or straw or other covering of any kind. The renewed bark, however, although now more than eighteen months old, is still only about half as thick as the original bark. Though not hopeful of very favourable results from this method, I have given instructions that 300 healthy trees be submitted to it during the rainy season.

4. *Expenditure for the year.*—The total expenditure on the plantation for the year (including the item of Rs. 584-4-11 for head office charges) was Rs. 53,469-4-1. Of this, the sum of Rs. 754-4-3, incurred on account on labour for the factory, has to be transferred to the debit of the quinology account, leaving a balance of Rs. 52,714-15-10 as plantation expenditure proper. This sum is made up as follows:—

	Rs.	A.	P.	Rs.	A.	P.
European establishment mallees, chuprassies, carpenters, blacksmiths, etc.	13,097	0	5			
Head office writer, etc. .	584	4	11			
Contingencies	3,055	3	9			
				16,736	9	1
Note.—The above charges are in the proportion to the rest of the expenditure of 46·5 per cent.						
Cultivation of old plantations (Rungbee, Rishap, Mungpoo)				20,466	13	0
Cost of collecting the bark crop				8,840	0	0
Erection of godowns at Mungpoo. . . .				3,050	0	0
Extensions of Mungpoo plantation . . .				1,482	11	9
Spent on new plantation at Sittong . .				2,138	14	0
Total				52,713	15	10

This divides itself into two portions, viz., the sum of Rs. 42,937-6-1, which represents the working expenses of the plantation for the year, and which is therefore to be set against the crop, and the sum of Rs. 9777-9-9, which is debitable to capital account. The composition of the working and capital expenditure is shown in the following table:

Working Expenses.

	Rs.	A.	P.	Rs.	A.	P.
Cultivation of the old plantations of Rungbee, Rishap, and Mungpoo during 1875-6 . .	20,466	13	0			
Proportion of European establishment, head office charges, skilled labour, and contingencies, equal to 46·5 per cent. of the above . .	9,518	9	1			
				29,985	6	1
Cost of collecting bark crop	8,840	0	0			
Add 46·5 per cent. . . .	4,112	0	0			
				12,952	0	0
Total Working Expenses				42,937	6	1

Capital Expenditure.

	Rs.	A.	P.	Rs.	A.	P.
Cost of extensions of plantation at Mungpoo	1,482	11	9			
Add 46·5 per cent. . .	690	0	0			
				2,172	11	9
Erection of bark godowns at Mungpoo	3,050	0	0			
Add 46·5 per cent. . .	1,420	0	0			
				4,470	0	0
Expended on new plantation at Sittong . . .	2,138	14	0			
Add 46·5 per cent. . .	996	0	0			
				3,134	14	0
Total Capital Expenditure				9,777	9	9

5. *Working Expenses.*—The charges against capital will be dealt with in the next paragraph, and the working expenses alone concern us in this one. Of the working charges above shown, Rs. 8840 represent the actual amount spent in labour on the collection of the bark crop from the trees. This charge includes the cost of uprooting coppicing, thinning, pruning, sawing, peeling, and carriage to the temporary drying sheds, and it amounts, as nearly as may be, to eight pies (one penny sterling) for each pound of dry bark. The remainder of the working expenses (viz. Rs. 34,097-7-1) was spent on the cultivation of the Rungbee, Rishap, and Mungpoo plantations, upkeep of roads and buildings, European establishment, head office charges, skilled labour (carpenters and blacksmiths), and on contingencies.

6. *Capital Account.* In accordance with the wishes of Government, the mode of keeping the plantation accounts was recently recast by the Accountant-General, and they are now kept in the form suggested by that officer. One of the changes made is the opening of a capital account. The sum put to the debit of this account at 1st April, 1875, is Rs. 3,50,000. To this has now to be added the expenditure on capital during the year. That expenditure amounts, as has been above shown, to Rs. 9777-9-9. In their letter reviewing the plantation report for the year 1872-3, the Government of India expressed their desire to receive an estimate of the cost at which, with our present experience, a new cinchona plantation could be formed. This estimate was duly furnished, and in accordance with it all extensions which are being made on the slopes of the Sittong spur are being treated as forming a separate plantation, which is called the Sittong plantation. This is under the same European supervision as the older plantations, but separate accounts are kept of all expenditure on it. The sum spent on Sittong during the year, including a proportion of the cost of European establishment, etc., was as above shown Rs. 3,134-14, and this forms the first charge against the Sittong capital account. It is accordingly not debitable to the capital of the old plantation, which includes only Rungbee, Rishap, and Mungpoo. The capital account of the latter, therefore, stands as follows:—

	Rs.	A.	P.
Capital at 1st April, 1875 . .	3,50,000	0	0
Expenditure during 1875-76 .	6,642	11	9
Quinologist's pay for 1875-76 .	10,000	0	0
Total Capital at 31st March, 1876 .	3,66,642	11	9

The Quinologist's pay has been added to capital, as the plantation not being yet in full working the charge can hardly be debited with fairness against the crop.

If interest be calculated at the rate of 4 per cent. on the above capital, an additional item of Rs. 14,664 will be added to the working expenses of the year.

7. *Cost of the bark produced.*—The bark taken during the year amounted, as has already been stated, to 211,931 pounds. From this there have, however, to be deducted 16,640 pounds which were accidentally destroyed by fire, leaving 195,291 pounds, against which the working expenses of the year (Rs. 42,937-6-1) are chargeable. The cost of production, therefore, of each pound of dry bark was 3 annas 6·21 pies, being a fraction over three annas and a half, and as near as may be five pence half penny sterling. If the charge for interest on capital (1 anna 2·23 pies) be added, these figures are raised to within a small fraction of four annas and nine pies, which is equal to seven pence and one-eighth sterling.

8. *Bark account.*—During the year 92,400 pounds of dry bark were made over to the Quinologist for conversion into cinchona febrifuge. The composition of this bark was as follows:—

	Pounds.
Dry *Succirubra* root-bark	4,800
„ stem-bark	42,800
„ branch-bark	44,800
Total .	92,400

To the Presidency Medical Depôt 2000 pounds were also supplied.

The remainder of the crop is stored at Mungpoo, and is being made over to the factory as required. It may be useful to put on record a complete statement of the bark yielded by the plantation since its commencement. The following table shows this at a glance:—

	Pounds.
Dry bark collected by pruning and thinning during 1869-70	2,400
Dry bark collected by pruning and thinning during 1870-71	12,500
Dry bark collected by pruning and thinning during 1871-72	39,000
Dry bark collected by pruning and thinning during 1872-73	Nil.
Dry bark collected by pruning and thinning during 1873-74	16,000
Dry bark collected by pruning and thinning during 1874-75	39,405
Dry Crop of 1875-76	211,931
Total . .	321,236

	Pounds.	
Supplied to Medical Depôt; sent to Her Majesty's Secretary of State, London; used in experiment; made over to Quinologist, etc., prior to 1st April, 1875 .	48,906	
Supplied to Medical Depôt, 1876-77 .	2,000	
Made over to Quinologist, 1876-77 . .	92,400	
Burnt accidentally	16,640	
		159,946
Balance in store, 31st March, 1876 . .		161,290

The total yield up to the end of the year has thus been 321,236 pounds of dry bark.

9. *Accidental burning of part of the crop.*—During the cold season a destructive fire occurred, by which a large shed, containing about 16,640 pounds of dry bark, was burnt to the ground. The fire appears to have originated through the carelessness of the man in charge of the shed. Certain changes were proposed by me in the arrangements to be followed in future in drying and storing bark, by adopting which similar accidents on such a large scale should be averted. Dry bark is, however, a substance which burns readily, and natives are proverbially careless about fire; there will, therefore, under any arrangements whatever, always remain a risk of loss by fire.

10. *Present condition of the plantation.*—The cold season was characterized by a drought unparalleled in Sikhim since meteorological observations began to be recorded in the district. The excessive dryness made any planting during the cold season an impossibility; but beyond killing entirely a few trees in very rocky ground, and injuring the upper shoots of a good many others, it did but little harm to the plantation. Trees standing in some of the wetter pieces of land, so common on the older parts of the plantation, seem even to have been benefited by the lengthened absence of rain. The present condition of the plantation is on the whole encouraging. The younger parts which occupy the Mungpoo ridge continue to be very luxuriant and healthy. A small part, however, of the lower Rishap plantation, which has for some years been rather sickly, still continues so; and as it does not seem probable that it will improve, I have decided to uproot it during next barking season. During the year no additions were made to the permanent plantations. This is chiefly attributable to the unusual drought of the cold weather. The nursery stock of red-barks on the old plantation has, however, been increased by 290,000, and 125,000 young plants have been provided for the new plantation at Sittong. These will be planted out, as far as possible, during the year 1876-77, and ought to add considerably to the area under trees. Of the yellow-bark tree (*C. Calisaya*), 2000 stock plants (kept under glass for purposes of propagation)

have been added during the year. The seedlings of this species, of which 116,000 were returned last year, were not planted out, experience having shown that *Calisaya* seed, however carefully it may have been collected from only the varieties yielding good bark, produces an uncertain and mongrel offspring. These 116,000 have therefore been written off. An addition of 25,000 has been made to the stock of young yellow-barks raised from cuttings. Of the new variety referred to in the former reports as a hybrid, no plants have been put out during the year, but the stock plants of it have been increased from 1000 to 5000. As seedlings of this sort show similar peculiarities to those of *Calisaya*, the seedling stock of 15,000 returned last year was not planted out, and has been written off. *Cinchona pitayensis* is a species allied to *C. officinalis*, which was introduced on this plantation about five years ago. Sixteen plants of it were returned in last report. These all pined away during the year, and none are now left. Regarding the other species in cultivation, I may remark that *officinalis* was long ago discovered to be unsuited to the climate of Sikhim. Of this species, 125,000 appear in the returns, but before another year passes the majority of these will be cut down. The numbers returned of *C. micrantha* and *C. pahudiana* are respectively 50,000 and 5092, and are the same as last year. Both species yield bark which is comparatively worthless, and no effort has for some years been made to multiply either.

11. *Manuring.*—The results of the application of manure to cinchonas, as noted in my last annual report, were not encouraging. I agree, however, with Mr. Wood in thinking it desirable to make a further trial of manuring, and I have accordingly asked Mr. Gammie to do this as soon as practicable. The manured plants reported on last year are now undistinguishable in appearance from their neighbours. It should not be forgotten that all the cinchonas in the plantation are to a certain extent regularly manured, for the weeds cut and uprooted in cleaning the plantation are laid in rows between the trees and the vegetable manure yielded by the decay of these is very considerable.

12. *Survey of the plantation.*—In accordance with the wishes of the Government, the whole plantation was surveyed and mapped last year by an officer of the Revenue Survey Department. Owing, however, to certain official changes which caused, I understand, the breaking up of the party to which this officer belonged, I have, I regret to say, not yet been able to get a copy of the map. The plantation has now arrived at a point in its history when it must begin to be worked on some systematic plan, with reference to the amount of bark to be annually taken from it, and it is high time that an accurate map of it were available. The boundaries of each year's planting should be shown on such a map as well as on the ground. I have impressed on Mr. Gammie the desirability of having, as soon as possible, substantial marks put in the ground which may clearly indicate the limits of the planting of each year.

13. *Distribution of seed.*—During the year twenty-one ounces of seed were given away to two applicants. This shows a great falling off from the former year, when no less than three hundred and fifty-eight ounces were distributed.

14. *Land rent.*—The sum of Rs. 1001-12-10, received for land rent and grazing dues from settlers on parts of the reserve unsuitable for cinchona, was paid into the Darjeeling treasury.

15. *Estimated crop of* 1876-77.—In his report for last year, the Government Quinologist, Mr. C. H. Wood, estimated the yield of the Rungbee, Rishap, and Mungpoo plantations, when in full working, at 366,000 pounds of dry bark per annum. These figures were arrived at as the result of Mr. Wood's own calculations, and were accepted by Government. My calculations lead me to believe that this amount of bark can, advantageously to the plantation, be taken during the year 1876-77, and I beg therefore to submit 366,000 pounds of dry bark as my estimate for the crop of the year now entered upon. Unless, however, arrangements are made for working the alkaloid factory on a larger scale than at present, I would hesitate to advise the whole of this amount being taken, as there would be a difficulty about storing such a bulky crop. I feel convinced, however, that in justice to the plantation this amount should be taken. If taken, I estimate that (including interest on capital, working expenses, and Quinologist's salary) it can be turned out at about the price estimated by Mr. Wood in his report already referred to, viz., three and a half annas, or five pence farthing per pound. Production of the raw material to this amount and at this price would enable Mr. Wood to supply during the year the "cinchona febrifuge"—as he has named his preparation of the mixed red-bark alkaloids—in a quantity vastly exceeding the total Government importations of quinine and the other cinchona alkaloids for the whole of India for the year 1875, and at a cost of less than one rupee per ounce.

16. *General Considerations.*—With regard to the "cinchona febrifuge" issued by the Quinologist, I may observe that, in most ordinary cases of malarious fever, it appears to be an efficient remedy. Powerful testimony to this effect is borne by the four physicians in and near Calcutta, to whom, about eighteen months ago, a quantity was given for trial and report. Coolies on the plantation often get fever by attending markets in the Terai, and they are invariably cured by a dose or two of this mixed alkaloid. In the neighbourhood of the Botanical Garden at Calcutta fever of a bad type is very prevalent, and I have given the cinchona febrifuge to garden coolies and to villagers living near the garden, in the same doses as quinine, and with as unvarying good effect. It is probable that for very severe and critical cases of malarious fever, especially amongst Europeans, sulphate of quinine will long remain in the estimation of the medical profession the best remedy; but everyone who has had much experience of India knows that bad cases of fever are more the exception than the rule, and that there is a simply incalculable amount of fever prevalent amongst the natives of the country which rarely takes the form of a violent or fatal attack, but which expends itself in a succession of attacks, each sufficient to incapacitate the sufferer from work for a time, and a repetition of which too often ultimately induces malarious cachexia and disease of the spleen. There appears to be ample medical evidence for believing that, for malarious fever of this ordinary type, the "cinchona febrifuge" is a most efficient remedy. Everybody who knows much of rural life in this country must also be aware that at present the great majority of such attacks of fever receive no medical treatment whatever, or at least none of an efficient kind, and for the simple reason that no febrifuge is accessible to the sufferers. Quinine is a costly drug, quite beyond the means of a large proportion of the population. Moreover, it is not to be had except at dispensaries and in large bazaars in neighbourhoods where Europeans happen to be settled. It is no exaggeration whatever to say that to three-fourths of the population of India, quinine is simply *unobtainable even by purchase*. Its high price leads, mereover, to its extensive adulteration, and there is too good reason for believing that much of the substance sold in the bazaars as quinine consists partly, and some of it entirely, of other preparations. A febrifuge even less efficient than the cinchona febrifuge would, if accessible to the vast fever-stricken population (and accessibility depends on cheapness), be an immense boon. It appears to be, therefore, a matter for congratulation that Government is now in possession of the means of throwing into the country next year several tons of an efficient febrifuge, and of year by year increasing the supply, and that too at an annually diminishing cost price per ounce.

17. A Manual of Cinchona Cultivation in India, which I prepared at the request of the Government of India, has been printed and published since my last annual report.

ESSENCE OF CUBEBS.*

BY A. OGLIALORO.

Whilst examining a specimen of essence of cubebs the author found that he obtained a hydrocarbon $C_{10}H_{16}$ boiling at 160°, which appears to have been unnoticed by any previous experimenter, although he did not succeed in separating the hydrocarbon of boiling point 230° mentioned by Schmidt. This induced him to prepare some of the essential oil from cubebs by distilling the substance in a current of steam in a copper still; the yield was about 4 per cent., and the product, when submitted to careful rectification after being dried over calcium chloride, yielded a small quantity of a hydrocarbon, $C_{10}H_{16}$, belonging to the terpene series, boiling at 158—163°, and a considerable portion boiling at 250—270°,—evidently a mixture,—but no trace of the hydrocarbon boiling at 230° observed by Schmidt.

The portion boiling at 250—270° was mixed with half its weight of ether and saturated with hydrochloric acid; by this means a crystalline hydrochloride of the composition $C_{15}H_{24}$,HCl, was separated, whilst the mother-liquor, after evaporation of the ether, and separation of a further portion of the hydrochloride which crystallized out, was washed with dilute alkali, dried, and submitted to fractional distillation. The greater portion passed over at 262—263°, and possessed a slight lævorotatory power although it is doubtful whether this is inherent in the hydrocarbon, or is due to the admixture of a small amount of that which forms the crystalline hydrochloride. The hydrochloride crystallizes from boiling alcohol in long colourless needles, which melt at 117—118°, and when heated for some time to 170—180° with water in sealed tubes, is completely decomposed into hydrochloric acid and a hydrocarbon of the formula $C_{15}H_{24}$. This, after purification by rectification from sodium, has a density of 0·9289 at 0°, and boils at 264—265°. It deflects the polarized ray to the left. The hydrochloride also has considerable action on polarized light.

THE AMERICAN LEECH TRADE.†

One of the oldest American leech dealers has been interviewed by the correspondent of a contemporary. His opinions are as follows:

"The American leech I believe to be utterly valueless. I have received fine-looking specimens from Mississippi and Pennsylvania, but I found them wholly worthless. They are far inferior to even some European varieties of the hirudo decora, which cannot easily be induced to bite unless blood be drawn to excite them. I consider six Swedish leeches equal to at least one hundred of any American variety. Those exported to America are generally full of blood, and at Rhode Island there are immense purging ponds in which the newly arrived leeches are placed, and left to digest their last meal. Until it has been perfectly digested they are useless. These ponds belong to Mr. Witte, who does nearly all the importing for American leech doctors, and he charges an extra price for the ponded leech, because the leeches must remain at least a year in the purging pond. It takes a year for them to get rid of one good meal. The leech can live on almost nothing; its vitality is absolutely prodigious. But it is a curious thing that they are constitutionally delicate creatures. If deprived for a considerable time of clay or turf to burrow in, they are liable to disease. They are carried off by epidemics peculiar to leech life, some of which appear to be skin diseases. I have to nurse them pretty carefully, and when I find one leech sick I put him in the leech hospital. A milk diet frequently restores sick leeches to perfect health."

SOUTH LONDON SCHOOL OF PHARMACY.

The fourth annual dinner in connection with the above school was held on Friday, December 22nd, at the Horns Assembly Rooms, Kennington Park, under the presidency of Dr. Muter, Mr. W. Baxter occupying the vice-chair.

The usual loyal toasts having been disposed of—

The Chairman in proposing the toast of the evening, "Success to the South London School of Pharmacy," said he was glad to see around him so many familiar faces. They all knew nothing was more gratifying to him than to know that after the relationship of lecturer and student had ceased, the relation of friend should continue, and the presence of so many old scholars that evening proved that this feeling was reciprocated. The toast needed no recommendation—"Good wine needs no bush"—and those present were living bushes of the South London School of Pharmacy. With regard to the examinations they had been going on in a very quiet manner, and he could honestly say that the examinations at Bloomsbury Square were the most perfect in England, and that the examiners were well up to their work in every respect. There were two points, however, which in his opinion needed a slight revision. The first was that of allowing books and notes at the Major examination. He looked upon a practical examination at which books and notes were allowed as a farce, because if a man knew his business he could do his analysis without the use of such helps. If these were abolished one great incentive towards "cramming" would be abolished. The second point was the too frequent examinations held during the year, tending to bring men up insufficiently prepared. The examination in October was one to which practically few men could go up efficiently prepared, because it took place at a time when no recognized school was open. If the examinations were held every three months, instead of every two months, a great deal of "cramming" and the temptation to do the work in the shortest possible time would be got rid of. In all other respects everything was satisfactory, and he honestly believed that the men turned out at Bloomsbury Square were men who really knew their business, and men to whom the public might trust their lives. In conclusion, he would ask them to drink with bumpers the toast he had the pleasure to propose.

Mr. Charles White (Churchwarden) then presented the prizes to the successful students of the past season. He said that the distribution of these prizes was to him a very great pleasure, and he took that opportunity of heartily congratulating those who had been successful, and at the same time sympathizing with those who had not been so fortunate. Success in after life was not confined only to those who gained a prize at school. The school, he understood, commenced nine years ago with one student, and now it had over one hundred, and its scholars occupied distinguished positions throughout the country. Lambeth might well be proud of having so useful an institution in its midst, and the worthy doctor and his assistants were entitled to the thanks of the community at large. The school had no rival, at all events in the south of London, and every care was taken of the student's welfare. In his opinion chemistry had been a science of wonder and mystery. The old alchemists used what little knowledge they possessed to impose upon their fellow men, but the chemists of the present day were a very different class of people.

The Vice-Chairman then proposed "The Successful Candidates." He did not say that their success was due to the superior educational staff of the school, but he did say without fear of contradiction that no man living had the power of imparting the knowledge he possessed better than Dr. Muter. He might express a hope that at their future meetings some members of the parent institution would honour them with their presence.

Messrs. Hart and Colegrove returned thanks on behalf of the successful students.

Various other toasts were proposed and responded to.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 30, 1876.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

MORE MILK OF SULPHUR PROSECUTIONS.

THREE more chemists and druggists have this week been prosecuted for the sale of milk of sulphur prepared according to the directions of the Pharmacopœia of 1721, and consequently containing hydrated calcium sulphate to the extent of about 60 per cent. The charge brought against them was that of having sold "adulterated" milk of sulphur, and notwithstanding the fact that the cases were defended by the Solicitor of the Chemists and Druggists' Trade Association, the Bench decided to convict and each of the defendants was fined twenty shillings and costs.

It appears to have been tacitly assumed by the magistrates that the term "milk of sulphur" ought to be interpreted as signifying a preparation consisting entirely of sulphur in a fine state of division, in fact the preparation which is comprised in the British Pharmacopœia under the name of sulphur præcipitatum. On no other ground that we can imagine could it have been held that the defendants in these cases did not supply the article asked for. Upon this assumption the decision of the magistrates cannot be objected to; but at the same time it is an assumption which altogether begs the question whether the sale of the familiar and popularly approved preparation containing hydrated calcium sulphate is an offence punishable under the provisions of the Sale of Food and Drugs Act.

This is a question which urgently calls for some authoritative decision, for there is little doubt that among the fourteen thousand chemists and druggists on the register, the great majority, especially in country places, are in the daily habit of selling the preparation of sulphur which contains hydrated calcium sulphate, and any one of them is liable to be brought before a police court upon the charge of selling an adulterated article, if it be admissible to adopt the assumption upon which the Runcorn magistrates appear to have arrived at their decision.

Although the trade in milk of sulphur is comparatively a small matter, since the article is sold in quantities of a few pence worth at a time, the credit of the greater number of chemists and druggists throughout the country is nevertheless at stake and in peril with regard to it.

Regarding the matter from this point of view it is singular that, while the magistrates assumed that the term "milk of sulphur" ought be understood as meaning the precipitated sulphur of the British Pharmacopœia, no attempt seems to have been made by the defence to raise an issue upon this point. Until that is decided one way or the other it is almost futile to attempt a defence in prosecutions for the sale of the preparation made according to the directions of the old Pharmacopœia. So long as that point remains undecided the production of evidence to the effect that there is a very extensive and general use of the old fashioned milk of sulphur, and that wholesale druggists are in the habit of selling thirteen times as much of it as of the preparation of the British Pharmacopœia, is open to the disadvantage of being regarded by the magisterial mind merely as evidence of the extent to which an abuse prevails, and so far from being a sufficient ground for acquittal it would, perhaps, from that point of view, constitute a strong reason for imposing a heavy penalty.

We are by no means unmindful of the fact that this subject is involved in considerable difficulty. There is unquestionably a wide diversity of opinion, even amongst members of the trade, as to what should be understood by the term "milk of sulphur." Many contend that it should only be applied to the preparation of the British Pharmacopœia, and that the older preparation should be regarded as obsolete; this opinion is also practically acted up to by many chemists and druggists, by their keeping only the precipitated sulphur, and systematically supplying that article when asked for milk of sulphur. In this way some confusion has been created, and the application of the old name as a synonym of precipitated sulphur by some writers on materia medica has tended to increase this confusion. On the other hand, it is maintained by many that among the class of persons using milk of sulphur there is not only a decided preference for the older preparation, but a decided objection to the more modern one. It is contended, and we must admit the justice of the statement, that this feeling prevails in some cases to such an extent that chemists and druggists must either supply the old-fashioned "milk of sulphur" or decline to meet the wants of their customers.

Practically, therefore, the case is a very perplexing one, and as it now stands the sale of the article popularly known as "milk of sulphur" must either be abandoned, or if it be continued it will be at the risk of condemnation as dealing in an adulterated article.

We observe that in the cases just tried at Runcorn notice of appeal has been given, and we hope that by bringing the question before a higher court, chemists and druggists may at least be relieved from the uncertainty that now prevails as to whether the sale of an article which is in one part of the country decided to be legitimate, may not in another county be treated as a punishable offence.

MEDICO-PHARMACEUTICAL ALLIANCES IN TURKEY.

According to Professor Landerer, the medical men and the pharmacists in Turkish towns work together in a way not unknown in this country. The physician sees his patients at the pharmacist's establishment, and there gives his orders as to the medicines, etc., they are to receive to the pharmacist, who has been awaiting the arrival of his medical friend sitting cross-legged on a bench and smoking his hookah.

The prices of medicine are not regulated by law, and a simple quinine mixture costs from 30 to 50 piastres (5*s.* to 9*s.*). When such a medical man undertakes a more important case, a fee for the cure, inclusive of medicine, ranging from 1000 to 2000 piastres (£9 to £18) is agreed upon, and one-half is paid in advance. If the unfortunate patient should die the physician loses the other half of the fee, and the pharmacist may send in his reckoning in the Greek kalends.

One of these genuine Turkish pharmacies presents a peculiar appearance. Glass and earthenware vessels of all shapes, round wooden boxes, with labels in all colours, or without any, a handsome pair of brass scales, a spatula, a pill machine, and a marble slab, on which to make pill masses, adorn the prescription counter; whilst for the general ornamentation of the pharmacy, but not for use, some glass retorts are hung against the walls.

The library of such an establishment consists of five or six books, principally Italian. Notwithstanding all this, these pharmacists and physicians are much respected in the interior of the Ottoman empire and they become wealthy men.

EARLIER CLOSING.

With respect to this subject it is gratifying to learn that an agreement to close at an earlier hour, made as far back as 1860, by the chemists and druggists of Bath, has been fairly carried out up to the present time. Of course there have been a few who have refused to be bound by the arrangement, but this has not induced others to fall away from their compact or to regret it. We are informed that it is now the practice of many pharmacists in Bath to put up the shutters, as a rule, at 7 o'clock, and to close the doors as soon after as convenient, and before 8 P.M. We have great pleasure in placing this on record, because the result of the practical experience of sixteen years ought to have considerable influence upon those whose doubts as to the practicability of earlier closing have hitherto hindered them from joining the movement.

The amount of revenue derived from "patent medicines" during the year ending the 31st of March last, was £123,136 9*s.* 10½*d.*, for which the number of stamps issued was 15,873,934.

EXAMINATIONS IN EDINBURGH.

December 20, 1876.

Present—Messrs. Ainslie, Borland, Buchanan, Gilmour, Kemp, Kinninmont and Young.

MAJOR EXAMINATION.

One candidate was examined and failed.

MINOR EXAMINATION.

Nine candidates were examined. *Five* failed. The following *four* passed, and were declared qualified to be registered as Chemists and Druggists:—

Cowap, John William ....Stockport.
Dick, Robert Gibson ....Edinburgh.
Gardner, Robert ....Dollar.
Gorrie, Daniel ....Perth.

December 21, 1876.

Present, as on the 20th.

Professor Maclagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Ten candidates were examined. *Three* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

McAlley, Robert ....Edinburgh.
Mackie, George ....Banff.
Manduell, Thomas ....Hindpool.
Nicholson, John ....Heaton Norris.
Robertson, William ....Peebles.
Simpson, William..................Sheffield.
Smith, Robert Frazer ....Glasgow.

MODIFIED EXAMINATION.

One candidate was examined and declared qualified to be registered as a Chemist and Druggist:—

Anderson, Hugh Mackay ......Leeds.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Thursday, the 7th inst., the members of the above Association assembled at their rooms in Halford Street, to listen to a lecture on the natural order "Umbelliferæ," by Mr. F. T. Mott, F.G.S. In the absence, through illness, of the President, the chair was occupied by the Vice-president, Mr. Hammond.

After a few words from the chairman, the lecturer stated that the ancient Greeks and Romans considered one of the plants of this order, viz., hemlock, as one of their most deadly poisons; and that it was by the juice of this herb that the learned Socrates met his death. The producing power of plants by the expansion and contraction of the stem in the formation of the cyme, raceme, corymb, pannicle, and umbel, together with their true characters and the manner in which the florets expand were fully illustrated by the aid of diagrams. Attention at this stage was drawn to the fact that the umbelliferous flower was not alone sufficient to mark off accurately plants as belonging to the umbelliferæ: but there were other great distinguishing characteristics in the leaves, flowers, fruit, and seeds by which they were able to be separated from other orders, all of which were carefully enunciated and explained by the lecturer. The number of species and genera of this order, together with the numbers of those to be found in Leicestershire, as also the portions of the continents which they inhabit, were all named.

The lecturer next spoke of the composition of the various plants contained in this order; those which are used as drugs, such as assafœtida, ammoniacum, and others contained gum resins, being natives of Asia, and warm climates; others which are used as aromatics found growing principally in Britain, such as anise, cumin, caraway, and others contained volatile oils; some again are rich in starches and sugar, making them valuable as pot herbs, such as fennel, parsley, and celery, although the latter of these three in its wild state is poisonous, nevertheless by cultivation and blanching the poisonous juice does not form, owing to the fact that to do so, the plant must have free access of air and light; whilst some of the plants are poisonous, such as *Conium maculatum*, *Cicuta virosa*, *Œnanthe crocata*, and *Æthusia cynapium*. Full descriptions of these, and the plants for which they may be mistaken, were given and illustrated by the aid of diagrams and dried specimens. The difficulty of distinguishing the different species of this order was also spoken about. With a few remarks as to the probable place this order may take in the future, the lecturer brought his interesting and instructive lecture to a close.

A most hearty vote of thanks was accorded to Mr. Mott, for his great kindness, and the proceedings terminated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, December 21, 1876. Professor Abel, F.R.S., President, in the chair. After the minutes of the preceding meeting had been read and confirmed, the names of Messrs. A. Gaved Phillips and F. Kopfer were read for the first time. The President read a letter from the Secretary of the Royal Society as to the nature and conditions under which grants would be made from the £4000 given by Government in aid of original research.

The first paper, entitled "A Further Study of Fluid Cavities," was read by Mr. W. N. Hartley, and the results of his examination of a large number of topazes, selected from the magnificent collection in the British Museum, showed that the cavities scarcely ever contained anything but water. If the view be accepted that topaz has been formed by the action of alkaline fluorides or cryolite on kaolin no carbon dioxide would be liberated, so that it might not necessarily be found in the fluid cavities. This is corroborated by the fact that in one and the same topaz, cavities may exist side by side one of which is nearly filled with liquid carbon dioxide, the other one-third with water, one-third with liquid, and one-third with gaseous carbon dioxide, the space occupied by the gaseous CO_2, having been produced by the contraction of the water on cooling. He inferred, moreover, that the critical temperature of water had not been reached, otherwise the contents of the adjacent cavities would have been uniform.

The author had also examined a very large number of rock sections, principally of granite and porphyry, almost all of which contained water cavities, but in none of them was the presence of carbon dioxide distinctly observed. A curious phenomenon in connection with the bubbles in the water cavities of rock crystal was sometimes observed, namely, that when heated the bubble became more dense than the liquid and sank, so that in large deep cavities it went entirely out of focus when observed with a half-inch objective. In one specimen of quartz it was found that the bubble began to sink at 131° C., but not before it had reached this temperature. The cause of this motion appears to be that the bubble consists of a gas so highly compressed that it is nearly of the same density as water at the ordinary temperature; on heating the water expands, thus still further condensing the gas in the cavity, which thus becomes heavier than the liquid, and consequently sinks in it.

It is very remarkable that the cavities are not only frequently arranged symmetrically around the axis of the crystal, but in some cases they take the form of the crystal in which they are enclosed, each side of the cavity being parallel to a face of the crystal. Drawings of sections of crystals were exhibited, in which this was very clearly shown. This is probably caused by the water exerting a resistance to compression comparable to a solid body at the high temperature at which the crystal was formed, but being mobile the shape of the enclosed water was altered so as to conform to the planes of crystallization of the mineral as the silica molecules grouped themselves around it.

The President, in thanking the author, remarked that this investigation in his hands had been prolific in interesting results. He hoped that his ingenious speculations bearing on the formation of these crystalline substances and the cavities contained in them would give rise to a valuable discussion.

In reply to a question put by Dr. Armstrong with reference to the occlusion of hydrogen by trap rocks recently investigated by an American chemist, Mr. Hartley said that in samples of trap from the neighbourhood of Edinburgh, which he had examined, he had noticed cavities, but they contained nothing; cavities containing liquefied carbon dioxide had been observed, however, in trap. He had not considered the question as to whether such cavities contained hydrogen, his attention having been chiefly confined to quartz, granite, porphyry, etc., most likely to have cavities containing liquefied carbon dioxide, the special object of his search.

Dr. H. E. Armstrong then gave a paper "On Thymoquinone." In a recent communication to the Berlin Chemical Society Liebermann pointed out that the "oximidonaphthol," $C_{10}H_5\left\{\begin{matrix}OH\\NH\\NH\end{matrix}\right\}$ of Graebe and Ludwig, prepared by the oxidation of diamidanaphthol, is more propably a compound of the formula $C_{10}H_5\left\{\begin{matrix}O\\NH\\NH_2\end{matrix}\right\}$ and that when it is oxidized to naphthaquinone the NH_2 group is displaced by OH; in other words, the OH group and one of the NH_2 groups in diamidanaphthol are concerned in the formation of the quinone, and not both the NH_2 groups, as Graebe and Ludwig supposed. It is to be presumed, therefore, that in the formation of oxythymoquinone from diamidothymol (recently effected by Carslangen) by oxidation, a similar reaction takes place, namely, that only one of the NH_2 groups and the OH group are concerned in the production of this quinone, the other NH_2 group being merely replaced by hydroxyl. Carslangen has also obtained the same oxythymoquinone by treating the monobromo derivative of thymoquinone with potassic hydrate. Ladenburgh has employed these results as the basis of a speculative theory as to the value of the several hydrogen atoms in benzene, in which he makes the perfectly gratuitous and unsupported assumption that in the first instance the thymol OH group remains unaffected, only the two amido groups taking part in the formation of the quinone, whilst in the second instance the thymol OH group does take part in the formation of the quinone. This Liebermann points out is not only unproved, but is improbable, Dr. Armstrong stated that for a long time he had been engaged in an investigation of thymol and its derivatives, and had already obtained results which show that Ladenburgh's assumption was incorrect, even if it had not been contrary to our knowledge of the law governing the substitution in the phenol derivatives that para and ortho compounds are first formed. The author had found that monamidothymol from nitrosothymol, in which the NH_2 group occupies the para position relatively to the OH group, yielded thymoquinone when distilled with ferric chloride equal in weight to more than half the weight of the thymol employed in the preparation of the nitroso-derivative. He also stated that the formula suggested by Liebermann for "oximidonaphthol," etc., had already been suggested by Mr. C. E. Groves and himself in a foot note in the new edition of Miller's 'Organic Chemistry' they are now preparing, the proof sheet containing the note being handed in to the President.

The President having thanked the author for his communication a paper "On High Melting Points with special reference to those of Metallic Salts," Part II., by Dr. T. Carnelly, was read. The method to be employed depends on the principle that if three salts, A, B, C, whose fusion points are in the order A, B, C, be arranged on a cold block of iron and then introduced into a muffle, kept at a constant high temperature, the ratio $\frac{y}{x}$ is approximately constant for the same three salts, whatever the temperature of the muffle, x being the number of seconds which elapse between the melting of A and B and F that between the melting of B and C. The arrangement of the muffle and iron blocks is shown in an engraving, and the methods of working given in detail. The results of a large number of experiments instituted to prove that the law just enumerated holds good under varying circumstances is given in a series of tables. The author proposes in a future communication to show how this principle may be employed in the actual determination of high melting points.

The Secretary then gave an outline of a paper "On the Estimation of Urea," by Mr. G. Turner, containing the results of his experiments in determining urea by Russell and West's method, the apparatus employed being a modification of that known as "Scheibler's calcimeter."

Dr. G. Bischoff read a short notice "On the Corrosion of Lead by the New River Company's Water," saying that he had observed the formation of a crust of lead carbonate on the exterior of a piece of gas tube which had been employed as a syphon in a cistern supplied by the New River Company, and which was consequently alternately exposed to the action of air and water as the level of the water in the cistern altered. This tube was the so-called "composition" tube usually employed by gasfitters, consisting of lead alloyed with a little antimony. An adjoining cistern of sheet lead with a lead overflow pipe shows nowhere any signs of similar corrosion.

In reference to a remark which the author made as to the protective influence which tin exerted when alloyed with lead, Mr. David Howard said that even when the amount of lead in the tin used for tinning vessels employed for culinary purposes did not exceed 5 or 10 per cent. it was found to be readily attacked by dilute acids, etc., so as to be likely to produce very injurious effects.

The President said that the lead tube lined with tin was made by drawing the two metals at the same time, and when faults occurred to this interior coating the lead was rapidly corroded although, no doubt, the faulty parts must be more or less alloyed with tin.

The meeting was then adjourned until Thursday, 18th January, when Messrs. C. T. Kingzett, and H. W. Hake will give a "Preliminary Account of Some New Reactions in Organic Chemistry, and their Ultimate Bearings;" there will also be papers "On Kekulé's and Ladenburgh's Benzene Symbols," by Dr. H. E. Armstrong, and "On Nitroso-orcin," by Dr. J. Stenhouse and Mr. C. E Groves.

Lectures are announced "On the Theory of the Bunsen Flame," by Professor Thorpe; and "On the Discrimination of Crystals by their Optical Properties," by Professor N. Story Maskelyne, both experimentally illustrated. These will probably take place on March 1 and April 5, respectively.

PHILADELPHIA COLLEGE OF PHARMACY.

The second meeting for the present session of this Society was held on Tuesday, November 21, Mr. Dillwyn Parrish, President, in the chair. The following paper was read:—

Preparations of Malt.

BY R. V. MATTISON, PH.G.

For several years past there seems to have been an observed tendency among physicians towards the use of a class of preparations more or less representing the saccharine and albumoid constituents of malted barley, and a number of medicinal preparations have been gradually introduced, some of which have found considerable favour among the profession as a slightly-tonic and valuable nutrient food, employed in dyspeptic and other stomachic disorders, caused by the non-assimilation of starch food.

Probably the most widely known in the United States is the "Hoff's Malt Extract," which most of the members present may remember particularly, on account of the great difficulty experienced in being able to obtain it during the late Franco-German war, and the notoriety which one of our eminently-respectable houses at that time attained, through being able to supply, as genuine, a preparation put up in the ordinary London Stout bottles, with *facsimile* German labels. The genuine preparation does not seem to the writer to be properly called an extract of malt, since it certainly partakes more of the nature of a malt liquor, the principal difference being that it is of sweeter taste and less spirituous—more sugar and less alcohol than the ordinary malted liquors of commerce. The fact, however, of its containing a notable proportion of alcohol renders it, in the opinion of the writer, an objectionable article; not objectionable as a malt liquor, understand, but as an *extract of malt*, since a large portion of the sugar has been converted by fermentation into alcohol.

The nutrient properties of a good malt extract consist in the amount of malt sugar, diastase, etc., that is obtainable therefrom by the assimilative organs of the human system, and to insure the proper amount of these principles depends upon the proper observance of four rules, viz.:

1. The barley must be malted properly and carefully, to insure the formation of as large a quantity of diastase as possible, that by its action in mashing all the starch may be converted into sugar. The chemical change may be thus represented, the starch taking up the elements of water:

$$\underset{\text{Starch.}}{3C_6H_{10}O_5} + H_2O = \underset{\text{Glucose.}}{C_6H_{12}O_6} + \underset{\text{Dextrin.}}{2C_6H_{10}O_5}$$

2. The ground malt must be *mashed* carefully, with due regard to the temperature, so as to insure the largest amount of sugar being extracted with the smallest amount of water.

3. The evaporation of the extract with a low degree of heat, to avoid charring any of the delicate constituents of the extract.

4. The most scrupulous cleanliness must be observed at all times in and about all mash-tubs, kettles, capsules or other vessels used in its preparation.
